`eps` = relative machine precision
`sfmin` = safe minimum, such that 1/sfmin does not overflow
`base` = base of the machine
`prec` = `eps*base`
`t` = number of (base) digits in the mantissa
`rnd` = 1.0 when rounding occurs in addition, 0.0 otherwise
`emin` = minimum exponent before (gradual) underflow
`rmin` = underflow threshold - $base^{(emin-1)}$
`emax` = largest exponent before overflow
`rmax` = overflow threshold - $(base^{emax})*(1-eps)$

Output Parameters

val Value returned by the routine.

p?lasnbt

Computes the position of the sign bit of a floating-point number. (C interface function).

Syntax

```
void pslasnbt(int *ieflag);
void pdlasnbt(int *ieflag);
```

Include Files

- C: `mkl_scalapack.h`

Description

The `p?lasnbt` routine finds the position of the signbit of a single/double precision floating point number. This routine assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, *ieflag* = `0` is returned.

Output Parameters

ieflag `INTEGER`.
This flag indicates the position of the signbit of any single/double precision floating point number.
ieflag = `0`, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.
ieflag = `1` indicates that the signbit is the 32-nd bit for a single precision routine.
In the case of a double precision routine:
ieflag = `1` indicates that the signbit is the 32-nd bit (Big Endian).
ieflag = `2` indicates that the signbit is the 64-th bit (Little Endian).

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

```
call pxerbla(ictxt, srname, info)
```

Include Files

- C: `mkl_scalapack.h`

Description

This routine is an error handler for the *ScaLAPACK* routines. It is called by a *ScaLAPACK* routine if an input parameter has an invalid value. A message is printed. Program execution is not terminated. For the ScaLAPACK driver and computational routines, a `RETURN` statement is issued following the call to `pxerbla`.

Control returns to the higher-level calling routine, and it is left to the user to determine how the program should proceed. However, in the specialized low-level ScaLAPACK routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pxerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of *`info`* on return from a ScaLAPACK routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Input Parameters

`ictxt`	(global) `INTEGER` The BLACS context handle, indicating the global context of the operation. The context itself is global.
`srname`	(global) `CHARACTER*6` The name of the routine which called `pxerbla`.
`info`	(global) `INTEGER`. The position of the invalid parameter in the parameter list of the calling routine.

Sparse Solver Routines

8

Intel® Math Kernel Library (Intel® MKL) provides user-callable sparse solver software to solve real or complex, symmetric, structurally symmetric or non-symmetric, positive definite, indefinite or Hermitian sparse linear system of equations.

The terms and concepts required to understand the use of the Intel MKL sparse solver routines are discussed in the Appendix A "Linear Solvers Basics". If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

This chapter describes the direct sparse solver PARDISO* and the alternative interface for the direct sparse solver referred to here as DSS interface; iterative sparse solvers (ISS) based on the reverse communication interface (RCI); and two preconditioners based on the incomplete LU factorization technique.

PARDISO* - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the PARDISO* solver. The interface is Fortran, but it can be called from C programs by observing Fortran parameter passing and naming conventions used by the supported compilers and operating systems. A discussion of the algorithms used in the PARDISO* software and more information on the solver can be found at http://www.pardiso-project.org.

The current implementation of the PARDISO solver additionally supports the out-of-core (OOC) version.

The PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse symmetric and unsymmetric linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [Schenk00-2]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [Schenk00, Schenk01, Schenk02, Schenk03]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

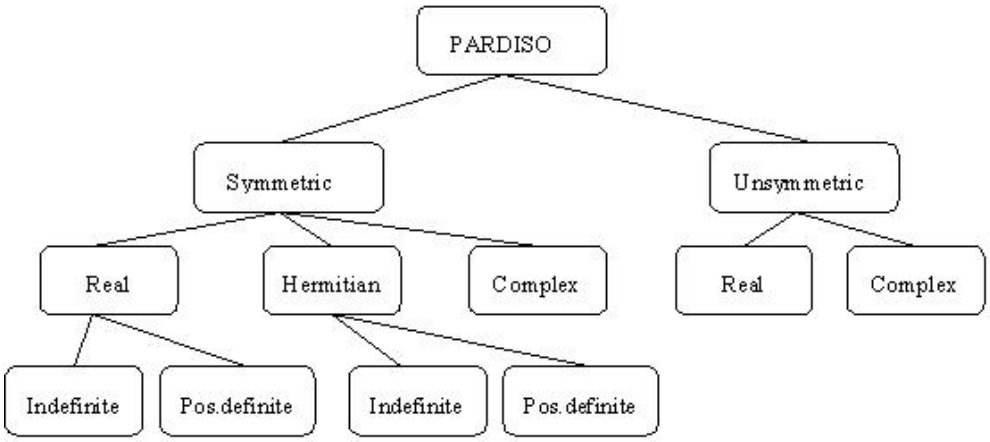
The following table lists the names of the PARDISO routines and describes their general use.

PARDISO Routines

Routine	Description
pardiso	Calculates the solution of a set of sparse linear equations with multiple right-hand sides.
pardisoinit	Initialize PARDISO with default parameters depending on the matrix type.
pardiso_64	Calculates the solution of a set of sparse linear equations with multiple right-hand sides, 64-bit integer version.
pardiso_getenv pardiso_setenv	Retrieves additional values from the PARDISO handle.
pardiso_getenv pardiso_setenv	Sets additional values in the PARDISO handle.

The PARDISO solver supports a wide range of sparse matrix types (see the figure below) and computes the solution of real or complex sparse linear system of equations on shared-memory multiprocessing architectures.

Sparse Matrices That Can Be Solved with the PARDISO* Solver



The PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

You can find a code example that uses the PARDISO interface routine to solve systems of linear equations in the `examples\solver\source` folder of your Intel MKL directory.

pardiso

Calculates the solution of a set of sparse linear equations with multiple right-hand sides.

Syntax

Fortran:

```
call pardiso (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm, msglvl, b, x, error)
```

C:

```
pardiso (pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs, iparm, &msglvl, b, x, &error);
```

Include Files

- FORTRAN 77: `mkl_pardiso.f77`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl_pardiso.h`

Description

The routine `pardiso` calculates the solution of a set of sparse linear equations

```
A*X = B
```

with multiple right-hand sides, using a parallel LU, LDL or LL^T factorization, where A is an n-by-n matrix, and X and B are n-by-$nrhs$ matrices.

Supported Matrix Types.

The analysis steps performed by `pardiso` depends on the structure of the input matrix A.

Symmetric Matrices: The solver first computes a symmetric fill-in reducing permutation P based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel MKL), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite matrices, and an approximation of X is found by forward and backward substitution and iterative refinements.

Whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinements may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinements is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix A that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

Structurally Symmetric Matrices: The solver first computes a symmetric fill-in reducing permutation P followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of X is found by forward and backward substitution and iterative refinements.

Unsymmetric Matrices: The solver first computes a non-symmetric permutation P_{MPS} and scaling matrices D_r and D_c with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation P based on the matrix $P_{MPS}A + (P_{MPS}A)_T$ followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_rAD_cP$$

with supernode pivoting matrices Q and R. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of $\texttt{alpha} = \texttt{eps}*||A2||_{\texttt{inf}}$, where $\texttt{eps}$ is the machine precision, $A2 = P*P_{MPS}*D_r*A*D_c*P$, and $||A2||_{\texttt{inf}}$ is the infinity norm of the scaled and permuted matrix A. Any tiny pivots encountered during elimination are set to the sign $(l_{II})*\texttt{eps}*||A2||_{\texttt{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

Direct-Iterative Preconditioning for Unsymmetric Linear Systems.

The solver enables to use a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most of applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but the same identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. PARDISO uses a numerical factorization $A = LU$ for the first system and applies the factors L and U for the next steps in a preconditioned Krylow-Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to unsymmetric matrices in PARDISO. You can select the method using only one input parameter. For further details see the parameter description ($iparm(4)$, $iparm(20)$).

Single and Double Precision Computations.

PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, and input matrices can have large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made more roughly, only numerically stable process can use single precision.

Separate Forward and Backward Substitution.

The solver execution step (see parameter `phase = 33` below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal . This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix `A` (`mtype = 2`) is factored by PARDISO as $A = L*L^T$. In this case the solution of the system $A*x=b$ can be found as sequence of substitutions: $L*y=b$ (forward substitution, `phase =331`) and $L^T*x=y$ (backward substitution, `phase =333`).

A real unsymmetric matrix `A` (`mtype = 11`) is factored by PARDISO as $A = L*U$. In this case the solution of the system $A*x=b$ can be found by the following sequence: $L*y=b$ (forward substitution, `phase =331`) and $U*x=y$ (backward substitution, `phase =333`).

Solving a system with a real symmetric indefinite matrix `A` (`mtype = -2`) is slightly different from the cases above. PARDISO factors this matrix as $A=LDL^T$, and the solution of the system $A*x=b$ can be calculated as the following sequence of substitutions: $L*y=b$ (forward substitution, `phase =331`) s: $D*v=y$ (diagonal substitution, `phase =332`) and, finally $L^T*x=v$ (backward substitution, `phase =333`). Diagonal substitution makes sense only for indefinite matrices (`mtype = -2, -4, 6`). For matrices of other types a solution can be found as described in the first two examples.

NOTE The number of refinement steps (`iparm(8)`) must be set to zero if a solution is calculated with separate substitutions (`phase = 331, 332, 333`), otherwise PARDISO produces the wrong result.

NOTE Different pivoting (`iparm(21)`) produces different LDL^T factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch and Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step (`phase=33`) regardless of the pivoting used.

Sparse Data Storage.

Sparse data storage in PARDISO follows the scheme described in Sparse Matrix Storage Format with `ja` standing for `columns`, `ia` for `rowIndex`, and `a` for `values`. The algorithms in PARDISO require column indices `ja` to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or unsymmetric matrices the diagonal elements are not necessary: they may be present or not.

NOTE The presence of diagonal elements for symmetric matrices is not mandatory starting from the Intel MKL 10.3 beta release.

CAUTION It's recommended to set explicitly zero diagonal elements for symmetric matrices because in the opposite case PARDISO creates internal copies of arrays `ia`, `ja` and `a` full of diagonal elements that requires additional memory and computational time. However, in general, memory and time overheads are not significant comparing to the memory and the time needed to factor and solve the matrix.

Input Parameters

NOTE Parameters types in this section are specified in FORTRAN 77 notation. See PARDISO Parameters in Tabular Form for detailed description of types of PARDISO parameters in C/Fortran 90 notations.

pt

INTEGER
Array, DIMENSION (64)
Pointer to the address of solver internal data. These addresses are passed to the solver and all related internal memory management is organized through this pointer.

NOTE *pt* is an integer array with 64 entries. It is very important that the pointer is initialized with zero at the first call of pardiso. After that first do not modify the pointer, as a serious memory leak can occur. The integer length must be 4 bytes on 32-bit operating systems and 8 bytes on 64-bit operating systems.

maxfct

INTEGER
Maximum number of factors with identical nonzero sparsity structure that must be keep at the same time in memory. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data management of the solver.
pardiso can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers *pt*.

mnum

INTEGER
Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be: $1 \leq mnum \leq maxfct$. In most applications this value is 1.

mtype

INTEGER
Defines the matrix type, which influences the pivoting method. The PARDISO solver supports the following matrices:

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite
3	complex and structurally symmetric
4	complex and Hermitian positive definite
-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and unsymmetric
13	complex and unsymmetric

phase

INTEGER
Controls the execution of the solver. Usually it is a two- or three-digit integer ij ($10i + j$, $1 \leq i \leq 3$, $i \leq j \leq 3$ for normal execution modes). The i digit indicates the starting phase of execution, j indicates the ending phase. PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including iterative refinements

  This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see above).
- Termination and Memory Release Phase (*phase*≤ 0)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

phase	**Solver Execution Steps**
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
331	like *phase*=33, but only forward substitution
332	like *phase*=33, but only diagonal substitution
333	like *phase*=33, but only backward substitution
0	Release internal memory for *L* and *U* matrix number *mnum*
-1	Release all internal memory for all matrices

n INTEGER
Number of equations in the sparse linear systems of equations *A*X = B*. Constraint: *n* > 0.

a DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision PARDISO (*iparm*(28)=0)
REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision PARDISO (*iparm*(28)=1)
DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision PARDISO (*iparm*(28)=0)
COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision PARDISO (*iparm*(28)=1)
Array. Contains the non-zero elements of the coefficient matrix *A* corresponding to the indices in *ja*. The size of *a* is the same as that of *ja* and the coefficient matrix can be either real or complex. The matrix must be stored in compressed sparse row format with increasing values of *ja* for each row. Refer to *values* array description in Storage Formats for the Direct Sparse Solvers for more details.

NOTE The non-zero elements of each row of the matrix *A* must be stored in increasing order. For symmetric or structural symmetric matrices, it is also important that the diagonal elements are available and stored in the matrix. If the matrix is symmetric, the array *a* is only accessed in the factorization phase, in the triangular solution and iterative refinement phase. Unsymmetric matrices are accessed in all phases of the solution process.

ia INTEGER

Array, dimension (*n*+1). For *i*≤*n*, *ia*(*i*) points to the first column index of row *i* in the array *ja* in compressed sparse row format. That is, *ia*(*I*) gives the index of the element in array *a* that contains the first non-zero element from row *i* of *A*. The last element *ia*(*n*+1) is taken to be equal to the number of non-zero elements in *A*, plus one. Refer to *rowIndex* array description in Storage Formats for the Direct Sparse Solvers for more details. The array *ia* is also accessed in all phases of the solution process. Indexing of *ia* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm*(35).

ja INTEGER

Array *ja*(*) contains column indices of the sparse matrix *A* stored in compressed sparse row format. The indices in each row must be sorted in increasing order. The array *ja* is also accessed in all phases of the solution process. For structurally symmetric matrices it is assumed that diagonal elements, which are zero, are also stored in the list of non-zero elements in *a* and *ja*. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in Storage Formats for the Direct Sparse Solvers.
Indexing of *ja* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm*(35).

perm INTEGER

Array, dimension (*n*). Holds the permutation vector of size *n*. You can use it to apply your own fill-in reducing ordering to the solver. The array *perm* is defined as follows. Let *A* be the original matrix and $B = P*A*P^T$ be the permuted matrix. Row (column) i of *A* is the *perm*(i) row (column) of *B*. The permutation vector *perm* is used by the solver if *iparm*(5) = 1.
The array *perm* is also used to return the permutation vector calculated during fill-in reducing ordering stage. The permutation vector is returned into the *perm* array if *iparm*(5) = 2.
Indexing of *perm* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm*(35).

NOTE The first elements of row, column and permutation are numbered as array elements 1 by default (Fortran style, or one based array indexing), but these first elements can be numbered as array elements 0 (C style, or zero based array indexing) by setting the appropriate value to the parameter *iparm*(35).

nrhs INTEGER

Number of right-hand sides that need to be solved for.

iparm INTEGER

Array, dimension (64). This array is used to pass various parameters to PARDISO and to return some useful information after execution of the solver. If *iparm*(1) = 0, PARDISO uses default values for *iparm*(2) through *iparm*(64).
The individual components of the *iparm* array are described below (some of them are described in the Output Parameters section).

iparm(1)**- use default values.**
If *iparm*(1) = 0, *iparm*(2) through *iparm*(64) are filled with default values, otherwise you must set all values in *iparm* from *iparm*(2) to *iparm*(64).

iparm(2) **- fill-in reducing ordering.**
iparm(2) controls the fill-in reducing ordering for the input matrix.
If *iparm*(2) = 0, the minimum degree algorithm is applied [Li99].
If *iparm*(2) = 2, the solver uses the nested dissection algorithm from the METIS package [Karypis98].
If *iparm*(2) = 3, the parallel (OpenMP) version of the nested dissection algorithm is used. It can decrease the time of computations on multi-core computers, especially when PARDISO Phase 1 takes significant time.
The default value of *iparm*(2) is 2.

CAUTION You can control the parallel execution of the solver by explicitly setting the environment variable MKL_NUM_THREADS. If fewer processors are available than specified, the execution may slow down instead of speeding up. If the variable MKL_NUM_THREADS is not defined, then the solver uses all available processors.

iparm(3)**- currently is not used.**

iparm(4) **- preconditioned CGS.**
This parameter controls preconditioned CGS [Sonn89] for unsymmetric or structurally symmetric matrices and Conjugate-Gradients for symmetric matrices. *iparm*(4) has the form *iparm*(4) = 10*L*+*K*.
The *K* and *L* values have the meanings as follows.

Value of *K*	Description
0	The factorization is always computed as required by *phase*.
1	CGS iteration replaces the computation of *LU*. The preconditioner is *LU* that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.
2	CGS iteration for symmetric matrices replaces the computation of *LU*. The preconditioner is *LU* that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.

Value *L*:
The value *L* controls the stopping criterion of the Krylow-Subspace iteration:

$eps_{CGS} = 10^{-L}$ is used in the stopping criterion
$||dx_i|| / ||dx_i|| < eps_{CGS}$
with $||dx_i|| = ||inv(L*U)*r_i||$ and r_i is the residue at iteration i of the preconditioned Krylow-Subspace iteration.
Strategy: A maximum number of 150 iterations is fixed with the assumption that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residue excursions are checked and can terminate the iteration process. If *phase* =23, then the factorization for a given *A* is automatically recomputed in cases where the Krylow-Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylow-Subspace iteration is returned. Using *phase* =33 results in an error message (*error* =-4) if the stopping criteria for the Krylow-Subspace iteration can not be reached. More information on the failure can be obtained from *iparm*(20).
The default is *iparm*(4)=0, and other values are only recommended for an advanced user. *iparm*(4) must be greater or equal to zero.
Examples:

iparm(4)	**Description**
31	*LU*-preconditioned CGS iteration with a stopping criterion of 1.0E-3 for unsymmetric matrices
61	*LU*-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for unsymmetric matrices
62	*LU*-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric matrices

iparm(5)**- user permutation.**
This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another possible use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of PARDISO.
This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of $P*A*P^T$), or for using the permutation vector more than once for equal or similar matrices. For definition of the permutation, see the description of the *perm* parameter.
If *parm*(5)=0 (default value), then the array *perm* is not used by PARDISO;
if *parm*(5)=1, then the user supplied fill-in reducing permutation in the array *perm* is used;
if *parm*(5)=2, then PARDISO returns the permutation vector into the array *perm.*

iparm(6)**- write solution on** *x***.**
If *iparm*(6) = 0 (default value), then the array *x* contains the solution and the value of *b* is not changed.
If *iparm*(6) = 1, then the solver stores the solution in the right-hand side *b*.
Note that the array *x* is always used. The default value of *iparm*(6) is 0.

iparm(8) **- iterative refinement step.**
On entry to the solve and iterative refinement step, *iparm*(8) must be set to the maximum number of iterative refinement steps that the solver performs. The solver does not perform more than the absolute value of

iparm(8) steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved.
If *iparm*(8) < 0, the accumulation of the residue uses extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of *iparm*(8)=0) and the number of executed iterations is reported in *iparm*(7).
The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization and *iparm*(8) = 0.
The number of performed iterative refinement steps is reported in *iparm*(7).
The default value for *iparm*(8) is 0.

iparm(9)
This parameter is reserved for future use. Its value must be set to 0.

iparm(10)**- pivoting perturbation.**
This parameter instructs PARDISO how to handle small pivots or zero pivots for unsymmetric matrices (*mtype* =11 or *mtype* =13) and symmetric matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04].
The magnitude of the potential pivot is tested against a constant threshold of
$alpha = eps*||A2||_{inf}$,
where $eps = 10^{(-iparm(10))}$, $A2 = P*P_{MPS}*D_r*A*D_c*P$, and $||A2||_{inf}$ is the infinity norm of the scaled and permuted matrix *A*. Any tiny pivots encountered during elimination are set to the sign $(l_{II})*eps*||A2||_{inf}$ - this trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $eps = 10^{(-iparm(10))}$.
For unsymmetric matrices (*mtype* =11 or *mtype* =13) the default value of *iparm*(10) is 13 and therefore eps = 1.0E-13.
For symmetric indefinite matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6) the default value of *iparm*(10) is 8, and therefore eps = 1.0E-8.

iparm(11)**- scaling vectors.**
PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied only to unsymmetric matrices (*mtype* =11 or *mtype* =13). The scaling can also be used for symmetric indefinite matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6) when the symmetric weighted matchings are applied (*iparm*(13)= 1).
Use *iparm*(11) = 1 (scaling) and *iparm*(13) = 1 (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in case of scaling and symmetric weighted matching.

The default value of *iparm*(11) is 1 for unsymmetric matrices (*mtype* =11 or *mtype* =13). The default value of *iparm*(11) is 0 for symmetric indefinite matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6).

iparm(12) **- solving with transposed or conjugate transposed matrix.**
If *iparm*(12)= 0, PARDISO solves a linear system $Ax = b$ (default value).
If *iparm*(12)= 1, PARDISO solves a conjugate transposed system $A^H x = b$ based on the factorization of the matrix A.
If *iparm*(12)= 2, PARDISO solves a transposed system $A^T x = b$ based on the factorization of the matrix A.

NOTE For real matrices the terms *conjugate transposed* and *transposed* are equivalent.

iparm(13) **- improved accuracy using (non-)symmetric weighted matchings.**
PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to our factorization methods and can be seen as a complement to the alternative idea of using more complete pivoting techniques during the numerical factorization.
Use *iparm*(11)=1 (scalings) and *iparm*(13)=1 (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase (*phase* =11) you must provide the numerical values of the matrix A in the case of scalings and symmetric weighted matchings.
The default value of *iparm*(13) is 1 for unsymmetric matrices (*mtype* =11 or *mtype* =13). The default value of *iparm*(13) is 0 for symmetric matrices (*mtype* =-2, *mtype* =-4, or *mtype* =6).

iparm(18) **- numbers of non-zero elements in the factors.**
If *iparm*(18)< 0 on entry, the solver reports the numbers of non-zero elements in the factors.
The default value of *iparm*(18)is -1.

iparm(19)**- MFLOPS of factorization.**
If *iparm*(19)< 0 on entry, the solver reports the number of MFLOPS (1.0E6) that are necessary to factor the matrix A. Reporting this number increases the reordering time.
The default value of *iparm*(19) is 0.

iparm(21) **- pivoting for symmetric indefinite matrices.**
iparm(21) controls the pivoting method for sparse symmetric indefinite matrices.
If *iparm*(21) = 0, then 1x1 diagonal pivoting is used.
If *iparm*(21) = 1, then 1x1 and 2x2 Bunch and Kaufman pivoting is used in the factorization process.

NOTE Use *iparm*(11) = 1 (scaling) and *iparm*(13) = 1 (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems.

The default value of *iparm*(21) is 1. Bunch and Kaufman pivoting is available for matrices: *mtype*=-2, *mtype*=-4, or *mtype*=6.

iparm(24) **- parallel factorization control.**
This parameter selects the scheduling method for the parallel numerical factorization.
If *iparm*(24) = 0 (default value), then PARDISO uses the previous parallel factorization.
If *iparm*(24) = 1, then PARDISO uses new two-level scheduling algorithm. This algorithm generally improves scalability in case of parallel factorization on many threads (more than eight).

The two-level scheduling factorization algorithm is enabled by default in previous MKL releases for matrices *mtype*=11. If you see performance degradation for such matrices with the default value, set manually *iparm*(24)=1.

iparm(25) **- parallel forward/backward solve control.**
If *iparm*(25) = 0 (default value), then PARDISO uses a parallel algorithm for the solve step.
If *iparm*(25) = 1, then PARDISO uses sequential forward and backward solve.

This feature is available only for *in-core* version.

iparm(27) **- matrix checker.**
If *iparm*(27)=0 (default value), PARDISO does not check the sparse matrix representation.
If *iparm*(27)=1, then PARDISO checks integer arrays *ia* and *ja*. In particular, PARDISO checks whether column indices are sorted in increasing order within each row.

iparm(28) **- sets single or double precision of PARDISO.**
If *iparm*(28)=0, then the input arrays (matrix *a*, vectors *x* and *b*) and all internal arrays must be presented in double precision.
If *iparm*(28)=1, then the input arrays must be presented in single precision. In this case all internal computations are performed in single precision.
Depending on the sign of *iparm*(8), refinement steps can be calculated in quad or double precision for double precision accuracy, and in double or single precision for single precision accuracy.
Default value of *iparm*(28) is 0 (double precision).

Important *iparm*(28) value is stored in the PARDISO handle between PARDISO calls, so the precision mode can be changed only during the solver's phase 1.

iparm(31) **- partial solution for sparse right-hand sides and sparse solution.**
This parameter controls the solution method if the right hand side contains a few nonzero components. It can be also used if only few components of the solution vector are needed, or if you want to reduce computation cost at solver step. To use this option define the input permutation vector *perm* so that *perm*(i) = 1 means that the i-the component in the right-hand side is nonzero or the i-th component in the solution vector is computed.
If *iparm*(31) =0 (default value), this option is disabled.
If *iparm*(31) =1, the right hand side must be sparse, and the *i*-th component in the solution vector is computed if *perm*(*i*) = 1. You can set *perm*(i) = 1 only if the i-th component of the right hand side is nonzero.
If *iparm*(31) =2, the right hand side must be sparse, all components of the solution vector are computed. *perm*(i) = 1 means that the *i*-th component of the right hand side is nonzero.
In the last case the computation cost at solver step is reduced due to reduced forward solver step.
To use *iparm*(31) =2, you must set the i-th component of the right hand side to zero explicitly if *perm*(i) is not equal to 1.
If *iparm*(31) =3, the right hand side can be of any type and you must set *perm*(i) = 1 to compute the *i*-th component in the solution vector.
The permutation vector *perm* must be present in all phases of Intel MKL PARDISO software. At the reordering step, the software overwrites the input vector *perm* by a permutation vector used by the software at the factorization and solver step. If *m* is the number of components such that *perm*(i) = 1, then the last *m* components of the output vector *perm* are a set of the indices i satisfying the condition *perm*(i) = 1 on input.

NOTE Turning on this option often increases time used by PARDISO for factorization and reordering steps, but it enables time to be reduced for the solver step.

Important This feature is available only for the *in-core* version, so to use it you must set *iparm*(60) =0. Set the parameters *iparm*(8) (iterative refinement steps), *iparm*(4) (preconditioned CGS), and *iparm*(5) (user permutation) to 0 as well.

iparm(32) - *iparm*(34) - these parameters are reserved for future use. Their values must be set to 0.

iparm(35) **- C or Fortran style array indexing.**
iparm(35) determines the indexing base for input matrices.
If *iparm*(35)=0 (default value), then PARDISO uses Fortran style indexing: first value is referenced as array element 1.
Otherwise PARDISO uses C style indexing: the first value is referenced as array element 0.

iparm(35) - *iparm*(59) - these parameters are reserved for future use. Their values must be set to 0.

iparm(60) **- version of PARDISO.**

iparm(60) controls what version of PARDISO - out-of-core (OC) version or in-core (IC) version - is used. The OC PARDISO can solve very large problems by holding the matrix factors in files on the disk. Because of that the amount of main memory required by OC PARDISO is significantly reduced.
If *iparm*(60) = 0 (default value), then IC PARDISO is used.
If *iparm*(60) = 1 - then IC PARDISO is used if the total memory of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: MKL_PARDISO_OOC_MAX_CORE_SIZE (its default value is 2000 MB) and MKL_PARDISO_OOC_MAX_SWAP_SIZE (its default value is 0 MB); otherwise OOC PARDISO is used. In this case amount of RAM used by OOC PARDISO can not exceed the value of MKL_PARDISO_OOC_MAX_CORE_SIZE.
If *iparm*(60) = 2 - then OOC PARDISO is used.
If *iparm*(60) is equal to 1 or 2, and the total peak memory needed for storing the local arrays is more than MKL_PARDISO_OOC_MAX_CORE_SIZE, the program stops with error -9. In this case, increase MKL_PARDISO_OOC_MAX_CORE_SIZE.
OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variable MKL_PARDISO_OOC_CFG_PATH and MKL_PARDISO_OOC_CFG_FILE_NAME. Path and name are as follows:
<MKL_PARDISO_OOC_CFG_PATH >/< MKL_PARDISO_OOC_CFG_FILE_NAME>
for Linux* OS, and
<MKL_PARDISO_OOC_CFG_PATH >\< MKL_PARDISO_OOC_CFG_FILE_NAME>
for Windows* OS.
By default, the name of the file is pardiso_ooc.cfg and it is placed to the current directory.
All temporary data files can be deleted or stored when the calculations are completed in accordance with the value of the environmental variable MKL_PARDISO_OOC_KEEP_FILE. If it is set to 1 (default value), then all files are deleted, if it is set to 0, then all files are stored.
By default, the OOC PARDISO uses the current directory for storing data, and all work arrays associated with the matrix factors are stored in files named ooc_temp with different extensions. These default values can be changed by using the environmental variable MKL_PARDISO_OOC_PATH.
To set the environmental variables MKL_PARDISO_OOC_MAX_CORE_SIZE, MKL_PARDISO_OOC_MAX_SWAP_SIZE, MKL_PARDISO_OOC_KEEP_FILE, and MKL_PARDISO_OOC_PATH, create the configuration file with the following lines:

```
MKL_PARDISO_OOC_PATH = <path>\ooc_file
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where <*path*> is the directory for storing data, *ooc_file* is the file name without any extension, *N* is the maximum size of RAM in megabytes available for PARDISO (default value is 2000 MB), *K* is the maximum swap size in megabytes available for PARDISO (default value is 0 MB). Do not set *N* greater than the size of the RAM and *K* greater than the size of the swap.

WARNING The maximum length of the path lines in the configuration files is 1000 characters.

Alternatively the environment variables can be set via command line.
For Linux* OS:

```
export MKL_PARDISO_OOC_PATH = <path>/ooc_file
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_CORE_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows* OS:

```
set MKL_PARDISO_OOC_PATH = <path>\ooc_file
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_CORE_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

NOTE The values specified in a command line have higher priorities - it means that if a variable is changed in the configuration file and in the command line, OOC PARDISO uses only value defined in the command line.

NOTE You can switch between IC and OOC modes after the reordering phase. There are some recommendations and limitations:

- Set *iparm*(60) before reordering phase to get better PARDISO performance.
- Two-level factorization algorithm is not supported in the OOC mode. If you set two-level algorithm in the OOC mode then PARDISO returns error -1.
- Switching between IC and OOC modes after reordering phase is not available in sequential mode. The program returns error -1.

iparm(61), *iparm*(62), *iparm*(64) - these parameters are reserved for future use. Their values must be set to 0.

msglvl INTEGER
Message level information. If *msglvl* = 0 then PARDISO generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

b DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision PARDISO (*iparm*(28)=0)
REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision PARDISO (*iparm*(28)=1)
DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision PARDISO (*iparm*(28)=0)
COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision PARDISO (*iparm*(28)=1)
Array, dimension (*n*, *nrhs*). On entry, contains the right-hand side vector/matrix *B*, which is placed in memory contiguously. The *b*(i+(k-1)×*nrhs*) must hold the i-th component of k-th right-hand side vector. Note that *b* is only accessed in the solution phase.

Output Parameters

(See also PARDISO Parameters in Tabular Form.)

pt This parameter contains internal address pointers.

iparm On output, some *iparm* values report information such as the numbers of non-zero elements in the factors.

iparm(7)**- number of performed iterative refinement steps.**
The number of iterative refinement steps that are actually performed during the solve step.

iparm(14)**- number of perturbed pivots.**
After factorization, *iparm*(14) contains the number of perturbed pivots during the elimination process for *mtype* =11, *mtype* =13, *mtype* =-2, *mtype* =-4, or *mtype* =-6.

iparm(15) **- peak memory symbolic factorization.**
The parameter *iparm*(15) reports the total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.

iparm(16) **- permanent memory symbolic factorization.**
The parameter *iparm*(16) reports the permanent memory in kilobytes from the analysis and symbolic factorization phase that the solver needs in the factorization and solve phases. This value is only computed in phase 1.

iparm(17) **- size of factors /memory numerical factorization and solution.**
The parameter *iparm*(17) provides the size in kilobytes of the total memory consumed by IC PARDISO for internal float point arrays. This parameter is computed in phase 1. See *iparm*(63) for the OOC mode. The total peak memory solver consumption for all phases is max(*iparm*(15), *iparm*(16)+*iparm*(17))

iparm(18) **- number of non-zero elements in factors.**
The solver reports the numbers of non-zero elements on the factors if *iparm*(18) < 0 on entry.

iparm(19) **- MFLOPS of factorization.**
The solver reports the number of operations in MFLOPS (1.0E6 operations) that are necessary to factor the matrix *A* if *iparm*(19) < 0 on entry.

iparm(20) **- CG/CGS diagnostics.**
The value is used to give CG/CGS diagnostics (for example, the number of iterations and cause of failure):
If *iparm*(20)> 0, CGS succeeded, and the number of iterations executed are reported in *iparm*(20).
If *iparm*(20)< 0, iterations executed, but CG/CGS failed. The error report details in *iparm*(20) are of the form: *iparm*(20)= – it_cgs*10 – cgs_error.
If *phase*= 23, then the factors *L* and *U* are recomputed for the matrix *A* and the error flag *error*=0 in case of a successful factorization. If *phase* = 33, then *error* = -4 signals failure.
Description of cgs_error is given in the table below:

cgs_error	Description
1	fluctuations of the residue are too large

cgs_error	Description
2	$\|\|dx_{max\_it\_cgs/2}\|\|$ is too large (slow convergence)
3	stopping criterion is not reached at max_it_cgs
4	perturbed pivots causes iterative refinement
5	factorization is too fast for this matrix. It is better to use the factorization method with *iparm*(4)=0

iparm(22) – **inertia: number of positive eigenvalues.**
The parameter *iparm*(22) reports the number of positive eigenvalues for symmetric indefinite matrices.

iparm(23) **- inertia: number of negative eigenvalues.**
The parameter *iparm*(23) reports the number of negative eigenvalues for symmetric indefinite matrices.

iparm(30) - **the number of the equation where PARDISO detects zero or negative pivot**
If the solver detects a zero or negative pivot for matrix types *mtype* = 2 (real positive definite matrix) and *mtype* = 4 (complex and Hermitian positive definite matrices), the factorization is stopped, PARDISO returns immediately with an error (*error* = -4) and *iparm*(30) contains the number of the equation where the first zero or negative pivot is detected.

iparm(63) **- size of the minimum OOC memory for numerical factorization and solution.**
The parameter *iparm*(63) provides the size in kilobytes of the minimum memory required by OOC PARDISO for internal float point arrays. This parameter is computed in phase 1.
Total peak memory consumption of OOC PARDISO can be estimated as max(*iparm*(15), *iparm*(16)+*iparm*(63))

b — On output, the array is replaced with the solution if *iparm*(6) = 1.

x — DOUBLE PRECISION - for real types of matrices (*mtype*=1, 2, -2 and 11) and for double precision PARDISO (*iparm*(28)=0)
REAL - for real types of matrices (*mtype*=1, 2, -2 and 11) and for single precision PARDISO (*iparm*(28)=1)
DOUBLE COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for double precision PARDISO (*iparm*(28)=0)
COMPLEX - for complex types of matrices (*mtype*=3, 6, 13, 14 and -4) and for single precision PARDISO (*iparm*(28)=1)
Array, dimension (*n*,*nrhs*). If *iparm*(6)=0 it contains solution vector/ matrix *X*, which is placed contiguously in memory. The *x*(i+(k–1)× *nrhs*) element must hold the i-th component of the k-th solution vector. Note that *x* is only accessed in the solution phase.

error — INTEGER
The error indicator according to the below table:

error	Information
0	no error
–1	input inconsistent
–2	not enough memory
–3	reordering problem

error	Information
-4	zero pivot, numerical factorization or iterative refinement problem
-5	unclassified (internal) error
-6	reordering failed (matrix types 11 and 13 only)
-7	diagonal matrix is singular
-8	32-bit integer overflow problem
-9	not enough memory for OOC
-10	problems with opening OOC temporary files
-11	read/write problems with the OOC data file

See Also

mkl_progress

pardisoinit

Initialize PARDISO with default parameters in accordance with the matrix type.

Syntax

Fortran:

```
call pardisoinit (pt, mtype, iparm)
```

C:

```
pardisoinit (pt, &mtype, iparm);
```

Include Files

- FORTRAN 77: `mkl_pardiso.f77`
- Fortran 90: `mkl_pardiso.f90`
- C: `mkl_pardiso.h`

Description

This function initializes PARDISO internal address pointer *pt* with zero values (as needed for the very first call of PARDISO) and sets default *iparm* values in accordance with the matrix type. Intel MKL supplies the `pardisoinit` routine to be compatible with PARDISO 3.2 or lower distributed by the University of Basel.

NOTE An alternative way to set default PARDISO *iparm* values is to call `pardiso` with *iparm*`(1)=0`. In this case you must initialize the internal address pointer *pt* with zero values manually.

NOTE The `pardisoinit` routine initializes only the in-core version of PARDISO. Switching on the out-of core version of PARDISO as well as changing default *iparm* values can be done after the call to `pardisoinit` but before the first call to `pardiso`.

Input Parameters

NOTE Parameters types in this section are specified in FORTRAN 77 notation. See PARDISO Parameters in Tabular Form section for detailed description of types of PARDISO parameters in C/Fortran 90 notations.

mtype — INTEGER
This scalar value defines the matrix type. Based on this value pardisoinit sets default values for the *iparm* array. Refer to the section PARDISO Parameters in Tabular Form for more details about the default values of PARDISO.

Output Parameters

pt — INTEGER for 32-bit architectures
INTEGER*8 for 64-bit architectures
Array, DIMENSION (64)
Solver internal data address pointer. These addresses are passed to the solver, and all related internal memory management is organized through this array. The pardisoinit routine nullifies the array *pt*.

NOTE It is very important that the pointer *pt* is initialized with zero before the first call of PARDISO. After that first call you should never modify the pointer, as a serious memory leak can occur.

iparm — INTEGER
Array, dimension (64). This array is used to pass various parameters to PARDISO and to return some useful information after execution of the solver. The pardisoinit routine fills-in the *iparm* array with the default values. Refer to the section PARDISO Parameters in Tabular Form for more details about the default values of PARDISO.

pardiso_64

Calculates the solution of a set of sparse linear equations with multiple right-hand sides, 64-bit integer version.

Syntax

Fortran:

```
call pardiso_64 (pt, maxfct, mnum, mtype, phase, n, a, ia, ja, perm, nrhs, iparm, msglvl, b, x, error)
```

C:

```
pardiso_64 (pt, &maxfct, &mnum, &mtype, &phase, &n, a, ia, ja, perm, &nrhs, iparm, &msglvl, b, x, &error);
```

Include Files

- FORTRAN 77: mkl_pardiso.f77
- Fortran 90: mkl_pardiso.f90
- C: mkl_pardiso.h

Description

pardiso_64 is an alternative ILP64 (64-bit integer) version of the pardiso routine (see Description section for more details). The interface of pardiso_64 is equal to the interface of pardiso, but it accepts and returns all INTEGER data as INTEGER*8.

Use pardiso_64 interface for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel MKL functionality. In other words, if you use 64-bit integer version (pardiso_64), you do not need to re-link your applications with ILP64 libraries. Take into account that pardiso_64 may perform slower than regular pardiso on reordering and symbolic factorization phase.

NOTE pardiso_64 is supported only in the 64-bit libraries. If pardiso_64 is called from the 32-bit libraries, it returns *error* =-12.

Input Parameters

The input parameters of pardiso_64 are equal to the input parameters of pardiso, but pardiso_64 accepts all INTEGER data as INTEGER*8.

Output Parameters

The output parameters of pardiso_64 are equal to output parameters of pardiso, but pardiso_64 returns all INTEGER data as INTEGER*8.

See Also

mkl_progress

pardiso_getenv, pardiso_setenv

Retrieves additional values from the PARDISO handle or sets them in it.

Syntax

```
error = pardiso_getenv(handle, param, value)
error = pardiso_setenv(handle, param, value)
```

outputtext(Interface):

```
_INTEGER_t pardiso_getenv (const _MKL_DSS_HANDLE_t handle, const enum
PARDISO_ENV_PARAM* param, char* value);
_INTEGER_t pardiso_setenv (_MKL_DSS_HANDLE_t handle, const enum PARDISO_ENV_PARAM*
param, const char* value);
```

Include Files

- FORTRAN 77: mkl_pardiso.f77
- Fortran 90: mkl_pardiso.f90
- C: mkl_pardiso.h

NOTE pardiso_setenv requires the *value* parameter to be converted to the string in C notation if it is called from Fortran. You can do this using mkl_cvt_to_null_terminated_str subroutine declared in the mkl_dss.f77 or mkl_dss.f90 include files (see example below).

Description

These functions operate with the PARDISO handle. The `pardiso_getenv` routine retrieves additional values from the PARDISO handle, and `pardiso_setenv` sets specified values in the PARDISO handle.

These functions enable retrieving and setting the name of the PARDISO OOC file.

To retrieve the PARDISO OOC file name, you can apply this function to any non-empty handle.

To set the the PARDISO OOC file name in the handle you must apply the function before reordering stage. That is you must apply the function only for the empty handle. This is because OOC file name is stored in the handle after reordering stage and it is not changed during further computations.

NOTE 1024-byte internal buffer is used inside PARDISO for storing OOC file name. Allocate 1024-byte buffer (*value* parameter) for passing it to `pardiso_getenv` function.

Input Parameters

handle	Input parameter for `pardiso_getenv`. Data object of the `MKL_DSS_HANDLE` type (see DSS Interface Description).
param	`INTEGER`. Specifies the required parameter. The only value is `PARDISO_OCC_FILE_NAME`, defined in the corresponding include file.
value	Input parameter for `pardiso_setenv`. `STRING`. Contains the name of the OOC file that must be used in the handle.

Output Parameters

value	Output parameter for `pardiso_getenv`. `STRING`. Contains the name of the OOC file that is used in the handle.
handle	Output parameter for `pardiso_setenv`. Data object of the `MKL_DSS_HANDLE` type (see DSS Interface Description).

Example (FORTRAN 90)

```
INCLUDE 'mkl_pardiso.f90'
INCLUDE 'mkl_dss.f90'
PROGRAM pardiso_sym_f90
USE mkl_pardiso
USE mkl_dss

INTEGER*8 pt(64)
CHARACTER*1024 file_name
INTEGER buff(256), bufLen, error

pt(1:64) = 0

file_name = 'pardiso_ooc_file'
bufLen = len_trim(file_name)
call mkl_cvt_to_null_terminated_str(buff, bufLen, trim(file_name))
error = pardiso_setenv(pt, PARDISO_OOC_FILE_NAME, buff)

! call pardiso() here

END PROGRAM
```

PARDISO Parameters in Tabular Form

The following table lists all parameters of PARDISO and gives their brief descriptions.

Parameter	Type	Description	Values	Comments	In/Out
pt(64)	**FORTRAN 77:** INTEGER on 32-bit architectures, INTEGER*8 on 64-bit architectures **Fortran 90:** TYPE(MKL_PARDISO_HANDLE), INTENT(INOUT) **C:** void*	Solver internal data address pointer	0	Must be initialized by zeros and never be modified later	in/out
maxfct	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	Maximal number of factors in memory	>0	Generally used value is 1	in
mnum	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	The number of matrix (from 1 to *maxfct*) to solve	[1; *maxfct*]	Generally used value is 1	in
mtype	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	Matrix type	1 2 -2 3 4 -4 6 11 13	Real and structurally symmetric Real and symmetric positive definite Real and symmetric indefinite Complex and structurally symmetric Complex and Hermitian positive definite Complex and Hermitian indefinite Complex and symmetric matrix Real and unsymmetric matrix Complex and unsymmetric matrix	in
phase	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	Controls the execution of the solver	11 12 13 22	Analysis Analysis, numerical factorization Analysis, numerical factorization, solve Numerical factorization	in

Parameter	Type	Description	Values	Comments	In/Out
			23	Numerical factorization, solve	
			33	Solve, iterative refinement	
			331	*phase*=33, but only forward substitution	
			332	*phase*=33, but only diagonal substitution	
			333	*phase*=33, but only backward substitution	
			0	Release internal memory for L and U of the matrix number *mnum*	
			-1	Release all internal memory for all matrices	
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	Number of equations in the sparse linear system *A***X* = *B*	>0		in
a(*)	**FORTRAN 77:** PARDISO_DATA_TYPE[1)] **Fortran 90:** PARDISO_DATA_TYPE[1)], INTENT(IN) **C:** void*	Contains the non-zero elements of the coefficient matrix *A*	*	The size of *a* is the same as that of *ja*, and the coefficient matrix can be either real or complex. The matrix must be stored in CSR format with increasing values of *ja* for each row	in
ia(n+1)	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	*rowIndex* array in CSR format	>=0	0 < *ia*(*i*) <= *ia*(*i*+1) *ia*(*i*) gives the index of the element in array *a* that contains the first non-zero element from row *i* of *A*. The last element *ia*(*n*+1) is taken to be equal to the number of non-zero elements in *A*, plus one. Note: *iparm*(35) indicates whether row/column indexing starts from 1 or 0.	in
ja(*)	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	*columns* array in CSR format	>=0	The indices in each row must be sorted in increasing order. For symmetric and structurally symmetric matrices zero diagonal elements are also stored in *a* and *ja*. For symmetric	in

Parameter	Type	Description	Values	Comments	In/Out
				matrices, the solver needs only the upper triangular part of the system. Note: *iparm*(35) indicates whether row/column indexing starts from 1 or 0.	
perm(n)	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(INOUT) **C:** _INTEGER_t*	Holds the permutation vector of size *n*	>=0	Let *B = P*A*PT* be the permuted matrix. Row (column) *i* of *A* is the *perm*(*i*) row (column) of *B*. The numbering of the array must describe a permutation. You can apply your own fill-in reducing ordering (*iparm*(5)=1) or return the permutation from the solver (*iparm*(5)=2). Note: *iparm*(35) indicates whether row/column indexing starts from 1 or 0.	in/out
nrhs	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	Number of right-hand sides that need to be solved for	>=0	Generally used value is 1	in
iparm(64)	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(INOUT) **C:** _INTEGER_t*	This array is used to pass various parameters to PARDISO and to return some useful information after execution of the solver	*	If *iparm*(1)=0 , PARDISO fills *iparm*(2) through *iparm*(64) with default values and uses them.	in/out
msglvl	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t*	Message level information	0 1	PARDISO generates no output PARDISO prints statistical information	in
*b(n*nrhs)*	**FORTRAN 77:** PARDISO_DATA_TYPE[1)] **Fortran 90:** PARDISO_DATA_TYPE[1)], INTENT(INOUT) **C:** void*	Right-hand side vectors	*	On entry, contains the right hand side vector/matrix *B*, which is placed contiguously in memory. The *b*(i+(k-1)×*nrhs*) element must hold the *i*-th component of *k*-th right-hand side vector. Note that *b* is only accessed in the solution phase.	in/out

Parameter	Type	Description	Values	Comments	In/Out
				On output, the array is replaced with the solution if *iparm*(6)=1.	
*x(n*nrhs)*	**FORTRAN 77:** PARDISO_DATA_TYPE[1)] **Fortran 90:** PARDISO_DATA_TYPE[1)], INTENT(OUT) **C:** void*	Solution vectors	*	On output, if *iparm*(6)=1, contains solution vector/ matrix *X* which is placed contiguously in memory. The *x*(i+(k-1)×*nrhs*) element must hold the *i*-th component of *k*-th solution vector. Note that *x* is only accessed in the solution phase.	out
error	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(OUT) **C:** _INTEGER_t*	Error indicator	0	No error	out
			-1	Input inconsistent	
			-2	Not enough memory	
			-3	Reordering problem	
			-4	Zero pivot, numerical factorization or iterative refinement problem	
			-5	Unclassified (internal) error	
			-6	Reordering failed (matrix types 11 and 13 only)	
			-7	Diagonal matrix is singular	
			-8	32-bit integer overflow problem	
			-9	Not enough memory for OOC	
			-10	Problems with opening OOC temporary files	
			-11	Read/write problems with the OOC data file	

[1)] See description of PARDISO_DATA_TYPE in the table below.

The following table lists the values of PARDISO_DATA_TYPE depending on the matrix types and values of the parameter *iparm*(28).

Data type value	Matrix type *mtype*	*iparm*(28)	comments
DOUBLE PRECISION	1, 2, -2, 11	0	Real matrices, double precision
REAL		1	Real matrices, single precision
DOUBLE COMPLEX	3, 6, 13, 4, -4	0	Complex matrices, double precision

Data type value	Matrix type *mtype*	*iparm*(28)	comments
COMPLEX		1	Complex matrices, single precision

The following table lists all individual components of the PARDISO *iparm()* parameter and their brief descriptions. Components not listed in the table must be initialized with 0. Default values in the column **Values** are denoted as X*.

Component	Description	Values	Comments	In/ Out
INPUT, INPUT/OUTPUT PARAMETERS				
iparm(1)	Use default values	0	*iparm*(2) -*iparm*(64) are filled with default values.	in
		!=0	You must supply all values in components *iparm*(2) -*iparm*(64)	
iparm(2)	Fill-in reducing ordering for the input matrix	0	The minimum degree algorithm.	in
		2*	The nested dissection algorithm from the METIS package	
		3	The parallel (OpenMP) version of the nested dissection algorithm.	
iparm(4)	Preconditioned CGS/ CG	0*	Do not perform preconditioned Krylow-Subspace iterations.	in
		10*L*+1	CGS iteration replaces the computation of LU. The preconditioner is LU that is computed at the previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns. *L* controls the stopping criterion of the Krylow-Subspace iteration: epsCGS = 10^(-*L*) is used in the stopping criterion ||dxi|| / ||dx0|| < epsCGS, with ||dxi|| = ||inv(L*U)*ri|| and ri is the residuum at iteration i of the preconditioned Krylow-Subspace iteration.	
		10*L*+2	Same as above, but CG iteration replaces the computation of LU. Designed for symmetric positive definite matrices.	
iparm(5)	User permutation	0*	User permutation in *perm* array is ignored.	in
		1	PARDISO uses the user supplied fill-in reducing permutation from *perm* array. *iparm*(2) is ignored.	
		2	PARDISO returns the permutation vector computed at phase 1 into *perm* array	
iparm(6)	Write solution on *x*	0*	The array *x* contains the solution; right-hand side vector *b* is kept unchanged.	in
		1	The solver stores the solution on the right-hand side *b*. Note that the array *x* is always used.	
iparm(8)	Iterative refinement step	0*	The solver automatically performs two steps of iterative refinements when perturbed pivots are obtained during the numerical factorization.	in

Component	Description	Values	Comments	In/Out
		>0	Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of *iparm*(8) steps of iterative refinement and stops the process if a satisfactory level of accuracy of the solution in terms of backward error is achieved. The number of executed iterations is reported in *iparm*(7).	
		<0	Same as above, but the accumulation of the residuum uses extended precision real and complex data types.	
iparm(10)	Pivoting perturbation	*	This parameter instructs PARDISO how to handle small pivots or zero pivots for unsymmetric matrices (*mtype* =11, *mtype* =13) and symmetric matrices (*mtype* =-2, *mtype* =-4, *mtype* =6). Small pivots are perturbed with eps = 10^(-*iparm*(10)).	in
		13*	The default value for unsymmetric matrices(*mtype* =11, *mtype*=13), eps = 10^(-13).	
		8*	The default value for symmetric indefinite matrices (*mtype* =-2, *mtype*=-4, *mtype*=6), eps = 10^(-8).	
iparm(11)	Scaling	0*	Disable scaling. Default for symmetric indefinite matrices.	in
		1*	Enable scaling. Default for unsymmetric matrices. Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to unsymmetric matrices (*mtype* = 11, *mtype* = 13). The scaling can also be used for symmetric indefinite matrices (*mtype* = -2, *mtype* = -4, *mtype* = 6) when the symmetric weighted matchings are applied (*iparm*(13) = 1). Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in case of scaling.	
iparm(12)	Solving with transposed or conjugate transposed matrix *A*	0*	Solve a $Ax=b$ linear system.	
		1	Solve a conjugate transposed system $A^Hx = b$ based on the factorization of the matrix *A*.	
		2	Solve a transposed system $A^Tx = b$ based on the factorization of the matrix *A*.	
iparm(13)	Improved accuracy using (non-) symmetric weighted matching	0*	Disable matching. Default for symmetric indefinite matrices.	in
		1*	Enable matching. Default for symmetric indefinite matrices. Maximum weighted matching algorithm to permute large elements close to the diagonal.	

Component	Description	Values	Comments	In/ Out
			It is recommended to use *iparm*(11) = 1 (scaling) and *iparm*(13) = 1 (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase (*phase*=11) you must provide the numerical values of the matrix *A* in case of symmetric weighted matching.	
iparm(18)	Report the number of non-zero elements in the factors	<0	Enable reporting if *iparm*(18) < 0 on entry. The default value is -1.	in/ out
		>=0	Disable reporting.	
iparm(19)	Report Mflops that are necessary to factor the matrix *A*.	<0	Enable report if *iparm*(18) < 0 on entry. This increases the reordering time.	in/ out
		>=0	Disable report. 0 is a default value.	
iparm(21)	Pivoting for symmetric indefinite matrices	0	Apply 1x1 diagonal pivoting during the factorization process.	in
		1*	Apply 1x1 and 2x2 Bunch and Kaufman pivoting during the factorization process.	
iparm(24)	parallel factorization control	0	PARDISO uses the previous algorithm for factorization. Default value.	in
		1	PARDISO uses new two-level factorization algorithm.	
iparm(25)	Parallel forward/ backward solve control	0	PARDISO uses the parallel algorithm for solve step. Default value.	in
		1	PARDISO uses the sequential forward and backward solve.	
iparm(27)	Matrix checker	0*	PARDISO does not check the sparse matrix representation.	in
		1	PARDISO checks integer arrays *ia* and *ja*. In particular, PARDISO checks whether column indices are sorted in increasing order within each row.	
iparm(28)	Single or double precision of PARDISO	0*	Input arrays (*a*, *x* and *b*) and all internal arrays must be presented in double precision.	in
		1	Input arrays (*a*, *x* and *b*) must be presented in single precision. In this case all internal computations are performed in single precision.	
iparm(31)	Enables to solve partially for sparse right-hand sides and sparse solution	0	Disables this option. Default value.	in
		1	The right hand side is assumed to be sparse, *perm*(i)=1 means that the i-th component of the right hand side is nonzero, and this component of the solution vector is computed.	

Component	Description	Values	Comments	In/Out
		2	The right hand side is assumed to be sparse, *perm*(i)=1 means that the i-th component of the right hand side is nonzero, and all components of the solution vector are computed.	
		3	The right hand side can be of any type. If *perm*(i)=1, the i-th component of the solution vector is computed.	
iparm(35)	One- or zero-based indexing of columns and rows	0*	One-based indexing: columns and rows indexing in arrays *ia*, *ja*, and *perm* starts from 1. Default value.	in
		1	Zero-based indexing: columns and rows indexing in arrays *ia*, *ja*, and *perm* starts from 0.	
iparm(60)	PARDISO mode	0*	In-core PARDISO	in
		1	In-core PARDISO is used if the total memory needed for storing the matrix factors is less than the value of the environment variable MKL_PARDISO_OOC_MAX_CORE_SIZE. Otherwise out-of-core (OOC) PARDISO is used.	
		2	Out-of-core (OOC) PARDISO The OOC PARDISO can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOC PARDISO is significantly reduced.	
OUTPUT PARAMETERS				
iparm(7)	Number of performed iterative refinement steps	>=0	Reports the number of iterative refinement steps that were actually performed during the solve step.	out
iparm(14)	Number of perturbed pivots	>=0	After factorization, contains the number of perturbed pivots for the matrix types: 11, 13, -2, -4 and -6.	out
iparm(15)	Peak memory on symbolic factorization	>0 KB	The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.	out
iparm(16)	Permanent memory on symbolic factorization	>0 KB	Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases. This value is only computed in phase 1.	out
iparm(17)	Size of factors/Peak memory on numerical factorization and solution	>0 KB	This parameter provides the size in kilobytes of the total memory consumed by in-core PARDISO for internal float point arrays. This parameter is computed in phase 1. See *iparm*(63) for the OOC mode. The total peak memory consumed by PARDISO is max(*iparm*(15), *iparm*(16)+*iparm*(17))	out
iparm(20)	CG/CGS diagnostics	>0	CGS succeeded, reports the number of completed iterations.	out
		<0	CG/CGS failed (*error*=-4 after the solution phase)	

Component	Description	Values	Comments	In/Out
			iparm(20)= - it_cgs*10 - cgs_error. Possible values of cgs_error: 1 - fluctuations of the residuum are too large 2 - ||dx at max_it_cgs/2|| is too large (slow convergence) 3 - stopping criterion is not reached at max_it_cgs 4 - perturbed pivots causes iterative refinement	
iparm(22)	Inertia: number of positive eigenvalues	>=0	PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices	out
iparm(23)	Inertia: number of negative eigenvalues	>=0	PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices.	out
iparm(30)	Number of zero or negative pivots	>=0	If PARDISO detects zero or negative pivot for *mtype*=2 or *mtype*=4 types, the factorization is stopped, PARDISO returns immediately with an *error* = -4, and *iparm*(30) reports the number of the equation where the first zero or negative pivot is detected.	out
iparm(63)	Size of the minimum OOC memory for numerical factorization and solution	>0 KB	This parameter provides the size in kilobytes of the minimum memory required by OOC PARDISO for internal float point arrays. This parameter is computed in phase 1. Total peak memory consumption of OOC PARDISO can be estimated as max(*iparm*(15), *iparm*(16)+*iparm*(63))	

Direct Sparse Solver (DSS) Interface Routines

Intel MKL supports the DSS interface, an alternative to the PARDISO* interface for the direct sparse solver. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and utilizes the general scheme described in Appendix A Linear Solvers Basics for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process and an auxiliary routine for passing character strings from Fortran routines to C routines.

The current implementation of the DSS interface additionally supports the out-of-core (OOC) mode.

Table "DSS Interface Routines" lists the names of the routines and describes their general use.

DSS Interface Routines

Routine	Description
dss_create	Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine.
dss_define_structure	Informs the solver of the locations of the non-zero elements of the array.
dss_reorder	Based on the non-zero structure of the matrix, computes a permutation vector to reduce fill-in during the factoring process.

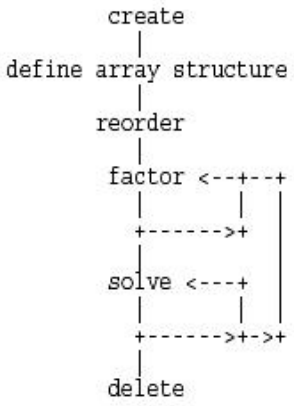
Routine	Description
dss_factor_real, dss_factor_complex	Computes the LU, LDL^T or LL^T factorization of a real or complex matrix.
dss_solve_real, dss_solve_complex	Computes the solution vector for a system of equations based on the factorization computed in the previous phase.
dss_delete	Deletes all data structures created during the solving process.
dss_statistics	Returns statistics about various phases of the solving process.
mkl_cvt_to_null_terminated_str	Passes character strings from Fortran routines to C routines.

To find a single solution vector for a single system of equations with a single right hand side, invoke the Intel MKL DSS interface routines in this order:

1. dss_create
2. dss_define_structure
3. dss_reorder
4. dss_factor_real, dss_factor_complex
5. dss_solve_real, dss_solve_complex
6. dss_delete

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is sometimes necessary to invoke the Intel MKL sparse routines in an order other than that listed, which is possible using the DSS interface. The solving process is conceptually divided into six phases. Figure "Typical order for invoking DSS interface routines" indicates the typical order in which the DSS interface routines can be invoked.

Typical order for invoking DSS interface routines



See the code examples that use the DSS interface routines to solve systems of linear equations in the `examples\solver\source` folder of your Intel MKL directory (`dss_sym_f.f`, `dss_sym_c.c`, `dss_sym_f90.f90`).

DSS Interface Description

Each DSS routine reads from or writes to a data object called a *handle*. Refer to Memory Allocation and Handles to determine the correct method for declaring a handle argument for each language. For simplicity, the descriptions in DSS routines refer to the data type as `MKL_DSS_HANDLE`.

C and C++ programmers should refer to Calling Sparse Solver and Preconditioner Routines from C C++ for information on mapping Fortran types to C/C++ types.

Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see Implementation Details). The routines accept options for setting the message and termination levels as described in Table "Symbolic Names for the Message and Termination Levels Options". Additionally, each routine accepts the option `MKL_DSS_DEFAULTS` that sets the default values (as documented) for *opt* to the routine.

Symbolic Names for the Message and Termination Levels Options

Message Level	Termination Level
MKL_DSS_MSG_LVL_SUCCESS	MKL_DSS_TERM_LVL_SUCCESS
MKL_DSS_MSG_LVL_INFO	MKL_DSS_TERM_LVL_INFO
MKL_DSS_MSG_LVL_WARNING	MKL_DSS_TERM_LVL_WARNING
MKL_DSS_MSG_LVL_ERROR	MKL_DSS_TERM_LVL_ERROR
MKL_DSS_MSG_LVL_FATAL	MKL_DSS_TERM_LVL_FATAL

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

You can specify both message and termination level for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
CALL dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL DSS routines do not make copies of the user input arrays.

WARNING Do not modify the contents of these arrays after they are passed to one of the solver routines.

DSS Routines

dss_create

Initializes the solver.

Syntax

C:

```
dss_create(handle, opt)
```

Fortran:

```
call dss_create(handle, opt)
```

Include Files

- FORTRAN 77: `mkl_dss.f77`
- Fortran 90: `mkl_dss.f90`
- C: `mkl_dss.h`

Description

The `dss_create` routine initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel MKL DSS routines must use the value of the handle returned by `dss_create`.

WARNING Do not write the value of handle directly.

The default value of the parameter *opt* is

`MKL_DSS_MSG_LVL_WARNING` + `MKL_DSS_TERM_LVL_ERROR`.

By default, the DSS routines use double precision for solving systems of linear equations. The precision used by the DSS routines can be set to single mode by adding the following value to the *opt* parameter:

`MKL_DSS_SINGLE_PRECISION`.

As for PARDISO, input data and internal arrays are required to have single precision.

By default, the DSS routines use Fortran style indexing for input arrays of integer types (the first value is referenced as array element 1). The indexing can be set to C style (the first value is referenced as array element 0) by adding the following value to the *opt* parameter:

`MKL_DSS_ZERO_BASED_INDEXING`.

This parameter can also control number of refinement steps used on the solution stage by specifying the two following values:

`MKL_DSS_REFINEMENT_OFF` - maximum number of refinement steps is set to zero;
`MKL_DSS_REFINEMENT_ON` (default value) - maximum number of refinement steps is set to 2.

By default, DSS uses in-core computations. To launch the out-of-core version of DSS (OOC DSS) you can add to this parameter one of two possible values: `MKL_DSS_OOC_STRONG` and `MKL_DSS_OOC_VARIABLE`.

`MKL_DSS_OOC_STRONG` - OOC DSS is used.

`MKL_DSS_OOC_VARIABLE` - if the memory needed for the matrix factors is less than the value of the environment variable `MKL_PARDISO_OOC_MAX_CORE_SIZE`, then the OOC DSS uses the in-core kernels of PARDISO, otherwise it uses the OOC computations.

The variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` defines the maximum size of RAM allowed for storing work arrays associated with the matrix factors. It is ignored if `MKL_DSS_OOC_STRONG` is set. The default value of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 MB. This value and default path and file name for storing temporary data can be changed using the configuration file `pardiso_ooc.cfg` or command line (See more details in the pardiso description above).

WARNING Do not change the OOC DSS settings after they are specified in the routine `dss_create`.

Input Parameters

Name	Type	Description
opt	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Parameter to pass the DSS options. The default value is MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.

Output Parameters

Name	Type	Description
handle	**FORTRAN 77:** INTEGER*8 **Fortran 90:** TYPE (MKL_DSS_HANDLE), INTENT(OUT) **C:** _MKL_DSS_HANDLE_t*	Pointer to the data structure storing intermediate DSS results (MKL_DSS_HANDLE).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_INVALID_OPTION

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

dss_define_structure

Communicates locations of non-zero elements in the matrix to the solver.

Syntax

C:

```
dss_define_structure(handle, opt, rowIndex, nRows, nCols, columns, nNonZeros);
```

Fortran:

```
call dss_define_structure(handle, opt, rowIndex, nRows, nCols, columns, nNonZeros);
```

Include Files

- FORTRAN 77: mkl_dss.f77
- Fortran 90: mkl_dss.f90
- C: mkl_dss.h

Description

The routine dss_define_structure communicates the locations of the *nNonZeros* number of non-zero elements in a matrix of *nRows * nCols* size to the solver.

The Intel MKL DSS software operates only on square matrices, so *nRows* must be equal to *nCols*.

To communicate the locations of non-zero elements in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying the value for the options argument *opt*. You can set the following values for real matrices:

- MKL_DSS_SYMMETRIC_STRUCTURE
- MKL_DSS_SYMMETRIC
- MKL_DSS_NON_SYMMETRIC

and for complex matrices:

- MKL_DSS_SYMMETRIC_STRUCTURE_COMPLEX
- MKL_DSS_SYMMETRIC_COMPLEX
- MKL_DSS_NON_SYMMETRIC_COMPLEX

The information about the matrix type must be defined in dss_define_structure.

2. Provide the actual locations of the non-zeros by means of the arrays *rowIndex* and *columns* (see Sparse Matrix Storage Format).

Input Parameters

Name	Type	Description
opt	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Parameter to pass the DSS options. The default value for the matrix structure is MKL_DSS_SYMMETRIC.
rowIndex	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Array of size min(*nRows*, *nCols*)+1. Defines the location of non-zero entries in the matrix.
nRows	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Number of rows in the matrix.
nCols	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Number of columns in the matrix.
columns	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Array of size *nNonZeros*. Defines the location of non-zero entries in the matrix.
nNonZeros	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Number of non-zero elements in the matrix.

Output Parameters

Name	Type	Description
handle	**FORTRAN 77:** INTEGER*8 **Fortran 90:** TYPE (MKL_DSS_HANDLE), INTENT(INOUT) **C:** _MKL_DSS_HANDLE_t*	Pointer to the data structure storing intermediate DSS results (MKL_DSS_HANDLE).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_STRUCTURE_ERR

MKL_DSS_ROW_ERR

MKL_DSS_COL_ERR

MKL_DSS_NOT_SQUARE

MKL_DSS_TOO_FEW_VALUES

MKL_DSS_TOO_MANY_VALUES

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

dss_reorder

Computes or sets a permutation vector that minimizes the fill-in during the factorization phase.

Syntax

C:

dss_reorder(*handle*, *opt*, *perm*)

Fortran:

call dss_reorder(*handle*, *opt*, *perm*)

Include Files

- FORTRAN 77: mkl_dss.f77
- Fortran 90: mkl_dss.f90
- C: mkl_dss.h

Description

If *opt* contains the option MKL_DSS_AUTO_ORDER, then the routine dss_reorder computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_METIS_OPENMP_ORDER, then the routine dss_reorder computes permutation vector using the parallel (OpenMP) nested dissections algorithm to minimize the fill-in during the factorization phase. This option can be used to decrease the time of dss_reorder call on multi-core computers. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_MY_ORDER, then you must supply a permutation vector in the array *perm*. In this case, the array *perm* is of length *nRows*, where *nRows* is the number of rows in the matrix as defined by the previous call to dss_define_structure.

If *opt* contains the option MKL_DSS_GET_ORDER, then the permutation vector computed during the dss_reorder call is copied to the array *perm*. In this case you must allocate the array *perm* beforehand. The permutation vector is computed in the same way as if the option MKL_DSS_AUTO_ORDER is set.

Input Parameters

Name	Type	Description
opt	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Parameter to pass the DSS options. The default value for the permutation type is MKL_DSS_AUTO_ORDER.
perm	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Array of length *nRows*. Contains a user-defined permutation vector (accessed only if *opt* contains MKL_DSS_MY_ORDER or MKL_DSS_GET_ORDER).

Output Parameters

Name	Type	Description
handle	**FORTRAN 77:** INTEGER*8 **Fortran 90:** TYPE (MKL_DSS_HANDLE), INTENT(INOUT) **C:** _MKL_DSS_HANDLE_t*	Pointer to the data structure storing intermediate DSS results (MKL_DSS_HANDLE).

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_REORDER_ERR

MKL_DSS_REORDER1_ERR

dss_factor_real, dss_factor_complex

Compute factorization of the matrix with previously specified location of non-zero elements.

Syntax

C:

```
dss_factor_real(handle, opt, rValues)
dss_factor_complex(handle, opt, cValues)
```

Fortran 77:

```
call dss_factor_real(handle, opt, rValues)
call dss_factor_complex(handle, opt, cValues)
```

Fortran 90:

outputtext(unified Fortran 90 interface):

```
call dss_factor(handle, opt, Values)
```

outputtext(or FORTRAN 77 like interface):

```
call dss_factor_real(handle, opt, rValues)
call dss_factor_complex(handle, opt, cValues)
```

Include Files

- FORTRAN 77: `mkl_dss.f77`
- Fortran 90: `mkl_dss.f90`
- C: `mkl_dss.h`

Description

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to `dss_define_structure` and whose non-zero values are given in the array *rValues*, *cValues* or *Values*. Data type These arrays must be of length *nNonZeros* as defined in a previous call to `dss_define_structure`.

NOTE The data type (single or double precision) of *rValues*, *cValues*, *Values* must be in correspondence with precision specified by the parameter *opt* in the routine `dss_create`.

The *opt* argument can contain one of the following options:

- `MKL_DSS_POSITIVE_DEFINITE`
- `MKL_DSS_INDEFINITE`
- `MKL_DSS_HERMITIAN_POSITIVE_DEFINITE`
- `MKL_DSS_HERMITIAN_INDEFINITE`

depending on your matrix's type.

NOTE This routine supports the Progress Routine feature. See Progress Function section for details.

Input Parameters

Name	Type	Description
handle	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `TYPE (MKL_DSS_HANDLE), INTENT(INOUT)` **C:** `_MKL_DSS_HANDLE_t*`	Pointer to the data structure storing intermediate DSS results (`MKL_DSS_HANDLE`).
opt	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `_INTEGER_t const*`	Parameter to pass the DSS options. The default value is `MKL_DSS_POSITIVE_DEFINITE`.
rValues	**FORTRAN 77:** `REAL*4` or `REAL*8`	Array of elements of the matrix *A*. Real data, single or double precision as it is specified by the parameter *opt* in the routine `dss_create`.

Name	Type	Description
	Fortran 90: `REAL(KIND=4), INTENT(IN)` or `REAL(KIND=8), INTENT(IN)` **C:** `VOID const*`	
cValues	**FORTRAN 77:** `COMPLEX*8` or `COMPLEX*16` **Fortran 90:** `COMPLEX(KIND=4), INTENT(IN)` or `COMPLEX(KIND=8), INTENT(IN)` **C:** `VOID const*`	Array of elements of the matrix *A*. Complex data, single or double precision as it is specified by the parameter *opt* in the routine `dss_create`.
Values	**Fortran 90:** `REAL(KIND=4), INTENT(OUT)`, or `REAL(KIND=8), INTENT(OUT)`, or `COMPLEX(KIND=4), INTENT(OUT)`, or `COMPLEX(KIND=8), INTENT(OUT)`	Array of elements of the matrix *A*. Real or complex data, single or double precision as it is specified by the parameter *opt* in the routine `dss_create`.

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_STATE_ERR`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OPTION_CONFLICT`

`MKL_DSS_VALUES_ERR`

`MKL_DSS_OUT_OF_MEMORY`

`MKL_DSS_ZERO_PIVOT`

`MKL_DSS_FAILURE`

`MKL_DSS_MSG_LVL_ERR`

dss_solve_real, dss_solve_complex

Compute the corresponding solution vector and place it in the output array.

Syntax

C:

```
dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)
dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Fortran 77:

```
call dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)
call dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Fortran 90:

outputtext(unified Fortran 90 interface):

```
call dss_solve(handle, opt, RhsValues, nRhs, SolValues)
```

outputtext(or FORTRAN 77 like interface):

```
call dss_solve_real(handle, opt, rRhsValues, nRhs, rSolValues)
call dss_solve_complex(handle, opt, cRhsValues, nRhs, cSolValues)
```

Include Files

- FORTRAN 77: `mkl_dss.f77`
- Fortran 90: `mkl_dss.f90`
- C: `mkl_dss.h`

Description

For each right hand side column vector defined in the arrays *rRhsValues*, *cRhsValues*, or *RhsValues*, these routines compute the corresponding solution vector and place it in the arrays *rSolValues*, *cSolValues*, or *SolValues* respectively.

NOTE The data type (single or double precision) of all arrays must be in correspondence with precision specified by the parameter *opt* in the routine `dss_create`.

The lengths of the right-hand side and solution vectors, *nCols* and *nRows* respectively, must be defined in a previous call to dss_define_structure.

By default, both routines perform the full solution step (it corresponds to *phase* = 33 in PARDISO). The parameter *opt* enables you to calculate the final solution step-by-step, calling forward and backward substitutions.

If it is set to `MKL_DSS_FORWARD_SOLVE`, the forward substitution (corresponding to *phase* = 331 in PARDISO) is performed;

if it is set to `MKL_DSS_DIAGONAL_SOLVE`, the diagonal substitution (corresponding to *phase* = 332 in PARDISO) is performed;

if it is set to `MKL_DSS_BACKWARD_SOLVE`, the backward substitution (corresponding to *phase* = 333 in PARDISO) is performed.

For more details about using these substitutions for different types of matrices, see the description of the PARDISO solver.

This parameter also can control the number of refinement steps that is used on the solution stage: if it is set to `MKL_DSS_REFINEMENT_OFF`, the maximum number of refinement steps equal to zero, and if it is set to `MKL_DSS_REFINEMENT_ON` (default value), the maximum number of refinement steps is equal to 2.

MKL_DSS_CONJUGATE_SOLVE option added to the parameter *opt* enables solving a conjugate transposed system $A^H x = b$ based on the factorization of the matrix *A*. This option is equivalent to the parameter *iparm*(12)= 1 in PARDISO.

MKL_DSS_TRANSPOSE_SOLVE option added to the parameter *opt* enables solving a transposed system $A^T x = b$ based on the factorization of the matrix *A*. This option is equivalent to the parameter *iparm*(12)= 2 in PARDISO.

Input Parameters

Name	Type	Description
handle	**FORTRAN 77:** INTEGER*8 **Fortran 90:** TYPE (MKL_DSS_HANDLE), INTENT(INOUT) **C:** _MKL_DSS_HANDLE_t*	Pointer to the data structure storing intermediate DSS results (MKL_DSS_HANDLE).
opt	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Parameter to pass the DSS options.
nRhs	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Number of the right-hand sides in the linear equation.
rRhsValues	**FORTRAN 77:** REAL*4 or REAL*8 **Fortran 90:** REAL(KIND=4), INTENT(IN) or REAL(KIND=8), INTENT(IN) **C:** VOID const*	Array of size *nRows * nRhs*. Contains real right-hand side vectors. Real data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.
cRhsValues	**FORTRAN 77:** COMPLEX*8 or COMPLEX*16 **Fortran 90:** COMPLEX(KIND=4), INTENT(IN) or COMPLEX(KIND=8), INTENT(IN) **C:** VOID const*	Array of size *nRows * nRhs*. Contains complex right-hand side vectors. Complex data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.
RhsValues	**Fortran 90:** REAL(KIND=4), INTENT(IN), or REAL(KIND=8), INTENT(IN), or COMPLEX(KIND=4), INTENT(IN), or COMPLEX(KIND=8), INTENT(IN)	Array of size *nRows * nRhs*. Contains right-hand side vectors. Real or complex data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

Output Parameters

Name	Type	Description
rSolValues	**FORTRAN 77:** REAL*4 or REAL*8 **Fortran 90:** REAL(KIND=4), INTENT(OUT) or REAL(KIND=8), INTENT(OUT) **C:** VOID const*	Array of size *nCols * nRhs*. Contains real solution vectors. Real data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.
cSolValues	**FORTRAN 77:** COMPLEX*8 or COMPLEX*16 **Fortran 90:** COMPLEX(KIND=4), INTENT(OUT) or COMPLEX(KIND=8), INTENT(OUT) **C:** VOID const*	Array of size *nCols * nRhs*. Contains complex solution vectors. Complex data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.
SolValues	**Fortran 90:** REAL(KIND=4), INTENT(OUT), or REAL(KIND=8), INTENT(OUT), or COMPLEX(KIND=4), INTENT(OUT), or COMPLEX(KIND=8), INTENT(OUT)	Array of size *nCols * nRhs*. Contains solution vectors. Real or complex data, single or double precision as it is specified by the parameter *opt* in the routine dss_create.

Return Values

MKL_DSS_SUCCESS

MKL_DSS_STATE_ERR

MKL_DSS_INVALID_OPTION

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_DIAG_ERR

MKL_DSS_FAILURE

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

MKL_DSS_OOC_MEM_ERR

MKL_DSS_OOC_OC_ERR

MKL_DSS_OOC_RW_ERR

dss_delete

Deletes all of the data structures created during the solutions process.

Syntax

C:

dss_delete(*handle*, *opt*)

Fortran:

```
call dss_delete(handle, opt)
```

Include Files

- FORTRAN 77: `mkl_dss.f77`
- Fortran 90: `mkl_dss.f90`
- C: `mkl_dss.h`

Description

The routine `dss_delete` deletes all data structures created during the solving process.

Input Parameters

Name	Type	Description
opt	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `_INTEGER_t const*`	Parameter to pass the DSS options. The default value is `MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

Output Parameters

Name	Type	Description
handle	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `TYPE (MKL_DSS_HANDLE), INTENT(INOUT)` **C:** `_MKL_DSS_HANDLE_t*`	Pointer to the data structure storing intermediate DSS results (`MKL_DSS_HANDLE`).

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_STATE_ERR`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OUT_OF_MEMORY`

`MKL_DSS_MSG_LVL_ERR`

`MKL_DSS_TERM_LVL_ERR`

dss_statistics

Returns statistics about various phases of the solving process.

Syntax

C:

```
dss_statistics(handle, opt, statArr, retValues)
```

Fortran:

```
call dss_statistics(handle, opt, statArr, retValues)
```

Include Files

- FORTRAN 77: `mkl_dss.f77`
- Fortran 90: `mkl_dss.f90`
- C: `mkl_dss.h`

Description

The `dss_statistics` routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- duration of problem solving,
- determinant of the input matrix,
- inertia of the input matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter *statArr*. The value of the statistics is returned in double precision in a return array, which you must allocate beforehand.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics can only be requested at the appropriate stages of the solving process. For example, requesting `FactorTime` before a matrix is factored leads to errors.

The following table shows the point at which each individual statistics item can be requested:

Statistics Calling Sequences

Type of Statistics	When to Call
`ReorderTime`	After `dss_reorder` is completed successfully.
`FactorTime`	After `dss_factor_real` or `dss_factor_complex` is completed successfully.
`SolveTime`	After `dss_solve_real` or `dss_solve_complex` is completed successfully.
`Determinant`	After `dss_factor_real` or `dss_factor_complex` is completed successfully.
`Inertia`	After `dss_factor_real` is completed successfully and the matrix is real, symmetric, and indefinite.
`Flops`	After `dss_factor_real` or `dss_factor_complex` is completed successfully.
`Peakmem`	After `dss_reorder` is completed successfully.
`Factormem`	After `dss_reorder` is completed successfully.
`Solvemem`	After `dss_factor_real` or `dss_factor_complex` is completed successfully.

Input Parameters

Name	Type	Description
handle	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `TYPE (MKL_DSS_HANDLE), INTENT(IN)`	Pointer to the data structure storing intermediate DSS results (`MKL_DSS_HANDLE`).

Name	Type	Description
	C: _MKL_DSS_HANDLE_t*	
opt	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** _INTEGER_t const*	Parameter to pass the DSS options.
statArr	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** char const*	Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect): ReorderTime — Amount of time taken to do the reordering. FactorTime — Amount of time taken to do the factorization. SolveTime — Amount of time taken to solve the problem after factorization. Determinant — Determinant of the matrix *A*. For real matrices: the determinant is returned as det_pow, det_base in two consecutive return array locations, where 1.0 ≤ abs(*det_base*) < 10.0 and determinant = *det_base*$*10^{(det\_pow)}$. For complex matrices: the determinant is returned as *det_pow*, *det_re*, *det_im* in three consecutive return array locations, where 1.0 ≤abs(*det_re*) + abs(*det_im*) < 10.0 and determinant = *det_re*, *det_im*$*10^{(det\_pow)}$. Inertia — Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (*p*,*n*,*z*), where *p* is the number of positive eigenvalues, *n* is the number of negative eigenvalues, and *z* is the number of zero eigenvalues. Inertia is returned as three consecutive return array locations *p*, *n*, *z*. Computing inertia is recommended only for stable matrices. Unstable matrices can lead to incorrect results. Inertia of a *k*-by-*k* real symmetric positive definite matrix is always (*k*, 0, 0). Therefore Inertia is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned. Flops — Number of floating point operations performed during the factorization. Peakmem — Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.

Name	Type	Description
		`Factormem` Permanent memory in kilobytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases.
		`Solvemem` Total double precision memory consumption (kilobytes) of the solver for the factorization and solve phases.

NOTE To avoid problems in passing strings from Fortran to C, Fortran users must call the `mkl_cvt_to_null_terminated_str` routine before calling `dss_statistics`. Refer to the description of `mkl_cvt_to_null_terminated_str` for details.

Output Parameters

Name	Type	Description
retValues	**FORTRAN 77:** `REAL*8` **Fortran 90:** `REAL(KIND=8), INTENT(OUT)` **C:** `VOID const*`	Value of the statistics returned.

Finding 'time used to reorder' and 'inertia' of a matrix

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics`(*handle*, *opt*, *statArr*, *retValue*), where *staArr* is "ReorderTime,Inertia"

In this example, *retValue* has the following values:

retValue[0]	Time to reorder.
retValue[1]	Positive Eigenvalues.
retValue[2]	Negative Eigenvalues.
retValue[3]	Zero Eigenvalues.

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_STATISTICS_INVALID_MATRIX`

`MKL_DSS_STATISTICS_INVALID_STATE`

`MKL_DSS_STATISTICS_INVALID_STRING`

`MKL_DSS_MSG_LVL_ERR`

`MKL_DSS_TERM_LVL_ERR`

mkl_cvt_to_null_terminated_str

Passes character strings from Fortran routines to C routines.

Syntax

`mkl_cvt_to_null_terminated_str (destStr, destLen, srcStr)`

Include Files

- FORTRAN 77: `mkl_dss.f77`
- Fortran 90: `mkl_dss.f90`

Description

The routine `mkl_cvt_to_null_terminated_str` passes character strings from Fortran routines to C routines. The strings are converted into integer arrays before being passed to C. Using this routine avoids the problems that can occur on some platforms when passing strings from Fortran to C. The use of this routine is highly recommended.

Input Parameters

destLen	`INTEGER`. Length of the output array *destStr*.
srcStr	`STRING`. Input string.

Output Parameters

destStr	`INTEGER`. One-dimensional array of integers.

Implementation Details

Several aspects of the Intel MKL DSS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, one of the following Intel MKL DSS language-specific header files can be included:

- `mkl_dss.f77` for F77 programs
- `mkl_dss.f90` for F90 programs
- `mkl_dss.h` for C programs

These header files define symbolic constants for returned error values, function options, certain defined data types, and function prototypes.

NOTE Constants for options, returned error values, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel MKL DSS software without including one of the above header files is not supported.

Memory Allocation and Handles

To simplify the use of the Intel MKL DSS routines, they do not require you to allocate any temporary working storage. The solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a *handle*.

Each of the Intel MKL DSS routines creates, uses or deletes a handle. Consequently, each program must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that must be used when declaring a handle object in the user code.

Fortran 90 programmers must declare a handle as:

```
INCLUDE "mkl_dss.f90"

TYPE(MKL_DSS_HANDLE) handle
```

C and C++ programmers must declare a handle as:

```
#include "mkl_dss.h"

_MKL_DSS_HANDLE_t handle;
```

FORTRAN 77 programmers using compilers that support eight byte integers, must declare a handle as:

```
INCLUDE "mkl_dss.f77"

INTEGER*8 handle
```

Otherwise they can replace the `INTEGER*8` data types with the `DOUBLE PRECISION` data type.

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the returned error values
- user options for the solver routines
- constants indicating message severity.

Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

Intel MKL supports the iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as RCI ISS interface . The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite system (RCI conjugate gradient solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI flexible generalized minimal residual solver, or RCI FGMRES) of linear algebraic equations. This interface uses the general RCI scheme described in [Dong95].

See the Appendix A Linear Solvers Basics for discussion of terms and concepts related to the ISS routines.

RCI means that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user must perform them and pass the result to the solver. This gives great universality to the solver as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines (see Sparse BLAS Level 2 and Level 3 Routines).

NOTE The RCI CG solver is implemented in two versions: for system of equations with a single right hand side, and for system of equations with multiple right hand sides.

The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and positive definite.

The FGMRES method may fail if the matrix is degenerate.

Table "RCI CG Interface Routines" lists the names of the routines, and describes their general use.

RCI ISS Interface Routines

Routine	Description
dcg_init, dcgmrhs_init, dfgmres_init	Initializes the solver.
dcg_check, dcgmrhs_check, dfgmres_check	Checks the consistency and correctness of the user defined data.
dcg, dcgmrhs, dfgmres	Computes the approximate solution vector.
dcg_get, dcgmrhs_get, dfgmres_get	Retrieves the number of the current iteration.

The Intel MKL RCI ISS interface routines are normally invoked in this order:

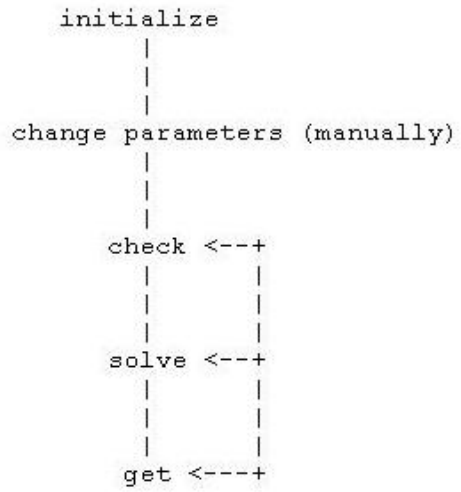
1. `<type>_init`
2. `<type>_check`
3. `<type>`

4. `<type>_get`

Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram in Figure "Typical Order for Invoking RCI ISS Interface Routines" indicates the typical order in which the RCI ISS interface routines can be invoked.

Typical Order for Invoking RCI ISS interface Routines



Code examples that use the RCI ISS interface routines to solve systems of linear equations can be found in the `examples\solver\source` folder of your Intel MKL directory (`cg_no_precon.f`, `cg_no_precon_c.c`, `cg_mrhs.f`, `cg_mrhs_precond.f`, `cg_mrhs_stop_crt.f`, `fgmres_no_precon_f.f`, `fgmres_no_precon_c.c`).

CG Interface Description

All types in this documentation refer to the common Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

C and C++ programmers should refer to the section Calling Sparse Solver and Preconditioner Routines from C C++ for information on mapping Fortran types to C/C++ types.

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right hand side (SRHS), and for a system of equations with multiple right hand sides (MRHS). The names of routines for a system with MRHS contain the suffix `mrhs`.

Routine Options

All of the RCI CG routines have common parameters for passing various options to the routines (see CG Common Parameters). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine dcg to compute the solution of a system of linear algebraic equations. The Intel MKL RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

CG Common Parameters

NOTE The default and initial values listed below are assigned to the parameters by calling the dcg_init/dcgmrhs_init routine.

n INTEGER, this parameter sets the size of the problem in the dcg_init/dcgmrhs_init routine. All the other routines uses the *ipar*(1) parameter instead. Note that the coefficient matrix *A* is a square matrix of size *n***n*.

x DOUBLE PRECISION array of size *n* for SRHS, or matrix of size (*n***nrhs*) for MRHS. This parameter contains the current approximation to the solution. Before the first call to the dcg/dcgmrhs routine, it contains the initial approximation to the solution.

nrhs INTEGER, this parameter sets the number of right-hand sides for MRHS routines.

b DOUBLE PRECISION array containing a single right-hand side vector, or matrix of size (*nrhs***n*) containing right-hand side vectors.

RCI_request INTEGER, this parameter gives information about the result of work of the RCI CG routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions:

- *RCI_request*= 1 — multiply the matrix by *tmp* (1:*n*,1), put the result in *tmp*(1:*n*,2), and return the control to the dcg/dcgmrhs routine;
- *RCI_request*= 2 — to perform the stopping tests. If they fail, return the control to the dcg/dcgmrhs routine. If the stopping tests succeed, it indicates that the solution is found and stored in the *x* array;
- *RCI_request*= 3 — for SRHS: apply the preconditioner to *tmp*(1:*n*,3), put the result in *tmp*(1:*n*,4), and return the control to the dcg routine;
  for MRHS: apply the preconditioner to *tmp*(:, 3+*ipar*(3)), put the result in *tmp*(:,3), and return the control to the dcgmrhs routine.

Note that the dcg_get/dcgmrhs_get routine does not change the parameter *RCI_request*. This enables use of this routine inside the *reverse communication* computations.

ipar INTEGER array, of size 128 for SRHS, and of size (128+2**nrhs*) for MRHS. This parameter specifies the integer set of data for the RCI CG computations:

- *ipar*(1) — specifies the size of the problem. The dcg_init/dcgmrhs_init routine assigns *ipar*(1)=*n*. All the other routines use this parameter instead of *n*. There is no default value for this parameter.

ipar(2)	specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files `dcg_errors.txt` and `dcg_check_warnings.txt`, respectively. Note that if *ipar*(6) and *ipar*(7) parameters are set to 0, error and warning messages are not generated at all.
ipar(3)	for SRHS: contains the current stage of the RCI CG computations. The initial value is 1; for MRHS: contains the right-hand side for which the calculations are currently performed.  **WARNING** Avoid altering this variable during computations.
ipar(4)	contains the current iteration number. The initial value is 0.
ipar(5)	specifies the maximum number of iterations. The default value is `min(150, n)`.
ipar(6)	if the value is not equal to 0, the routines output error messages in accordance with the parameter *ipar*(2). Otherwise, the routines do not output error messages at all, but return a negative value of the parameter *RCI_request*. The default value is 1.
ipar(7)	if the value is not equal to 0, the routines output warning messages in accordance with the parameter *ipar*(2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter *RCI_request*. The default value is 1.
ipar(8)	if the value is not equal to 0, the `dcg`/`dcgmrhs` routine performs the stopping test for the maximum number of iterations: *ipar*(4) ≤ *ipar*(5). Otherwise, the method is stopped and the corresponding value is assigned to the *RCI_request*. If the value is 0, the routine does not perform this stopping test. The default value is 1.
ipar(9)	if the value is not equal to 0, the `dcg`/`dcgmrhs` routine performs the residual stopping test: *dpar*(5) ≤ *dpar*(4)= *dpar*(1)**dpar*(3)+ *dpar*(2). Otherwise, the method is stopped and corresponding value is assigned to the *RCI_request*. If the value is 0, the routine does not perform this stopping test. The default value is 0.
ipar(10)	if the value is not equal to 0, the `dcg`/`dcgmrhs` routine requests a user-defined stopping test by setting the output parameter *RCI_request*=2. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

NOTE At least one of the parameters *ipar*(8)-*ipar*(10) must be set to 1.

ipar(11) — if the value is equal to 0, the dcg/dcgmrhs routine runs the non-preconditioned version of the corresponding CG method. Otherwise, the routine runs the preconditioned version of the CG method, and by setting the output parameter *RCI_request*=3, indicates that you must perform the preconditioning step. The default value is 0.

ipar(11:128), *ipar*(11:128+2**nrhs*) — are reserved and not used in the current RCI CG SRHS and MRHS routines.

NOTE You must declare the array *ipar* with length 128. While defining the array in the code using RCI CG SRHS as INTEGER *ipar*(11) works, there is no guarantee of future compatibility with Intel MKL.

dpar — DOUBLE PRECISION array, for SRHS of size 128, for MRHS of size (128+2**nrhs*); this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

dpar(1) — specifies the relative tolerance. The default value is 1.0D-6.

dpar(2) — specifies the absolute tolerance. The default value is 0.0D-0.

dpar(3) — specifies the square norm of the initial residual (if it is computed in the dcg/dcgmrhs routine). The initial value is 0.

dpar(4) — service variable equal to *dpar*(1)**dpar*(3)+*dpar*(2) (if it is computed in the dcg/dcgmrhs routine). The initial value is 0.

dpar(5) — - specifies the square norm of the current residual. The initial value is 0.0.

dpar(6) — specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.

dpar(7) — contains the *alpha* parameter of the CG method. The initial value is 0.0.

dpar(8) — contains the *beta* parameter of the CG method, it is equal to *dpar*(5)/*dpar*(6) The initial value is 0.0.

dpar(9:128), *dpar*(9:128+2**nrhs*) — are reserved and not used in the current RCI CG SRHS and MRHS routines respectively.

NOTE You must declare the array *dpar* with length 128. While defining the array in the code using RCI CG SRHS as `DOUBLE PRECISION dpar(8)` works, there is no guarantee of future compatibility with Intel MKL.

tmp `DOUBLE PRECISION` array of size `(n,4)` for SRHS, and `(n,3+nrhs)` for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

`tmp(:,1)`	specifies the current search direction. The initial value is 0.0.
`tmp(:,2)`	contains the matrix multiplied by the current search direction. The initial value is 0.0.
`tmp(:,3)`	contains the current residual. The initial value is 0.0.
`tmp(:,4)`	contains the inverse of the preconditioner applied to the current residual. There is no initial value for this parameter.

NOTE You can define this array in the code using RCI CG SRHS as `DOUBLE PRECISION tmp(n,3)` if you run only non-preconditioned CG iterations.

Schemes of Using the RCI CG Routines

The following pseudocode shows the general schemes of using the RCI CG routines.

```
...
generate matrix A
generate preconditioner C (optional)
   call dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)
   change parameters in ipar, dpar if necessary
   call dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)
1  call dcg(n, x, b, RCI_request, ipar, dpar, tmp)
   if (RCI_request.eq.1) then
    multiply the matrix A by tmp(1:n,1) and put the result in tmp(1:n,2)
   It is possible to use MKL Sparse BLAS Level 2 subroutines for this operation
c  proceed with CG iterations
     goto 1
   endif
   if (RCI_request.eq.2)then
    do the stopping test
    if (test not passed) then
c  proceed with CG iterations
```

```
     go to 1
    else
c  stop CG iterations
     goto 2
    endif
   endif
   if (RCI_request.eq.3) then (optional)
   apply the preconditioner C inverse to tmp(1:n,3) and put the result in tmp(1:n,4)
c  proceed with CG iterations
    goto 1
   end
```

2 call dcg_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

current iteration number is in *itercount*

the computed approximation is in the array *x*

FGMRES Interface Description

All types in this documentation refer to the common Fortran types, INTEGER, and DOUBLE PRECISION.

C and C++ programmers should refer to the section Calling Sparse Solver and Preconditioner Routines from C C++ for information on mapping Fortran types to C/C++ types.

Routine Options

All of the RCI FGMRES routines have common parameters for passing various options to the routines (see FGMRES Common Parameters). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine dfgmres to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL RCI FGMRES routines do not make copies of the user input arrays.

FGMRES Common Parameters

NOTE The default and initial values listed below are assigned to the parameters by calling the dfgmres_init routine.

n — INTEGER, this parameter sets the size of the problem in the dfgmres_init routine. All the other routines uses *ipar*(1) parameter instead. Note that the coefficient matrix *A* is a square matrix of size *n***n*.

x DOUBLE PRECISION array, this parameter contains the current approximation to the solution vector. Before the first call to the dfgmres routine, it contains the initial approximation to the solution vector.

b DOUBLE PRECISION array, this parameter contains the right-hand side vector. Depending on user requests (see the parameter *ipar*(13), it may later contain the approximate solution.

RCI_request INTEGER, this parameter gives information about the result of work of the RCI FGMRES routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions:

- *RCI_request*= 1 — multiply the matrix by *tmp*(*ipar*(22)), put the result in *tmp*(*ipar*(23)), and return the control to the dfgmres routine;
- *RCI_request*= 2 — perform the stopping tests. If they fail, return the control to the dfgres routine. Otherwise, the solution can be updated by a subsequent call to dfgmres_get routine;
- *RCI_request*= 3 — apply the preconditioner to *tmp*(*ipar*(22)), put the result in *tmp*(*ipar*(23)), and return the control to the dfgmres routine.
- *RCI_request*= 4 — check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the dfgmres routine if it is not zero, otherwise complete the solution process by calling dfgmres_get routine.

ipar(128) INTEGER array, this parameter specifies the integer set of data for the RCI FGMRES computations:

- *ipar*(1) — specifies the size of the problem. The dfgmres_init routine assigns *ipar*(1)=*n*. All the other routines uses this parameter instead of *n*. There is no default value for this parameter.
- *ipar*(2) — specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file MKL_RCI_FGMRES_Log.txt. Note that if *ipar*(6) and *ipar*(7) parameters are set to 0, error and warning messages are not generated at all.
- *ipar*(3) — contains the current stage of the RCI FGMRES computations., The initial value is 1.

  WARNING Avoid altering this variable during computations.

- *ipar*(4) — contains the current iteration number. The initial value is 0.

ipar(5)	specifies the maximum number of iterations. The default value is *min* (150,*n*).
ipar(6)	if the value is not 0, the routines output error messages in accordance with the parameter *ipar*(2). If it is 0, the routines do not output error messages at all, but return a negative value of the parameter *RCI_request*. The default value is 1.
ipar(7)	if the value is not 0, the routines output warning messages in accordance with the parameter *ipar*(2). Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter *RCI_request*. The default value is 1.
ipar(8)	if the value is not equal to 0, the dfmres routine performs the stopping test for the maximum number of iterations: *ipar*(4) ≤ *ipar*(5). If the value is 0, the dfgmres routine does not perform this stopping test. The default value is 1.
ipar(9)	if the value is not 0, the dfgmres routine performs the residual stopping test: *dpar*(5) ≤ *dpar*(4).If the value is 0, the dfgmres routine does not perform this stopping test. The default value is 0.
ipar(10)	if the value is not 0, the dfgmres routine indicates that the user-defined stopping test be performed by setting *RCI_request*=2. If the value is 0, the dfgmres routine does not perform the user-defined stopping test. The default value is 1.

NOTE At least one of the parameters *ipar*(8)-*ipar*(10) must be set to 1.

ipar(11)	if the value is 0, the dfgmres routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method, and requests that you perform the preconditioning step by setting the output parameter *RCI_request*=3. The default value is 0.
ipar(12)	if the value is not equal to 0, the dfgmres routine performs the automatic test for zero norm of the currently generated vector: *dpar*(7) ≤ *dpar*(8), where *dpar*(8) contains the tolerance value. Otherwise, the routine indicates that you must perform this check by setting the output parameter *RCI_request*=4. The default value is 0.
ipar(13)	if the value is equal to 0, the dfgmres_get routine updates the solution to the vector *x* according to the computations done by the dfgmres routine. If the value is positive, the routine writes the solution to the right hand side vector *b*. If the value is

negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0.

NOTE It is possible to call the `dfgmres_get` routine at any place in the code, but you must pay special attention to the parameter *ipar*(13). The RCI FGMRES iterations can be continued after the call to `dfgmres_get` routine only if the parameter *ipar*(13) is not equal to zero. If *ipar*(13) is positive, then the updated solution overwrites the right hand side in the vector *b*. If you want to run the restarted version of FGMRES with the same right hand side, then it must be saved in a different memory location before the first call to the `dfgmres_get` routine with positive *ipar*(13).

ipar(14) contains the internal iteration counter that counts the number of iterations before the restart takes place. The initial value is 0.

WARNING Do not alter this variable during computations.

ipar(15) specifies the number of the non-restarted FGMRES iterations. To run the restarted version of the FGMRES method, assign the number of iterations to *ipar*(15) before the restart. The default value is *min*(150, *n*), which means that by default the non-restarted version of FGMRES method is used.

ipar(16) service variable specifying the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see Matrix Arguments in the Appendix B for details) is started in the *tmp* array.

ipar(17) service variable specifying the location of the rotation cosines from which the vector of cosines is started in the *tmp* array.

ipar(18) service variable specifying the location of the rotation sines from which the vector of sines is started in the *tmp* array.

ipar(19) service variable specifying the location of the rotated residual vector from which the vector is started in the *tmp* array.

ipar(20) service variable, specifies the location of the least squares solution vector from which the vector is started in the *tmp* array.

ipar(21) service variable specifying the location of the set of preconditioned vectors from which the set is started in the *tmp* array. The memory locations in the *tmp* array starting from *ipar*(21) are used only for the preconditioned FGMRES method.

ipar(22) specifies the memory location from which the first vector (source) used in operations requested via *RCI_request* is started in the *tmp* array.

ipar(23) specifies the memory location from which the second vector (source) used in operations requested via *RCI_request* is started in the *tmp* array.

ipar(24:128) are reserved and not used in the current RCI FGMRES routines.

NOTE You must declare the array *ipar* with length 128. While defining the array in the code as INTEGER *ipar*(23) works, there is no guarantee of future compatibility with Intel MKL.

dpar(128) DOUBLE PRECISION array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:

dpar(1) specifies the relative tolerance. The default value is 1.0D-6.

dpar(2) specifies the absolute tolerance. The default value is 0.0D-0.

dpar(3) specifies the Euclidean norm of the initial residual (if it is computed in the dfgmres routine). The initial value is 0.0.

dpar(4) service variable equal to *dpar*(1)***dpar*(3)+*dpar*(2) (if it is computed in the dfgmres routine). The initial value is 0.0.

dpar(5) specifies the Euclidean norm of the current residual. The initial value is 0.0.

dpar(6) specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.

dpar(7) contains the norm of the generated vector. The initial value is 0.0.

NOTE In terms of [Saad03] this parameter is the coefficient $h_{k+1,k}$ of the Hessenberg matrix.

dpar(8) contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0D-12.

dpar(9:128) are reserved and not used in the current RCI FGMRES routines.

NOTE You must declare the array *dpar* with length 128. While defining the array in the code as DOUBLE PRECISION *dpar*(8) works, there is no guarantee of future compatibility with Intel MKL.

tmp DOUBLE PRECISION array of size ((2**ipar*(15)+1)**n* + *ipar*(15)*(*ipar*(15)+9)/2 + 1)) used to supply the double precision temporary space for the RCI FGMRES computations, specifically:

tmp(1:ipar(16)-1)	contains the sequence of vectors generated by the FGMRES method. The initial value is 0.0.
tmp(ipar(16):ipar(17)-1)	contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of *tmp* array.
tmp(ipar(17):ipar(18)-1)	contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.
tmp(ipar(18):ipar(19)-1)	contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.
tmp(ipar(19):ipar(20)-1)	contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of *tmp* array.
tmp(ipar(20):ipar(21)-1)	contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of *tmp* array.
tmp(ipar(21):)	contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of *tmp* array is not used if the non-preconditioned version of FGMRES method is called. There is no initial value for this part of *tmp* array.

NOTE You can define this array in the code as DOUBLE PRECISION *tmp*((2**ipar*(15)+1)**n* + *ipar*(15)*(*ipar*(15)+9)/2 + 1)) if you run only non-preconditioned FGMRES iterations.

Schemes of Using the RCI FGMRES Routines

The following pseudocode shows the general schemes of using the RCI FGMRES routines.

...

generate matrix *A*

generate preconditioner *C* (optional)

call dfgmres_init(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

change parameters in *ipar*, *dpar* if necessary

call dfgmres_check(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

1 call dfgmres(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

if (*RCI_request*.eq.1) then

multiply the matrix *A* by *tmp*(*ipar*(22)) and put the result in *tmp*(*ipar*(23))

It is possible to use MKL Sparse BLAS Level 2 subroutines for this operation

```
c  proceed with FGMRES iterations
    goto 1
   endif
   if (RCI_request.eq.2) then
    do the stopping test
    if (test not passed) then
c  proceed with FGMRES iterations
     go to 1
    else
c  stop FGMRES iterations
     goto 2
    endif
   endif
   if (RCI_request.eq.3) then (optional)
```

apply the preconditioner *C* inverse to *tmp*(*ipar*(22)) and put the result in *tmp*(*ipar*(23))

```
c  proceed with FGMRES iterations
    goto 1
   endif
   if (RCI_request.eq.4) then
```

check the norm of the next orthogonal vector, it is contained in *dpar*(7)

```
    if (the norm is not zero up to rounding/computational errors) then
c  proceed with FGMRES iterations
     goto 1
    else
c  stop FGMRES iterations
     goto 2
    endif
   endif
```

2 call dfgmres_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

current iteration number is in *itercount*

the computed approximation is in the array *x*

For the FGMRES method, the array *x* initially contains the current approximation to the solution. It can be updated only by calling the routine dfgmres_get, which updates the solution in accordance with the computations performed by the routine dfgmres.

The above pseudocode demonstrates two main differences in the use of RCI FGMRES interface comparing with the CG Interface Description. The first difference relates to *RCI_request*=3: it uses different locations in the *tmp* array, which is two-dimensional for CG and one-dimensional for FGMRES. The second difference relates to *RCI_request*=4: the RCI CG interface never produces *RCI_request*=4.

RCI ISS Routines

dcg_init

Initializes the solver.

Syntax

`dcg_init(n, x, b, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcg_init` initializes the solver. After initialization, all subsequent invocations of the Intel MKL RCI CG routines use the values of all parameters returned by the routine `dcg_init`. Advanced users can skip this step and set these parameters directly in the appropriate routines.

WARNING You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	`INTEGER`.Sets the size of the problem.
x	`DOUBLE PRECISION` array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.
b	`DOUBLE PRECISION` array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request	`INTEGER`. Gives information about the result of the routine.
ipar	`INTEGER` array of size `128`. Refer to the CG Common Parameters.
dpar	`DOUBLE PRECISION` array of size `128`. Refer to the CG Common Parameters.
tmp	`DOUBLE PRECISION` array of size `(n,4)`. Refer to the CG Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -10000	Indicates failure to complete the task.

dcg_check

Checks consistency and correctness of the user defined data.

Syntax

`dcg_check(n, x, b, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the solver returns the correct result. It only reduces the chance of making a mistake in the parameters of the method. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

n	`INTEGER`. Sets the size of the problem.
x	`DOUBLE PRECISION` array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.
b	`DOUBLE PRECISION` array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request	`INTEGER`. Gives information about result of the routine.
ipar	`INTEGER` array of size `128`. Refer to the CG Common Parameters.
dpar	`DOUBLE PRECISION` array of size `128`. Refer to the CG Common Parameters.
tmp	`DOUBLE PRECISION` array of size `(n,4)`. Refer to the CG Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -1100	Indicates that the task is interrupted and the errors occur.
RCI_request= -1001	Indicates that there are some warning messages.
RCI_request= -1010	Indicates that the routine changed some parameters to make them consistent or correct.
RCI_request= -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dcg

Computes the approximate solution vector.

Syntax

`dcg(n, x, b, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `dcg` routine computes the approximate solution vector using the CG method [Young71]. The routine `dcg` uses the vector in the array *x* before the first call as an initial approximation to the solution. The parameter *RCI_request* gives you information about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

n	`INTEGER`. Sets the size of the problem.
x	`DOUBLE PRECISION` array of size *n*. Contains the initial approximation to the solution vector.
b	`DOUBLE PRECISION` array of size *n*. Contains the right-hand side vector.
tmp	`DOUBLE PRECISION` array of size `(n,4)`. Refer to the CG Common Parameters.

Output Parameters

RCI_request	`INTEGER`. Gives information about result of work of the routine.
x	`DOUBLE PRECISION` array of size *n*. Contains the updated approximation to the solution vector.
ipar	`INTEGER` array of size *128*. Refer to the CG Common Parameters.
dpar	`DOUBLE PRECISION` array of size *128*. Refer to the CG Common Parameters.
tmp	`DOUBLE PRECISION` array of size `(n,4)`. Refer to the CG Common Parameters.

Return Values

RCI_request=0	Indicates that the task completed normally and the solution is found and stored in the vector *x*. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the *RCI_request*= 2.
RCI_request=-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
RCI_request=-2	Indicates that the routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
RCI_request=- 10	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value *dpar*(6) was altered outside of the routine, or the `dcg_check` routine was not called.

RCI_request=-11	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values *ipar*(8), *ipar*(9), *ipar*(10) were altered outside of the routine, or the dcg_check routine was not called.
RCI_request= 1	Indicates that you must multiply the matrix by *tmp*(1:*n*, 1), put the result in the *tmp*(1:*n*,2), and return the control back to the routine dcg.
RCI_request= 2	Indicates that you must perform the stopping tests. If they fail, return control back to the dcg routine. Otherwise, the solution is found and stored in the vector *x*.
RCI_request= 3	Indicates that you must apply the preconditioner to *tmp*(:, 3), put the result in the *tmp*(:, 4), and return the control back to the routine dcg.

dcg_get

Retrieves the number of the current iteration.

Syntax

dcg_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine dcg_get retrieves the current iteration number of the solutions process.

Input Parameters

n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION array of size *n*. Contains the initial approximation vector to the solution.
b	DOUBLE PRECISION array of size *n*. Contains the right-hand side vector.
RCI_request	INTEGER. This parameter is not used.
ipar	INTEGER array of size 128. Refer to the CG Common Parameters.
dpar	DOUBLE PRECISION array of size 128. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION array of size (*n*,4). Refer to the CG Common Parameters.

Output Parameters

itercount	INTEGER argument. Returns the current iteration number.

Return Values

The routine dcg_get has not return values.

dcgmrhs_init

Initializes the RCI CG solver with MHRS.

Syntax

`dcgmrhs_init(n, x, nrhs, b, method, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcgmrhs_init` initializes the solver. After initialization all subsequent invocations of the Intel MKL RCI CG with multiple right hand sides (MRHS) routines use the values of all parameters that are returned by `dcgmrhs_init`. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

WARNING You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcgmrhs_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	`INTEGER`. Sets the size of the problem.
x	`DOUBLE PRECISION` matrix of size *n*nrhs*. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to *b*.
nrhs	`INTEGER`. Sets the number of right-hand sides.
b	`DOUBLE PRECISION` matrix of size *nrhs*n*. Contains the right-hand side vectors.
method	`INTEGER`. Specifies the method of solution: A value of 1 indicates CG with multiple right hand sides (default value)

Output Parameters

RCI_request	`INTEGER`. Gives information about the result of the routine.
ipar	`INTEGER` array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
dpar	`DOUBLE PRECISION` array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
tmp	`DOUBLE PRECISION` array of size *(n, 3+nrhs)*. Refer to the CG Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -10000	Indicates failure to complete the task.

dcgmrhs_check

Checks consistency and correctness of the user defined data.

Syntax

`dcgmrhs_check(n, x, nrhs, b, RCI_request, ipar, dpar, tmp)`

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine dcgmrhs_check checks the consistency and correctness of the parameters to be passed to the solver routine dcgmrhs. While this operation reduces the chance of making a mistake in the parameters, it does not guarantee that the solver returns the correct result.

If you are sure that the correct data is *specified* in the solver parameters, you can skip this operation.

The lengths of all vectors must be defined in a previous call to the dcgmrhs_init routine.

Input Parameters

n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION matrix of size *n*nrhs*. THAT IS TEST Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to *b*.
nrhs	INTEGER. This parameter sets the number of right-hand sides.
b	DOUBLE PRECISION matrix of size (*nrhs*,*n*). Contains the right-hand side vectors.

Output Parameters

RCI_request	INTEGER. Gives information about the results of the routine.
ipar	INTEGER array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
dpar	DOUBLE PRECISION array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION array of size (*n*, 3+*nrhs*). Refer to the CG Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -1100	Indicates that the task is interrupted and the errors occur.
RCI_request= -1001	Indicates that there are some warning messages.
RCI_request= -1010	Indicates that the routine changed some parameters to make them consistent or correct.
RCI_request= -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dcgmrhs

Computes the approximate solution vectors.

Syntax

dcgmrhs(*n*, *x*, *nrhs*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine dcgmrhs computes approximate solution vectors using the CG with multiple right hand sides (MRHS) method [Young71]. The routine dcgmrhs uses the value that was in the *x* before the first call as an initial approximation to the solution. The parameter *RCI_request* gives information about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the dcgmrhs_init routine.

Input Parameters

n	INTEGER. Sets the size of the problem, and the sizes of arrays *x* and *b*.
x	DOUBLE PRECISION matrix of size *n*nrhs*. Contains the initial approximation to the solution vectors.
nrhs	INTEGER. Sets the number of right-hand sides.
b	DOUBLE PRECISION matrix of size *(nrhs*n)*. Contains the right-hand side vectors.
tmp	DOUBLE PRECISION array of size *(n, 3+nrhs)*. Refer to the CG Common Parameters.

Output Parameters

RCI_request	INTEGER. Gives information about result of work of the routine.
x	DOUBLE PRECISION matrix of size *n*-by-*nrhs*. Contains the updated approximation to the solution vectors.
ipar	INTEGER array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
dpar	DOUBLE PRECISION array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION array of size *(n, 3+nrhs)*. Refer to the CG Common Parameters.

Return Values

RCI_request=0	Indicates that the task completed normally and the solution is found and stored in the vector *x*. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the *RCI_request= 2*.
RCI_request=-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if both tests are requested by the user.
RCI_request=-2	The routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
RCI_request=- 10	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value *dpar(6)* was altered outside of the routine, or the dcg_check routine was not called.
RCI_request=-11	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values *ipar(8)*, *ipar(9)*, *ipar(10)* were altered outside of the routine, or the dcg_check routine was not called.

RCI_request= 1	Indicates that you must multiply the matrix by *tmp*(1:*n*, 1), put the result in the *tmp*(1:*n*,2), and return the control back to the routine dcg.
RCI_request= 2	Indicates that you must perform the stopping tests. If they fail, return control back to the dcg routine. Otherwise, the solution is found and stored in the vector *x*.
RCI_request= 3	Indicates that you must apply the preconditioner to *tmp*(:, 3), put the result in the *tmp*(:, 4), and return the control back to the routine dcg.

dcgmrhs_get

Retrieves the number of the current iteration.

Syntax

dcgmrhs_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine dcgmrhs_get retrieves the current iteration number of the solving process.

Input Parameters

n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION matrix of size *n*nrhs*. Contains the initial approximation to the solution vectors.
nrhs	INTEGER. Sets the number of right-hand sides.
b	DOUBLE PRECISION matrix of size (*nrhs*,*n*). Contains the right-hand side .
RCI_request	INTEGER. This parameter is not used.
ipar	INTEGER array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
dpar	DOUBLE PRECISION array of size *(128+2*nrhs)*. Refer to the CG Common Parameters.
tmp	DOUBLE PRECISION array of size (*n*, 3+*nrhs*). Refer to the CG Common Parameters.

Output Parameters

itercount	INTEGER argument. Returns the current iteration number.

Return Values

The routine dcgmrhs_get has no return values.

dfgmres_init

Initializes the solver.

Syntax

dfgmres_init(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dfgmres_init` initializes the solver. After initialization all subsequent invocations of Intel MKL RCI FGMRES routines use the values of all parameters that are returned by `dfgmres_init`. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

WARNING You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	`INTEGER`. Sets the size of the problem.
x	`DOUBLE PRECISION` array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.
b	`DOUBLE PRECISION` array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request	`INTEGER`. Gives information about the result of the routine.
ipar	`INTEGER` array of size `128`. Refer to the FGMRES Common Parameters.
dpar	`DOUBLE PRECISION` array of size `128`. Refer to the FGMRES Common Parameters.
tmp	`DOUBLE PRECISION` array of size `((2*`*ipar*`(15)+1)*`*n* `+`*ipar*`(15)*`*ipar*`(15)+9)/2 + 1)`. Refer to the FGMRES Common Parameters.

Return Values

RCI_request`= 0`	Indicates that the task completed normally.
RCI_request`= -10000`	Indicates failure to complete the task.

dfgmres_check

Checks consistency and correctness of the user defined data.

Syntax

`dfgmres_check(`*n*`, `*x*`, `*b*`, `*RCI_request*`, `*ipar*`, `*dpar*`, `*tmp*`)`

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine dfgmres_check checks consistency and correctness of the parameters to be passed to the solver routine dfgmres. However, this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the routine. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors are assumed to have been defined in a previous call to the dfgmres_init routine.

Input Parameters

n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.
b	DOUBLE PRECISION array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request	INTEGER. Gives information about result of the routine.
ipar	INTEGER array of size *128*. Refer to the FGMRES Common Parameters.
dpar	DOUBLE PRECISION array of size *128*. Refer to the FGMRES Common Parameters.
tmp	DOUBLE PRECISION array of size ((2**ipar*(15)+1)**n* +*ipar*(15)**ipar*(15)+9)/2 + 1). Refer to the FGMRES Common Parameters.

Return Values

RCI_request= 0	Indicates that the task completed normally.
RCI_request= -1100	Indicates that the task is interrupted and the errors occur.
RCI_request= -1001	Indicates that there are some warning messages.
RCI_request= -1010	Indicates that the routine changed some parameters to make them consistent or correct.
RCI_request= -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dfgmres

Makes the FGMRES iterations.

Syntax

dfgmres(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*)

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine dfgmres performs the FGMRES iterations [Saad03], using the value that was in the array *x* before the first call as an initial approximation of the solution vector. To update the current approximation to the solution, the dfgmres_get routine must be called. The RCI FGMRES iterations can be continued after the call to the dfgmres_get routine only if the value of the parameter *ipar*(13) is not equal to 0 (default value). Note that the updated solution overwrites the right hand side in the vector *b* if the parameter

ipar(13) is positive, and the restarted version of the FGMRES method can not be run. If you want to keep the right hand side, you must be save it in a different memory location before the first call to the dfgmres_get routine with a positive *ipar*(13).

The parameter *RCI_request* gives information about the task completion and requests results of certain operations that the solver requires.

The lengths of all the vectors must be defined in a previous call to the dfgmres_init routine.

Input Parameters

n	INTEGER. Sets the size of the problem.
x	DOUBLE PRECISION array of size *n*. Contains the initial approximation to the solution vector.
b	DOUBLE PRECISION array of size *n*. Contains the right-hand side vector.
tmp	DOUBLE PRECISION array of size ((2**ipar*(15)+1)**n* +*ipar*(15)**ipar*(15)+9)/2 + 1). Refer to the FGMRES Common Parameters.

Output Parameters

RCI_request	INTEGER. Informs about result of work of the routine.
ipar	INTEGER array of size *128*. Refer to the FGMRES Common Parameters.
dpar	DOUBLE PRECISION array of size *128*. Refer to the FGMRES Common Parameters.
tmp	DOUBLE PRECISION array of size ((2**ipar*(15)+1)**n* +*ipar*(15)**ipar*(15)+9)/2 + 1). Refer to the FGMRES Common Parameters.

Return Values

RCI_request=0	Indicates that the task completed normally and the solution is found and stored in the vector *x*. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the *RCI_request*= 2 or 4.
RCI_request=-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
RCI_request= -10	Indicates that the routine was interrupted because of an attempt to divide by zero. Usually this happens if the matrix is degenerate or almost degenerate. However, it may happen if the parameter *dpar* is altered, or if the method is not stopped when the solution is found.
RCI_request= -11	Indicates that the routine was interrupted because it entered an infinite cycle. Usually this happens because the values *ipar*(8), *ipar*(9), *ipar*(10) were altered outside of the routine, or the dfgmres_check routine was not called.
RCI_request= -12	Indicates that the routine was interrupted because errors were found in the method parameters. Usually this happens if the parameters *ipar* and *dpar* were altered by mistake outside the routine.

RCI_request= 1	Indicates that you must multiply the matrix by *tmp*(*ipar*(22)), put the result in the *tmp*(*ipar*(23)), and return the control back to the routine dfgmres.
RCI_request= 2	Indicates that you must perform the stopping tests. If they fail, return control to the dfgmres routine. Otherwise, the FGMRES solution is found, and you can run the fgmres_get routine to update the computed solution in the vector *x*.
RCI_request= 3	Indicates that you must apply the inverse preconditioner to *ipar*(22), put the result in the *ipar*(23), and return the control back to the routine dfgmres.
RCI_request= 4	Indicates that you must check the norm of the currently generated vector. If it is not zero within the computational/ rounding errors, return control to the dfgmres routine. Otherwise, the FGMRES solution is found, and you can run the dfgmres_get routine to update the computed solution in the vector *x*.

dfgmres_get

Retrieves the number of the current iteration and updates the solution.

Syntax

dfgmres_get(*n*, *x*, *b*, *RCI_request*, *ipar*, *dpar*, *tmp*, *itercount*)

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine dfgmres_get retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the dfgmres routine. To retrieve the current iteration number only, set the parameter *ipar*(13) = -1 beforehand. Normally, you should do this before proceeding further with the computations. If the intermediate solution is needed, the method parameters must be set properly. For details see FGMRES Common Parameters and the Iterative Sparse Solver code examples in the examples\solver\source folder of your Intel MKL directory (cg_no_precon.f, cg_no_precon_c.c, cg_mrhs.f, cg_mrhs_precond.f, cg_mrhs_stop_crt.f, fgmres_no_precon_f.f, fgmres_no_precon_c.c).

Input Parameters

n	INTEGER. Sets the size of the problem.
ipar	INTEGER array of size *128*. Refer to the FGMRES Common Parameters.
dpar	DOUBLE PRECISION array of size *128*. Refer to the FGMRES Common Parameters.
tmp	DOUBLE PRECISION array of size ((2**ipar*(15)+1)**n* +*ipar*(15)**ipar*(15)+9)/2 + 1). Refer to the FGMRES Common Parameters.

Output Parameters

x	DOUBLE PRECISION array of size *n*. If *ipar*(13) = 0, it contains the updated approximation to the solution according to the computations done in dfgmres routine. Otherwise, it is not changed.
b	DOUBLE PRECISION array of size *n*. If *ipar*(13) > 0, it contains the updated approximation to the solution according to the computations done in dfgmres routine. Otherwise, it is not changed.
RCI_request	INTEGER. Gives information about result of the routine.
itercount	INTEGER argument. Contains the value of the current iteration number.

Return Values

RCI_request = 0	Indicates that the task completed normally.
RCI_request = -12	Indicates that the routine was interrupted because errors were found in the routine parameters. Usually this happens if the parameters *ipar* and *dpar* are altered by mistake outside of the routine.
RCI_request = -10000	Indicates that the routine failed to complete the task.

Implementation Details

Several aspects of the Intel MKL RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel MKL RCI ISS language-specific header files.

The C-language header file defines these function prototypes:

```
void dcg_init(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp);

void dcg_check(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp);

void dcg(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar, double
*tmp);

void dcg_get(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp, int *itercount);

void dcgmrhs_init(int *n, double *x, int *nRhs, double *b, int *method, int
*rci_request, int *ipar, double dpar, double *tmp);

void dcgmrhs_check(int *n, double *x, int *nRhs, double *b, int *rci_request, int
*ipar, double dpar, double *tmp);

void dcgmrhs(int *n, double *x, int *nRhs, double *b, int *rci_request, int *ipar,
double dpar, double *tmp);

void dcgmrhs_get(int *n, double *x, int *nRhs, double *b, int *rci_request, int *ipar,
double dpar, double *tmp, int *itercount);

void dfgmres_init(int *n, double *x, double *b, int *rci_request, int *ipar, double
dpar, double *tmp);

void dfgmres_check(int *n, double *x, double *b, int *rci_request, int *ipar, double
dpar, double *tmp);

void dfgmres(int *n, double *x, double *b, int *rci_request, int *ipar, double dpar,
double *tmp);
```

```
void dfgmres_get(int *n, double *x, double *b, int *rci_request, int *ipar, double
dpar, double *tmp, int *itercount);
```

NOTE Intel MKL does not support the RCI ISS interface unless you include the language-specific header file.

Preconditioners based on Incomplete LU Factorization Technique

Preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms *preconditioner* and *accelerator* are synonyms, hereafter only *preconditioner* is used.

Intel MKL provides two preconditioners, ILU0 and ILUT, for sparse matrices presented in the format accepted in the Intel MKL direct sparse solvers (three-array variation of the CSR storage format described in Sparse Matrix Storage Format). The used algorithms used are described in [Saad03].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: lower and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT algorithm is that it calculates each element of the preconditioner and saves each one if it satisfies two conditions simultaneously: its value is greater than the product of the given tolerance and matrix row norm, and its value is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel MKL RCI FGMRES solver (see Sparse Solver Routines). Avoid using these preconditioners with MKL RCI CG solver because in general, they produce a non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel MKL triangular solver routine `mkl_dcsrtrsv` must be applied twice: for the lower triangular part of the preconditioner, and then for its upper triangular part.

NOTE Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. Whether or not the preconditioner produces an acceptable result can only be determined in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial solution, and even ruin the convergence. It is your responsibility as a user to choose a suitable preconditioner.

General Scheme of Using ILUT and RCI FGMRES Routines

The general scheme for use is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. You can see all these differences in the code examples for both preconditioners in the `examples\solver\source` folder of your Intel MKL directory (`dcsrilu0_expl1.c`, `dcsrilu0_expl2.f`, `dcsrilut_expl1.c`, `dcsrilut_expl2.f`).

The following pseudocode shows the general scheme of using the ILUT preconditioner in the RCI FGMRES context.

...

generate matrix *A*

generate preconditioner *C* (optional)

call `dfgmres_init(n, x, b, RCI_request, ipar, dpar, tmp)`

```
   change parameters in ipar, dpar if necessary
   call dcsrilut(n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
   call dfgmres_check(n, x, b, RCI_request, ipar, dpar, tmp)
1  call dfgmres(n, x, b, RCI_request, ipar, dpar, tmp)
   if (RCI_request.eq.1) then
    multiply the matrix A by tmp(ipar(22)) and put the result in tmp(ipar(23))
c  proceed with FGMRES iterations
    goto 1
   endif
   if (RCI_request.eq.2) then
    do the stopping test
    if (test not passed) then
c proceed with FGMRES iterations
     go to 1
    else
c  stop FGMRES iterations.
     goto 2
    endif
   endif
   if (RCI_request.eq.3) then
c   Below, trvec is an intermediate vector of length at least n
c   Here is the recommended use of the result produced by the ILUT routine.
c   via standard Intel MKL Sparse Blas solver routine mkl_dcsrtrsv.
   call mkl_dcsrtrsv('L','N','U', n, bilut, ibilut, jbilut, tmp(ipar(22)),trvec)
   call mkl_dcsrtrsv('U','N','N', n, bilut, ibilut, jbilut, trvec, tmp(ipar(23)))
c proceed with FGMRES iterations
    goto 1
   endif
   if (RCI_request.eq.4) then
   check the norm of the next orthogonal vector, it is contained in dpar(7)
    if (the norm is not zero up to rounding/computational errors) then
c  proceed with FGMRES iterations
     goto 1
    else
c  stop FGMRES iterations
     goto 2
    endif
```

```
endif
```

2 call `dfgmres_get(n, x, b, RCI_request, ipar, dpar, tmp, itercount)`

current iteration number is in *itercount*

the computed approximation is in the array *x*

ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel MKL preconditioner routines are discussed in the Appendix A Linear Solvers Basics.

In this section the FORTRAN style notations are used. All types refer to the standard Fortran types, `INTEGER`, and `DOUBLE PRECISION`.

C and C++ programmers must refer to the section Calling Sparse Solver and Preconditioner Routines from C C++ for information on mapping Fortran types to C/C++ types.

User Data Arrays

The preconditioner routines take arrays of user data as input. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL preconditioner routines do not make copies of the user input arrays.

Common Parameters

Some parameters of the preconditioners are common with the FGMRES Common Parameters. The routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

For the ILU0 preconditioner:

ipar(2) - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter *ipar*(6) is set to 0, then error messages are not generated at all.

ipar(6) - specifies whether error messages are generated. If its value is not equal to 0, the ILU0 routine returns error messages as specified by the parameter *ipar*(2). Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter *ierr*. The default value is 1.

For the ILUT preconditioner:

ipar(2) - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter *ipar*(6) is set to 0, then error messages are not generated at all.

ipar(6) - specifies whether error messages are generated. If its value is not equal to 0, the ILUT routine returns error messages as specified by the parameter *ipar*(2). Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter *ierr*. The default value is 1.

ipar(7) - if its value is greater than 0, the ILUT routine generates warning messages as specified by the parameter *ipar*(2) and continues calculations. If its value is equal to 0, the routine returns a positive value of the parameter *ierr*. If its value is less than 0, the routine generates a warning message as specified by the parameter *ipar*(2) and returns a positive value of the parameter *ierr*. The default value is 1.

dcsrilu0

ILU0 preconditioner based on incomplete LU factorization of a sparse matrix.

Syntax

Fortran:

```
call dcsrilu0(n, a, ia, ja, bilu0, ipar, dpar, ierr)
```

C:

```
dcsrilu0(&n, a, ia, ja, bilu0, ipar, dpar, &ierr);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine `dcsrilu0` computes a preconditioner *B* [Saad03] of a given sparse matrix *A* stored in the format accepted in the direct sparse solvers:

*A~B=L*U* , where *L* is a lower triangular matrix with a unit diagonal, *U* is an upper triangular matrix with a non-unit diagonal, and the portrait of the original matrix *A* is used to store the incomplete factors *L* and *U*.

Input Parameters

n — `INTEGER`. Size (number of rows or columns) of the original square *n*-by-*n* matrix *A*.

a — `DOUBLE PRECISION`. Array containing the set of elements of the matrix *A*. Its length is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the Sparse Matrix Storage Format for more details.

ia — `INTEGER`. Array of size `(n+1)` containing begin indices of rows of the matrix *A* such that *ia*`(i)` is the index in the array *A* of the first non-zero element from the row `i`. The value of the last element *ia*`(n+1)` is equal to the number of non-zero elements in the matrix *A* plus one. Refer to the *rowIndex* array description in the Sparse Matrix Storage Format for more details.

ja — `INTEGER`. Array containing the column indices for each non-zero element of the matrix *A*. Its size is equal to the size of the array *a*. Refer to the *columns* array description in the Sparse Matrix Storage Format for more details.

NOTE Column indices must be in ascending order for each row of matrix.

ipar — `INTEGER` array of size *128*. This parameter specifies the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the *ipar* array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

ipar(31) specifies how the routine operates when a zero diagonal element occurs during calculation. If this parameter is set to 0 (the default value set by the routine dfgmres_init), then the calculations are stopped and the routine returns a non-zero error value. Otherwise, the diagonal element is set to the value of *dpar*(32) and the calculations continue.

NOTE You must declare the array *ipar* with length 128. While defining the array in the code as INTEGER *ipar*(31) works, there is no guarantee of future compatibility with Intel MKL.

dpar DOUBLE PRECISION array of size *128*. This parameter specifies the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the *dpar* array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries specific to ILU0 are listed below.

dpar(31) specifies a small value, which is compared with the computed diagonal elements. When *ipar*(31) is not 0, then diagonal elements less than *dpar*(31) are set to *dpar*(32). The default value is 1.0D-16.

NOTE This parameter can be set to the negative value, because the calculation uses its absolute value.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

dpar(32) specifies the value that is assigned to the diagonal element if its value is less than *dpar*(31) (see above). The default value is 1.0D-10.

NOTE You must declare the array *dpar* with length 128. While defining the array in the code as DOUBLE PRECISION *ipar*(32) works, there is no guarantee of future compatibility with Intel MKL.

Output Parameters

bilu0 DOUBLE PRECISION. Array *B* containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in direct sparse solvers. Its size is equal to the number of non-zero elements in the matrix *A*. Refer to the *values* array description in the Sparse Matrix Storage Format section for more details.

ierr INTEGER. Error flag, gives information about the routine completion.

NOTE To present the resulting preconditioning matrix in the CSR format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

Return Values

ierr=0	Indicates that the task completed normally.
ierr=-101	Indicates that the routine was interrupted and that error occurred: at least one diagonal element is omitted from the matrix in CSR format (see Sparse Matrix Storage Format).
ierr=-102	Indicates that the routine was interrupted because the matrix contains a diagonal element with the value of zero.
ierr=-103	Indicates that the routine was interrupted because the matrix contains a diagonal element which is so small that it could cause an overflow, or that it would cause a bad approximation to ILU0.
ierr=-104	Indicates that the routine was because the memory is insufficient for the internal work array.
ierr=-105	Indicates that the routine was because the input matrix size *n* is less than or equal to 0.
ierr=-106	Indicates that the routine was because the column indices *ja* are not in the ascending order.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilu0 (n, a, ia, ja, bilu0, ipar, dpar, ierr)
INTEGER n, ierr, ipar(128)
INTEGER ia(*), ja(*)
DOUBLE PRECISION a(*), bilu0(*), dpar(128)
```

C:

```
void dcsrilu0 (int *n, double *a, int *ia, int *ja, double  *bilu0, int *ipar, double *dpar, int *ierr);
```

dcsrilut

ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.

Syntax

Fortran:

```
call dcsrilut(n, a, ia, ja, bilut, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
```

C:

```
dcsrilut(&n, a, ia, ja, bilut, bilut, ibilut, jbilut, &tol, &maxfil, ipar, dpar, &ierr);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The routine dcsrilut computes a preconditioner *B* [Saad03] of a given sparse matrix *A* stored in the format accepted in the direct sparse solvers:

*A~B=L*U* , where *L* is a lower triangular matrix with unit diagonal and *U* is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors *L* and *U*:

1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter *tol*, and

2) the number of the non-zero elements in each row of the resulting *L* and *U* factors must not be greater than the value of the parameter *maxfil*.

Input Parameters

n — INTEGER. Size (number of rows or columns) of the original square *n*-by-*n* matrix *A*.

a — DOUBLE PRECISION. Array containing all non-zero elements of the matrix *A*. The length of the array is equal to their number. Refer to *values* array description in the Sparse Matrix Storage Format section for more details.

ia — INTEGER. Array of size (*n*+1) containing indices of non-zero elements in the array *A*. *ia*(i) is the index of the first non-zero element from the row i. The value of the last element *ia*(*n*+1) is equal to the number of non-zeros in the matrix *A* plus one. Refer to the *rowIndex* array description in the Sparse Matrix Storage Format for more details.

ja — INTEGER. Array of size equal to the size of the array *a*. This array contains the column numbers for each non-zero element of the matrix *A*. Refer to the *columns* array description in the Sparse Matrix Storage Format for more details.

NOTE Column numbers must be in ascending order for each row of matrix.

tol — DOUBLE PRECISION. Tolerance for threshold criterion for the resulting entries of the preconditioner.

maxfil — INTEGER. Maximum fill-in, which is half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner can not exceed (2**maxfil*+1).

ipar — INTEGER array of size *128*. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the *ipar* array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.

ipar(31) specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter *tol*. If *ipar*(31) = 0, then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to a value determined by *dpar*(31) (see its description below), and the calculations continue.

NOTE There is no default value for *ipar*(31) even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

NOTE You must declare the array *ipar* with length 128. While defining the array in the code as INTEGER *ipar*(31) works, there is no guarantee of future compatibility with Intel MKL.

dpar DOUBLE PRECISION array of size *128*. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the *dpar* array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

dpar(31) used to adjust the value of small diagonal elements. Diagonal elements with a value less than the current matrix row norm multiplied by *tol* are replaced with the value of *dpar*(31) multiplied by the matrix row norm.

NOTE There is no default value for *dpar*(31) entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

NOTE You must declare the array *dpar* with length 128. While defining the array in the code as DOUBLE PRECISION *ipar*(31) works, there is no guarantee of future compatibility with Intel MKL.

Output Parameters

bilut DOUBLE PRECISION. Array containing non-zero elements of the resulting preconditioning matrix *B*, stored in the format accepted in the direct sparse solvers. Refer to the *values* array description in the Sparse Matrix Storage Format for more details. The size of the array is equal to (2**maxfil*+1)**n*-*maxfil**(*maxfil*+1)+1.

NOTE Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.

ibilut INTEGER. Array of size (*n*+1) containing indices of non-zero elements in the array *bilut*. *ibilut*(i) is the index of the first non-zero element from the row i. The value of the last element *ibilut*(*n*+1) is equal to the number of non-zeros in the matrix *B* plus one. Refer to the *rowIndex* array description in the Sparse Matrix Storage Format for more details.

jbilut	INTEGER. Array, its size is equal to the size of the array *bilut*. This array contains the column numbers for each non-zero element of the matrix *B*. Refer to the *columns* array description in the Sparse Matrix Storage Format for more details.
ierr	INTEGER. Error flag, informs about the routine completion.

Return Values

ierr=0	Indicates that the task completed normally.
ierr=-101	Indicates that the routine was interrupted because of an error: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.
ierr=-102	Indicates that the routine was interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as *ipar*(31)=0.
ierr=-103	Indicates that the routine was interrupted because the element *ia*(i+1) is less than or equal to the element *ia*(i) (see Sparse Matrix Storage Format).
ierr=-104	Indicates that the routine was interrupted because the memory is insufficient for the internal work arrays.
ierr=-105	Indicates that the routine was interrupted because the input value of *maxfil* is less than 0.
ierr=-106	Indicates that the routine was interrupted because the size *n* of the input matrix is less than 0.
ierr=-107	Indicates that the routine was interrupted because an element of the array *ja* is less than 0, or greater than *n* (see Sparse Matrix Storage Format).
ierr=101	The value of *maxfil* is greater than or equal to *n*. The calculation is performed with the value of *maxfil* set to (*n*-1).
ierr=102	The value of *tol* is less than 0. The calculation is performed with the value of the parameter set to (-*tol*)
ierr=103	The absolute value of *tol* is greater than value of *dpar*(31); it can result in instability of the calculation.
ierr=104	The value of *dpar*(31) is equal to 0. It can cause calculations to fail.

Interfaces

FORTRAN 77 and Fortran 95:

```
SUBROUTINE dcsrilut (n, a, ia, ja, bilut, ibilut, jbilut, tol, maxfil, ipar, dpar, ierr)
INTEGER n, ierr, ipar(*), maxfil
INTEGER ia(*), ja(*), ibilut(*), jbilut(*)
DOUBLE PRECISION a(*), bilut(*), dpar(*), tol
```

C:

```
void dcsrilut (int *n, double *a, int *ia, int *ja, double *bilut, int *ibilut, int *jbilut, double
*tol, int *maxfil, int *ipar, double *dpar, int *ierr);
```

Calling Sparse Solver and Preconditioner Routines from C/C++

All of the Intel MKL sparse solver and preconditioner routines is designed to be called easily from FORTRAN 77 or Fortran 90. However, any of these routines can be invoked directly from C or C++ if you are familiar with the inter-language calling conventions of your platforms. These conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from Fortran to C/C++, and the platform specific method of decoration for Fortran external names.

To promote portability, the C header files provide a set of macros and type definitions intended to hide the inter-language calling conventions and provide an interface to the Intel MKL sparse solver routines that appears natural for C/C++.

For example, consider a hypothetical library routine `foo` that takes a real vector of length *n*, and returns an integer status. Fortran users would access such a function as:

```
INTEGER n, status, foo
REAL x(*)
status = foo(x, n)
```

As noted above, to invoke `foo`, C users need to know what C data types correspond to Fortran types `INTEGER` and `REAL`; what argument passing mechanism the Fortran compiler uses; and what, if any, name decoration the Fortran compiler performs when generating the external symbol `foo`.

However, by using the C specific header file, for example `mkl_solver.h`, the invocation of `foo`, within a C program would look as follows:

```
#include "mkl_solver.h"
_INTEGER_t i, status;
_REAL_t x[];
status = foo( x, i );
```

Note that in the above example, the header file `mkl_solver.h` provides definitions for the types `_INTEGER_t` and `_REAL_t` that correspond to the Fortran types `INTEGER` and `REAL`.

To simplify calling of the Intel MKL sparse solver routines from C and C++, the following approach of providing C definitions of Fortran types is used: if an argument or a result from a sparse solver is documented as having the Fortran language specific type *XXX*, then the C and C++ header files provide an appropriate C language type definitions for the name *_XXX*_t.

Caveat for C Users

One of the key differences between C/C++ and Fortran is the argument passing mechanisms for the languages: Fortran programs pass arguments by reference and C/C++ programs pass arguments by value. In the above example, the header file `mkl_solver.h` attempts to hide this difference by defining a macro `foo`, which takes the address of the appropriate arguments. For example, on the Tru64 UNIX* operating system `mkl_solver.h` defines the macro as follows:

```
#define foo(a,b) foo_((a), &(b))
```

Note how constants are treated when using the macro form of `foo`. `foo( x, 10 )` is converted into `foo_( x, &10 )`. In a strictly ANSI compliant C compiler, taking the address of a constant is not permitted, so a strictly conforming program would look like:

```
INTEGER_t iTen = 10;

_REAL_t * x;

status = foo( x, iTen );
```

However, some C compilers in a non-ANSI compliant mode enable taking the address of a constant for ease of use with Fortran programs. The form `foo( x, 10 )` is acceptable for such compilers.

9 Vector Mathematical Functions

This chapter describes Intel® MKL Vector Mathematical Functions Library (VML), which computes a mathematical function of each of the vector elements. VML includes a set of highly optimized functions (arithmetic, power, trigonometric, exponential, hyperbolic, special, and rounding) that operate on vectors of real and complex numbers.

Application programs that improve performance with VML include nonlinear programming software, computation of integrals, financial calculations, computer graphics, and many others.

VML functions fall into the following groups according to the operations they perform:

- VML Mathematical Functions compute values of mathematical functions, such as sine, cosine, exponential, or logarithm, on vectors stored contiguously in memory.
- VML Pack/Unpack Functions convert to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix B for details on vector indexing methods).
- VML Service Functions set/get the accuracy modes and the error codes.

The VML mathematical functions take an input vector as an argument, compute values of the respective function element-wise, and return the results in an output vector. All the VML mathematical functions can perform in-place operations, where the input and output arrays are at the same memory locations.

The Intel MKL interfaces are given in the following include files:

- `mkl_vml.f77`, which declares the FORTRAN 77 interfaces
- `mkl_vml.f90`, which declares the Fortran 90 interfaces; the `mkl_vml.fi` include file available in the previous versions of Intel MKL is retained for backward compatibility
- `mkl_vml_functions.h`, which declares the C interfaces

The following directories provide examples that demonstrate how to use the VML functions:

`${MKL}/examples/vmlc/source`

`${MKL}/examples/vmlf/source`

See VML performance and accuracy data in the online VML Performance and Accuracy Data document available at http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/

Data Types, Accuracy Modes, and Performance Tips

VML includes mathematical and pack/unpack vector functions for single and double precision vector arguments of real and compex types. The library provides Fortran- and C-interfaces for all functions, including the associated service functions. The Function Naming Conventions section below shows how to call these functions from different languages.

Performance depends on a number of factors, including vectorization and threading overhead. The recommended usage is as follows:

- Use VML for vector lengths larger than 40 elements.

- Use the Intel® Compiler for vector lengths less than 40 elements.

All VML vector functions support the following accuracy modes:

- High Accuracy (HA), the default mode
- Low Accuracy (LA), which improves performance by reducing accuracy of the two least significant bits
- Enhanced Performance (EP), which provides better performance at the cost of significantly reduced accuracy. Approximately half of the bits in the mantissa are correct.

Note that using the EP mode does not guarantee accurate processing of corner cases and special values. Although the default accuracy is HA, LA is sufficient in most cases. For applications that require less accuracy (for example, media applications, some Monte Carlo simulations, etc.), the EP mode may be sufficient.

VML handles special values in accordance with the C99 standard [C99].

Use the `vmlSetMode(mode)` function (see Table "Values of the *mode* Parameter") to switch between the HA, LA, and EP modes. The `vmlGetMode()` function returns the current mode.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

Function Naming Conventions

Function Naming Conventions

The VML function names are lowercase for Fortran (`vsabs`) and of mixed (lower and upper) case for C (`vsAbs`).

The VML mathematical and pack/unpack function names have the following structure:

v[*m*]<*?*><name><*mod*>

where

- *v* is a prefix indicating vector operations.
- [*m*] is an optional prefix for mathematical functions that indicates additional argument to specify a VML mode for a given function call (see `vmlSetMode` for possible values and their description).
- <*?*> is a precision prefix that indicates one of the following the data types:

s	`REAL` for the Fortran interface, or `float` for the C interface
d	`DOUBLE PRECISION` for the Fortran interface, or `double` for the C interface.
c	`COMPLEX` for the Fortran interface, or `MKL_Complex8` for the C interface.
z	`DOUBLE COMPLEX` for the Fortran interface, or `MKL_Complex16` for the C interface.

- <name> indicates the function short name, with some of its letters in uppercase for the C interface. See examples in Table "VML Mathematical Functions".
- <*mod*> field (written in uppercase for the C interface) is present only in the pack/unpack functions and indicates the indexing method used:

i	indexing with a positive increment
v	indexing with an index vector
m	indexing with a mask vector.

The VML service function names have the following structure:

vml<name>

where

<name> indicates the function short name, with some of its letters in uppercase for the C interface. See examples in Table "VML Service Functions".

To call VML functions from an application program, use conventional function calls. For example, call the vector single precision real exponential function as

`call vsexp ( n, a, y )` for the Fortran interface, or

`call vmsexp ( n, a, y, mode )` for the Fortran interface with a specified mode, or

`vsExp ( n, a, y );` for the C interface.

Function Interfaces

VML interfaces include the function names and argument lists. The following sections describe the Fortran and C interfaces for the VML functions. Note that some of the functions have multiple input and output arguments

Some VML functions may also take scalar arguments as input. See the function description for the naming conventions of such arguments.

VML Mathematical Functions

Fortran:

```
call v<?><name>( n, a, [scalar input arguments,] y )
call v<?><name>( n, a, b, [scalar input arguments,] y )
call v<?><name>( n, a, y, z )
call vm<?><name>( n, a, [scalar input arguments,] y, mode )
call vm<?><name>( n, a, b, [scalar input arguments,] y, mode )
call vm<?><name>( n, a, y, z, mode )
```

C:

```
v<?><name>( n, a, [scalar input arguments,] y );
v<?><name>( n, a, b, [scalar input arguments,] y );
v<?><name>( n, a, y, z );
vm<?><name>( n, a, [scalar input arguments,] y, mode );
vm<?><name>( n, a, b, [scalar input arguments,] y, mode );
vm<?><name>( n, a, y, z, mode );
```

Pack Functions

Fortran:

```
call v<?>packi( n, a, inca, y )
call v<?>packv( n, a, ia, y )
call v<?>packm( n, a, ma, y )
```

C:

```
v<?>PackI( n, a, inca, y );
v<?>PackV( n, a, ia, y );
v<?>PackM( n, a, ma, y );
```

Unpack Functions

Fortran:

```
call v<?>unpacki( n, a, y, incy )
call v<?>unpackv( n, a, y, iy )
call v<?>unpackm( n, a, y, my )
```

C:

```
v<?>UnpackI( n, a, y, incy );
v<?>UnpackV( n, a, y, iy );
v<?>UnpackM( n, a, y, my );
```

Service Functions

Fortran:

```
oldmode = vmlsetmode( mode )
mode = vmlgetmode( )
olderr = vmlseterrstatus ( err )
err = vmlgeterrstatus( )
olderr = vmlclearerrstatus( )
oldcallback = vmlseterrorcallback( callback )
callback = vmlgeterrorcallback( )
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldmode = vmlSetMode( mode );
mode = vmlGetMode( void );
olderr = vmlSetErrStatus ( err );
err = vmlGetErrStatus( void );
olderr = vmlClearErrStatus( void );
oldcallback = vmlSetErrorCallBack( callback );
callback = vmlGetErrorCallBack( void );
oldcallback = vmlClearErrorCallBack( void );
```

Note that *oldmode*, *oldcerr*, and *oldcallback* refer to settings prior to the call.

Input Parameters

n	number of elements to be calculated
a	first input vector
b	second input vector
inca	vector increment for the input vector *a*
ia	index vector for the input vector *a*
ma	mask vector for the input vector *a*
incy	vector increment for the output vector *y*
iy	index vector for the output vector *y*
my	mask vector for the output vector *y*
err	error code
mode	VML mode
callback	address of the callback function

Output Parameters

y	first output vector
z	second output vector
err	error code
mode	VML mode
olderr	former error code
oldmode	former VML mode
callback	address of the callback function
oldcallback	address of the former callback function

See the data types of the parameters used in each function in the respective function description section. All the Intel MKL VML mathematical functions can perform in-place operations.

Vector Indexing Methods

VML mathematical functions work only with unit stride. To accommodate arrays with other increments, or more complicated indexing, you can gather the elements into a contiguous vector and then scatter them after the computation is complete.

VML uses the three following indexing methods to do this task:

- positive increment
- index vector
- mask vector

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the *<mod>* field in Function Naming Conventions). For more information on the indexing methods, see Vector Arguments in VML in Appendix B.

Error Diagnostics

The VML mathematical functions incorporate the error handling mechanism, which is controlled by the following service functions:

`vmlGetErrStatus`, `vmlSetErrStatus`, `vmlClearErrStatus`	These functions operate with a global variable called VML Error Status. The VML Error Status flags an error, a warning, or a successful execution of a VML function.
`vmlGetErrCallBack`, `vmlSetErrCallBack`, `vmlClearErrCallBack`	These functions enable you to customize the error handling. For example, you can identify a particular argument in a vector where an error occurred or that caused a warning.
`vmlSetMode`, `vmlGetMode`	These functions get and set a VML mode. If you set a new VML mode using the `vmlSetMode` function, you can store the previous VML mode returned by the routine and restore it at any point of your application.

If both an error and a warning situation occur during the function call, the VML Error Status variable keeps only the value of the error code. See Table "Values of the VML Error Status" for possible values. If a VML function does not encounter errors or warnings, it sets the VML Error Status to `VML_STATUS_OK`.

If you use the Fortran interface, call the error reporting function `XERBLA` to receive information about correctness of input arguments (`VML_STATUS_BADSIZE` and `VML_STATUS_BADMEM`). See Table "Values of the VML Error Status" for details.

You can use the `vmlSetMode` and `vmlGetMode` functions to modify error handling behavior. Depending on the VML mode, the error handling behavior includes the following operations:

- setting the VML Error Status to a value corresponding to the observed error or warning
- setting the *errno* variable to one of the values described in Table "Set Values of the *errno* Variable"
- writing error text information to the *stderr* stream
- raising the appropriate exception on an error, if necessary
- calling the additional error handler callback function that is set by `vmlSetErrorCallBack`.

Set Values of the *errno* Variable

Value of *errno*	Description
0	No errors are detected.
EINVAL	The array dimension is not positive.
EACCES	`NULL` pointer is passed.
EDOM	At least one of array values is out of a range of definition.
ERANGE	At least one of array values caused a singularity, overflow or underflow.

VML Mathematical Functions

This section describes VML functions that compute values of mathematical functions on real and complex vector arguments with unit increment.

Each function is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data both for Fortran- and C-interfaces, as well as a description of the input/output arguments.

The input range of parameters is equal to the mathematical range of the input data type, unless the function description specifies input threshold values, which mark off the precision overflow, as follows:

- *FLT_MAX* denotes the maximum number representable in single precision real data type
- *DBL_MAX* denotes the maximum number representable in double precision real data type

Table "VML Mathematical Functions" lists available mathematical functions and associated data types.

VML Mathematical Functions

Function	Data Types	Description
Arithmetic Functions		
v?Add	*s*, *d*, *c*, *z*	Addition of vector elements
v?Sub	*s*, *d*, *c*, *z*	Subtraction of vector elements
v?Sqr	*s*, *d*	Squaring of vector elements
v?Mul	*s*, *d*, *c*, *z*	Multiplication of vector elements
v?MulByConj	*c*, *z*	Multiplication of elements of one vector by conjugated elements of the second vector
v?Conj	*c*, *z*	Conjugation of vector elements
v?Abs	*s*, *d*, *c*, *z*	Computation of the absolute value of vector elements
v?Arg	*c*, *z*	Computation of the argument of vector elements
v?LinearFrac	*s*, *d*	Linear fraction transformation of vectors
Power and Root Functions		
v?Inv	*s*, *d*	Inversion of vector elements

Function	Data Types	Description
v?Div	*s*, *d*, *c*, *z*	Division of elements of one vector by elements of the second vector
v?Sqrt	*s*, *d*, *c*, *z*	Computation of the square root of vector elements
v?InvSqrt	*s*, *d*	Computation of the inverse square root of vector elements
v?Cbrt	*s*, *d*	Computation of the cube root of vector elements
v?InvCbrt	*s*, *d*	Computation of the inverse cube root of vector elements
v?Pow2o3	*s*, *d*	Raising each vector element to the power of 2/3
v?Pow3o2	*s*, *d*	Raising each vector element to the power of 3/2
v?Pow	*s*, *d*, *c*, *z*	Raising each vector element to the specified power
v?Powx	*s*, *d*, *c*, *z*	Raising each vector element to the constant power
v?Hypot	*s*, *d*	Computation of the square root of sum of squares
Exponential and Logarithmic Functions		
v?Exp	*s*, *d*, *c*, *z*	Computation of the exponential of vector elements
v?Expm1	*s*, *d*	Computation of the exponential of vector elements decreased by 1
v?Ln	*s*, *d*, *c*, *z*	Computation of the natural logarithm of vector elements
v?Log10	*s*, *d*, *c*, *z*	Computation of the denary logarithm of vector elements
v?Log1p	*s*, *d*	Computation of the natural logarithm of vector elements that are increased by 1
Trigonometric Functions		
v?Cos	*s*, *d*, *c*, *z*	Computation of the cosine of vector elements
v?Sin	*s*, *d*, *c*, *z*	Computation of the sine of vector elements
v?SinCos	*s*, *d*	Computation of the sine and cosine of vector elements
v?CIS	*c*, *z*	Computation of the complex exponent of vector elements (cosine and sine combined to complex value)
v?Tan	*s*, *d*, *c*, *z*	Computation of the tangent of vector elements
v?Acos	*s*, *d*, *c*, *z*	Computation of the inverse cosine of vector elements
v?Asin	*s*, *d*, *c*, *z*	Computation of the inverse sine of vector elements
v?Atan	*s*, *d*, *c*, *z*	Computation of the inverse tangent of vector elements
v?Atan2	*s*, *d*	Computation of the four-quadrant inverse tangent of elements of two vectors
Hyperbolic Functions		
v?Cosh	*s*, *d*, *c*, *z*	Computation of the hyperbolic cosine of vector elements
v?Sinh	*s*, *d*, *c*, *z*	Computation of the hyperbolic sine of vector elements
v?Tanh	*s*, *d*, *c*, *z*	Computation of the hyperbolic tangent of vector elements
v?Acosh	*s*, *d*, *c*, *z*	Computation of the inverse hyperbolic cosine of vector elements
v?Asinh	*s*, *d*, *c*, *z*	Computation of the inverse hyperbolic sine of vector elements
v?Atanh	*s*, *d*, *c*, *z*	Computation of the inverse hyperbolic tangent of vector elements.
Special Functions		
v?Erf	*s*, *d*	Computation of the error function value of vector elements
v?Erfc	*s*, *d*	Computation of the complementary error function value of vector elements
v?CdfNorm	*s*, *d*	Computation of the cumulative normal distribution function value of vector elements
v?ErfInv	*s*, *d*	Computation of the inverse error function value of vector elements
v?ErfcInv	*s*, *d*	Computation of the inverse complementary error function value of vector elements
v?CdfNormInv	*s*, *d*	Computation of the inverse cumulative normal distribution function value of vector elements
v?LGamma	*s*, *d*	Computation of the natural logarithm for the absolute value of the gamma function of vector elements
v?TGamma	*s*, *d*	Computation of the gamma function of vector elements
Rounding Functions		
v?Floor	*s*, *d*	Rounding towards minus infinity
v?Ceil	*s*, *d*	Rounding towards plus infinity
v?Trunc	*s*, *d*	Rounding towards zero infinity

Function	Data Types	Description
v?Round	*s*, *d*	Rounding to nearest integer
v?NearbyInt	*s*, *d*	Rounding according to current mode
v?Rint	*s*, *d*	Rounding according to current mode and raising inexact result exception
v?Modf	*s*, *d*	Computation of the integer and fraction parts

Special Value Notations

This section defines notations of special values for complex functions. The definitions are provided in text, tables, or formulas.

- `z`, `z1`, `z2`, etc. denote complex numbers.
- `i`, $i^2=-1$ is the imaginary unit.
- `x`, `X`, `x1`, `x2`, etc. denote real imaginary parts.
- `y`, `Y`, `y1`, `y2`, etc. denote imaginary parts.
- `X` and `Y` represent any finite positive IEEE-754 floating point values, if not stated otherwise.
- Quiet `NaN` and signaling `NaN` are denoted with `QNAN` and `SNAN`, respectively.
- The IEEE-754 positive infinities or floating-point numbers are denoted with a `+` sign before `X`, `Y`, etc.
- The IEEE-754 negative infinities or floating-point numbers are denoted with a – sign before `X`, `Y`, etc.

`CONJ(z)` and `CIS(z)` are defined as follows:

`CONJ(x+i·y)=x-i·y`

`CIS(y)=cos(y)+i·sin(y).`

The special value tables show the result of the function for the `z` argument at the intersection of the `RE(z)` column and the `i*IM(z)` row. If the function raises an exception on the argument `z`, the lower part of this cell shows the raised exception and the VML Error Status. An empty cell indicates that this argument is normal and the result is defined mathematically.

Arithmetic Functions

Arithmetic functions perform the basic mathematical operations like addition, subtraction, multiplication or computation of the absolute value of the vector elements.

v?Add

Performs element by element addition of vector `a` and vector `b`.

Syntax

Fortran:

```
call vsadd( n, a, b, y )
call vmsadd( n, a, b, y, mode )
call vdadd( n, a, b, y )
call vmdadd( n, a, b, y, mode )
call vcadd( n, a, b, y )
call vmcadd( n, a, b, y, mode )
call vzadd( n, a, b, y )
call vmzadd( n, a, b, y, mode )
```

C:

```
vsAdd( n, a, b, y );
vmsAdd( n, a, b, y, mode );
vdAdd( n, a, b, y );
vmdAdd( n, a, b, y, mode );
vcAdd( n, a, b, y );
vmcAdd( n, a, b, y, mode );
vzAdd( n, a, b, y );
vmzAdd( n, a, b, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a, *b*	**FORTRAN 77:** `REAL` for `vsadd`, `vmsadd` `DOUBLE PRECISION` for `vdadd`, `vmdadd` `COMPLEX` for `vcadd`, `vmcadd` `DOUBLE COMPLEX` for `vzadd`, `vmzadd` **Fortran 90:** `REAL, INTENT(IN)` for `vsadd`, `vmsadd` `DOUBLE PRECISION, INTENT(IN)` for `vdadd`, `vmdadd` `COMPLEX, INTENT(IN)` for `vcadd`, `vmcadd` `DOUBLE COMPLEX, INTENT(IN)` for `vzadd`, `vmzadd` **C:** `const float*` for `vsAdd`, `vmsadd` `const double*` for `vdAdd`, `vmdadd` `const MKL_Complex8*` for `vcAdd`, `vmcadd` `const MKL_Complex16*` for `vzAdd`, `vmzadd`	**FORTRAN:** Arrays that specify the input vectors *a* and *b*. **C:** Pointers to arrays that contain the input vectors *a* and *b*.

Name	Type	Description
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsadd`, `vmsadd` `DOUBLE PRECISION` for `vdadd`, `vmdadd` `COMPLEX`, for `vcadd`, `vmcadd` `DOUBLE COMPLEX` for `vzadd`, `vmzadd` **Fortran 90:** `REAL, INTENT(OUT)` for `vsadd`, `vmsadd` `DOUBLE PRECISION, INTENT(OUT)` for `vdadd`, `vmdadd` `COMPLEX, INTENT(OUT)` for `vcadd`, `vmcadd` `DOUBLE COMPLEX, INTENT(OUT)` for `vzadd`, `vmzadd` **C:** `float*` for `vsAdd`, `vmsadd` `double*` for `vdAdd`, `vmdadd` `MKL_Complex8*` for `vcAdd`, `vmcadd` `MKL_Complex16*` for `vzAdd`, `vmzadd`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Add` function performs element by element addition of vector *a* and vector *b*.

Special values for Real Function v?Add(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	+0	
-0	-0	-0	
+∞	+∞	+∞	
+∞	-∞	QNAN	INVALID
-∞	+∞	QNAN	INVALID
-∞	-∞	-∞	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	

Argument 1	Argument 2	Result	Exception
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

```
Add(x1+i*y1,x2+i*y2) = (x1+x2) + i*(y1+y2)
```

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x1, x2, y1, y2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?Sub

Performs element by element subtraction of vector b from vector a.

Syntax

Fortran:

```
call vssub( n, a, b, y )
call vmssub( n, a, b, y, mode )
call vdsub( n, a, b, y )
call vmdsub( n, a, b, y, mode )
call vcsub( n, a, b, y )
call vmcsub( n, a, b, y, mode )
call vzsub( n, a, b, y )
call vmzsub( n, a, b, y, mode )
```

C:

```
vsSub( n, a, b, y );
vmsSub( n, a, b, y, mode );
vdSub( n, a, b, y );
vmdSub( n, a, b, y, mode );
vcSub( n, a, b, y );
vmcSub( n, a, b, y, mode );
vzSub( n, a, b, y );
vmzSub( n, a, b, y, mode );
```

Include Files

-∞	-∞	QNAN	INVALID
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

`Sub(x1+i*y1,x2+i*y2) = (x1-x2) + i*(y1-y2).`

Overflow in a complex function occurs (supported in the `HA`/`LA` accuracy modes only) when `x1`, `x2`, `y1`, `y2` are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VML Error Status to `VML_STATUS_OVERFLOW`.

v?Sqr

Performs element by element squaring of the vector.

Syntax

Fortran:

```
call vssqr( n, a, y )
call vmssqr( n, a, y, mode )
call vdsqr( n, a, y )
call vmdsqr( n, a, y, mode )
```

C:

```
vsSqr( n, a, y );
vmsSqr( n, a, y, mode );
vdSqr( n, a, y );
vmdSqr( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vssqr, vmssqr` `DOUBLE PRECISION` for `vdsqr, vmdsqr` **Fortran 90:** `REAL, INTENT(IN)` for `vssqr, vmssqr` `DOUBLE PRECISION, INTENT(IN)` for `vdsqr, vmdsqr` **C:** `const float*` for `vsSqr, vmssqr` `const double*` for `vdSqr, vmdsqr`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vssqr, vmssqr` `DOUBLE PRECISION` for `vdsqr, vmdsqr`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	Fortran 90: `REAL, INTENT(OUT)` for `vssqr, vmssqr` `DOUBLE PRECISION, INTENT(OUT)` for `vdsqr, vmdsqr` **C:** `float*` for `vsSqr, vmssqr` `double*` for `vdSqr, vmdsqr`	

Description

The `v?Sqr` function performs element by element squaring of the vector.

Special Values for Real Function v?Sqr(x)

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

v?Mul

Performs element by element multiplication of vector `a` and vector `b`.

Syntax

Fortran:

```
call vsmul( n, a, b, y )
call vmsmul( n, a, b, y, mode )
call vdmul( n, a, b, y )
call vmdmul( n, a, b, y, mode )
call vcmul( n, a, b, y )
call vmcmul( n, a, b, y, mode )
call vzmul( n, a, b, y )
call vmzcmul( n, a, b, y, mode )
```

C:

```
vsMul( n, a, b, y );
vmsMul( n, a, b, y, mode );
vdMul( n, a, b, y );
vmdMul( n, a, b, y, mode );
vcMul( n, a, b, y );
vmcMul( n, a, b, y, mode );
vzMul( n, a, b, y );
```

```
vmzMul( n, a, b, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a, *b*	**FORTRAN 77:** `REAL` for `vsmul`, `vmsmul` `DOUBLE PRECISION` for `vdmul`, `vmdmul` `COMPLEX` for `vcmul`, `vmcmul` `DOUBLE COMPLEX` for `vzmul`, `vmzmul` **Fortran 90:** `REAL, INTENT(IN)` for `vsmul`, `vmsmul` `DOUBLE PRECISION, INTENT(IN)` for `vdmul`, `vmdmul` `COMPLEX, INTENT(IN)` for `vcmul`, `vmcmul` `DOUBLE COMPLEX, INTENT(IN)` for `vzmul`, `vmzmul` **C:** `const float*` for `vsMul`, `vmsmul` `const double*` for `vdMul`, `vmdmul` `const MKL_Complex8*` for `vcMul`, `vmcMul` `const MKL_Complex16*` for `vzMul`, `vmzMul`	**FORTRAN:** Arrays that specify the input vectors *a* and *b*. **C:** Pointers to arrays that contain the input vectors *a* and *b*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsmul`, `vmsmul`	**FORTRAN:** Array that specifies the output vector *y*.

Name	Type	Description
	`DOUBLE PRECISION` for `vdmul`, `vmdmul` `COMPLEX`, for `vcmul`, `vmcmul` `DOUBLE COMPLEX` for `vzmul`, `vmzmul` **Fortran 90:** `REAL, INTENT(OUT)` for `vsmul`, `vmsmul` `DOUBLE PRECISION, INTENT(OUT)` for `vdmul`, `vmdmul` `COMPLEX, INTENT(OUT)` for `vcmul`, `vmcmul` `DOUBLE COMPLEX, INTENT(OUT)` for `vzmul`, `vmzmul` **C:** `float*` for `vsMul`, `vmsmul` `double*` for `vdMul`, `vmdmul` `MKL_Complex8*` for `vcMul`, `vmcMul` `MKL_Complex16*` for `vzMul`, `vmzMul`	**C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Mul` function performs element by element multiplication of vector *a* and vector *b*.

Special values for Real Function v?Mul(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	-0	
-0	+0	-0	
-0	-0	+0	
+0	+∞	QNAN	INVALID
+0	-∞	QNAN	INVALID
-0	+∞	QNAN	INVALID
-0	-∞	QNAN	INVALID
+∞	+0	QNAN	INVALID
+∞	-0	QNAN	INVALID
-∞	+0	QNAN	INVALID
-∞	-0	QNAN	INVALID
+∞	+∞	+∞	
+∞	-∞	-∞	
-∞	+∞	-∞	
-∞	-∞	+∞	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

`Mul(x1+i*y1,x2+i*y2) = (x1*x2-y1*y2) + i*(x1*y2+y1*x2).`

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x1, x2, y1, y2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?MulByConj

Performs element by element multiplication of vector a element and conjugated vector b element.

Syntax

Fortran:

```
call vcmulbyconj( n, a, b, y )
call vmcmulbyconj( n, a, b, y, mode )
call vzmulbyconj( n, a, b, y )
call vmzmulbyconj( n, a, b, y, mode )
```

C:

```
vcMulByConj( n, a, b, y );
vmcMulByConj( n, a, b, y, mode );
vzMulByConj( n, a, b, y );
vmzMulByConj( n, a, b, y, mode );
```

Include Files

- FORTRAN 77: mkl_vml.f77
- Fortran 90: mkl_vml.f90
- C: mkl_vml_functions.h

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a, *b*	**FORTRAN 77:** COMPLEX for vcmulbyconj, vmcmulbyconj DOUBLE COMPLEX for vzmulbyconj, vmzmulbyconj **Fortran 90:** COMPLEX, INTENT(IN) for vcmulbyconj, vmcmulbyconj DOUBLE COMPLEX, INTENT(IN) for vzmulbyconj, vmzmulbyconj **C:** const MKL_Complex8* for vcMulByConj, vmcMulByConj	**FORTRAN:** Arrays that specify the input vectors *a* and *b*. **C:** Pointers to arrays that contain the input vectors *a* and *b*.

Name	Type	Description
	`const MKL_Complex16*` for `vzMulByConj`, `vmzMulByConj`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `COMPLEX` for `vcmulbyconj`, `vmcmulbyconj` `DOUBLE COMPLEX` for `vzmulbyconj`, `vmzmulbyconj` **Fortran 90:** `COMPLEX, INTENT(OUT)` for `vcmulbyconj`, `vmcmulbyconj` `DOUBLE COMPLEX, INTENT(OUT)` for `vzmulbyconj`, `vmzmulbyconj` **C:** `MKL_Complex8*` for `vcMulByConj`, `vmcMulByConj` `MKL_Complex16*` for `vzMulByConj`, `vmzMulByConj`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?MulByConj` function performs element by element multiplication of vector *a* element and conjugated vector *b* element.

Specifications for special values of the functions are found according to the formula

`MulByConj(x1+i*y1,x2+i*y2) = Mul(x1+i*y1,x2-i*y2).`

Overflow in a complex function occurs (supported in the `HA`/`LA` accuracy modes only) when `x1`, `x2`, `y1`, `y2` are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VML Error Status to `VML_STATUS_OVERFLOW`.

v?Conj

Performs element by element conjugation of the vector.

Syntax

Fortran:

```
call vcconj( n, a, y )
call vmcconj( n, a, y, mode )
call vzconj( n, a, y )
call vmzconj( n, a, y, mode )
```

C:

```
vcConj( n, a, y );
vmcConj( n, a, y, mode );
vzConj( n, a, y );
vmzConj( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `COMPLEX, INTENT(IN)` for `vcconj, vmcconj` `DOUBLE COMPLEX, INTENT(IN)` for `vzconj, vmzconj` **Fortran 90:** `COMPLEX, INTENT(IN)` for `vcconj, vmcconj` `DOUBLE COMPLEX, INTENT(IN)` for `vzconj, vmzconj` **C:** `const MKL_Complex8*` for `vcConj, vmcconj` `const MKL_Complex16*` for `vzConj, vmzconj`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `COMPLEX`, for `vcconj, vmcconj` `DOUBLE COMPLEX` for `vzconj, vmzconj` **Fortran 90:** `COMPLEX, INTENT(OUT)` for `vcconj, vmcconj`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`DOUBLE COMPLEX`, `INTENT(OUT)` for `vzconj`, `vmzconj` **C:** `MKL_Complex8*` for `vcConj`, `vmcconj` `MKL_Complex16*` for `vzConj`, `vmzconj`	

Description

The `v?Conj` function performs element by element conjugation of the vector.

No special values are specified. The function does not raise floating-point exceptions.

v?Abs

Computes absolute value of vector elements.

Syntax

Fortran:

```
call vsabs( n, a, y )
call vmsabs( n, a, y, mode )
call vdabs( n, a, y )
call vmdabs( n, a, y, mode )
call vcabs( n, a, y )
call vmcabs( n, a, y, mode )
call vzabs( n, a, y )
call vmzabs( n, a, y, mode )
```

C:

```
vsAbs( n, a, y );
vmsAbs( n, a, y, mode );
vdAbs( n, a, y );
vmdAbs( n, a, y, mode );
vcAbs( n, a, y );
vmcAbs( n, a, y, mode );
vzAbs( n, a, y );
vmzAbs( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** REAL for vsabs, vmsabs DOUBLE PRECISION for vdabs, vmdabs COMPLEX for vcabs, vmcabs DOUBLE COMPLEX for vzabs, vmzabs **Fortran 90:** REAL, INTENT(IN) for vsabs, vmsabs DOUBLE PRECISION, INTENT(IN) for vdabs, vmdabs COMPLEX, INTENT(IN) for vcabs, vmcabs DOUBLE COMPLEX, INTENT(IN) for vzabs, vmzabs **C:** const float* for vsabs, vmsabs const double* for vdabs, vmdabs const MKL_Complex8* for vcAbs, vmcAbs const MKL_Complex16* for vzAbs, vmzAbs	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsabs, vmsabs, vcabs, vmcabs DOUBLE PRECISION for vdabs, vmdabs, vzabs, vmzabs **Fortran 90:** REAL, INTENT(OUT) for vsabs, vmsabs, vcabs, vmcabs DOUBLE PRECISION, INTENT(OUT) for vdabs, vmdabs, vzabs, vmzabs	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	C: `float*` for `vsabs`, `vmsabs`, `vcAbs`, `vmcAbs` `double*` for `vdabs`, `vmdabs`, `vzAbs`, `vmzAbs`	

Description

The `v?Abs` function computes an absolute value of vector elements.

Special Values for Real Function v?Abs(x)

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Abs(z) = Hypot(RE(z),IM(z)).`

v?Arg

Computes argument of vector elements.

Syntax

Fortran:

```
call vcarg( n, a, y )
call vmcarg( n, a, y, mode )
call vzarg( n, a, y )
call vmzarg( n, a, y, mode )
```

C:

```
vcArg( n, a, y );
vmcArg( n, a, y, mode );
vzArg( n, a, y );
vmzArg( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a	**FORTRAN77:** COMPLEX for vcarg, vmcarg DOUBLE COMPLEX for vzarg, vmzarg **Fortran 90:** COMPLEX, INTENT(IN) for vcarg, vmcarg DOUBLE COMPLEX, INTENT(IN) for vzarg, vmzarg **C:** const MKL_Complex8* for vcArg, vmcArg const MKL_Complex16* for vzArg, vmcArg	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vcarg, vmcarg DOUBLE PRECISION for vzarg, vmzarg **Fortran 90:** REAL, INTENT(OUT) for vcarg, vmcarg DOUBLE PRECISION, INTENT(OUT) for vzarg, vmzarg **C:** float* for vcArg, vmcArg double* for vzArg, vmcArg	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?Arg function computes argument of vector elements.

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Arg(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+3·π/4	+π/2	+π/2	+π/2	+π/2	+π/4	NAN
+i·Y	+π		+π/2	+π/2		+0	NAN
+i·0	+π	+π	+π	+0	+0	+0	NAN
-i·0	-π	-π	-π	-0	-0	-0	NAN
-i·Y	-π		-π/2	-π/2		-0	NAN
-i·∞	-3·π/4	-π/2	-π/2	-π/2	-π/2	-π/4	NAN
+i·NAN	NAN	NAN	NAN	NAN	NAN	NAN	NAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Arg(z)=Atan2(IM(z),RE(z))`.

v?LinearFrac

Performs linear fraction transformation of vectors `a` and `b` with scalar parameters.

Syntax

Fortran:

```
call vslinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
call vmslinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode )
call vdlinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
call vmdlinearfrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode )
```

C:

```
vsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y );
vmsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
vdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
vmdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.

Name	Type	Description
a, *b*	**FORTRAN 77:** REAL for vslinearfrac DOUBLE PRECISION for vdlinearfrac **Fortran 90:** REAL, INTENT(IN) for vslinearfrac DOUBLE PRECISION, INTENT(IN) for vdlinearfrac **C:** const float* for vsLinearFrac const double* for vdLinearFrac	**FORTRAN:** Arrays that specify the input vectors *a* and *b*. **C:** Pointers to arrays that contain the input vectors *a* and *b*.
scalea, *scaleb*	**FORTRAN 77:** REAL for vslinearfrac DOUBLE PRECISION for vdlinearfrac **Fortran 90:** REAL, INTENT(IN) for vslinearfrac DOUBLE PRECISION, INTENT(IN) for vdlinearfrac **C:** const float* for vsLinearFrac const double* for vdLinearFrac	Constant values for shifting addends of vectors *a* and *b*.
shifta, *shiftb*	**FORTRAN 77:** REAL for vslinearfrac DOUBLE PRECISION for vdlinearfrac **Fortran 90:** REAL, INTENT(IN) for vslinearfrac DOUBLE PRECISION, INTENT(IN) for vdlinearfrac **C:** const float* for vsLinearFrac const double* for vdLinearFrac	Constant values for scaling multipliers of vectors *a* and *b*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vslinearfrac DOUBLE PRECISION for vdlinearfrac **Fortran 90:** REAL, INTENT(OUT) for vslinearfrac	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	DOUBLE PRECISION, INTENT(OUT) for vdlinearfrac **C:** float* for vsLinearFrac double* for vdLinearFrac	

Description

The v?LinearFrac function performs linear fraction transformation of vectors *a* by vector *b* with scalar parameters: scaling multipliers *scalea*, *scaleb* and shifting addends *shifta*, *shiftb*:

$y[i]=(scalea \cdot a[i]+shifta)/(scaleb \cdot b[i]+shiftb)$, $i=1,2 \ldots n$

The v?LinearFrac function is implemented in the EP accuracy mode only, therefore no special values are defined for this function. Correctness is guaranteed within the threshold limitations defined for each input parameter (see the table below); otherwise, the behavior is unspecified.

Threshold Limitations on Input Parameters
$2^{E_{MIN}/2} \le \lvert scalea \rvert \le 2^{(E_{MAX}-2)/2}$
$2^{E_{MIN}/2} \le \lvert scaleb \rvert \le 2^{(E_{MAX}-2)/2}$
$\lvert shifta \rvert \le 2^{E_{MAX}-2}$
$\lvert shiftb \rvert \le 2^{E_{MAX}-2}$
$2^{E_{MIN}/2} \le a[i] \le 2^{(E_{MAX}-2)/2}$
$2^{E_{MIN}/2} \le b[i] \le 2^{(E_{MAX}-2)/2}$
$a[i] \ne -(shifta/scalea)*(1-\delta_1), \lvert\delta_1\rvert \le 2^{1-(p-1)/2}$
$b[i] \ne -(shiftb/scaleb)*(1-\delta_2), \lvert\delta_2\rvert \le 2^{1-(p-1)/2}$

E_{MIN} and E_{MAX} are the maximum and minimum exponents and p is the number of significant bits (precision) for corresponding data type according to the ANSI/IEEE Std 754-2008 standard ([IEEE754]):

- for single precision E_{MIN} = -126, E_{MAX} = 127, p = 24
- for double precision E_{MIN} = -1022, E_{MAX} = 1023, p = 53

The thresholds become less strict for common cases with *scalea*=0 and/or *scaleb*=0:

- if *scalea*=0, there are no limitations for the values of *a*[i] and *shifta*
- if *scaleb*=0, there are no limitations for the values of *b*[i] and *shiftb*

Power and Root Functions

v?Inv

Performs element by element inversion of the vector.

Syntax

Fortran:

```
call vsinv( n, a, y )
call vmsinv( n, a, y, mode )
call vdinv( n, a, y )
```

```
call vmdinv( n, a, y, mode )
```

C:

```
vsInv( n, a, y );
vmsInv( n, a, y, mode );
vdInv( n, a, y );
vmdInv( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsinv, vmsinv` `DOUBLE PRECISION` for `vdinv, vmdinv` **Fortran 90:** `REAL, INTENT(IN)` for `vsinv, vmsinv` `DOUBLE PRECISION, INTENT(IN)` for `vdinv, vmdinv` **C:** `const float*` for `vsInv, vmsInv` `const double*` for `vdInv, vmdInv`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsinv, vmsinv` `DOUBLE PRECISION` for `vdinv, vmdinv`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	Fortran 90: `REAL, INTENT(OUT)` for `vsinv, vmsinv` `DOUBLE PRECISION, INTENT(OUT)` for `vdinv, vmdinv` **C:** `float*` for `vsInv, vmsInv` `double*` for `vdInv, vmdInv`	

Description

The `v?Inv` function performs element by element inversion of the vector.

Special Values for Real Function v?Inv(x)

Argument	Result	VML Error Status	Exception
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
+∞	+0		
-∞	-0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Div

Performs element by element division of vector `a` by vector `b`

Syntax

Fortran:

```
call vsdiv( n, a, b, y )
call vmsdiv( n, a, b, y, mode )
call vddiv( n, a, b, y )
call vmddiv( n, a, b, y, mode )
call vcdiv( n, a, b, y )
call vmcdiv( n, a, b, y, mode )
call vzdiv( n, a, b, y )
call vmzdiv( n, a, b, y, mode )
```

C:

```
vsDiv( n, a, b, y );
vmsDiv( n, a, b, y, mode );
vdDiv( n, a, b, y );
vmdDiv( n, a, b, y, mode );
vcDiv( n, a, b, y );
vmcDiv( n, a, b, y, mode );
vzDiv( n, a, b, y );
```

```
vmzDiv( n, a, b, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a, *b*	**FORTRAN 77:** `REAL` for `vsdiv`, `vmsdiv` `DOUBLE PRECISION` for `vddiv`, `vmddiv` `COMPLEX` for `vcdiv`, `vmcdiv` `DOUBLE COMPLEX` for `vzdiv`, `vmzdiv` **Fortran 90:** `REAL, INTENT(IN)` for `vsdiv`, `vmsdiv` `DOUBLE PRECISION, INTENT(IN)` for `vddiv`, `vmddiv` `COMPLEX, INTENT(IN)` for `vcdiv`, `vmcdiv` `DOUBLE COMPLEX, INTENT(IN)` for `vzdiv`, `vmzdiv` **C:** `const float*` for `vsDiv`, `vmsDiv` `const double*` for `vdDiv`, `vmdDiv` `const MKL_Complex8*` for `vcDiv`, `vmcDiv` `const MKL_Complex16*` for `vzDiv`, `vmzDiv`	**FORTRAN:** Arrays that specify the input vectors *a* and *b*. **C:** Pointers to arrays that contain the input vectors *a* and *b*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Precision Overflow Thresholds for Real v?Div Function

Data Type	Threshold Limitations on Input Parameters
single precision	`abs(a[i]) < abs(b[i]) * FLT_MAX`
double precision	`abs(a[i]) < abs(b[i]) * DBL_MAX`

Precision overflow thresholds for the complex `v?Div` function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsdiv, vmsdiv DOUBLE PRECISION for vddiv, vmddiv COMPLEX for vcdiv, vmcdiv DOUBLE COMPLEX for vzdiv, vmzdiv **Fortran 90:** REAL, INTENT(OUT) for vsdiv, vmsdiv DOUBLE PRECISION, INTENT(OUT) for vddiv, vmddiv COMPLEX, INTENT(OUT) for vcdiv, vmcdiv DOUBLE COMPLEX, INTENT(OUT) for vzdiv, vmzdiv **C:** float* for vsDiv, vmsDiv double* for vdDiv, vmdDiv MKL_Complex8* for vcDiv, vmcDiv MKL_Complex16* for vzDiv, vmzDiv	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?Div function performs element by element division of vector *a* by vector *b*.

Special values for Real Function v?Div(x)

Argument 1	Argument 2	Result	VML Error Status	Exception
X > +0	+0	+∞	VML_STATUS_SING	ZERODIVIDE
X > +0	-0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	+0	-∞	VML_STATUS_SING	ZERODIVIDE
X < +0	-0	+∞	VML_STATUS_SING	ZERODIVIDE
+0	+0	QNAN	VML_STATUS_SING	
-0	-0	QNAN	VML_STATUS_SING	
X > +0	+∞	+0		
X > +0	-∞	-0		
+∞	+∞	QNAN		
-∞	-∞	QNAN		
QNAN	QNAN	QNAN		
SNAN	SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

Div(x1+i*y1,x2+i*y2) = (x1+i*y1)*(x2-i*y2)/(x2*x2+y2*y2).

Overflow in a complex function occurs when x2+i*y2 is not zero, x1, x2, y1, y2 are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In that case, the function returns ∞ in that part of the result, raises the OVERFLOW exception, and sets the VML Error Status to VML_STATUS_OVERFLOW.

v?Sqrt

Computes a square root of vector elements.

Syntax

Fortran:

```
call vssqrt( n, a, y )
call vmssqrt( n, a, y, mode )
call vdsqrt( n, a, y )
call vmdsqrt( n, a, y, mode )
call vcsqrt( n, a, y )
call vmcsqrt( n, a, y, mode )
call vzsqrt( n, a, y )
call vmzsqrt( n, a, y, mode )
```

C:

```
vsSqrt( n, a, y );
vmsSqrt( n, a, y, mode );
vdSqrt( n, a, y );
vmdSqrt( n, a, y, mode );
vcSqrt( n, a, y );
vmcSqrt( n, a, y, mode );
vzSqrt( n, a, y );
vmzSqrt( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vssqrt`, `vmssqrt` `DOUBLE PRECISION` for `vdsqrt`, `vmdsqrt` `COMPLEX` for `vcsqrt`, `vmcsqrt`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	`DOUBLE COMPLEX` for `vzsqrt`, `vmzsqrt` **Fortran 90:** `REAL, INTENT(IN)` for `vssqrt`, `vmssqrt` `DOUBLE PRECISION, INTENT(IN)` for `vdsqrt`, `vmdsqrt` `COMPLEX, INTENT(IN)` for `vcsqrt`, `vmcsqrt` `DOUBLE COMPLEX, INTENT(IN)` for `vzsqrt`, `vmzsqrt` **C:** `const float*` for `vsSqrt`, `vmsSqrt` `const double*` for `vdSqrt`, `vmdSqrt` `const MKL_Complex8*` for `vcSqrt`, `vmcSqrt` `const MKL_Complex16*` for `vzSqrt`, `vmzSqrt`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN:** `REAL` for `vssqrt`, `vmssqrt` `DOUBLE PRECISION` for `vdsqrt`, `vmdsqrt` `COMPLEX` for `vcsqrt`, `vmcsqrt` `DOUBLE COMPLEX` for `vzsqrt`, `vmzsqrt` **Fortran 90:** `REAL, INTENT(OUT)` for `vssqrt`, `vmssqrt` `DOUBLE PRECISION, INTENT(OUT)` for `vdsqrt`, `vmdsqrt` `COMPLEX, INTENT(OUT)` for `vcsqrt`, `vmcsqrt` `DOUBLE COMPLEX, INTENT(OUT)` for `vzsqrt`, `vmzsqrt` **C:** `float*` for `vsSqrt`, `vmsSqrt` `double*` for `vdSqrt`, `vmdSqrt`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`MKL_Complex8*` for `vcSqrt`, `vmcSqrt` `MKL_Complex16*` for `vzSqrt`, `vmzSqrt`	

Description

The `v?Sqrt` function computes a square root of vector elements.

Special Values for Real Function v?Sqrt(x)

Argument	Result	VML Error Status	Exception
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Sqrt(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞	+∞+i·∞
+i·Y	+0+i·∞					+∞+i·0	QNAN+i·QNAN
+i·0	+0+i·∞		+0+i·0	+0+i·0		+∞+i·0	QNAN+i·QNAN
-i·0	+0-i·∞		+0-i·0	+0-i·0		+∞-i·0	QNAN+i·QNAN
-i·Y	+0-i·∞					+∞-i·0	QNAN+i·QNAN
-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞	+∞-i·∞
+i·NAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- `Sqrt(CONJ(z))=CONJ(Sqrt(z))`.

v?InvSqrt

Computes an inverse square root of vector elements.

Syntax

Fortran:

```
call vsinvsqrt( n, a, y )
call vmsinvsqrt( n, a, y, mode )
call vdinvsqrt( n, a, y )
call vmdinvsqrt( n, a, y, mode )
```

C:

```
vsInvSqrt( n, a, y );
vmsInvSqrt( n, a, y, mode );
vdInvSqrt( n, a, y );
vmdInvSqrt( n, a, y, mode );
```

Include Files

- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsinvsqrt, vmsinvsqrt` `DOUBLE PRECISION` for `vdinvsqrt, vmdinvsqrt` **Fortran 90:** `REAL, INTENT(IN)` for `vsinvsqrt, vmsinvsqrt` `DOUBLE PRECISION, INTENT(IN)` for `vdinvsqrt, vmdinvsqrt` **C:** `const float*` for `vsInvSqrt, vmsInvSqrt` `const double*` for `vdInvSqrt, vmdInvSqrt`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsinvsqrt, vmsinvsqrt` `DOUBLE PRECISION` for `vdinvsqrt, vmdinvsqrt` **Fortran 90:** `REAL, INTENT(OUT)` for `vsinvsqrt, vmsinvsqrt`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	DOUBLE PRECISION, INTENT(OUT) for vdinvsqrt, vmdinvsqrt **C:** float* for vsInvSqrt, vmsInvSqrt double* for vdInvSqrt, vmdInvSqrt	

Description

The v?InvSqrt function computes an inverse square root of vector elements.

Special Values for Real Function v?InvSqrt(x)

Argument	Result	VML Error Status	Exception
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Cbrt

Computes a cube root of vector elements.

Syntax

Fortran:

```
call vscbrt( n, a, y )
call vmscbrt( n, a, y, mode )
call vdcbrt( n, a, y )
call vmdcbrt( n, a, y, mode )
```

C:

```
vsCbrt( n, a, y );
vmsCbrt( n, a, y, mode );
vdCbrt( n, a, y );
vmdCbrt( n, a, y, mode );
```

Include Files

- FORTRAN 77: mkl_vml.f77
- Fortran 90: mkl_vml.f90
- C: mkl_vml_functions.h

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** REAL for vscbrt, vmscbrt DOUBLE PRECISION for vdcbrt, vmdcbrt **Fortran 90:** REAL, INTENT(IN) for vscbrt, vmscbrt DOUBLE PRECISION, INTENT(IN) for vdcbrt, vmdcbrt **C:** const float* for vsCbrt, vmsCbrt const double* for vdCbrt, vmdCbrt	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vscbrt, vmscbrt DOUBLE PRECISION for vdcbrt, vmdcbrt **Fortran 90:** REAL, INTENT(OUT) for vscbrt, vmscbrt DOUBLE PRECISION, INTENT(OUT) for vdcbrt, vmdcbrt **C:** float* for vsCbrt, vmsCbrt double* for vdCbrt, vmdCbrt	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?Cbrt function computes a cube root of vector elements.

Special Values for Real Function v?Cbrt(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	

Argument	Result	Exception
-∞	-∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

v?InvCbrt

Computes an inverse cube root of vector elements.

Syntax

Fortran:

```
call vsinvcbrt( n, a, y )
call vmsinvcbrt( n, a, y, mode )
call vdinvcbrt( n, a, y )
call vmdinvcbrt( n, a, y, mode )
```

C:

```
vsInvCbrt( n, a, y );
vmsInvCbrt( n, a, y, mode );
vdInvCbrt( n, a, y );
vmdInvCbrt( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsinvcbrt`, `vmsinvcbrt` `DOUBLE PRECISION` for `vdinvcbrt`, `vmdinvcbrt` **Fortran 90:** `REAL, INTENT(IN)` for `vsinvcbrt`, `vmsinvcbrt` `DOUBLE PRECISION, INTENT(IN)` for `vdinvcbrt`, `vmdinvcbrt` **C:** `const float*` for `vsInvCbrt`, `vmsInvCbrt`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	`const double*` for `vdInvCbrt`, `vmdInvCbrt`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsinvcbrt`, `vmsinvcbrt` `DOUBLE PRECISION` for `vdinvcbrt`, `vmdinvcbrt` **Fortran 90:** `REAL, INTENT(OUT)` for `vsinvcbrt, vmsinvcbrt` `DOUBLE PRECISION, INTENT(OUT)` for `vdinvcbrt, vmdinvcbrt` **C:** `float*` for `vsInvCbrt`, `vmsInvCbrt` `double*` for `vdInvCbrt, vmdInvCbrt`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?InvCbrt` function computes an inverse cube root of vector elements.

Special Values for Real Function v?InvCbrt(x)

Argument	Result	VML Error Status	Exception
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
+∞	+0		
-∞	-0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Pow2o3

Raises each element of a vector to the constant power 2/3.

Syntax

Fortran:

```
call vspow2o3( n, a, y )
call vmspow2o3( n, a, y, mode )
call vdpow2o3( n, a, y )
call vmdpow2o3( n, a, y, mode )
```

C:

```
vsPow2o3( n, a, y );
vmsPow2o3( n, a, y, mode );
vdPow2o3( n, a, y );
vmdPow2o3( n, a, y, mode );
```

Include Files

- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vspow2o3, vmspow2o3` `DOUBLE PRECISION` for `vdpow2o3, vmdpow2o3` **Fortran 90:** `REAL, INTENT(IN)` for `vspow2o3, vmspow2o3` `DOUBLE PRECISION, INTENT(IN)` for `vdpow2o3, vmdpow2o3` **C:** `const float*` for `vsPow2o3, vmsPow2o3` `const double*` for `vdPow2o3, vmdPow2o3`	**FORTRAN:** Arrays, specify the input vector *a*. **C:** Pointers to arrays that contain the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vspow2o3, vmspow2o3` `DOUBLE PRECISION` for `vdpow2o3, vmdpow2o3` **Fortran 90:** `REAL, INTENT(OUT)` for `vspow2o3, vmspow2o3`	**FORTRAN:** Array, specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`DOUBLE PRECISION, INTENT(OUT)` for `vdpow2o3, vmdpow2o3` **C:** `float*` for `vsPow2o3, vmsPow2o3` `double*` for `vdPow2o3, vmdPow2o3`	

Description

The `v?Pow2o3` function raises each element of a vector to the constant power 2/3.

Special Values for Real Function v?Pow2o3(x)

Argument	Result	Exception
+0	+0	
-0	+0	
+∞	+∞	
-∞	+∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

v?Pow3o2

Raises each element of a vector to the constant power 3/2.

Syntax

Fortran:

```
call vspow3o2( n, a, y )
call vmspow3o2( n, a, y, mode )
call vdpow3o2( n, a, y )
call vmdpow3o2( n, a, y, mode )
```

C:

```
vsPow3o2( n, a, y );
vmsPow3o2( n, a, y, mode );
vdPow3o2( n, a, y );
vmdPow3o2( n, a, y, mode );
```

Include Files

+0	+0		
-0	-0		
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Pow

Computes `a` *to the power* `b` *for elements of two vectors.*

Syntax

Fortran:

```
call vspow( n, a, b, y )
call vmspow( n, a, b, y, mode )
call vdpow( n, a, b, y )
call vmdpow( n, a, b, y, mode )
call vcpow( n, a, b, y )
call vmcpow( n, a, b, y, mode )
call vzpow( n, a, b, y )
call vmzpow( n, a, b, y, mode )
```

C:

```
vsPow( n, a, b, y );
vmsPow( n, a, b, y, mode );
vdPow( n, a, b, y );
vmdPow( n, a, b, y, mode );
vcPow( n, a, b, y );
vmcPow( n, a, b, y, mode );
vzPow( n, a, b, y );
vmzPow( n, a, b, y, mode );
```

Include Files

- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)`	Specifies the number of elements to be calculated.

Name	Type	Description
	C: `const int`	
a, *b*	**FORTRAN 77:** `REAL` for `vspow`, `vmspow` `DOUBLE PRECISION` for `vdpow`, `vmdpow` `COMPLEX` for `vcpow`, `vmcpow` `DOUBLE COMPLEX` for `vzpow`, `vmzpow` **Fortran 90:** `REAL, INTENT(IN)` for `vspow`, `vmspow` `DOUBLE PRECISION, INTENT(IN)` for `vdpow`, `vmdpow` `COMPLEX, INTENT(IN)` for `vcpow`, `vmcpow` `DOUBLE COMPLEX, INTENT(IN)` for `vzpow`, `vmzpow` **C:** `const float*` for `vsPow`, `vmsPow` `const double*` for `vdPow`, `vmdPow` `const MKL_Complex8*` for `vcPow`, `vmcPow` `const MKL_Complex16*` for `vzPow`, `vmzPow`	**FORTRAN:** Arrays that specify the input vectors *a* and *b*. **C:** Pointers to arrays that contain the input vectors *a* and *b*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Precision Overflow Thresholds for Real v?Pow Function

Data Type	Threshold Limitations on Input Parameters
single precision	$abs(a[i]) < (FLT\_MAX)^{1/b[i]}$
double precision	$abs(a[i]) < (DBL\_MAX)^{1/b[i]}$

Precision overflow thresholds for the complex `v?Pow` function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vspow`, `vmspow` `DOUBLE PRECISION` for `vdpow`, `vmdpow` `COMPLEX` for `vcpow`, `vmcpow` `DOUBLE COMPLEX` for `vzpow`, `vmzpow`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	Fortran 90: `REAL, INTENT(OUT)` for `vspow, vmspow` `DOUBLE PRECISION, INTENT(OUT)` for `vdpow, vmdpow` `COMPLEX, INTENT(OUT)` for `vcpow, vmcpow` `DOUBLE COMPLEX, INTENT(OUT)` for `vzpow, vmzpow` **C:** `float*` for `vsPow, vmsPow` `double*` for `vdPow, vmdPow` `MKL_Complex8*` for `vcPow, vmcPow` `MKL_Complex16*` for `vzPow, vmzPow`	

Description

The `v?Pow` function computes *a* to the power *b* for elements of two vectors.

The real function `v(s/d)Pow` has certain limitations on the input range of *a* and *b* parameters. Specifically, if *a[i]* is positive, then *b[i]* may be arbitrary. For negative *a[i]*, the value of *b[i]* must be an integer (either positive or negative).

The complex function `v(c/z)Pow` has no input range limitations.

Special values for Real Function v?Pow(x)

SNAN	SNAN	QNAN		INVALID

Overflow in a complex function occurs (supported in the `HA`/`LA` accuracy modes only) when `x1`, `x2`, `y1`, `y2` are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VML Error Status to `VML_STATUS_OVERFLOW`.

v?Powx

Raises each element of a vector to the constant power.

Syntax

Fortran:

```
call vspowx( n, a, b, y )
```

```
call vmspowx( n, a, b, y, mode )
call vdpowx( n, a, b, y )
call vmdpowx( n, a, b, y, mode )
call vcpowx( n, a, b, y )
call vmcpowx( n, a, b, y, mode )
call vzpowx( n, a, b, y )
call vmzpowx( n, a, b, y, mode )
```

C:

```
vsPowx( n, a, b, y );
vmsPowx( n, a, b, y, mode );
vdPowx( n, a, b, y );
vmdPowx( n, a, b, y, mode );
vcPowx( n, a, b, y );
vmcPowx( n, a, b, y, mode );
vzPowx( n, a, b, y );
vmzPowx( n, a, b, y, mode );
```

Include Files

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vspowx`, `vmspowx` `DOUBLE PRECISION` for `vdpowx`, `vmdpowx` `COMPLEX` for `vcpowx`, `vmcpowx` `DOUBLE COMPLEX` for `vzpowx`, `vmzpowx` **Fortran 90:** `REAL, INTENT(IN)` for `vspowx`, `vmspowx` `DOUBLE PRECISION, INTENT(IN)` for `vdpowx`, `vmdpowx` `COMPLEX, INTENT(IN)` for `vcpowx`, `vmcpowx`	**FORTRAN:** Array *a* that specifies the input vector **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	DOUBLE COMPLEX, INTENT(IN) for vzpowx, vmzpowx **C:** const float* for vsPowx, vmsPowx const double* for vdPowx, vmdPowx const MKL_Complex8* for vcPowx, vmcPowx const MKL_Complex16* for vzPowx, vmzPowx	
b	**FORTRAN 77:** REAL for vspowx, vmspowx DOUBLE PRECISION for vdpowx, vmdpowx COMPLEX for vcpowx, vmcpowx DOUBLE COMPLEX for vzpowx, vmzpowx **Fortran 90:** REAL, INTENT(IN) for vspowx, vmspowx DOUBLE PRECISION, INTENT(IN) for vdpowx, vmdpowx COMPLEX, INTENT(IN) for vcpowx, vmcpowx DOUBLE COMPLEX, INTENT(IN) for vzpowx, vmzpowx **C:** const float* for vsPowx, vmsPowx const double* for vdPowx, vmdPowx const MKL_Complex8* for vcPowx, vmcPowx const MKL_Complex16* for vzPowx, vmzPowx	**FORTRAN:** Scalar value *b* that is the constant power. **C:** Constant value for power *b*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Powx Function

Data Type	Threshold Limitations on Input Parameters
single precision	abs(*a*[i]) < (FLT_MAX)$^{1/b}$
double precision	abs(*a*[i]) < (DBL_MAX)$^{1/b}$

Precision overflow thresholds for the complex v?Powx function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vspowx, vmspowx DOUBLE PRECISION for vdpowx, vmdpowx COMPLEX for vcpowx, vmcpowx DOUBLE COMPLEX for vzpowx, vmzpowx **Fortran 90:** REAL, INTENT(OUT) for vspowx, vmspowx DOUBLE PRECISION, INTENT(OUT) for vdpowx, vmdpowx COMPLEX, INTENT(OUT) for vcpowx, vmcpowx DOUBLE COMPLEX, INTENT(OUT) for vzpowx, vmzpowx **C:** float* for vsPowx, vmsPowx double* for vdPowx, vmdPowx MKL_Complex8* for vcPowx, vmcPowx MKL_Complex16* for vzPowx, vmzPowx	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?Powx function raises each element of a vector to the constant power.

The real function v(s/d)Powx has certain limitations on the input range of *a* and *b* parameters. Specifically, if *a[i]* is positive, then *b* may be arbitrary. For negative *a[i]*, the value of *b* must be an integer (either positive or negative).

The complex function v(c/z)Powx has no input range limitations.

Special values are the same as for the v?Pow function.

v?Hypot

Computes a square root of sum of two squared elements.

Syntax

Fortran:

```
call vshypot( n, a, b, y )
call vmshypot( n, a, b, y, mode )
call vdhypot( n, a, b, y )
call vmdhypot( n, a, b, y, mode )
```

C:

```
vsHypot( n, a, b, y );
vmsHypot( n, a, b, y, mode );
vdHypot( n, a, b, y );
vmdHypot( n, a, b, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Number of elements to be calculated.
a, *b*	**FORTRAN 77:** `REAL` for `vshypot`, `vmshypot` `DOUBLE PRECISION` for `vdhypot`, `vmdhypot` **Fortran 90:** `REAL, INTENT(IN)` for `vshypot, vmshypot` `DOUBLE PRECISION, INTENT(IN)` for `vdhypot, vmdhypot` **C:** `const float*` for `vsHypot`, `vmsHypot` `const double*` for `vdHypot`, `vmdHypot`	**FORTRAN:** Arrays that specify the input vectors *a* and *b* **C:** Pointers to arrays that contain the input vectors *a* and *b*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Precision Overflow Thresholds for Hypot Function

Data Type	Threshold Limitations on Input Parameters
single precision	`abs(a[i]) < sqrt(FLT_MAX)` `abs(b[i]) < sqrt(FLT_MAX)`
double precision	`abs(a[i]) < sqrt(DBL_MAX)` `abs(b[i]) < sqrt(DBL_MAX)`

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vshypot, vmshypot DOUBLE PRECISION for vdhypot, vmdhypot **Fortran 90:** REAL, INTENT(OUT) for vshypot, vmshypot DOUBLE PRECISION, INTENT(OUT) for vdhypot, vmdhypot **C:** float* for vsHypot, vmsHypot double* for vdHypot, vmdHypot	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The function v?Hypot computes a square root of sum of two squared elements.

Special values for Real Function v?Hypot(x)

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
-0	-0	+0	
+∞	any value	+∞	
any value	+∞	+∞

any value	SNAN	QNAN	INVALID
QNAN	any value	QNAN	
any value	QNAN	QNAN	

Exponential and Logarithmic Functions

v?Exp

Computes an exponential of vector elements.

Syntax

Fortran:

```
call vsexp( n, a, y )
call vmsexp( n, a, y, mode )
call vdexp( n, a, y )
call vmdexp( n, a, y, mode )
call vcexp( n, a, y )
call vmcexp( n, a, y, mode )
call vzexp( n, a, y )
call vmzexp( n, a, y, mode )
```

C:

```
vsExp( n, a, y );
vmsExp( n, a, y, mode );
vdExp( n, a, y );
vmdExp( n, a, y, mode );
vcExp( n, a, y );
vmcExp( n, a, y, mode );
vzExp( n, a, y );
vmzExp( n, a, y, mode );
```

Include Files

- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsexp, vmsexp` `DOUBLE PRECISION` for `vdexp, vmdexp` `COMPLEX` for `vcexp, vmcexp` `DOUBLE COMPLEX` for `vzexp, vmzexp` **Fortran 90:** `REAL, INTENT(IN)` for `vsexp, vmsexp` `DOUBLE PRECISION, INTENT(IN)` for `vdexp, vmdexp` `COMPLEX, INTENT(IN)` for `vcexp, vmcexp` `DOUBLE COMPLEX, INTENT(IN)` for `vzexp, vmzexp` **C:** `const float*` for `vsExp, vmsExp` `const double*` for `vdExp, vmdExp` `const MKL_Complex8*` for `vcExp, vmcExp` `const MKL_Complex16*` for `vzExp, vmzExp`	**FORTRAN:** Array, specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Precision Overflow Thresholds for Real v?Exp Function

Data Type	Threshold Limitations on Input Parameters
single precision	`a[i] < Ln( FLT_MAX )`
double precision	`a[i] < Ln( DBL_MAX )`

Precision overflow thresholds for the complex `v?Exp` function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsexp`, `vmsexp` `DOUBLE PRECISION` for `vdexp`, `vmdexp` `COMPLEX` for `vcexp`, `vmcexp` `DOUBLE COMPLEX` for `vzexp`, `vmzexp` **Fortran 90:** `REAL, INTENT(OUT)` for `vsexp`, `vmsexp` `DOUBLE PRECISION, INTENT(OUT)` for `vdexp`, `vmdexp` `COMPLEX, INTENT(OUT)` for `vcexp`, `vmcexp` `DOUBLE COMPLEX, INTENT(OUT)` for `vzexp`, `vmzexp` **C:** `float*` for `vsExp`, `vmsExp` `double*` for `vdExp`, `vmdExp` `MKL_Complex8*` for `vcExp`, `vmcExp` `MKL_Complex16*` for `vzExp`, `vmzExp`	**FORTRAN:** Array, specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Exp` function computes an exponential of vector elements.

Special Values for Real Function v?Exp(x)

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < underflow	+0	VML_STATUS_UNDERFLOW	UNDERFLOW
+∞	+∞		

Argument	Result	VML Error Status	Exception
-∞	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Exp(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+0+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID
+i·Y	+0·CIS(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	+0·CIS(0)		+1+i·0	+1+i·0		+∞+i·0	QNAN+i·0
-i·0	+0·CIS(0)		+1-i·0	+1-i·0		+∞-i·0	QNAN-i·0
-i·Y	+0·CIS(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	+0-i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·NAN	+0+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises the `INVALID` exception when real or imaginary part of the argument is `SNAN`
- raises the `INVALID` exception on argument `z=-∞+i·QNAN`
- raises the `OVERFLOW` exception and sets the VML Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when `RE(z)`, `IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.

v?Expm1

Computes an exponential of vector elements decreased by 1.

Syntax

Fortran:

```
call vsexpm1( n, a, y )
call vmsexpm1( n, a, y, mode )
call vdexpm1( n, a, y )
call vdexpm1( n, a, y, mode )
```

C:

```
vsExpm1( n, a, y );
vmsExpm1( n, a, y, mode );
vdExpm1( n, a, y );
vmdExpm1( n, a, y, mode );
```

Include Files

- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsexpm1`, `vmsexpm1` `DOUBLE PRECISION` for `vdexpm1`, `vmdexpm1` **Fortran 90:** `REAL, INTENT(IN)` for `vsexpm1`, `vmsexpm1` `DOUBLE PRECISION, INTENT(IN)` for `vdexpm1`, `vmdexpm1` **C:** `const float*` for `vsExpm1`, `vmsExpm1` `const double*` for `vdExpm1`, `vmdExpm1`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Precision Overflow Thresholds for Expm1 Function

Data Type	Threshold Limitations on Input Parameters
single precision	`a[i] < Ln( FLT_MAX )`
double precision	`a[i] < Ln( DBL_MAX )`

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsexpm1`, `vmsexpm1` `DOUBLE PRECISION` for `vdexpm1`, `vmdexpm1` **Fortran 90:** `REAL, INTENT(OUT)` for `vsexpm1`, `vmsexpm1` `DOUBLE PRECISION, INTENT(OUT)` for `vdexpm1`, `vmdexpm1`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	C: `float*` for `vsExpm1`, `vmsExpm1` `double*` for `vdExpm1`, `vmdExpm1`	

Description

The `v?Expm1` function computes an exponential of vector elements decreased by 1.

Special Values for Real Function v?Expm1(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	+0		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	-1		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Ln

Computes natural logarithm of vector elements.

Syntax

Fortran:

```
call vsln( n, a, y )
call vmsln( n, a, y, mode )
call vdln( n, a, y )
call vmdln( n, a, y, mode )
call vcln( n, a, y )
call vmcln( n, a, y, mode )
call vzln( n, a, y )
call vmzln( n, a, y, mode )
```

C:

```
vsLn( n, a, y );
vmsLn( n, a, y, mode );
vdLn( n, a, y );
vmdLn( n, a, y, mode );
vcLn( n, a, y );
vmcLn( n, a, y, mode );
vzLn( n, a, y );
vmzLn( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`

- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsln, vmsln` `DOUBLE PRECISION` for `vdln, vmdln` `COMPLEX` for `vcln, vmcln` `DOUBLE COMPLEX` for `vzln, vmzln` **Fortran 90:** `REAL, INTENT(IN)` for `vsln, vmsln` `DOUBLE PRECISION, INTENT(IN)` for `vdln, vmdln` `COMPLEX, INTENT(IN)` for `vcln, vmcln` `DOUBLE COMPLEX, INTENT(IN)` for `vzln, vmzln` **C:** `const float*` for `vsLn, vmsLn` `const double*` for `vdLn, vmdLn` `const MKL_Complex8*` for `vcLn, vmcLn` `const MKL_Complex16*` for `vzLn, vmzLn`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsln, vmsln` `DOUBLE PRECISION` for `vdln, vmdln` `COMPLEX` for `vcln, vmcln` `DOUBLE COMPLEX` for `vzln, vmzln` **Fortran 90:** `REAL, INTENT(OUT)` for `vsln, vmsln` `DOUBLE PRECISION, INTENT(OUT)` for `vdln, vmdln`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`COMPLEX`, `INTENT(OUT)` for `vcln`, `vmcln`	
	`DOUBLE COMPLEX`, `INTENT(OUT)` for `vzln`, `vmzln`	
	C: `float*` for `vsLn`, `vmsLn`	
	`double*` for `vdLn`, `vmdLn`	
	`MKL_Complex8*` for `vcLn`, `vmcLn`	
	`MKL_Complex16*` for `vzLn`, `vmzLn`	

Description

The `v?Ln` function computes natural logarithm of vector elements.

Special Values for Real Function v?Ln(x)

Argument	Result	VML Error Status	Exception
+1	+0		
X < +0	QNAN	VML_STATUS_ERRDOM	INVALID
+0	-∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Ln(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN

v?Log10

Computes denary logarithm of vector elements.

Syntax

Fortran:

```
call vslog10( n, a, y )
call vmslog10( n, a, y, mode )
call vdlog10( n, a, y )
call vmdlog10( n, a, y, mode )
call vclog10( n, a, y )
call vmclog10( n, a, y, mode )
call vzlog10( n, a, y )
call vmzlog10( n, a, y, mode )
```

C:

```
vsLog10( n, a, y );
vmsLog10( n, a, y, mode );
vdLog10( n, a, y );
vmdLog10( n, a, y, mode );
vcLog10( n, a, y );
vmcLog10( n, a, y, mode );
vzLog10( n, a, y );
vmzLog10( n, a, y, mode );
```

Include Files

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`

v?Log1p

Computes a natural logarithm of vector elements that are increased by 1.

Syntax

Fortran:

```
call vslog1p( n, a, y )
call vmslog1p( n, a, y, mode )
call vdlog1p( n, a, y )
call vmdlog1p( n, a, y, mode )
```

C:

```
vsLog1p( n, a, y );
vmsLog1p( n, a, y, mode );
vdLog1p( n, a, y );
vmdLog1p( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vslog1p`, `vmslog1p` `DOUBLE PRECISION` for `vdlog1p`, `vmdlog1p` **Fortran 90:** `REAL, INTENT(IN)` for `vslog1p`, `vmslog1p` `DOUBLE PRECISION, INTENT(IN)` for `vdlog1p`, `vmdlog1p` **C:** `const float*` for `vsLog1p`, `vmsLog1p` `const double*` for `vdLog1p`, `vmdLog1p`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Name	Type	Description
	C: `const MKL_INT64`	

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vslog1p`, `vmslog1p` `DOUBLE PRECISION` for `vdlog1p`, `vmdlog1p` **Fortran 90:** `REAL, INTENT(OUT)` for `vslog1p, vmslog1p` `DOUBLE PRECISION, INTENT(OUT)` for `vdlog1p, vmdlog1p` **C:** `float*` for `vsLog1p, vmsLog1p` `double*` for `vdLog1p, vmdLog1p`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Log1p` function computes a natural logarithm of vector elements that are increased by 1.

Special Values for Real Function v?Log1p(x)

Argument	Result	VML Error Status	Exception
-1	-∞	VML_STATUS_SING	ZERODIVIDE
X < -1	QNAN	VML_STATUS_ERRDOM	INVALID

Trigonometric Functions

v?Cos

Computes cosine of vector elements.

Syntax

Fortran:

```
call vscos( n, a, y )
call vmscos( n, a, y, mode )
call vdcos( n, a, y )
call vmdcos( n, a, y, mode )
call vccos( n, a, y )
call vmccos( n, a, y, mode )
```

```
call vzcos( n, a, y )
call vmzcos( n, a, y, mode )
```

C:

```
vsCos( n, a, y );
vmsCos( n, a, y, mode );
vdCos( n, a, y );
vmdCos( n, a, y, mode );
vcCos( n, a, y );
vmcCos( n, a, y, mode );
vzCos( n, a, y );
vmzCos( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vscos, vmscos` `DOUBLE PRECISION` for `vdcos, vmdcos` `COMPLEX` for `vccos, vmccos` `DOUBLE PRECISION` for `vzcos, vmzcos` **Fortran 90:** `REAL, INTENT(IN)` for `vscos, vmscos` `DOUBLE PRECISION, INTENT(IN)` for `vdcos, vmdcos` `COMPLEX, INTENT(IN)` for `vccos, vmccos` `DOUBLE PRECISION, INTENT(IN)` for `vzcos, vmzcos` **C:** `const float*` for `vsCos, vmsCos` `const double*` for `vdCos, vmdCos` `const MKL_Complex8*` for `vcCos, vmcCos`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	`const MKL_Complex16*` for `vzCos`, `vmzCos`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vscos`, `vmscos` `DOUBLE PRECISION` for `vdcos`, `vmdcos` `COMPLEX` for `vccos`, `vmccos` `DOUBLE PRECISION` for `vzcos`, `vmzcos` **Fortran 90:** `REAL, INTENT(OUT)` for `vscos`, `vmscos` `DOUBLE PRECISION, INTENT(OUT)` for `vdcos`, `vmdcos` `COMPLEX, INTENT(OUT)` for `vccos`, `vmccos` `DOUBLE PRECISION, INTENT(OUT)` for `vzcos`, `vmzcos` **C:** `float*` for `vsCos`, `vmsCos` `double*` for `vdCos`, `vmdCos` `MKL_Complex8*` for `vcCos`, `vmcCos` `MKL_Complex16*` for `vzCos`, `vmzCos`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Cos` function computes cosine of vector elements.

Note that arguments `abs(a[i])` $\leq 2^{13}$ and `abs(a[i])` $\leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Cos(x)

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
+∞	QNAN	VML_STATUS_ERRDOM	INVALID

Argument	Result	VML Error Status	Exception
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Cos(z) = Cosh(i*z).`

v?Sin

Computes sine of vector elements.

Syntax

Fortran:

```
call vssin( n, a, y )
call vmssin( n, a, y, mode )
call vdsin( n, a, y )
call vmdsin( n, a, y, mode )
call vcsin( n, a, y )
call vmcsin( n, a, y, mode )
call vzsin( n, a, y )
call vmzsin( n, a, y, mode )
```

C:

```
vsSin( n, a, y );
vmsSin( n, a, y, mode );
vdSin( n, a, y );
vmdSin( n, a, y, mode );
vcSin( n, a, y );
vmcSin( n, a, y, mode );
vzSin( n, a, y );
vmzSin( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.

Name	Type	Description
a	**FORTRAN 77:** REAL for vssin, vmssin DOUBLE PRECISION for vdsin, vmdsin COMPLEX for vcsin, vmcsin DOUBLE PRECISION for vzsin, vmzsin **Fortran 90:** REAL, INTENT(IN) for vssin, vmssin DOUBLE PRECISION, INTENT(IN) for vdsin, vmdsin COMPLEX, INTENT(IN) for vcsin, vmcsin DOUBLE PRECISION, INTENT(IN) for vzsin, vmzsin **C:** const float* for vsSin, vmsSin const double* for vdSin, vmdSin const MKL_Complex8* for vcSin, vmcSin const MKL_Complex16* for vzSin, vmzSin	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vssin, vmssin DOUBLE PRECISION for vdsin, vmdsin COMPLEX for vcsin, vmcsin DOUBLE PRECISION for vzsin, vmzsin **Fortran 90:** REAL, INTENT(OUT) for vssin, vmssin DOUBLE PRECISION, INTENT(OUT) for vdsin, vmdsin	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`COMPLEX, INTENT(OUT)` for `vcsin, vmcsin` `DOUBLE PRECISION, INTENT(OUT)` for `vzsin, vmzsin` **C:** `float*` for `vsSin, vmsSin` `double*` for `vdSin, vmdSin` `MKL_Complex8*` for `vcSin, vmcSin` `MKL_Complex16*` for `vzSin, vmzSin`	

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.f90` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes sine of vector elements.

Note that arguments `abs(a[i])` $\leq 2^{13}$ and `abs(a[i])` $\leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Sin(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Sin(z) = –i*Sinh(i*z).`

v?SinCos

Computes sine and cosine of vector elements.

Syntax

Fortran:

```
call vssincos( n, a, y, z )
call vmssincos( n, a, y, z, mode )
call vdsincos( n, a, y, z )
call vmdsincos( n, a, y, z, mode )
```

C:

```
vsSinCos( n, a, y, z );
vmsSinCos( n, a, y, z, mode );
vdSinCos( n, a, y, z );
```

```
vmdSinCos( n, a, y, z, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vssincos, vmssincos` `DOUBLE PRECISION` for `vdsincos, vmdsincos` **Fortran 90:** `REAL, INTENT(IN)` for `vssincos, vmssincos` `DOUBLE PRECISION, INTENT(IN)` for `vdsincos, vmdsincos` **C:** `const float*` for `vsSinCos, vmsSinCos` `const double*` for `vdSinCos, vmdSinCos`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y, *z*	**FORTRAN 77:** `REAL` for `vssincos, vmssincos` `DOUBLE PRECISION` for `vdsincos, vmdsincos` **Fortran 90:** `REAL, INTENT(OUT)` for `vssincos, vmssincos` `DOUBLE PRECISION, INTENT(OUT)` for `vdsincos, vmdsincos` **C:** `float*` for `vsSinCos, vmsSinCos` `double*` for `vdSinCos, vmdSinCos`	**FORTRAN:** Arrays that specify the output vectors *y* (for sine values) and *z* (for cosine values). **C:** Pointers to arrays that contain the output vectors *y* (for sinevalues) and *z*(for cosine values).

Description

This function is declared in `mkl_vml.f77` for FORTRAN 77 interface, in `mkl_vml.f90` for Fortran 90 interface, and in `mkl_vml_functions.h` for C interface.

The function computes sine and cosine of vector elements.

Note that arguments `abs(a[i])` $\leq 2^{13}$ and `abs(a[i])` $\leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?SinCos(x)

Argument	Result 1	Result 2	VML Error Status	Exception
+0	+0	+1		
-0	-0	+1		
+∞	QNAN	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN	QNAN		
SNAN	QNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Sin(z) = -i*Sinh(i*z).`

v?CIS

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Syntax

Fortran:

```
call vccis( n, a, y )
call vmccis( n, a, y, mode )
call vzcis( n, a, y )
call vmzcis( n, a, y, mode )
```

C:

```
vcCIS( n, a, y );
vmcCIS( n, a, y, mode );
vzCIS( n, a, y );
vmzCIS( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** REAL for vccis, vmccis DOUBLE PRECISION for vzcis, vmzcis **Fortran 90:** REAL, INTENT(IN) for vccis, vmccis DOUBLE PRECISION, INTENT(IN) for vzcis, vmzcis **C:** const float* for vcCIS, vmcCIS const double* for vzCIS, vmzCIS	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** COMPLEX for vccis, vmccis DOUBLE COMPLEX for vzcis, vmzcis **Fortran 90:** COMPLEX, INTENT(OUT) for vccis, vmccis DOUBLE COMPLEX, INTENT(OUT) for vzcis, vmzcis **C:** MKL_Complex8* for vcCIS, vmcCIS MKL_Complex16* for vzCIS, vmzCIS	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?CIS function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?CIS(x)

x	CIS(x)
+ ∞	QNAN+i·QNAN

x	CIS(x)
	INVALID
+ 0	+1+i·0
- 0	+1-i·0
- ∞	QNAN+i·QNAN INVALID
NAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when the argument is `SNAN`
- raises `INVALID` exception and sets the VML Error Status to `VML_STATUS_ERRDOM` for `x=+∞`, `x=-∞`

v?Tan

Computes tangent of vector elements.

Syntax

Fortran:

```
call vstan( n, a, y )
call vmstan( n, a, y, mode )
call vdtan( n, a, y )
call vmdtan( n, a, y, mode )
call vctan( n, a, y )
call vmctan( n, a, y, mode )
call vztan( n, a, y )
call vmztan( n, a, y, mode )
```

C:

```
vsTan( n, a, y );
vmsTan( n, a, y, mode );
vdTan( n, a, y );
vmdTan( n, a, y, mode );
vcTan( n, a, y );
vmcTan( n, a, y, mode );
vzTan( n, a, y );
vmzTan( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** REAL for vstan, vmstan DOUBLE PRECISION for vdtan, vmdtan COMPLEX for vctan, vmctan DOUBLE COMPLEX for vztan, vmztan **Fortran 90:** REAL, INTENT(IN) for vstan, vmstan DOUBLE PRECISION, INTENT(IN) for vdtan, vmdtan COMPLEX, INTENT(IN) for vctan, vmctan DOUBLE COMPLEX, INTENT(IN) for vztan, vmztan **C:** const float* for vsTan, vmsTan const double* for vdTan, vmdTan const MKL_Complex8* for vcTan, vmcTan const MKL_Complex16* for vzTan, vmzTan	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vstan, vmstan DOUBLE PRECISION for vdtan, vmdtan COMPLEX for vctan, vmctan DOUBLE COMPLEX for vztan, vmztan **Fortran 90:** REAL, INTENT(OUT) for vstan, vmstan	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`DOUBLE PRECISION, INTENT(OUT)` for `vdtan, vmdtan`	
	`COMPLEX, INTENT(OUT)` for `vctan, vmctan`	
	`DOUBLE COMPLEX, INTENT(OUT)` for `vztan, vmztan`	
	C: `float*` for `vsTan, vmsTan`	
	`double*` for `vdTan, vmdTan`	
	`MKL_Complex8*` for `vcTan, vmcTan`	
	`MKL_Complex16*` for `vzTan, vmzTan`	

Description

The `v?Tan` function computes tangent of vector elements.

Note that arguments `abs(a[i])` $\leq 2^{13}$ and `abs(a[i])` $\leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigigonometric function arguments for which VML provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VML High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VML Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function v?Tan(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

`Tan(z) = -i*Tanh(i*z).`

v?Acos

Computes inverse cosine of vector elements.

Syntax

Fortran:

```
call vsacos( n, a, y )
call vmsacos( n, a, y, mode )
call vdacos( n, a, y )
call vmdacos( n, a, y, mode )
call vcacos( n, a, y )
call vmcacos( n, a, y, mode )
call vzacos( n, a, y )
call vmzacos( n, a, y, mode )
```

C:

```
vsAcos( n, a, y );
vmsAcos( n, a, y, mode );
vdAcos( n, a, y );
vmdAcos( n, a, y, mode );
vcAcos( n, a, y );
vmcAcos( n, a, y, mode );
vzAcos( n, a, y );
vmzAcos( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsacos`, `vmsacos` `DOUBLE PRECISION` for `vdacos`, `vmdacos` `COMPLEX` for `vcacos`, `vmcacos` `DOUBLE COMPLEX` for `vzacos`, `vmzacos` **Fortran 90:** `REAL, INTENT(IN)` for `vsacos`, `vmsacos` `DOUBLE PRECISION, INTENT(IN)` for `vdacos`, `vmdacos` `COMPLEX, INTENT(IN)` for `vcacos`, `vmcacos` `DOUBLE COMPLEX, INTENT(IN)` for `vzacos`, `vmzacos` **C:** `const float*` for `vsAcos`, `vmsAcos` `const double*` for `vdAcos`, `vmdAcos` `const MKL_Complex8*` for `vcAcos`, `vmcAcos`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	`const MKL_Complex16*` for `vzAcos`, `vmzAcos`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsacos`, `vmsacos` `DOUBLE PRECISION` for `vdacos`, `vmdacos` `COMPLEX` for `vcacos`, `vmcacos` `DOUBLE COMPLEX` for `vzacos`, `vmzacos` **Fortran 90:** `REAL, INTENT(OUT)` for `vsacos`, `vmsacos` `DOUBLE PRECISION, INTENT(OUT)` for `vdacos`, `vmdacos` `COMPLEX, INTENT(OUT)` for `vcacos`, `vmcacos` `DOUBLE COMPLEX, INTENT(OUT)` for `vzacos`, `vmzacos` **C:** `float*` for `vsAcos`, `vmsAcos` `double*` for `vdAcos`, `vmdAcos` `MKL_Complex8*` for `vcAcos`, `vmcAcos` `MKL_Complex16*` for `vzAcos`, `vmzAcos`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Acos` function computes inverse cosine of vector elements.

Special Values for Real Function v?Acos(x)

Argument	Result	VML Error Status	Exception
+0	+π/2		
-0	+π/2		
+1	+0		
-1	+π		
|X| > 1	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID

Argument	Result	VML Error Status	Exception
QNAN	QNAN		
SNAN	QNAN		INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Acos(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	$+\frac{3\pi}{4} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{2} - i \cdot \infty$	$+\frac{\pi}{4} - i \cdot \infty$	QNAN-i·∞
+i·Y	+π-i·∞					+0-i·∞	QNAN+i·QNAN
+i·0	+π-i·∞		$+\frac{\pi}{2} - i \cdot 0$	$+\frac{\pi}{2} - i \cdot 0$		+0-i·∞	QNAN+i·QNAN
-i·0	+π+i·∞		$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$		+0+i·∞	QNAN+i·QNAN
-i·Y	+π+i·∞					+0+i·∞	QNAN+i·QNAN
-i·∞	$+\frac{3\pi}{4} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{2} + i \cdot \infty$	$+\frac{\pi}{4} + i \cdot \infty$	QNAN+i·∞
+i·NAN	QNAN+i·∞	QNAN+i·QNAN	$+\frac{\pi}{2} + i \cdot QNAN$	$+\frac{\pi}{2} + i \cdot QNAN$	QNAN+i·QNAN	QNAN+i·∞	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Acos(CONJ(z))=CONJ(Acos(z))`.

v?Asin

Computes inverse sine of vector elements.

Syntax

Fortran:

```
call vsasin( n, a, y )
call vmsasin( n, a, y, mode )
call vdasin( n, a, y )
call vmdasin( n, a, y, mode )
call vcasin( n, a, y )
call vmcasin( n, a, y, mode )
call vzasin( n, a, y )
call vmzasin( n, a, y, mode )
```

C:

```
vsAsin( n, a, y );
vmsAsin( n, a, y, mode );
vdAsin( n, a, y );
vmdAsin( n, a, y, mode );
```

```
vcAsin( n, a, y );
vmcAsin( n, a, y, mode );
vzAsin( n, a, y );
vmzAsin( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsasin, vmsasin` `DOUBLE PRECISION` for `vdasin, vmdasin` `COMPLEX` for `vcasin, vmcasin` `DOUBLE COMPLEX` for `vzasin, vmzasin` **Fortran 90:** `REAL, INTENT(IN)` for `vsasin, vmsasin` `DOUBLE PRECISION, INTENT(IN)` for `vdasin, vmdasin` `COMPLEX, INTENT(IN)` for `vcasin, vmcasin` `DOUBLE COMPLEX, INTENT(IN)` for `vzasin, vmzasin` **C:** `const float*` for `vsAsin, vmsAsin` `const double*` for `vdAsin, vmdAsin` `const MKL_Complex8*` for `vcAsin, vmcAsin` `const MKL_Complex16*` for `vzAsin, vmzAsin`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsasin, vmsasin DOUBLE PRECISION for vdasin, vmdasin COMPLEX for vcasin, vmcasin DOUBLE COMPLEX for vzasin, vmzasin **Fortran 90:** REAL, INTENT(OUT) for vsasin, vmsasin DOUBLE PRECISION, INTENT(OUT) for vdasin, vmdasin COMPLEX, INTENT(OUT) for vcasin, vmcasin DOUBLE COMPLEX, INTENT(OUT) for vzasin, vmzasin **C:** float* for vsAsin, vmsAsin double* for vdAsin, vmdAsin MKL_Complex8* for vcAsin, vmcAsin MKL_Complex16* for vzAsin, vmzAsin	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?Asin function computes inverse sine of vector elements.

Special Values for Real Function v?Asin(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
+1	+π/2		
-1	-π/2		
|X| > 1	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

```
Asin(z) = -i*Asinh(i*z).
```

v?Atan

Computes inverse tangent of vector elements.

Syntax

Fortran:

```
call vsatan( n, a, y )
call vmsatan( n, a, y, mode )
call vdatan( n, a, y )
call vmdatan( n, a, y, mode )
call vcatan( n, a, y )
call vmcatan( n, a, y, mode )
call vzatan( n, a, y )
call vmzatan( n, a, y, mode )
```

C:

```
vsAtan( n, a, y );
vmsAtan( n, a, y, mode );
vdAtan( n, a, y );
vmdAtan( n, a, y, mode );
vcAtan( n, a, y );
vmcAtan( n, a, y, mode );
vzAtan( n, a, y );
vmzAtan( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsatan`, `vmsatan` `DOUBLE PRECISION` for `vdatan`, `vmdatan` `COMPLEX` for `vcatan`, `vmcatan` `DOUBLE COMPLEX` for `vzatan`, `vmzatan` **Fortran 90:** `REAL, INTENT(IN)` for `vsatan`, `vmsatan`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	DOUBLE PRECISION, INTENT(IN) for vdatan, vmdatan COMPLEX, INTENT(IN) for vcatan, vmcatan DOUBLE COMPLEX, INTENT(IN) for vzatan, vmzatan **C:** const float* for vsAtan, vmsAtan const double* for vdAsin, vmdAtan const MKL_Complex8* for vcAtan, vmcAtan const MKL_Complex16* for vzAsin, vmzAtan	
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsatan, vmsatan DOUBLE PRECISION for vdatan, vmdatan COMPLEX for vcatan, vmcatan DOUBLE COMPLEX for vzatan, vmzatan **Fortran 90:** REAL, INTENT(OUT) for vsatan, vmsatan DOUBLE PRECISION, INTENT(OUT) for vdatan, vmdatan COMPLEX, INTENT(OUT) for vcatan, vmcatan DOUBLE COMPLEX, INTENT(OUT) for vzatan, vmzatan **C:** float* for vsAtan, vmsAtan double* for vdAsin, vmdAtan MKL_Complex8* for vcAtan, vmcAtan MKL_Complex16* for vzAsin, vmzAtan	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?Atan function computes inverse tangent of vector elements.

Special Values for Real Function v?Atan(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
+∞	+π/2		
-∞	-π/2		
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

Atan(z) = -i*Atanh(i*z).

v?Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

Fortran:

```
call vsatan2( n, a, b, y )
call vmsatan2( n, a, b, y, mode )
call vdatan2( n, a, b, y )
call vmdatan2( n, a, b, y, mode )
```

C:

```
vsAtan2( n, a, b, y );
vmsAtan2( n, a, b, y, mode );
vdAtan2( n, a, b, y );
vmdAtan2( n, a, b, y, mode );
```

Include Files

- FORTRAN 77: mkl_vml.f77
- Fortran 90: mkl_vml.f90
- C: mkl_vml_functions.h

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a, *b*	**FORTRAN 77:** REAL for vsatan2, vmsatan2	**FORTRAN:** Arrays that specify the input vectors *a* and *b*.

Name	Type	Description
	`DOUBLE PRECISION` for `vdatan2`, `vmdatan2` **Fortran 90:** `REAL, INTENT(IN)` for `vsatan2`, `vmsatan2` `DOUBLE PRECISION, INTENT(IN)` for `vdatan2`, `vmdatan2` **C:** `const float*` for `vsAtan2`, `vmsAtan2` `const double*` for `vdAtan2`, `vmdAtan2`	**C:** Pointers to arrays that contain the input vectors *a* and *b*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsatan2`, `vmsatan2` `DOUBLE PRECISION` for `vdatan2`, `vmdatan2` **Fortran 90:** `REAL, INTENT(OUT)` for `vsatan2`, `vmsatan2` `DOUBLE PRECISION, INTENT(OUT)` for `vdatan2`, `vmdatan2` **C:** `float*` for `vsAtan2`, `vmsAtan2` `double*` for `vdAtan2`, `vmdAtan2`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Atan2` function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector*y* are computed as the four-quadrant arctangent of `a[i] / b[i]`.

Special values for Real Function v?Atan2(x)

Hyperbolic Functions

v?Cosh

Computes hyperbolic cosine of vector elements.

Syntax

Fortran:

```
call vscosh( n, a, y )
call vmscosh( n, a, y, mode )
call vdcosh( n, a, y )
call vmdcosh( n, a, y, mode )
```

```
call vccosh( n, a, y )
call vmccosh( n, a, y, mode )
call vzcosh( n, a, y )
call vmzcosh( n, a, y, mode )
```

C:

```
vsCosh( n, a, y );
vmsCosh( n, a, y, mode );
vdCosh( n, a, y );
vmdCosh( n, a, y, mode );
vcCosh( n, a, y );
vmcCosh( n, a, y, mode );
vzCosh( n, a, y );
vmzCosh( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vscosh, vmscosh` `DOUBLE PRECISION` for `vdcosh, vmdcosh` `COMPLEX` for `vccosh, vmccosh` `DOUBLE COMPLEX` for `vzcosh, vmzcosh` **Fortran 90:** `REAL, INTENT(IN)` for `vscosh, vmscosh` `DOUBLE PRECISION, INTENT(IN)` for `vdcosh, vmdcosh` `COMPLEX, INTENT(IN)` for `vccosh, vmccosh` `DOUBLE COMPLEX, INTENT(IN)` for `vzcosh, vmzcosh` **C:** `const float*` for `vsCosh, vmsCosh`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	`const double*` for `vdCosh`, `vmdCosh` `const MKL_Complex8*` for `vcCosh`, `vmcCosh` `const MKL_Complex16*` for `vzCosh`, `vmzCosh`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Precision Overflow Thresholds for Real v?Cosh Function

Data Type	Threshold Limitations on Input Parameters
single precision	`-Ln(FLT_MAX)-Ln2 <a[i] < Ln(FLT_MAX)+Ln2`
double precision	`-Ln(DBL_MAX)-Ln2 <a[i] < Ln(DBL_MAX)+Ln2`

Precision overflow thresholds for the complex `v?Cosh` function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vscosh`, `vmscosh` `DOUBLE PRECISION` for `vdcosh`, `vmdcosh` `COMPLEX` for `vccosh`, `vmccosh` `DOUBLE COMPLEX` for `vzcosh`, `vmzcosh` **Fortran 90:** `REAL, INTENT(OUT)` for `vscosh`, `vmscosh` `DOUBLE PRECISION, INTENT(OUT)` for `vdcosh`, `vmdcosh` `COMPLEX, INTENT(OUT)` for `vccosh`, `vmccosh` `DOUBLE COMPLEX, INTENT(OUT)` for `vzcosh`, `vmzcosh` **C:** `float*` for `vsCosh`, `vmsCosh` `double*` for `vdCosh`, `vmdCosh` `MKL_Complex8*` for `vcCosh`, `vmcCosh` `MKL_Complex16*` for `vzCosh`, `vmzCosh`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Cosh` function computes hyperbolic cosine of vector elements.

Special Values for Real Function v?Cosh(x)

Argument	Result	VML Error Status	Exception
+0	+1		
-0	+1		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < -overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Cosh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN-i·0 INVALID	QNAN+i·0 INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·Y	+∞·Cos(Y)-i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	+∞-i·0		+1-i·0	+1+i·0		+∞+i·0	QNAN+i·0
-i·0	+∞+i·0		+1+i·0	+1-i·0		+∞-i·0	QNAN-i·0
-i·Y	+∞·Cos(Y)-i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	+∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·0 INVALID	QNAN-i·0 INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·NAN	+∞+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN-i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises the `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- raises the `OVERFLOW` exception and sets the VML Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when `RE(z)`, `IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- `Cosh(CONJ(z))=CONJ(Cosh(z))`
- `Cosh(-z)=Cosh(z).`

v?Sinh

Computes hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vssinh( n, a, y )
call vmssinh( n, a, y, mode )
call vdsinh( n, a, y )
call vmdsinh( n, a, y, mode )
```

```
call vcsinh( n, a, y )
call vmcsinh( n, a, y, mode )
call vzsinh( n, a, y )
call vmzsinh( n, a, y, mode )
```

C:

```
vsSinh( n, a, y );
vmsSinh( n, a, y, mode );
vdSinh( n, a, y );
vmdSinh( n, a, y, mode );
vcSinh( n, a, y );
vmcSinh( n, a, y, mode );
vzSinh( n, a, y );
vmzSinh( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vssinh, vmssinh` `DOUBLE PRECISION` for `vdsinh, vmdsinh` `COMPLEX` for `vcsinh, vmcsinh` `DOUBLE COMPLEX` for `vzsinh, vmzsinh` **Fortran 90:** `REAL, INTENT(IN)` for `vssinh, vmssinh` `DOUBLE PRECISION, INTENT(IN)` for `vdsinh, vmdsinh` `COMPLEX, INTENT(IN)` for `vcsinh, vmcsinh` `DOUBLE COMPLEX, INTENT(IN)` for `vzsinh, vmzsinh` **C:** `const float*` for `vsSinh, vmsSinh`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	`const double*` for `vdSinh`, `vmdSinh` `const MKL_Complex8*` for `vcSinh`, `vmcSinh` `const MKL_Complex16*` for `vzSinh`, `vmzSinh`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Precision Overflow Thresholds for Real v?Sinh Function

Data Type	Threshold Limitations on Input Parameters
single precision	`-Ln(FLT_MAX)-Ln2 <a[i] < Ln(FLT_MAX)+Ln2`
double precision	`-Ln(DBL_MAX)-Ln2 <a[i] < Ln(DBL_MAX)+Ln2`

Precision overflow thresholds for the complex `v?Sinh` function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vssinh`, `vmssinh` `DOUBLE PRECISION` for `vdsinh`, `vmdsinh` `COMPLEX` for `vcsinh`, `vmcsinh` `DOUBLE COMPLEX` for `vzsinh`, `vmzsinh` **Fortran 90:** `REAL, INTENT(OUT)` for `vssinh`, `vmssinh` `DOUBLE PRECISION, INTENT(OUT)` for `vdsinh`, `vmdsinh` `COMPLEX, INTENT(OUT)` for `vcsinh`, `vmcsinh` `DOUBLE COMPLEX, INTENT(OUT)` for `vzsinh`, `vmzsinh` **C:** `float*` for `vsSinh`, `vmsSinh` `double*` for `vdSinh`, `vmdSinh` `MKL_Complex8*` for `vcSinh`, `vmcSinh` `MKL_Complex16*` for `vzSinh`, `vmzSinh`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Sinh` function computes hyperbolic sine of vector elements.

Special Values for Real Function v?Sinh(x)

Argument	Result	VML Error Status	Exception
+0	+0		
-0	-0		
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
X < -overflow	-∞	VML_STATUS_OVERFLOW	OVERFLOW
+∞	+∞		
-∞	-∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Sinh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	-∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	-0+i·QNAN INVALID	+0+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·Y	-∞·Cos(Y)+ i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
+i·0	-∞+i·0		-0+i·0	+0+i·0		+∞+i·0	QNAN+i·0
-i·0	-∞-i·0		-0-i·0	+0-i·0		+∞-i·0	QNAN-i·0
-i·Y	-∞·Cos(Y)+ i·∞·Sin(Y)					+∞·CIS(Y)	QNAN+i·QNAN
-i·∞	-∞+i·QNAN INVALID	QNAN+i·QNAN INVALID	-0+i·QNAN INVALID	+0+i·QNAN INVALID	QNAN+i·QNAN INVALID	+∞+i·QNAN INVALID	QNAN+i·QNAN
+i·NAN	-∞+i·QNAN	QNAN+i·QNAN	-0+i·QNAN	+0+i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises the `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- raises the `OVERFLOW` exception and sets the VML Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when `RE(z)`, `IM(z)` are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- `Sinh(CONJ(z))=CONJ(Sinh(z))`
- `Sinh(-z)=-Sinh(z)`.

v?Tanh

Computes hyperbolic tangent of vector elements.

Syntax

Fortran:

```
call vstanh( n, a, y )
call vmstanh( n, a, y, mode )
call vdtanh( n, a, y )
call vmdtanh( n, a, y, mode )
call vctanh( n, a, y )
```

```
call vmctanh( n, a, y, mode )
call vztanh( n, a, y )
call vmztanh( n, a, y, mode )
```

C:

```
vsTanh( n, a, y );
vmsTanh( n, a, y, mode );
vdTanh( n, a, y );
vmdTanh( n, a, y, mode );
vcTanh( n, a, y );
vmcTanh( n, a, y, mode );
vzTanh( n, a, y );
vmzTanh( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vstanh, vmstanh` `DOUBLE PRECISION` for `vdtanh, vmdtanh` `COMPLEX` for `vctanh, vmctanh` `DOUBLE COMPLEX` for `vztanh, vmztanh` **Fortran 90:** `REAL, INTENT(IN)` for `vstanh, vmstanh` `DOUBLE PRECISION, INTENT(IN)` for `vdtanh, vmdtanh` `COMPLEX, INTENT(IN)` for `vctanh, vmctanh` `DOUBLE COMPLEX, INTENT(IN)` for `vztanh, vmztanh` **C:** `const float*` for `vsTanh, vmsTanh` `const double*` for `vdTanh, vmdTanh`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	`const MKL_Complex8*` for `vcTanh`, `vmcTanh` `const MKL_Complex16*` for `vzTanh`, `vmzTanh`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vstanh`, `vmstanh` `DOUBLE PRECISION` for `vdtanh`, `vmdtanh` `COMPLEX` for `vctanh`, `vmctanh` `DOUBLE COMPLEX` for `vztanh`, `vmztanh` **Fortran 90:** `REAL, INTENT(OUT)` for `vstanh`, `vmstanh` `DOUBLE PRECISION, INTENT(OUT)` for `vdtanh`, `vmdtanh` `COMPLEX, INTENT(OUT)` for `vctanh`, `vmctanh` `DOUBLE COMPLEX, INTENT(OUT)` for `vztanh`, `vmztanh` **C:** `float*` for `vsTanh`, `vmsTanh` `double*` for `vdTanh`, `vmdTanh` `MKL_Complex8*` for `vcTanh`, `vmcTanh` `MKL_Complex16*` for `vzTanh`, `vmzTanh`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `v?Tanh` function computes hyperbolic tangent of vector elements.

Special Values for Real Function v?Tanh(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+1	
-∞	-1	
QNAN	QNAN	

Argument	Result	Exception
SNAN	QNAN	INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Tanh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	-1+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+1+i·0	QNAN+i·QNAN
+i·Y	-1+i·0·Tan(Y)					+1+i·0·Tan(Y)	QNAN+i·QNAN
+i·0	-1+i·0		-0+i·0	+0+i·0		+1+i·0	QNAN+i·0
-i·0	-1-i·0		-0-i·0	+0-i·0		+1-i·0	QNAN-i·0
-i·Y	-1+i·0·Tan(Y)					+1+i·0·Tan(Y)	QNAN+i·QNAN
-i·∞	-1-i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	+1-i·0	QNAN+i·QNAN
+i·NAN	-1+i·0	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	+1+i·0	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Tanh(CONJ(z))=CONJ(Tanh(z))`
- `Tanh(-z)=-Tanh(z).`

v?Acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

Syntax

Fortran:

```
call vsacosh( n, a, y )
call vmsacosh( n, a, y, mode )
call vdacosh( n, a, y )
call vmdacosh( n, a, y, mode )
call vcacosh( n, a, y )
call vmcacosh( n, a, y, mode )
call vzacosh( n, a, y )
call vmzacosh( n, a, y, mode )
```

C:

```
vsAcosh( n, a, y );
vmsAcosh( n, a, y, mode );
vdAcosh( n, a, y );
vmdAcosh( n, a, y, mode );
```

```
vcAcosh( n, a, y );
vmcAcosh( n, a, y, mode );
vzAcosh( n, a, y );
vmzAcosh( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsacosh, vmsacosh` `DOUBLE PRECISION` for `vdacosh, vmdacosh` `COMPLEX` for `vcacosh, vmcacosh` `DOUBLE COMPLEX` for `vzacosh, vmzacosh` **Fortran 90:** `REAL, INTENT(IN)` for `vsacosh, vmsacosh` `DOUBLE PRECISION, INTENT(IN)` for `vdacosh, vmdacosh` `COMPLEX, INTENT(IN)` for `vcacosh, vmcacosh` `DOUBLE COMPLEX, INTENT(IN)` for `vzacosh, vmzacosh` **C:** `const float*` for `vsAcosh, vmsAcosh` `const double*` for `vdAcosh, vmdAcosh` `const MKL_Complex8*` for `vcAcosh, vmcAcosh` `const MKL_Complex16*` for `vzAcosh, vmzAcosh`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsacosh, vmsacosh DOUBLE PRECISION for vdacosh, vmdacosh COMPLEX for vcacosh, vmcacosh DOUBLE COMPLEX for vzacosh, vmzacosh **Fortran 90:** REAL, INTENT(OUT) for vsacosh, vmsacosh DOUBLE PRECISION, INTENT(OUT) for vdacosh, vmdacosh COMPLEX, INTENT(OUT) for vcacosh, vmcacosh DOUBLE COMPLEX, INTENT(OUT) for vzacosh, vmzacosh **C:** float* for vsAcosh, vmsAcosh double* for vdAcosh, vmdAcosh MKL_Complex8* for vcAcosh, vmcAcosh MKL_Complex16* for vzAcosh, vmzAcosh	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?Acosh function computes inverse hyperbolic cosine (nonnegative) of vector elements.

Special Values for Real Function v?Acosh(x)

Argument	Result	VML Error Status	Exception
+1	+0		
X < +1	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Acosh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	$+\infty + i \cdot \frac{3\pi}{4}$	+∞+i·π/2	+∞+i·π/2	+∞+i·π/2	+∞+i·π/2	+∞+i·π/4	+∞+i·QNAN
+i·Y	+∞+i·π					+∞+i·0	QNAN+i·QNAN

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·0	+∞+i·π		+0+i·π/2	+0+i·π/2		+∞+i·0	QNAN+i·QNAN
-i·0	+∞+i·π		+0+i·π/2	+0+i·π/2		+∞+i·0	QNAN+i·QNAN
-i·Y	+∞+i·π					+∞+i·0	QNAN+i·QNAN
-i·∞	$+\infty - i \cdot \frac{3\pi}{4}$	+∞-i·π/2	+∞-i·π/2	+∞-i·π/2	+∞-i·π/2	+∞-i·π/4	+∞+i·QNAN
+i·NAN	+∞+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	QNAN+i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Acosh(CONJ(z))=CONJ(Acosh(z))`.

v?Asinh

Computes inverse hyperbolic sine of vector elements.

Syntax

Fortran:

```
call vsasinh( n, a, y )
call vmsasinh( n, a, y, mode )
call vdasinh( n, a, y )
call vmdasinh( n, a, y, mode )
call vcasinh( n, a, y )
call vmcasinh( n, a, y, mode )
call vzasinh( n, a, y )
call vmzasinh( n, a, y, mode )
```

C:

```
vsAsinh( n, a, y );
vmsAsinh( n, a, y, mode );
vdAsinh( n, a, y );
vmdAsinh( n, a, y, mode );
vcAsinh( n, a, y );
vmcAsinh( n, a, y, mode );
vzAsinh( n, a, y );
vmzAsinh( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** REAL for vsasinh, vmsasinh DOUBLE PRECISION for vdasinh, vmdasinh COMPLEX for vcasinh, vmcasinh DOUBLE COMPLEX for vzasinh, vmzasinh **Fortran 90:** REAL, INTENT(IN) for vsasinh, vmsasinh DOUBLE PRECISION, INTENT(IN) for vdasinh, vmdasinh COMPLEX, INTENT(IN) for vcasinh, vmcasinh DOUBLE COMPLEX, INTENT(IN) for vzasinh, vmzasinh **C:** const float* for vsAsinh, vmsAsinh const double* for vdAsinh, vmdAsinh const MKL_Complex8* for vcAsinh, vmcAsinh const MKL_Complex16* for vzAsinh, vmzAsinh	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsasinh, vmsasinh DOUBLE PRECISION for vdasinh, vmdasinh COMPLEX for vcasinh, vmcasinh	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`DOUBLE COMPLEX` for `vzasinh`, `vmzasinh` **Fortran 90:** `REAL, INTENT(OUT)` for `vsasinh, vmsasinh` `DOUBLE PRECISION, INTENT(OUT)` for `vdasinh, vmdasinh` `COMPLEX, INTENT(OUT)` for `vcasinh, vmcasinh` `DOUBLE COMPLEX, INTENT(OUT)` for `vzasinh, vmzasinh` **C:** `float*` for `vsAsinh, vmsAsinh` `double*` for `vdAsinh, vmdAsinh` `MKL_Complex8*` for `vcAsinh, vmcAsinh` `MKL_Complex16*` for `vzAsinh, vmzAsinh`	

Description

The `v?Asinh` function computes inverse hyperbolic sine of vector elements.

Special Values for Real Function v?Asinh(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
QNAN	QNAN	
SNAN	QNAN	INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Asinh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	-∞+i·π/4	-∞+i·π/2	+∞+i·π/2	+∞+i·π/2	+∞+i·π/2	+∞+i·π/4	+∞+i·QNAN
+i·Y	-∞+i·0					+∞+i·0	QNAN+i·QNAN
+i·0	+∞+i·0		+0+i·0	+0+i·0		+∞+i·0	QNAN+i·QNAN
-i·0	-∞-i·0		-0-i·0	+0-i·0		+∞-i·0	QNAN-i·QNAN
-i·Y	-∞-i·0					+∞-i·0	QNAN+i·QNAN
-i·∞	-∞-i·π/4	-∞-i·π/2	-∞-i·π/2	+∞-i·π/2	+∞-i·π/2	+∞-i·π/4	+∞+i·QNAN
+i·NAN	-∞+i·QNAN	QNAN +i·QNAN	QNAN +i·QNAN	QNAN +i·QNAN	QNAN +i·QNAN	+∞+i·QNAN	QNAN+i·QNAN

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- Asinh(CONJ(z))=CONJ(Asinh(z))
- Asinh(-z)=-Asinh(z).

v?Atanh

Computes inverse hyperbolic tangent of vector elements.

Syntax

Fortran:

```
call vsatanh( n, a, y )
call vmsatanh( n, a, y, mode )
call vdatanh( n, a, y )
call vmdatanh( n, a, y, mode )
call vcatanh( n, a, y )
call vmcatanh( n, a, y, mode )
call vzatanh( n, a, y )
call vmzatanh( n, a, y, mode )
```

C:

```
vsAtanh( n, a, y );
vmsAtanh( n, a, y, mode );
vdAtanh( n, a, y );
vmdAtanh( n, a, y, mode );
vcAtanh( n, a, y );
vmcAtanh( n, a, y, mode );
vzAtanh( n, a, y );
vmzAtanh( n, a, y, mode );
```

Include Files

- FORTRAN 77: mkl_vml.f77
- Fortran 90: mkl_vml.f90
- C: mkl_vml_functions.h

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** REAL for vsatanh, vmsatanh	**FORTRAN:** Array that specifies the input vector *a*.

Name	Type	Description
	DOUBLE PRECISION for vdatanh, vmdatanh COMPLEX for vcatanh, vmcatanh DOUBLE COMPLEX for vzatanh, vmzatanh **Fortran 90:** REAL, INTENT(IN) for vsatanh, vmsatanh DOUBLE PRECISION, INTENT(IN) for vdatanh, vmdatanh COMPLEX, INTENT(IN) for vcatanh, vmcatanh DOUBLE COMPLEX, INTENT(IN) for vzatanh, vmzatanh **C:** const float* for vsAtanh, vmsAtanh const double* for vdAtanh, vmdAtanh const MKL_Complex8* for vcAtanh, vmcAtanh const MKL_Complex16* for vzAtanh, vmzAtanh	**C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsatanh, vmsatanh DOUBLE PRECISION for vdatanh, vmdatanh COMPLEX for vcatanh, vmcatanh DOUBLE COMPLEX for vzatanh, vmzatanh **Fortran 90:** REAL, INTENT(OUT) for vsatanh, vmsatanh DOUBLE PRECISION, INTENT(OUT) for vdatanh, vmdatanh COMPLEX, INTENT(OUT) for vcatanh, vmcatanh	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`DOUBLE COMPLEX`, `INTENT(OUT)` for `vzatanh`, `vmzatanh` **C:** `float*` for `vsAtanh`, `vmsAtanh` `double*` for `vdAtanh`, `vmdAtanh` `MKL_Complex8*` for `vcAtanh`, `vmcAtanh` `MKL_Complex16*` for `vzAtanh`, `vmzAtanh`	

Description

The `v?Atanh` function computes inverse hyperbolic tangent of vector elements.

Special Values for Real Function v?Atanh(x)

Argument	Result	VML Error Status	Exception
+1	+∞	VML_STATUS_SING	ZERODIVIDE
-1	-∞	VML_STATUS_SING	ZERODIVIDE
|X| > 1	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

See the Special Value Notations section for the conventions used in the table below.

Special Values for Complex Function v?Atanh(z)

RE(z) i·IM(z)	-∞	-X	-0	+0	+X	+∞	NAN
+i·∞	-0+i·π/2	-0+i·π/2	-0+i·π/2	+0+i·π/2	+0+i·π/2	+0+i·π/2	+0+i·π/2
+i·Y	-0+i·π/2					+0+i·π/2	QNAN+i·QNAN
+i·0	-0+i·π/2		-0+i·0	+0+i·0		+0+i·π/2	QNAN+i·QNAN
-i·0	-0-i·π/2		-0-i·0	+0-i·0		+0-i·π/2	QNAN-i·QNAN
-i·Y	-0-i·π/2					+0-i·π/2	QNAN+i·QNAN
-i·∞	-0-i·π/2	-0-i·π/2	-0-i·π/2	+0-i·π/2	+0-i·π/2	+0-i·π/2	+0-i·π/2
+i·NAN	-0+i·QNAN	QNAN +i·QNAN	-0+i·QNAN	+0+i·QNAN	QNAN +i·QNAN	+0+i·QNAN	QNAN+i·QNAN

Notes:

- `Atanh(+-1+-i*0)=+-∞+-i*0`, and `ZERODIVIDE` exception is raised
- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- `Atanh(CONJ(z))=CONJ(Atanh(z))`
- `Atanh(-z)=-Atanh(z)`.

Special Functions

v?Erf

Computes the error function value of vector elements.

Syntax

Fortran:

```
call vserf( n, a, y )
call vmserf( n, a, y, mode )
call vderf( n, a, y )
call vmderf( n, a, y, mode )
```

C:

```
vsErf( n, a, y );
vmsErf( n, a, y, mode );
vdErf( n, a, y );
vmdErf( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vserf, vmserf` `DOUBLE PRECISION` for `vderf, vmderf` **Fortran 90:** `REAL, INTENT(IN)` for `vserf, vmserf` `DOUBLE PRECISION, INTENT(IN)` for `vderf, vmderf` **C:** `const float*` for `vsErf, vmsErf` `const double*` for `vdErf, vmdErf`	**FORTRAN:** Array, specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Name	Type	Description
	Fortran 90: `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vserf`, `vmserf` `DOUBLE PRECISION` for `vderf`, `vmderf` **Fortran 90:** `REAL, INTENT(OUT)` for `vserf, vmserf` `DOUBLE PRECISION, INTENT(OUT)` for `vderf, vmderf` **C:** `float*` for `vsErf, vmsErf` `double*` for `vdErf, vmdErf`	**FORTRAN:** Array, specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `Erf` function computes the error function values for elements of the input vector *a* and writes them to the output vector *y*.

The error function is defined as given by:

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt \ .$$

Useful relations:

1. $\mathrm{erfc}(x) = 1 - \mathrm{erf}(x)$,

where `erfc` is the complementary error function.

2. $\Phi(x) = \frac{1}{2} \mathrm{erf}\,(x/\sqrt{2})$,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

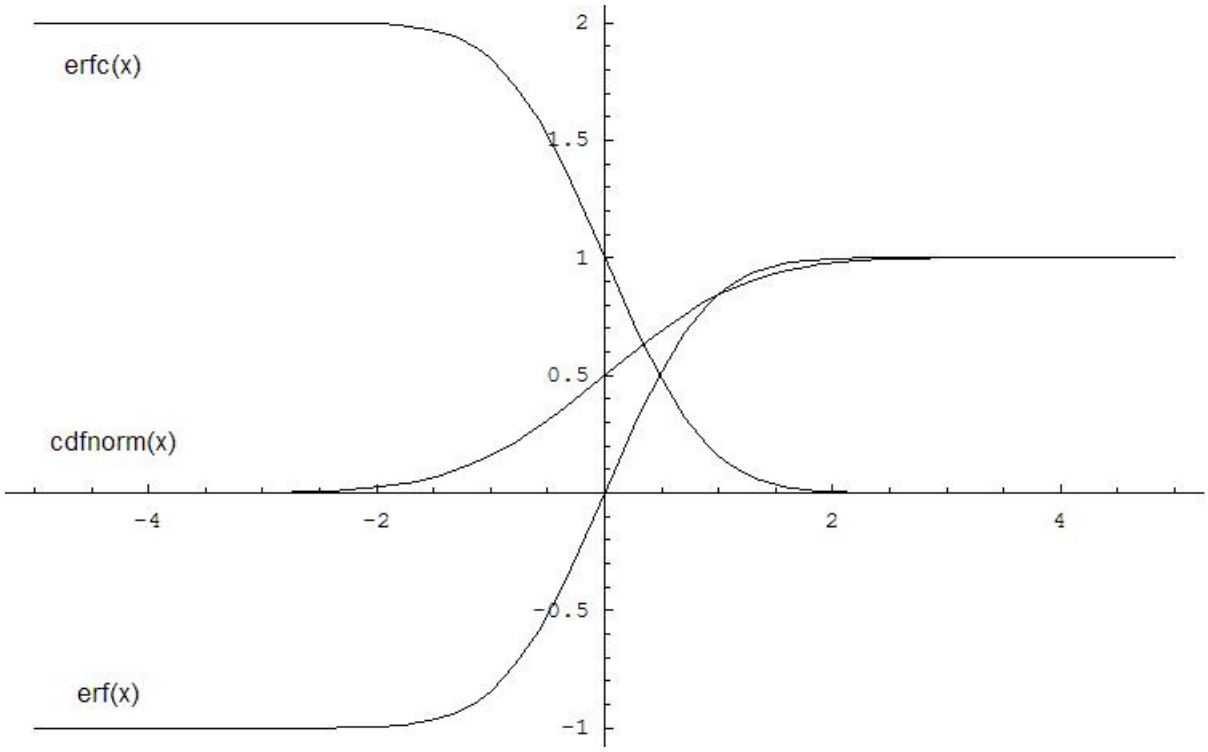
is the cumulative normal distribution function.

3. $\Phi^{-1}(x) = \sqrt{2}\,\mathrm{erf}^{-1}(2x - 1)$,

where $\Phi^{-1}(x)$ and $\mathtt{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\mathtt{erf}(x)$ respectively.

The following figure illustrates the relationships among `Erf` family functions (`Erf`, `Erfc`, `CdfNorm`).

Erf Family Functions Relationship



Useful relations for these functions:

$$\mathrm{erf}(x) + \mathrm{erfc}(x) = 1$$

$$\mathrm{cdfnorm}(x) = \frac{1}{2}\left(1 + \mathrm{erf}\left(\frac{x}{\sqrt{2}}\right)\right) = 1 - \frac{1}{2}\,\mathrm{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vserfc`, `vmserfc` `DOUBLE PRECISION` for `vderfc`, `vmderfc` **Fortran 90:** `REAL, INTENT(IN)` for `vserfc, vmserfc` `DOUBLE PRECISION, INTENT(IN)` for `vderfc, vmderfc` **C:** `const float*` for `vsErfc`, `vmsErfc` `const double*` for `vdErfc, vmdErfc`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Name	Type	Description
	C: `const MKL_INT64`	

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vserfc`, `vmserfc` `DOUBLE PRECISION` for `vderfc`, `vmderfc` **Fortran 90:** `REAL, INTENT(OUT)` for `vserfc, vmserfc` `DOUBLE PRECISION, INTENT(OUT)` for `vderfc, vmderfc` **C:** `float*` for `vsErfc, vmsErfc` `double*` for `vdErfc, vmdErfc`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `Erfc` function computes the complementary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The complementary error function is defined as follows:

Useful relations:

1. $\mathrm{erfc}(x) = 1 - \mathrm{erf}(x)$.

2. $\Phi(x) = \frac{1}{2}\,\mathrm{erf}\,(x/\sqrt{2})$,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp\,(-t^2/2)dt$$

is the cumulative normal distribution function.

3. $\Phi^{-1}(x) = \sqrt{2}\,\mathrm{erf}^{-1}(2x - 1)$,

where $\Phi^{-1}(x)$ and $\mathrm{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\mathrm{erf}(x)$ respectively.

See also Figure "Erf Family Functions Relationship" in `Erf` function description for `Erfc` function relationship with the other functions of `Erf` family.

n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vscdfnorm`, `vmscdfnorm` `DOUBLE PRECISION` for `vdcdfnorm`, `vmdcdfnorm`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	Fortran 90: `REAL, INTENT(IN)` for `vscdfnorm, vmscdfnorm` `DOUBLE PRECISION, INTENT(IN)` for `vdcdfnorm, vmdcdfnorm` **C:** `const float*` for `vsCdfNorm, vmsCdfNorm` `const double*` for `vdCdfNorm, vmdCdfNorm`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vscdfnorm, vmscdfnorm` `DOUBLE PRECISION` for `vdcdfnorm, vmdcdfnorm` **Fortran 90:** `REAL, INTENT(OUT)` for `vscdfnorm, vmscdfnorm` `DOUBLE PRECISION, INTENT(OUT)` for `vdcdfnorm, vmdcdfnorm` **C:** `float*` for `vsCdfNorm, vmsCdfNorm` `double*` for `vdCdfNorm, vmdCdfNorm`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `CdfNorm` function computes the cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The cumulative normal distribution function is defined as given by:

$$\mathrm{CdfNorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{x} e^{-\frac{t^2}{2}} dt \ .$$

Useful relations:

$$\mathrm{cdfnorm}(x) = \frac{1}{2}\left(1 + \mathrm{erf}\left(\frac{x}{\sqrt{2}}\right)\right) = 1 - \frac{1}{2}\,\mathrm{erfc}\left(\frac{x}{\sqrt{2}}\right)$$

where Erf and Erfc are the error and complementary error functions.

See also Figure "Erf Family Functions Relationship" in Erf function description for CdfNorm function relationship with the other functions of Erf family.

n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.

Name	Type	Description
a	**FORTRAN 77:** REAL for vserfinv, vmserfinv DOUBLE PRECISION for vderfinv, vmderfinv **Fortran 90:** REAL, INTENT(IN) for vserfinv, vmserfinv DOUBLE PRECISION, INTENT(IN) for vderfinv, vmderfinv **C:** const float* for vsErfInv, vmsErfInv const double* for vdErfInv, vmdErfInv	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vserfinv, vmserfinv DOUBLE PRECISION for vderfinv, vmderfinv **Fortran 90:** REAL, INTENT(OUT) for vserfinv, vmserfinv DOUBLE PRECISION, INTENT(OUT) for vderfinv, vmderfinv **C:** float* for vsErfInv, vmsErfInv double* for vdErfInv, vmdErfInv	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The ErfInv function computes the inverse error function values for elements of the input vector *a* and writes them to the output vector *y*

y = erf^{-1}(*a*),

where erf(*x*) is the error function defined as given by:

$$\mathrm{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt \ .$$

Useful relations:

1. $\mathrm{erf}^{-1}(x) = \mathrm{erfc}^{-1}(1 - x)$,

where `erfc` is the complementary error function.

2. $\Phi(x) = \frac{1}{2}\,\mathrm{erf}\,(x/\sqrt{2})$,

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp\,(-t^2/2)dt$$

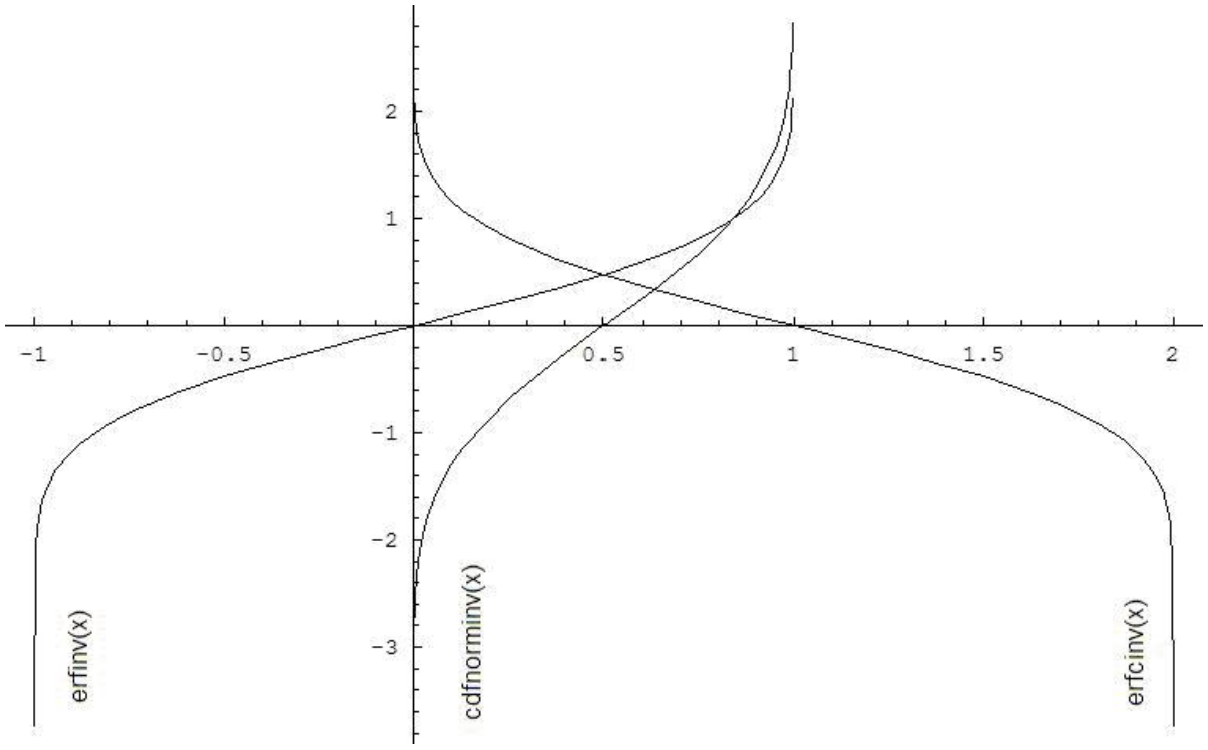
is the cumulative normal distribution function.

3. $\Phi^{-1}(x) = \sqrt{2}\,\mathrm{erf}^{-1}(2x - 1)$,

where $\Phi^{-1}(x)$ and $\mathrm{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\mathrm{erf}(x)$ respectively.

Figure "ErfInv Family Functions Relationship" illustrates the relationships among `ErfInv` family functions (`ErfInv`, `ErfcInv`, `CdfNormInv`).

ErfInv Family Functions Relationship



Useful relations for these functions:

$$\mathrm{erfcinv}(x) = \mathrm{erfinv}(1 - x)$$

$$\text{cdfnorminv}(x) = \sqrt{2}\,\text{erfinv}(2x - 1) = \sqrt{2}\,\text{erfcinv}(2 - 2x)$$

y	**FORTRAN 77:** `REAL` for `vscdfnorminv, vmscdfnorminv` `DOUBLE PRECISION` for `vdcdfnorminv, vmdcdfnorminv` **Fortran 90:** `REAL, INTENT(OUT)` for `vscdfnorminv, vmscdfnorminv` `DOUBLE PRECISION, INTENT(OUT)` for `vdcdfnorminv, vmdcdfnorminv` **C:** `float*` for `vsCdfNormInv, vmsCdfNormInv` `double*` for `vdCdfNormInv, vmdCdfNormInv`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The `CdfNormInv` function computes the inverse cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse cumulative normal distribution function is defined as given by:

$$\mathrm{CdfNormInv}(x) = \mathrm{CdfNorm}^{-1}(x) ,$$

where `CdfNorm(x)` denotes the cumulative normal distribution function.

Useful relations:

$$\mathrm{cdfnorminv}(x) = \sqrt{2}\,\mathrm{erfinv}(2x - 1) = \sqrt{2}\,\mathrm{erfcinv}(2 - 2x)$$

where `erfinv(x)` denotes the inverse error function and `erfcinv(x)` denotes the inverse complementary error functions.

See also Figure "ErfInv Family Functions Relationship" in `ErfInv` function description for `CdfNormInv` function relationship with the other functions of `ErfInv` family.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vslgamma, vmslgamma` `DOUBLE PRECISION` for `vdlgamma, vmdlgamma` **Fortran 90:** `REAL, INTENT(OUT)` for `vslgamma, vmslgamma` `DOUBLE PRECISION, INTENT(OUT)` for `vdlgamma, vmdlgamma` **C:** `float*` for `vsLGamma, vmsLGamma` `double*` for `vdLGamma, vmdLGamma`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?LGamma function computes the natural logarithm of the absolute value of gamma function for elements of the input vector *a* and writes them to the output vector *y*. Precision overflow thresholds for the v?LGamma function are beyond the scope of this document. If the result does not meet the target precision, the function raises the OVERFLOW exception and sets the VML Error Status to VML_STATUS_OVERFLOW.

Special Values for Real Function v?LGamma(x)

Argument	Result	VML Error Status	Exception
+1	+0		
+2	+0		
+0	+?	VML_STATUS_SING	ZERODIVIDE
-0	+?	VML_STATUS_SING	ZERODIVIDE
negative integer	+?	VML_STATUS_SING	ZERODIVIDE
-?	+?		
+?	+?		
X > overflow	+?	VML_STATUS_OVERFLOW	OVERFLOW
QNAN	QNAN		
SNAN	QNAN		INVALID

v?TGamma

Computes the gamma function of vector elements.

Syntax

Fortran:

```
call vstgamma( n, a, y )
call vmstgamma( n, a, y, mode )
call vdtgamma( n, a, y )
call vmdtgamma( n, a, y, mode )
```

C:

```
vsTGamma( n, a, y );
vmsTGamma( n, a, y, mode );
vdTGamma( n, a, y );
vmdTGamma( n, a, y, mode );
```

Include Files

- FORTRAN 77: mkl_vml.f77
- Fortran 90: mkl_vml.f90
- C: mkl_vml_functions.h

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.

Name	Type	Description
a	**FORTRAN 77:** REAL for vstgamma, vmstgamma DOUBLE PRECISION for vdtgamma, vmdtgamma **Fortran 90:** REAL, INTENT(IN) for vstgamma, vmstgamma DOUBLE PRECISION, INTENT(IN) for vdtgamma, vmdtgamma **C:** const float* for vsTGamma, vmsTGamma const double* for vdTGamma, vmdTGamma	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vstgamma, vmstgamma DOUBLE PRECISION for vdtgamma, vmdtgamma **Fortran 90:** REAL, INTENT(OUT) for vstgamma, vmstgamma DOUBLE PRECISION, INTENT(OUT) for vdtgamma, vmdtgamma **C:** float* for vsTGamma, vmsTGamma double* for vdTGamma, vmdTGamma	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?TGamma function computes the gamma function for elements of the input vector *a* and writes them to the output vector *y*. Precision overflow thresholds for the v?TGamma function are beyond the scope of this document. If the result does not meet the target precision, the function raises the OVERFLOW exception and sets the VML Error Status to VML_STATUS_OVERFLOW.

Special Values for Real Function v?TGamma(x)

Argument	Result	VML Error Status	Exception
+0	+∞	VML_STATUS_SING	ZERODIVIDE
-0	-∞	VML_STATUS_SING	ZERODIVIDE
negative integer	QNAN	VML_STATUS_ERRDOM	INVALID
-∞	QNAN	VML_STATUS_ERRDOM	INVALID
+∞	+∞		

Argument	Result	VML Error Status	Exception
X > overflow	+∞	VML_STATUS_OVERFLOW	OVERFLOW
QNAN	QNAN		
SNAN	QNAN		INVALID

Rounding Functions

v?Floor

Computes an integer value rounded towards minus infinity for each vector element.

Syntax

Fortran:

```
call vsfloor( n, a, y )
call vmsfloor( n, a, y, mode )
call vdfloor( n, a, y )
call vmdfloor( n, a, y, mode )
```

C:

```
vsFloor( n, a, y );
vmsFloor( n, a, y, mode );
vdFloor( n, a, y );
vmdFloor( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsfloor, vmsfloor` `DOUBLE PRECISION` for `vdfloor, vmdfloor` **Fortran 90:** `REAL, INTENT(IN)` for `vsfloor, vmsfloor` `DOUBLE PRECISION, INTENT(IN)` for `vdfloor, vmdfloor`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	C: `const float*` for `vsFloor`, `vmsfloor` `const double*` for `vdFloor`, `vmdfloor`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8)`, `INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsfloor`, `vmsfloor` `DOUBLE PRECISION` for `vdfloor`, `vmdfloor` **Fortran 90:** `REAL`, `INTENT(OUT)` for `vsfloor`, `vmsfloor` `DOUBLE PRECISION`, `INTENT(OUT)` for `vdfloor`, `vmdfloor` **C:** `float*` for `vsFloor`, `vmsfloor` `double*` for `vdFloor`, `vmdfloor`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The function computes an integer value rounded towards minus infinity for each vector element.

Special Values for Real Function v?Floor(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Ceil

Computes an integer value rounded towards plus infinity for each vector element.

Syntax

Fortran:

```
call vsceil( n, a, y )
call vmsceil( n, a, y, mode )
call vdceil( n, a, y )
```

```
call vmdceil( n, a, y, mode )
```

C:

```
vsCeil( n, a, y );
vmsCeil( n, a, y, mode );
vdCeil( n, a, y );
vmdCeil( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsceil, vmsceil` `DOUBLE PRECISION` for `vdceil, vmdceil` **Fortran 90:** `REAL, INTENT(IN)` for `vsceil, vmsceil` `DOUBLE PRECISION, INTENT(IN)` for `vdceil, vmdceil` **C:** `const float*` for `vsCeil, vmsceil` `const double*` for `vdCeil, vmdceil`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsceil, vmsceil` `DOUBLE PRECISION` for `vdceil, vmdceil` **Fortran 90:** `REAL, INTENT(OUT)` for `vsceil, vmsceil`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`DOUBLE PRECISION, INTENT(OUT)` for `vdceil, vmdceil` **C:** `float*` for `vsCeil, vmsceil` `double*` for `vdCeil, vmdceil`	

Description

The function computes an integer value rounded towards plus infinity for each vector element.

Special Values for Real Function v?Ceil(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Trunc

Computes an integer value rounded towards zero for each vector element.

Syntax

Fortran:

```
call vstrunc( n, a, y )
call vmstrunc( n, a, y, mode )
call vdtrunc( n, a, y )
call vmdtrunc( n, a, y, mode )
```

C:

```
vsTrunc( n, a, y );
vmsTrunc( n, a, y, mode );
vdTrunc( n, a, y );
vmdTrunc( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)`	Specifies the number of elements to be calculated.

Name	Type	Description
	C: `const int`	
a	**FORTRAN 77:** `REAL` for `vstrunc`, `vmstrunc` `DOUBLE PRECISION` for `vdtrunc`, `vmdtrunc` **Fortran 90:** `REAL, INTENT(IN)` for `vstrunc, vmstrunc` `DOUBLE PRECISION, INTENT(IN)` for `vdtrunc, vmdtrunc` **C:** `const float*` for `vsTrunc`, `vmstrunc` `const double*` for `vdTrunc`, `vmdtrunc`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vstrunc`, `vmstrunc` `DOUBLE PRECISION` for `vdtrunc`, `vmdtrunc` **Fortran 90:** `REAL, INTENT(OUT)` for `vstrunc, vmstrunc` `DOUBLE PRECISION, INTENT(OUT)` for `vdtrunc, vmdtrunc` **C:** `float*` for `vsTrunc, vmstrunc` `double*` for `vdTrunc, vmdtrunc`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The function computes an integer value rounded towards zero for each vector element.

Special Values for Real Function v?Trunc(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Round

Computes a value rounded to the nearest integer for each vector element.

Syntax

Fortran:

```
call vsround( n, a, y )
call vmsround( n, a, y, mode )
call vdround( n, a, y )
call vmdround( n, a, y, mode )
```

C:

```
vsRound( n, a, y );
vmsRound( n, a, y, mode );
vdRound( n, a, y );
vmdRound( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsround`, `vmsround` `DOUBLE PRECISION` for `vdround`, `vmdround` **Fortran 90:** `REAL, INTENT(IN)` for `vsround, vmsround` `DOUBLE PRECISION, INTENT(IN)` for `vdround, vmdround` **C:** `const float*` for `vsRound`, `vmsround` `const double*` for `vdRound`, `vmdround`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Name	Type	Description
	C: `const MKL_INT64`	

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsround`, `vmsround` `DOUBLE PRECISION` for `vdround`, `vmdround` **Fortran 90:** `REAL, INTENT(OUT)` for `vsround, vmsround` `DOUBLE PRECISION, INTENT(OUT)` for `vdround, vmdround` **C:** `float*` for `vsRound, vmsround` `double*` for `vdRound, vmdround`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The function computes a value rounded to the nearest integer for each vector element.

The resulting mode affects the results computed for inputs that fall half-way between consecutive integres. For example:

- `f(0.5) = 0`, for rounding modes set to round to nearest round toward zero or to minus infinity.
- `f(0.5) = 1`, for rounding modes set to plus infinity.
- `f(-1.5) = -2`, for rounding modes set to round to nearest or to minus infinity.
- `f(-1.5) = -1`, for rounding modes set to round toward zero or to plus infinity.

Special Values for Real Function v?Round(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?NearbyInt

Computes a rounded integer value in the current rounding mode for each vector element.

Syntax

Fortran:

```
call vsnearbyint( n, a, y )
call vmsnearbyint( n, a, y, mode )
call vdnearbyint( n, a, y )
call vmdnearbyint( n, a, y, mode )
```

C:

```
vsNearbyInt( n, a, y );
vmsNearbyInt( n, a, y, mode );
vdNearbyInt( n, a, y );
vmdNearbyInt( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsnearbyint, vmsnearbyint` `DOUBLE PRECISION` for `vdnearbyint, vmdnearbyint` **Fortran 90:** `REAL, INTENT(IN)` for `vsnearbyint, vmsnearbyint` `DOUBLE PRECISION, INTENT(IN)` for `vdnearbyint, vmdnearbyint` **C:** `const float*` for `vsNearbyInt, vmsnearbyint` `const double*` for `vdNearbyInt, vmdnearbyint`	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** `REAL` for `vsnearbyint, vmsnearbyint` `DOUBLE PRECISION` for `vdnearbyint, vmdnearbyint` **Fortran 90:** `REAL, INTENT(OUT)` for `vsnearbyint, vmsnearbyint`	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Name	Type	Description
	`DOUBLE PRECISION, INTENT(OUT)` for `vdnearbyint, vmdnearbyint` **C:** `float*` for `vsNearbyInt, vmsnearbyint` `double*` for `vdNearbyInt, vmdnearbyint`	

Description

The `v?NearbyInt` function computes a rounded integer value in a current rounding mode for each vector element.

Halfway values, that is, 0.5, -1.5, and the like, are rounded off towards even values.

Special Values for Real Function v?NearbyInt(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Rint

Computes a rounded integer value in the current rounding mode for each vector element with inexact result exception raised for each changed value.

Syntax

Fortran:

```
call vsrint( n, a, y )
call vmsrint( n, a, y, mode )
call vdrint( n, a, y )
call vmdrint( n, a, y, mode )
```

C:

```
vsRint( n, a, y );
vmsRint( n, a, y, mode );
vdRint( n, a, y );
vmdRint( n, a, y, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** REAL for vsrint, vmsrint DOUBLE PRECISION for vdrint, vmdrint **Fortran 90:** REAL, INTENT(IN) for vsrint, vmsrint DOUBLE PRECISION, INTENT(IN) for vdrint, vmdrint **C:** const float* for vsRint, vmsrint const double* for vdRint, vmdrint	**FORTRAN:** Array that specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Overrides global VML mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsrint, vmsrint DOUBLE PRECISION for vdrint, vmdrint **Fortran 90:** REAL, INTENT(OUT) for vsrint, vmsrint DOUBLE PRECISION, INTENT(OUT) for vdrint, vmdrint **C:** float* for vsRint, vmsrint double* for vdRint, vmdrint	**FORTRAN:** Array that specifies the output vector *y*. **C:** Pointer to an array that contains the output vector *y*.

Description

The v?Rint function computes a rounded floating-point integer value using the current rounding mode for each vector element.

The resulting mode affects the results computed for inputs that fall half-way between consecutive integres. For example:

- f(0.5) = 0, for rounding modes set to round to nearest round toward zero or to minus infinity.
- f(0.5) = 1, for rounding modes set to plus infinity.

- `f(-1.5) = -2`, for rounding modes set to round to nearest or to minus infinity.
- `f(-1.5) = -1`, for rounding modes set to round toward zero or to plus infinity.

Special Values for Real Function v?Rint(x)

Argument	Result	Exception
+0	+0	
-0	-0	
+∞	+∞	
-∞	-∞	
SNAN	QNAN	INVALID
QNAN	QNAN	

v?Modf

Computes a truncated integer value and the remaining fraction part for each vector element.

Syntax

Fortran:

```
call vsmodf( n, a, y, z )
call vmsmodf( n, a, y, z, mode )
call vdmodf( n, a, y, z )
call vmdmodf( n, a, y, z, mode )
```

C:

```
vsModf( n, a, y, z );
vmsModf( n, a, y, z, mode );
vdModf( n, a, y, z );
vmdModf( n, a, y, z, mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsmodf`, `vmsmodf` `DOUBLE PRECISION` for `vdmodf`, `vmdmodf`	**FORTRAN:** Array, specifies the input vector *a*. **C:** Pointer to an array that contains the input vector *a*.

Name	Type	Description
	Fortran 90: `REAL, INTENT(IN)` for `vsmodf, vmsmodf` `DOUBLE PRECISION, INTENT(IN)` for `vdmodf, vmdmodf` **C:** `const float*` for `vsModf, vmsmodf` `const double*` for `vdModf, vmdmodf`	
mode	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const MKL_INT64`	Overrides global VML mode setting for this function call. See `vmlSetMode` for possible values and their description.

Output Parameters

Name	Type	Description
y, *z*	**FORTRAN 77:** `REAL` for `vsmodf, vmsmodf` `DOUBLE PRECISION` for `vdmodf, vmdmodf` **Fortran 90:** `REAL, INTENT(OUT)` for `vsmodf, vmsmodf` `DOUBLE PRECISION, INTENT(OUT)` for `vdmodf, vmdmodf` **C:** `float*` for `vsModf, vmsmodf` `double*` for `vdModf, vmdmodf`	**FORTRAN:** Array, specifies the output vector *y* and *z*. **C:** Pointer to an array that contains the output vector *y* and *z*.

Description

The function computes a truncated integer value and the remaining fraction part for each vector element.

Halfway values, such as 0.5, -1.5, are rounded off towards even values. An inexact result exception is raised for each changed value.

Special Values for Real Function v?Modf(x)

VML Pack/Unpack Functions

This section describes VML functions that convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix B for details on vector indexing methods).

The table below lists available VML Pack/Unpack functions, together with data types and indexing methods associated with them.

VML Pack/Unpack Functions

Function Short Name	Data Types	Indexing Methods	Description
v?Pack	s, d, c, z	I,V,M	Gathers elements of arrays, indexed by different methods.
v?Unpack	s, d, c, z	I,V,M	Scatters vector elements to arrays with different indexing.

See Also

Vector Arguments in VML

v?Pack

Copies elements of an array with specified indexing to a vector with unit increment.

Syntax

Fortran:

```
call vspacki( n, a, inca, y )
call vspackv( n, a, ia, y )
call vspackm( n, a, ma, y )
call vdpacki( n, a, inca, y )
call vdpackv( n, a, ia, y )
call vdpackm( n, a, ma, y )
call vcpacki( n, a, inca, y )
call vcpackv( n, a, ia, y )
call vcpackm( n, a, ma, y )
call vzpacki( n, a, inca, y )
call vzpackv( n, a, ia, y )
call vzpackm( n, a, ma, y )
```

C:

```
vsPackI( n, a, inca, y );
vsPackV( n, a, ia, y );
vsPackM( n, a, ma, y );
vdPackI( n, a, inca, y );
vdPackV( n, a, ia, y );
vdPackM( n, a, ma, y );
vcPackI( n, a, inca, y );
```

```
vcPackV( n, a, ia, y );
vcPackM( n, a, ma, y );
vzPackI( n, a, inca, y );
vzPackV( n, a, ia, y );
vzPackM( n, a, ma, y );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vspacki, vspackv, vspackm` `DOUBLE PRECISION` for `vdpacki, vdpackv, vdpackm` `COMPLEX` for `vcpacki, vcpackv, vcpackm` `DOUBLE COMPLEX` for `vzpacki, vzpackv, vzpackm` **Fortran 90:** `REAL, INTENT(IN)` for `vspacki, vspackv, vspackm` `DOUBLE PRECISION, INTENT(IN)` for `vdpacki, vdpackv, vdpackm` `COMPLEX, INTENT(IN)` for `vcpacki, vcpackv, vcpackm` `DOUBLE COMPLEX, INTENT(IN)` for `vzpacki, vzpackv, vzpackm` **C:** `const float*` for `vsPackI, vsPackV, vsPackM` `const double*` for `vdPackI, vdPackV, vdPackM` `const MKL_Complex8*` for `vcPackI, vcPackV, vcPackM` `const MKL_Complex16*` for `vzPackI, vzPackV, vzPackM`	**FORTRAN:** Array, `DIMENSION` at least `(1 + (n-1)*inca)` for `v?packi`, Array, `DIMENSION` at least `max( n,max(ia[j]) ), j=0, …, n-1` for `v?packv`, Array, `DIMENSION` at least `n` for `v?packm`. Specifies the input vector `a`. **C:** Specifies pointer to an array that contains the input vector `a`. The arrays must be: for `v?PackI`, at least `(1 + (n-1)*inca)` for `v?PackV`, at least `max( n,max(ia[j]) ), j=0, …, n-1` for `v?PackM`, at least `n`.

Name	Type	Description
inca	**FORTRAN 77:** INTEGER for vspacki, vdpacki, vcpacki, vzpacki **Fortran 90:** INTEGER, INTENT(IN) for vspacki, vdpacki, vcpacki, vzpacki **C:** const int for vsPackI, vdPackI, vcPackI, vzPackI	Specifies the increment for the elements of *a*.
ia	**FORTRAN 77:** INTEGER for vspackv, vdpackv, vcpackv, vzpackv **Fortran 90:** INTEGER, INTENT(IN) for vspackv, vdpackv, vcpackv, vzpackv **C:** const int* for vsPackV, vdPackV, vcPackV, vzPackV	**FORTRAN:** Array, DIMENSION at least *n*. Specifies the index vector for the elements of *a*. **C:** Specifies the pointer to an array of size at least *n* that contains the index vector for the elements of *a*.
ma	**FORTRAN 77:** INTEGER for vspackm, vdpackm, vcpackm, vzpackm **Fortran 90:** INTEGER, INTENT(IN) for vspackm, vdpackm, vcpackm, vzpackm **C:** const int* for vsPackM, vdPackM, vcPackM, vzPackM	**FORTRAN:** Array, DIMENSION at least *n*, Specifies the mask vector for the elements of *a*. **C:** Specifies the pointer to an array of size at least *n* that contains the mask vector for the elements of *a*.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vspacki, vspackv, vspackm DOUBLE PRECISION for vdpacki, vdpackv, vdpackm COMPLEX for vcpacki, vcpackv, vcpackm DOUBLE COMPLEX for vzpacki, vzpackv, vzpackm **Fortran 90:** REAL, INTENT(OUT) for vspacki, vspackv, vspackm DOUBLE PRECISION, INTENT(OUT) for vdpacki, vdpackv, vdpackm COMPLEX, INTENT(OUT) for vcpacki, vcpackv, vcpackm	**FORTRAN:** Array, DIMENSION at least *n*. Specifies the output vector *y*. **C:** Pointer to an array of size at least *n* that contains the output vector *y*.

Name	Type	Description
	`DOUBLE COMPLEX`, `INTENT(OUT)` for `vzpacki`, `vzpackv`, `vzpackm` **C:** `float*` for `vsPackI`, `vsPackV`, `vsPackM` `double*` for `vdPackI`, `vdPackV`, `vdPackM` `const MKL_Complex8*` for `vcPackI`, `vcPackV`, `vcPackM` `const MKL_Complex16*` for `vzPackI`, `vzPackV`, `vzPackM`	

v?Unpack

Copies elements of a vector with unit increment to an array with specified indexing.

Syntax

Fortran:

```
call vsunpacki( n, a, y, incy )
call vsunpackv( n, a, y, iy )
call vsunpackm( n, a, y, my )
call vdunpacki( n, a, y, incy )
call vdunpackv( n, a, y, iy )
call vdunpackm( n, a, y, my )
call vcunpacki( n, a, y, incy )
call vcunpackv( n, a, y, iy )
call vcunpackm( n, a, y, my )
call vzunpacki( n, a, y, incy )
call vzunpackv( n, a, y, iy )
call vzunpackm( n, a, y, my )
```

C:

```
vsUnpackI( n, a, y, incy );
vsUnpackV( n, a, y, iy );
vsUnpackM( n, a, y, my );
vdUnpackI( n, a, y, incy );
vdUnpackV( n, a, y, iy );
vdUnpackM( n, a, y, my );
vcUnpackI( n, a, y, incy );
vcUnpackV( n, a, y, iy );
```

```
vcUnpackM( n, a, y, my );
vzUnpackI( n, a, y, incy );
vzUnpackV( n, a, y, iy );
vzUnpackM( n, a, y, my );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the number of elements to be calculated.
a	**FORTRAN 77:** `REAL` for `vsunpacki, vsunpackv, vsunpackm` `DOUBLE PRECISION` for `vdunpacki, vdunpackv, vdunpackm` `COMPLEX` for `vcunpacki, vcunpackv, vcunpackm` `DOUBLE COMPLEX` for `vzunpacki, vzunpackv, vznpackm` **Fortran 90:** `REAL, INTENT(IN)` for `vsunpacki, vsunpackv, vsunpackm` `DOUBLE PRECISION, INTENT(IN)` for `vdunpacki, vdunpackv, vdunpackm` `COMPLEX, INTENT(IN)` for `vcunpacki, vcunpackv, vcunpackm` `DOUBLE COMPLEX, INTENT(IN)` for `vzunpacki, vzunpackv, vzunpackm` **C:** `const float*` for `vsUnpackI, vsUnpackV, vsUnpackM` `const double*` for `vdUnpackI, vdUnpackV, vdUnpackM` `const MKL_Complex8*` for `vcUnpackI, vcUnpackV, vcUnpackM` `const MKL_Complex16*` for `vzUnpackI, vzUnpackV, vzUnpackM`	**FORTRAN:** Array, `DIMENSION` at least *n*. Specifies the input vector *a*. **C:** Specifies the pointer to an array of size at least *n* that contains the input vector *a*.
incy	**FORTRAN 77:** `INTEGER` for `vsunpacki, vdunpacki, vcunpacki, vzunpacki`	Specifies the increment for the elements of *y*.

Name	Type	Description
	Fortran 90: INTEGER, INTENT(IN) for vsunpacki, vdunpacki, vcunpacki, vzunpacki **C:** const int for vsUnpackI, vdUnpackI, vcUnpackI, vzUnpackI	
iy	**FORTRAN 77:** INTEGER for vsunpackv, vdunpackv, vcunpackv, vzunpackv **Fortran 90:** INTEGER, INTENT(IN) for vsunpackv, vdunpackv, vcunpackv, vzunpackv **C:** const int* for vsUnpackV, vdUnpackV, vcUnpackV, vzUnpackV	**FORTRAN:** Array, DIMENSION at least *n*. Specifies the index vector for the elements of *y*. **C:** Specifies the pointer to an array of size at least *n* that contains the index vector for the elements of *a*.
my	**FORTRAN 77:** INTEGER for vsunpackm, vdunpackm, vcunpackm, vzunpackm **Fortran 90:** INTEGER, INTENT(IN) for vsunpackm, vdunpackm, vcunpackm, vzunpackm **C:** const int* for vsUnpackM, vdUnpackM, vcUnpackM, vzUnpackM	**FORTRAN:** Array, DIMENSION at least *n*, Specifies the mask vector for the elements of *y*. **C:** Specifies the pointer to an array of size at least *n* that contains the mask vector for the elements of *a*.

Output Parameters

Name	Type	Description
y	**FORTRAN 77:** REAL for vsunpacki, vsunpackv, vsunpackm DOUBLE PRECISION for vdunpacki, vdunpackv, vdunpackm COMPLEX, INTENT(IN) for vcunpacki, vcunpackv, vcunpackm DOUBLE COMPLEX, INTENT(IN) for vzunpacki, vzunpackv, vzunpackm **Fortran 90:** REAL, INTENT(OUT) for vsunpacki, vsunpackv, vsunpackm DOUBLE PRECISION, INTENT(OUT) for vdunpacki, vdunpackv, vdunpackm COMPLEX, INTENT(OUT) for vcunpacki, vcunpackv, vcunpackm DOUBLE COMPLEX, INTENT(OUT) for vzunpacki, vzunpackv, vzunpackm	**FORTRAN:** Array, DIMENSION for v?unpacki, at least (1 + (*n*-1)**incy*) for v?unpackv, at least max(*n*,max(*iy*[j])),j=0,..., *n*-1 for v?unpackm, at least *n* **C:** Specifies the pointer to an array that contains the output vector *y*. The array must be: for v?UnpackI, at least (1 + (*n*-1)**incy*) for v?UnpackV, at least max(*n*,max(*ia*[j])),j=0,..., *n*-1, for v?UnpackM, at least *n*.

Name	Type	Description
	C: `float*` for `vsUnpackI`, `vsUnpackV`, `vsUnpackM` `double*` for `vdUnpackI`, `vdUnpackV`, `vdUnpackM` `const MKL_Complex8*` for `vcUnpackI`, `vcUnpackV`, `vcUnpackM` `const MKL_Complex16*` for `vzUnpackI`, `vzUnpackV`, `vzUnpackM`	

VML Service Functions

The VML Service functions enable you to set/get the accuracy mode and error code. These functions are available both in the Fortran and C interfaces. The table below lists available VML Service functions and their short description.

VML Service Functions

Function Short Name	Description
`vmlSetMode`	Sets the VML mode
`vmlGetMode`	Gets the VML mode
`vmlSetErrStatus`	Sets the VML Error Status
`vmlGetErrStatus`	Gets the VML Error Status
`vmlClearErrStatus`	Clears the VML Error Status
`vmlSetErrorCallBack`	Sets the additional error handler callback function
`vmlGetErrorCallBack`	Gets the additional error handler callback function
`vmlClearErrorCallBack`	Deletes the additional error handler callback function

vmlSetMode

Sets a new mode for VML functions according to the `mode` *parameter and stores the previous VML mode to* `oldmode`*.*

Syntax

Fortran:

```
oldmode = vmlsetmode( mode )
```

C:

```
oldmode = vmlSetMode( mode );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
mode	**FORTRAN 77:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8), INTENT(IN) **C:** const MKL_INT64	Specifies the VML mode to be set.

Output Parameters

Name	Type	Description
oldmode	**FORTRAN:** INTEGER*8 **Fortran 90:** INTEGER(KIND=8) **C:** MKL_INT64	Specifies the former VML mode.

Description

The vmlSetMode function sets a new mode for VML functions according to the *mode* parameter and stores the previous VML mode to *oldmode*. The mode change has a global effect on all the VML functions within a thread.

NOTE You can override the global mode setting and change the mode for a given VML function call by using a respective vm[s,d]<Func> variant of the function.

The *mode* parameter is designed to control accuracy, handling of denormalized numbers, and error handling. Table "Values of the *mode* Parameter" lists values of the *mode* parameter. You can obtain all other possible values of the *mode* parameter from the *mode* parameter values by using bitwise OR (|) operation to combine one value for accuracy, one value for handling of denormalized numbers, and one vlaue for error control options. The default value of the *mode* parameter is VML_HA | VML_FTZDAZ_OFF | VML_ERRMODE_DEFAULT.

The VML_FTZDAZ_ON mode is specifically designed to improve the performance of computations that involve denormalized numbers at the cost of reasonable accuracy loss. This mode changes the numeric behavior of the functions: denormalized input values are treated as zeros (DAZ = denormals-are-zero) and denormalized results are flushed to zero (FTZ = flush-to-zero). Accuracy loss may occur if input and/or output values are close to denormal range.

Values of the *mode* Parameter

Value of *mode*	Description
Accuracy Control	
VML_HA	high accuracy versions of VML functions
VML_LA	low accuracy versions of VML functions
VML_EP	enhanced performance accuracy versions of VML functions
Denormalized Numbers Handling Control	
VML_FTZDAZ_ON	Faster processing of denormalized inputs is enabled.
VML_FTZDAZ_OFF	Faster processing of denormalized inputs is disabled.
Error Mode Control	
VML_ERRMODE_IGNORE	No action is set for computation errors.
VML_ERRMODE_ERRNO	On error, the *errno* variable is set.

Value of *mode*	Description
VML_ERRMODE_STDERR	On error, the error text information is written to *stderr*.
VML_ERRMODE_EXCEPT	On error, an exception is raised.
VML_ERRMODE_CALLBACK	On error, an additional error handler function is called.
VML_ERRMODE_DEFAULT	On error, the *errno* variable is set, an exception is raised, and an additional error handler function is called.

Examples

The following example shows how to set low accuracy, fast processing for denormalized numbers and errno error mode in the Fortran and C languages:

```
oldmode = vmlsetmode( VML_LA )
call vmlsetmode( IOR(VML_LA, VML_FTZDAZ_ON, VML_ERRMODE_ERRNO) )

vmlSetMode( VML_LA );
vmlSetMode( VML_LA | VML_FTZDAZ_ON | VML_ERRMODE_ERRNO );
```

vmlGetMode

Gets the VML mode.

Syntax

Fortran:

```
mod = vmlgetmode()
```

C:

```
mod = vmlGetMode( void );
```

Include Files

- FORTRAN 77: mkl_vml.f77
- Fortran 90: mkl_vml.f90
- C: mkl_vml_functions.h

Output Parameters

Name	Type	Description
mod	**FORTRAN:** INTEGER **C:** int	Specifies the packed *mode* parameter.

Description

The function vmlGetMode() returns the VML *mode* parameter that controls accuracy, handling of denormalized numbers, and error handling options. The *mod* variable value is a combination of the values listed in the table "Values of the *mode* Parameter". You can obtain these values using the respective mask from the table "Values of Mask for the *mode* Parameter".

Values of Mask for the *mode* Parameter

Value of mask	Description
VML_ACCURACY_MASK	Specifies mask for accuracy *mode* selection.

Value of mask	Description
VML_FTZDAZ_MASK	Specifies mask for FTZDAZ *mode* selection.
VML_ERRMODE_MASK	Specifies mask for error *mode* selection.

See example below:

Examples

```
mod = vmlgetmode()
accm = IAND(mod, VML_ACCURACY_MASK)
denm = IAND(mod, VML_FTZDAZ_MASK)
errm = IAND(mod, VML_ERRMODE_MASK)

accm = vmlGetMode(void )& VML_ACCURACY_MASK;
denm = vmlGetMode(void )& VML_FTZDAZ_MASK;
errm = vmlGetMode(void )& VML_ERRMODE_MASK;
```

vmlSetErrStatus

Sets the new VML Error Status according to `err` *and stores the previous VML Error Status to* `olderr`.

Syntax

Fortran:

```
olderr = vmlseterrstatus( err )
```

C:

```
olderr = vmlSetErrStatus( err );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name	Type	Description
err	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Specifies the VML error status to be set.

Output Parameters

Name	Type	Description
olderr	**FORTRAN:** `INTEGER` **C:** `int`	Specifies the former VML error status.

Description

Table "Values of the VML Status" lists possible values of the *err* parameter.

Values of the VML Status

Status	Description
Successful Execution	
VML_STATUS_OK	The execution was completed successfully.
Warnings	
VML_STATUS_ACCURACYWARNING	The execution was completed successfully in a different accuracy mode.
Errors	
VML_STATUS_BADSIZE	The function does not support the preset accuracy mode. The Low Accuracy mode is used instead.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.
VML_STATUS_SING	At least one of the input array values causes a divide-by-zero exception or produces an invalid (QNaN) result.
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

Examples

```
olderr = vmlSetErrStatus( VML_STATUS_OK );
olderr = vmlSetErrStatus( VML_STATUS_ERRDOM );
olderr = vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

vmlGetErrStatus

Gets the VML Error Status.

Syntax

Fortran:

```
err = vmlgeterrstatus( )
```

C:

```
err = vmlGetErrStatus( void );
```

Include Files

- FORTRAN 77: mkl_vml.f77
- Fortran 90: mkl_vml.f90
- C: mkl_vml_functions.h

Output Parameters

Name	Type	Description
err	**FORTRAN:** INTEGER **C:** int	Specifies the VML error status.

vmlClearErrStatus

Sets the VML Error Status to `VML_STATUS_OK` *and stores the previous VML Error Status to* `olderr`*.*

Syntax

Fortran:

```
olderr = vmlclearerrstatus( )
```

C:

```
olderr = vmlClearErrStatus( void );
```

Include Files

- FORTRAN 77: `mkl_vml.f77`
- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Output Parameters

Name	Type	Description
olderr	**FORTRAN:** `INTEGER` **C:** `int`	Specifies the former VML error status.

vmlSetErrorCallBack

Sets the additional error handler callback function and gets the old callback function.

Syntax

Fortran:

```
oldcallback = vmlseterrorcallback( callback )
```

C:

```
oldcallback = vmlSetErrorCallBack( callback );
```

Include Files

- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Input Parameters

Name		Description
FORTRAN: *callback*	Address of the callback function.	The callback function has the following format: `INTEGER FUNCTION ERRFUNC(par)` `TYPE (ERROR_STRUCTURE) par` `! ...` `! user error processing` `! ...` `ERRFUNC = 0` `! if ERRFUNC= 0 - standard VML error handler` `! is called after the callback` `! if ERRFUNC != 0 - standard VML error handler` `! is not called` `END` The passed error structure is defined as follows: `TYPE ERROR_STRUCTURE SEQUENCE` `INTEGER*4 ICODE` `INTEGER*4 IINDEX` `REAL*8 DBA1` `REAL*8 DBA2` `REAL*8 DBR1` `REAL*8 DBR2` `CHARACTER(64) CFUNCNAME` `INTEGER*4 IFUNCNAMELEN` `REAL*8 DBA1IM` `REAL*8 DBA2IM` `REAL*8 DBR1IM` `REAL*8 DBR2IM` `END TYPE ERROR_STRUCTURE`
C: *callback*	Pointer to the callback function.	The callback function has the following format: `static int __stdcall MyHandler(DefVmlErrorContext* pContext)` `{` `/* Handler body */` `};`

Name	Description
	The passed error structure is defined as follows: `typedef struct _DefVmlErrorContext` `{` `int iCode;/* Error status value */` `int iIndex;/* Index for bad array` `element, or bad array` `dimension, or bad` `array pointer */` `double dbA1; /* Error argument 1 */` `double dbA2; /* Error argument 2 */` `double dbR1; /* Error result 1 */` `double dbR2; /* Error result 2 */` `char cFuncName[64]; /* Function name */` `int iFuncNameLen; /* Length of functionname*/` `double dbA1Im; /* Error argument 1, imag part*/` `double dbA2Im; /* Error argument 2, imag part*/` `double dbR1Im; /* Error result 1, imag part*/` `double dbR2Im; /* Error result 2, imag part*/` `} DefVmlErrorContext;`

Output Parameters

Name	Type	Description
oldcallback	**Fortran 90:** `INTEGER` **C:** `int`	**FORTRAN:** Address of the former callback function. **C:** Pointer to the former callback function.

NOTE This function does not have a FORTRAN 77 interface due to the use of internal structures.

Description

The callback function is called on each VML mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see "Values of the *mode* Parameter").

Use the `vmlSetErrorCallBack()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code
- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns *0*.

vmlGetErrorCallBack

Gets the additional error handler callback function.

Syntax

Fortran:

```
callback = vmlgeterrorcallback( )
```

C:

```
callback = vmlGetErrorCallBack( void );
```

Include Files

- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Output Parameters

Name	Description
callback	**Fortran 90:** Address of the callback function **C:** Pointer to the callback function

vmlClearErrorCallBack

Deletes the additional error handler callback function and retrieves the former callback function.

Syntax

Fortran:

```
oldcallback = vmlclearerrorcallback( )
```

C:

```
oldcallback = vmlClearErrorCallBack( void );
```

Include Files

- Fortran 90: `mkl_vml.f90`
- C: `mkl_vml_functions.h`

Output Parameters

Name	Type	Description
oldcallback	**Fortran 90:** `INTEGER` **C:** `int`	**FORTRAN:** Address of the former callback function **C:** Pointer to the former callback function

10 Statistical Functions

Statistical functions in Intel® MKL are known as Vector Statistical Library (VSL) that is designed for the purpose of

- generating vectors of pseudorandom and quasi-random numbers
- performing mathematical operations of convolution and correlation
- computing basic statistical estimates for single and double precision multi-dimensional datasets

The corresponding functionality is described in the respective Random Number Generators, Convolution and Correlation, and VSL Summary Statistics sections.

See VSL performance data in the online VSL Performance Data document available at http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/

The basic notion in VSL is a task. The task object is a data structure or descriptor that holds the parameters related to a specific statistical operation: random number generation, convolution and correlation, or summary statistics estimation. Such parameters can be an identifier of a random number generator, its internal state and parameters, data arrays, their shape and dimensions, an identifier of the operation and so forth. You can modify the VSL task parameters using the respective service functionality of the library.

Random Number Generators

Intel MKL VSL provides a set of routines implementing commonly used pseudo- or quasi-random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and the library of vector mathematical functions (VML, see Chapter 9, "Vector Mathematical Functions").

VSL provides interfaces both for Fortran and C languages. For users of the C and C++ languages the `mkl_vsl.h` header file is provided. For users of the Fortran 90 or Fortran 95 language the `mkl_vsl.f90` header file is provided. The `mkl_vsl.fi` header file available in the previous versions of Intel MKL is retained for backward compatibility. For users of the FORTRAN 77 language the `mkl_vsl.f77` header file is provided. All header files are found in the following directory:

```
${MKL}/include
```

The `mkl_vsl.f90` header is intended for using via the Fortran `include` clause and is compatible with both standard forms of F90/F95 sources - the free and 72-columns fixed forms. If you need to use the VSL interface with 80- or 132-columns fixed form sources, you may add a new file to your project. That file is formatted as a 72-columns fixed-form source and consists of a single `include` clause as follows:

```
include 'mkl_vsl.f90'
```

This `include` clause causes the compiler to generate the module files `mkl_vsl.mod` and `mkl_vsl_type.mod`, which are used to process the Fortran use clauses referencing to the VSL interface:

```
use mkl_vsl_type
```

```
use mkl_vsl
```

Because of this specific feature, you do not need to include the `mkl_vsl.f90` header into each source of your project. You only need to include the header into some of the sources. In any case, make sure that the sources that depend on the VSL interface are compiled after those that include the header so that the module files `mkl_vsl.mod` and `mkl_vsl_type.mod` are generated prior to using them.

The `mkl_vsl.f77` header is intended for using via the Fortran `include` clause as follows:

```
include 'mkl_vsl.f77'
```

NOTE For Fortran 90 interface, VSL provides both subroutine-style interface and function-style interface. Default interface in this case is a function-style interface. Function-style interface, unlike subroutine-style interface, allows the user to get error status of each routine. Subroutine-style interface is provided for backward compatibility only. To use subroutine-style interface, manually include `mkl_vsl_subroutine.fi` file instead of `mkl_vsl.f90` by changing the line `include 'mkl_vsl.f90'` in `include\mkl.fi` with the line `include 'mkl_vsl_subroutine.fi'`.

For the FORTRAN 77 interface, VSL provides only function-style interface.

All VSL routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are either pseudorandom number generators or quasi-random number generators. Detailed description of the generators can be found in Distribution Generators section.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in Service Routines section.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see Advanced Service Routines section).

The last two categories are referred to as service routines.

Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to the '*Random Numbers*' section in VSL Notes document provided at the Intel® MKL web page.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See VSL Notes for the description of methods available for each generator.

An RNG task determines environment in which random number generation is performed, in particular parameters of the BRNG and its internal state. Output of VSL generators is a stream of random numbers that are used in Monte Carlo simulations. A *random stream descriptor* and a *random stream* are used as synonyms of an *RNG task* in the document unless the context requires otherwise.

The *random stream descriptor* specifies which BRNG should be used in a given transformation method. See the *Random Streams and RNGs in Parallel Computation* section of VSL Notes.

The term *computational node* means a logical or physical unit that can process data in parallel.

Mathematical Notation

The following notation is used throughout the text:

N	The set of natural numbers $N = \{1, 2, 3 \ldots\}$.
Z	The set of integers $Z = \{\ldots -3, -2, -1, 0, 1, 2, 3 \ldots\}$.
R	The set of real numbers.
$\lfloor a \rfloor$	The floor of a (the largest integer less than or equal to a).
$\oplus$ or **xor**	Bitwise exclusive OR.
C_α^κ or $\binom{\alpha}{\kappa}$	Binomial coefficient or combination $(\alpha \in R,\ \alpha \geq 0;\ k \in N \cup \{0\})$.

$$C_\alpha^0 = 1$$

For $\alpha \geq k$ binomial coefficient is defined as

$$C_\alpha^\kappa = \frac{\alpha(\alpha - 1) \ldots (\alpha - \kappa + 1)}{\kappa!}$$

If $\alpha < k$, then

$$C_\alpha^\kappa = 0$$

$\Phi(x)$	Cumulative Gaussian distribution function

$$\Phi(x) = \int_{-\infty}^{x} \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$$

defined over $-\infty < x < +\infty$.
$\Phi(-\infty) = 0$, $\Phi(+\infty) = 1$.

$\Gamma(\alpha)$	The complete gamma function

$$\Gamma(\alpha) = \int_0^\infty t^{\alpha-1} e^{-t}\, dt$$

where $\alpha > 0$.

$B(p, q)$	The complete beta function

$$B(p,q) = \int_0^1 t^{p-1}(1 - t)^{q-1} dt$$

where $p>0$ and $q>0$.

LCG(*a*,*c*, *m*)	Linear Congruential Generator $x_{n+1} = (ax_n + c) \bmod m$, where *a* is called the *multiplier*, *c* is called the *increment*, and *m* is called the *modulus* of the generator.
MCG(*a*,*m*)	Multiplicative Congruential Generator $x_{n+1} = (ax_n) \bmod m$ is a special case of Linear Congruential Generator, where the increment *c* is taken to be 0.
GFSR(*p*, *q*)	Generalized Feedback Shift Register Generator $x_n = x_{n-p} \oplus x_{n-q}$.

Naming Conventions

The names of the Fortran routines in VSL random number generators are lowercase (`virnguniform`). The names are not case-sensitive.

In C, the names of the routines, types, and constants are case-sensitive and can be lowercase and uppercase `viRngUniform`).

The names of generator routines have the following structure:

`v<type of result>rng<distribution>` for the Fortran interface

`v<type of result>Rng<distribution>` for the C interface,

where

- `v` is the prefix of a VSL vector function.
- <*type of result*> is either `s`, `d`, or `i` and specifies one of the following types:

`s`	`REAL` for the Fortran interface `float` for the C interface
`d`	`DOUBLE PRECISION` for the Fortran interface `double` for the C interface
`i`	`INTEGER` for the Fortran interface `int` for the C interface Prefixes `s` and `d` apply to continuous distributions only, prefix `i` applies only to discrete case.

- `rng` indicates that the routine is a random generator.
- <*distribution*> specifies the type of statistical distribution.

Names of service routines follow the template below:

```
vsl<name>
```

where

- `vsl` is the prefix of a VSL service function.
- <*name*> contains a short function name.

For a more detailed description of service routines, refer to Service Routines and Advanced Service Routines sections.

Prototype of each generator routine corresponding to a given probability distribution fits the following structure:

```
status = <function name>( method, stream, n, r, [<distribution parameters>] )
```

where

- *method* defines the method of generation. A detailed description of this parameter can be found in table "Values of <*method*> in *method* parameter". See the next page, where the structure of the *method* parameter name is explained.
- *stream* defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in Random Streams and Service Routines.
- *n* defines the number of random values to be generated. If *n* is less than or equal to zero, no values are generated. Furthermore, if *n* is negative, an error condition is set.

- *r* defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least *n* random numbers.
- *status* defines the error status of a VSL routine. See Error Reporting section for a detailed description of error status values.

Additional parameters included into *<distribution parameters>* field are individual for each generator routine and are described in detail in Distribution Generators section.

To invoke a distribution generator, use a call to the respective VSL routine. For example, to obtain a vector *r*, composed of *n* independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value *a* and standard deviation *sigma*, write the following:

for the Fortran interface

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
```

for the C interface

```
status = vsRngGaussian( method, stream, n, r, a, sigma )
```

The name of a *method* parameter has the following structure:

```
VSL_RNG_METHOD_method<distribution>_<method>
```

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

where

- *<distribution>* is the probability distribution.
- *<method>* is the method name.

Type of the name structure for the *method* parameter corresponds to fast and accurate modes of random number generation (see "Distribution Generators" section and VSL Notes for details).

Method names `VSL_RNG_METHOD_<distribution>_<method>`

and

`VSL_RNG_METHOD_<distribution>_<method>_ACCURATE`

should be used with

`v<precision>Rng<distribution>`

function only, where

- *<precision>* is

s	for single precision continuous distribution
d	for double precision continuous distribution
i	for discrete distribution

- *<distribution>* is the probability distribution.

is the probability distribution.Table "Values of *<method>* in *method* parameter" provides specific predefined values of the *method* name. The third column contains names of the functions that use the given method.

Values of *<method>* in *method* parameter

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (continuous), Uniform (discrete), UniformBits, UniformBits32, UniformBits64

Method	Short Description	Functions
BOXMULLER	BOXMULLER generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula: $x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	Gaussian, GaussianMV
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas: $x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	Gaussian, GaussianMV, Lognormal
ICDF	Inverse cumulative distribution function method.	Exponential, Laplace, Weibull, Cauchy, Rayleigh, Gumbel, Bernoulli, Geometric, Gaussian, GaussianMV
GNORM	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \le \alpha < 1$, a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.	Gamma
CJA	For $min(p, q) > 1$, Cheng method is used; for $min(p, q) < 1$, Johnk method is used, if $q + K \cdot p^2 + C \le 0$ (K = 0.852..., C=-0.956...) otherwise, Atkinson switching algorithm is used; for $max(p, q) < 1$, method of Johnk is used; for $min(p, q) < 1$, $max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Johnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used;for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.	Beta
BTPE	Acceptance/rejection method for $ntrial \cdot \min(p, 1 - p) \ge 30$ with decomposition into 4 regions: – 2 parallelograms – triangle – left exponential tail – right exponential tail	Binomial

Method	Short Description	Functions
H2PE	Acceptance/rejection method for large mode of distribution with decomposition into 3 regions: – rectangular – left exponential tail – right exponential tail	Hypergeometric
PTPE	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into 4 regions: – 2 parallelograms – triangle – left exponential tail – right exponential tail; otherwise, table lookup method is used.	Poisson
POISNORM	for $\lambda \geq 1$, method based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.	Poisson, PoissonV
NBAR	Acceptance/rejection method for , $\frac{(a-1)\cdot(1-p)}{p} \geq 100$ with decomposition into 5 regions: – rectangular – 2 trapezoid – left exponential tail – right exponential tail	NegBinomial

NOTE In this document, routines are often referred to by their base name (`Gaussian`) when this does not lead to ambiguity. In the routine reference, the full name (`vsrnggaussian`, `vsRngGaussian`) is always used in prototypes and code examples.

Basic Generators

VSL provides the following BRNGs, which differ in speed and other properties:

- the 32-bit multiplicative congruential pseudorandom number generator *MCG(1132489760, 2^{31} -1)* [L'Ecuyer99]
- the 32-bit generalized feedback shift register pseudorandom number generator *GFSR(250,103)* [Kirkpatrick81]
- the combined multiple recursive pseudorandom number generator *MRG-32k3a* [L'Ecuyer99a]
- the 59-bit multiplicative congruential pseudorandom number generator *MCG(13^{13}, 2^{59})* from NAG Numerical Libraries [NAG]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [NAG]
- Mersenne Twister pseudorandom number generator *MT19937* [Matsumoto98] with period length 2^{19937}-1 of the produced sequence

- Set of 6024 Mersenne Twister pseudorandom number generators *MT2203* [Matsumoto98], [Matsumoto00]. Each of them generates a sequence of period length equal to 2^{2203}-1. Parameters of the generators provide mutual independence of the corresponding sequences.
- SIMD-oriented Fast Mersenne Twister pseudorandom number generator *SFMT19937* [Saito08] with a period length equal to 2^{19937}-1 of the produced sequence.

Besides these pseudorandom number generators, VSL provides two basic quasi-random number generators:

- Sobol quasi-random number generator [Sobol76], [Bratley88], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in VSL Notes.
- Niederreiter quasi-random number generator [Bratley92], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vslNewStreamEx` function. See additional details on interface for registration of the parameters in the library in VSL Notes.

See some testing results for the generators in VSL Notes and comparative performance data at http://software.intel.com/sites/products/documentation/hpc/mkl/vsl/vsl_data/vsl_performance_data.htm.

VSL provides means of registration of such user-designed generators through the steps described in Advanced Service Routines section.

For some basic generators, VSL provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 6024 generators designed to create up to 6024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

You may want to design and use your own basic generators. VSL provides means of registration of such user-designed generators through the steps described in Advanced Service Routines section.

There is also an option to utilize externally generated random numbers in VSL distribution generator routines. For this purpose VSL provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over (`a`,`b`) interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over (`a`,`b`) interval.

Such basic generators are called the abstract basic random number generators.

See VSL Notes for a more detailed description of the generator properties.

BRNG Parameter Definition

Predefined values for the *brng* input parameter are as follows:

Values of *brng* parameter

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MRG32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 6024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SFMT19937	A SIMD-oriented Fast Mersenne Twister pseudorandom number generator.
VSL_BRNG_SOBOL	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \le s \le 40$; user-defined dimensions are also available.
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \le s \le 318$; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.

See VSL Notes for detailed description.

Random Streams

Random stream (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. You can operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See VSL Notes for details.

NOTE Random streams associated with abstract basic random number generator are called the abstract random streams. See VSL Notes for detailed description of abstract streams and their use.

You can create unlimited number of random streams by VSL Service Routines like NewStream and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine DeleteStream.

VSL provides service functions SaveStreamF and LoadStreamF to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See VSL Notes for detailed description.

Data Types

FORTRAN 77:

```
INTEGER*4 vslstreamstate(2)
```

Fortran 90:

```
TYPE
        VSL_STREAM_STATE

INTEGER*4 descriptor1

INTEGER*4 descriptor2

END
        TYPE VSL_STREAM_STATE
```

C:

```
typedef (void*) VSLStreamStatePtr;
```

See Advanced Service Routines for the format of the stream state structure for user-designed generators.

Error Reporting

VSL RNG routines return status codes of the performed operation to report errors to the calling program. The application should perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

VSL_ERROR_<*ERROR_NAME*> - indicates VSL errors common for all VSL domains.

VSL_RNG_ERROR_<*ERROR_NAME*> - indicates VSL RNG errors.

VSL RNG errors are of negative values while warnings are of positive values. The status code of zero value indicates successful completion of the operation: VSL_ERROR_OK (or synonymic VSL_STATUS_OK).

Status Codes

Status Code	Description
Common VSL	
VSL_ERROR_OK, VSL_STATUS_OK	No error, execution is successful.
VSL_ERROR_BADARGS	Input argument value is not valid.
VSL_ERROR_CPU_NOT_SUPPORTED	CPU version is not supported.
VSL_ERROR_FEATURE_NOT_IMPLEMENTED	Feature invoked is not implemented.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory.
VSL_ERROR_NULL_PTR	Input pointer argument is NULL.
VSL_ERROR_UNKNOWN	Unknown error.
VSL RNG Specific	
VSL_RNG_ERROR_BAD_FILE_FORMAT	File format is unknown.

Status Code	Description
VSL_RNG_ERROR_BAD_MEM_FORMAT	Descriptive random stream format is unknown.
VSL_RNG_ERROR_BAD_NBITS	The value in NBits field is bad.
VSL_RNG_ERROR_BAD_NSEEDS	The value in NSeeds field is bad.
VSL_RNG_ERROR_BAD_STREAM	The random stream is invalid.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	The value in StreamStateSize field is bad.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax.
VSL_RNG_ERROR_BAD_WORD_SIZE	The value in WordSize field is bad.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_RNG_ERROR_FILE_CLOSE	Error in closing the file.
VSL_RNG_ERROR_FILE_OPEN	Error in opening the file.
VSL_RNG_ERROR_FILE_READ	Error in reading the file.
VSL_RNG_ERROR_FILE_WRITE	Error in writing the file.
VSL_RNG_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator is exceeded.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.

VSL RNG Usage Model

A typical algorithm for VSL random number generators is as follows:

1. Create and initialize stream/streams. Functions vslNewStream, vslNewStreamEx, vslCopyStream, vslCopyStreamState, vslLeapfrogStream, vslSkipAheadStream.
2. Call one or more RNGs.
3. Process the output.
4. Delete the stream/streams. Function vslDeleteStream.

NOTE You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following C example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters *a* = 5 and *sigma* = 2. Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

C Example of VSL RNG Usage

```
#include <stdio.h>
#include "mkl_vsl.h"

int main()
{
   double r[1000]; /* buffer for random numbers */
   double s; /* average */
   VSLStreamStatePtr stream;
   int i, j;

   /* Initializing */
   s = 0.0;
   vslNewStream( &stream, VSL_BRNG_MT19937, 777 );

   /* Generating */
   for ( i=0; i<10; i++ );
   {
      vdRngGaussian( VSL_RNG_METHOD_GAUSSIAN_ICDF, stream, 1000, r, 5.0, 2.0 );
      for ( j=0; j<1000; j++ );
      {
         s += r[j];
      }
   }
   s /= 10000.0;

   /* Deleting the stream */
   vslDeleteStream( &stream );

   /* Printing results */
   printf( "Sample mean of normal distribution = %f\n", s );

   return 0;
}
```

The Fortran version of the same example is below:

Fortran Example of VSL RNG Usage

```
      include 'mkl_vsl.f90'

      program MKL_VSL_GAUSSIAN

      USE MKL_VSL_TYPE
      USE MKL_VSL

      real(kind=8) r(1000)  ! buffer for random numbers
      real(kind=8) s        ! average
      real(kind=8) a, sigma ! parameters of normal distribution

      TYPE (VSL_STREAM_STATE) :: stream

      integer(kind=4) errcode
      integer(kind=4) i,j
      integer brng,method,seed,n

      n = 1000
      s = 0.0
      a = 5.0
```

```
      sigma  = 2.0
      brng=VSL_BRNG_MT19937
      method=VSL_RNG_METHOD_GAUSSIAN_ICDF
      seed=777

!     ***** Initializing *****
      errcode=vslnewstream( stream, brng,  seed )

!     ***** Generating *****
      do i = 1,10
          errcode=vdrnggaussian( method, stream, n, r, a, sigma )
          do j = 1, 1000
              s = s + r(j)
          end do
      end do

      s = s / 10000.0

!     ***** Deinitialize *****
      errcode=vsldeletestream( stream )

!     ***** Printing results *****
      print *,"Sample mean of normal distribution = ", s

      end
```

Additionally, examples that demonstrate usage of VSL random number generators are available in the following directories:

`${MKL}/examples/vslc/source`

`${MKL}/examples/vslf/source`

Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. Table "Service Routines" lists all available service routines

Service Routines

Routine	Short Description
vslNewStream	Creates and initializes a random stream.
vslNewStreamEx	Creates and initializes a random stream for the generators with multiple initial conditions.
vsliNewAbstractStream	Creates and initializes an abstract random stream for integer arrays.
vsldNewAbstractStream	Creates and initializes an abstract random stream for double precision floating-point arrays.
vslsNewAbstractStream	Creates and initializes an abstract random stream for single precision floating-point arrays.
vslDeleteStream	Deletes previously created stream.
vslCopyStream	Copies a stream to another stream.
vslCopyStreamState	Creates a copy of a random stream state.
vslSaveStreamF	Writes a stream to a binary file.
vslLoadStreamF	Reads a stream from a binary file.

Routine	Short Description
vslSaveStreamM	Writes a random stream descriptive data, including state, to a memory buffer.
vslLoadStreamM	Creates a new stream and reads stream descriptive data, including state, from the memory buffer.
vslGetStreamSize	Computes size of memory necessary to hold the random stream.
vslLeapfrogStream	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
vslSkipAheadStream	Initializes the stream by the skip-ahead method.
vslGetStreamStateBrng	Obtains the index of the basic generator responsible for the generation of a given random stream.
vslGetNumRegBrngs	Obtains the number of currently registered basic generators.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream (vslNewStream, vslNewStreamEx, vslCopyStream, vslCopyStreamState, vslLeapfrogStream, vslSkipAheadStream).
2. Generating random numbers with given distribution, see Distribution Generators.
3. Deleting the stream (vslDeleteStream).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the vslDeleteStream function to delete all the streams afterwards.

vslNewStream

Creates and initializes a random stream.

Syntax

Fortran:

```
status = vslnewstream( stream, brng, seed )
```

C:

```
status = vslNewStream( &stream, brng, seed );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
brng	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Index of the basic generator to initialize the stream. See Table Values of *brng* parameter for specific value.

Name	Type	Description
seed	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const unsigned int`	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that brng can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(OUT)` **C:** `VSLStreamStatePtr*`	Stream state descriptor

Description

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. See VSL Notes for a more detailed description of stream initialization for different basic generators.

NOTE This function is not applicable for abstract basic random number generators. Please use `vsliNewAbstractStream`, `vslsNewAbstractStream` or `vsldNewAbstractStream` to utilize integer, single-precision or double-precision external random data respectively.

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_RNG_ERROR_INVALID_BRNG_INDEX`	BRNG index is invalid.
`VSL_ERROR_MEM_FAILURE`	System cannot allocate memory for *stream*.

vslNewStreamEx

Creates and initializes a random stream for generators with multiple initial conditions.

Syntax

Fortran:

```
status = vslnewstreamex( stream, brng, n, params )
```

C:

```
status = vslNewStreamEx( &stream, brng, n, params );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
brng	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Index of the basic generator to initialize the stream. See Table "Values of *brng* parameter" for specific value.
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Number of initial conditions contained in *params*
params	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER(KIND=4), INTENT(IN) **C:** const unsigned int	Array of initial conditions necessary for the basic generator *brng* to initialize the stream. In the case of a quasi-random number generator only the first element in *params* parameter is used to set the dimension. If the dimension is greater than the dimension that *brng* can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE(VSL_STREAM_STATE), INTENT(OUT) **C:** VSLStreamStatePtr*	Stream state descriptor

Description

The vslNewStreamEx function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use vslNewStream, which is analogous to vslNewStreamEx except that it takes only one 32-bit initial condition. In particular, vslNewStreamEx may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in VSL Notes.

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See VSL Notes for the format for their passing and registration in VSL.

NOTE This function is not applicable for abstract basic random number generators. Please use vsliNewAbstractStream, vslsNewAbstractStream or vsldNewAbstractStream to utilize integer, single-precision or double-precision external random data respectively.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.

VSL_ERROR_MEM_FAILURE	System cannot allocate memory for *stream*.

vsliNewAbstractStream

Creates and initializes an abstract random stream for integer arrays.

Syntax

Fortran:

```
status = vslinewabstractstream( stream, n, ibuf, icallback )
```

C:

```
status = vsliNewAbstractStream( &stream, n, ibuf, icallback );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Size of the array *ibuf*
ibuf	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER(KIND=4), INTENT(IN) **C:** const unsigned int	Array of *n* 32-bit integers
icallback	See *Note* below	**Fortran:** Address of the callback function used for *ibuf* update **C:** Pointer to the callback function used for *ibuf* update

NOTE Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION IUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
INTEGER*4 ibuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION IUPDATEFUNC[C]( stream, n, ibuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN)     :: n[reference]
INTEGER(KIND=4),INTENT(OUT)    :: ibuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)     :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)     :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)     :: idx[reference]
```

Format of the callback function in C:

```
int iUpdateFunc( VSLStreamStatePtr stream, int* n, unsigned int ibuf[], int* nmin, int* nmax,
int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. Table `icallback` Callback Function Parameters gives the description of the callback function parameters.

icallback Callback Function Parameters

Parameters	Short Description
stream	Abstract random stream descriptor
n	Size of *ibuf*
ibuf	Array of random numbers associated with the stream *stream*
nmin	Minimal quantity of numbers to update
nmax	Maximal quantity of numbers that can be updated
idx	Position in cyclic buffer *ibuf* to start update $0 \le idx < n$.

Output Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), TINTENT(OUT)` **C:** `VSLStreamStatePtr*`	Descriptor of the stream state structure

Description

The `vsliNewAbstractStream` function creates a new abstract stream and associates it with an integer array *ibuf* and your callback function *icallback* that is intended for updating of *ibuf* content.

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_BADARGS`	Parameter *n* is not positive.
`VSL_ERROR_MEM_FAILURE`	System cannot allocate memory for *stream*.
`VSL_ERROR_NULL_PTR`	Either buffer or callback function parameter is a `NULL` pointer.

vsldNewAbstractStream

Creates and initializes an abstract random stream for double precision floating-point arrays.

Syntax

Fortran:

```
status = vsldnewabstractstream( stream, n, dbuf, a, b, dcallback )
```

C:

```
status = vsldNewAbstractStream( &stream, n, dbuf, a, b, dcallback );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Size of the array *dbuf*
dbuf	**FORTRAN 77:** `DOUBLE PRECISION` **Fortran 90:** `REAL(KIND=8), INTENT(IN)` **C:** `const double`	Array of *n* double precision floating-point random numbers with uniform distribution over interval (`a`,`b`)
a	**FORTRAN 77:** `DOUBLE PRECISION` **Fortran 90:** `REAL(KIND=8), INTENT(IN)` **C:** `const double`	Left boundary `a`
b	**FORTRAN 77:** `DOUBLE PRECISION` **Fortran 90:** `REAL(KIND=8), INTENT(IN)` **C:** `const double`	Right boundary `b`
dcallback	See *Note* below	**Fortran:** Address of the callback function used for update of the array *dbuf* **C:** Pointer to the callback function used for update of the array *dbuf*

Output Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(OUT)` **C:** `VSLStreamStatePtr*`	Descriptor of the stream state structure

NOTE Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION DUPDATEFUNC( stream, n, dbuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
DOUBLE PRECISION dbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION DUPDATEFUNC[C]( stream, n, dbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER   :: stream[reference]
INTEGER(KIND=4),INTENT(IN)       :: n[reference]
REAL(KIND=8),INTENT(OUT)         :: dbuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)       :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)       :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)       :: idx[reference]
```

Format of the callback function in C:

```
int dUpdateFunc( VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int* nmax, int*
idx );
```

The callback function returns the number of elements in the array actually updated by the function. Table `dcallback` Callback Function Parameters gives the description of the callback function parameters.

dcallback Callback Function Parameters

Parameters	Short Description
stream	Abstract random stream descriptor
n	Size of *dbuf*
dbuf	Array of random numbers associated with the stream *stream*
nmin	Minimal quantity of numbers to update
nmax	Maximal quantity of numbers that can be updated
idx	Position in cyclic buffer *dbuf* to start update $0 \le idx < n$.

Description

The vsldNewAbstractStream function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval (a,b). The function associates the stream with a double precision array *dbuf* and your callback function *dcallback* that is intended for updating of *dbuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter *n* is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for *stream*.
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

vslsNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

Syntax

Fortran:

```
status = vslsnewabstractstream( stream, n, sbuf, a, b, scallback )
```

C:

```
status = vslsNewAbstractStream( &stream, n, sbuf, a, b, scallback );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Size of the array *sbuf*
sbuf	**FORTRAN 77:** REAL **Fortran 90:** REAL(KIND=4), INTENT(IN) **C:** const float	Array of *n* single precision floating-point random numbers with uniform distribution over interval (a,b)
a	**FORTRAN 77:** REAL **Fortran 90:** REAL(KIND=4), INTENT(IN) **C:** const float	Left boundary a

Name	Type	Description
b	**FORTRAN 77:** `REAL` **Fortran 90:** `REAL(KIND=4), INTENT(IN)` **C:** `const float`	Right boundary `b`
scallback	See *Note* below	**Fortran:** Address of the callback function used for update of the array *sbuf* **C:** Pointer to the callback function used for update of the array *sbuf*

Output Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(OUT)` **C:** `VSLStreamStatePtr*`	Descriptor of the stream state structure

NOTE Format of the callback function in FORTRAN 77:

```
INTEGER FUNCTION SUPDATEFUNC( stream, n, ibuf, nmin, nmax, idx )
INTEGER*4 stream(2)
INTEGER n
REAL sbuf(n)
INTEGER nmin
INTEGER nmax
INTEGER idx
```

Format of the callback function in Fortran 90:

```
INTEGER FUNCTION SUPDATEFUNC[C]( stream, n, sbuf, nmin, nmax, idx )
TYPE(VSL_STREAM_STATE),POINTER :: stream[reference]
INTEGER(KIND=4),INTENT(IN)     :: n[reference]
REAL(KIND=4),   INTENT(OUT)    :: sbuf[reference](0:n-1)
INTEGER(KIND=4),INTENT(IN)     :: nmin[reference]
INTEGER(KIND=4),INTENT(IN)     :: nmax[reference]
INTEGER(KIND=4),INTENT(IN)     :: idx[reference]
```

Format of the callback function in C:

```
int sUpdateFunc( VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int* nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. Table `scallback` Callback Function Parameters gives the description of the callback function parameters.

scallback Callback Function Parameters

Parameters	Short Description
stream	Abstract random stream descriptor
n	Size of *sbuf*
sbuf	Array of random numbers associated with the stream *stream*
nmin	Minimal quantity of numbers to update
nmax	Maximal quantity of numbers that can be updated
idx	Position in cyclic buffer *sbuf* to start update $0 \le idx < n$.

Description

The vslsNewAbstractStream function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (a,b). The function associates the stream with a single precision array *sbuf* and your callback function *scallback* that is intended for updating of *sbuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter *n* is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for *stream*.
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

vslDeleteStream

Deletes a random stream.

Syntax

Fortran:

```
status = vsldeletestream( stream )
```

C:

```
status = vslDeleteStream( &stream );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input/Output Parameters

Name	Type	Description
stream	**FORTRAN 77:** INTEGER*4 stream(2)	**Fortran:** Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the descriptor becomes invalid.

Name	Type	Description
	Fortran 90: `TYPE(VSL_STREAM_STATE), INTENT(OUT)` **C:** `VSLStreamStatePtr*`	**C:** Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to `NULL`.

Description

The function deletes the random stream created by one of the initialization functions.

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*`stream`* parameter is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*`stream`* is not a valid random stream.

vslCopyStream

Creates a copy of a random stream.

Syntax

Fortran:

```
status = vslcopystream( newstream, srcstream )
```

C:

```
status = vslCopyStream( &newstream, srcstream );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
`srcstream`	**FORTRAN 77:** `INTEGER*4 srcstream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(IN)` **C:** `const VSLStreamStatePtr`	**Fortran:** Descriptor of the stream to be copied **C:** Pointer to the stream state structure to be copied

Output Parameters

Name	Type	Description
`newstream`	**FORTRAN 77:** `INTEGER*4 newstream(2)`	Copied random stream descriptor

Name	Type	Description
	Fortran 90: `TYPE(VSL_STREAM_STATE), INTENT(OUT)` **C:** `VSLStreamStatePtr*`	

Description

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*srcstream* parameter is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*srcstream* is not a valid random stream.
`VSL_ERROR_MEM_FAILURE`	System cannot allocate memory for *newstream*.

vslCopyStreamState

Creates a copy of a random stream state.

Syntax

Fortran:

```
status = vslcopystreamstate( deststream, srcstream )
```

C:

```
status = vslCopyStreamState( deststream, srcstream );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
srcstream	**FORTRAN 77:** `INTEGER*4 srcstream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(IN)` **C:** `const VSLStreamStatePtr`	**Fortran:** Descriptor of the destination stream where the state of *scrstream* stream is copied **C:** Pointer to the stream state structure, from which the state structure is copied

Output Parameters

Name	Type	Description
deststream	**FORTRAN 77:** `INTEGER*4 deststream(2)`	**Fortran:** Descriptor of the stream with the state to be copied

Name	Type	Description
	Fortran 90: `TYPE(VSL_STREAM_STATE), INTENT(OUT)` **C:** `VSLStreamStatePtr`	**C:** Pointer to the stream state structure where the stream state is copied

Description

The `vslCopyStreamState` function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike `vslCopyStream` function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `vslCopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	Either *srcstream* or *deststream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	Either *srcstream* or *deststream* is not a valid random stream.
`VSL_RNG_ERROR_BRNGS_INCOMPATIBLE`	BRNG associated with *srcstream* is not compatible with BRNG associated with *deststream*.

vslSaveStreamF

Writes random stream descriptive data, including stream state, to binary file.

Syntax

Fortran:

```
errstatus = vslsavestreamf( stream, fname )
```

C:

```
errstatus = vslSaveStreamF( stream, fname );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(IN)`	Random stream to be written to the file

Name	Type	Description
	C: `const VSLStreamStatePtr`	
fname	**FORTRAN 77:** `CHARACTER(*)` **Fortran 90:** `CHARACTER(*), INTENT(IN)` **C:** `const char*`	**Fortran:** File name specified as a C-style null-terminated string **C:** File name specified as a Fortran-style character string

Output Parameters

Name	Type	Description
errstatus	**Fortran:** `INTEGER` **C:** `int`	Error status of the operation

Description

The `vslSaveStreamF` function writes the random stream descriptive data, including the stream state, to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. The random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. The random stream can be read from the binary file using the `vslLoadStreamF` function.

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	Either *fname* or *stream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.
`VSL_RNG_ERROR_FILE_OPEN`	Indicates an error in opening the file.
`VSL_RNG_ERROR_FILE_WRITE`	Indicates an error in writing the file.
`VSL_RNG_ERROR_FILE_CLOSE`	Indicates an error in closing the file.
`VSL_ERROR_MEM_FAILURE`	System cannot allocate memory for internal needs.

vslLoadStreamF

Creates new stream and reads stream descriptive data, including stream state, from binary file.

Syntax

Fortran:

```
errstatus = vslloadstreamf( stream, fname )
```

C:

```
errstatus = vslLoadStreamF( &stream, fname );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
fname	**FORTRAN 77:** CHARACTER(*) **Fortran 90:** CHARACTER(*), INTENT(IN) **C:** const char*	**Fortran:** File name specified as a C-style null-terminated string **C:** File name specified as a Fortran-style character string

Output Parameters

Name	Type	Description
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE(VSL_STREAM_STATE), INTENT(OUT) **C:** VSLStreamStatePtr*	**Fortran:** Descriptor of a new random stream **C:** Pointer to a new random stream
errstatus	**Fortran:** INTEGER **C:** int	Error status of the operation

Description

The vslLoadStreamF function creates a new stream and reads stream descriptive data, including the stream state, from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use vslSaveStreamF function.

CAUTION Calling vslLoadStreamF with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling vslLoadStreamF, you should call the vslDeleteStream function first to deallocate the resources.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*fname* is a NULL pointer.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_RNG_ERROR_BAD_FILE_FORMAT	Unknown file format.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is unsupported.

vslSaveStreamM

Writes random stream descriptive data, including stream state, to a memory buffer.

Syntax

Fortran:

```
errstatus = vslsavestreamm( stream, memptr )
```

C:

```
errstatus = vslSaveStreamM( stream, memptr );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(IN)` **C:** `const VSLStreamStatePtr`	Random stream to be written to the memory
memptr	**FORTRAN 77:** `INTEGER*1` **Fortran 90:** `INTEGER(KIND=1), DIMENSION(*), INTENT(IN)` **C:** `char*`	**Fortran:** Memory buffer to save random stream descriptive data to **C:** Memory buffer to save random stream descriptive data to

Output Parameters

Name	Type	Description
errstatus	**Fortran:** `INTEGER` **C:** `int`	Error status of the operation

Description

The `vslSaveStreamM` function writes the random stream descriptive data, including the stream state, to the memory at *memptr*. Random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. The *memptr* parameter must be a valid pointer to the memory of size sufficient to hold the random stream *stream*. Use the service routine `vslGetStreamSize` to determine this amount of memory.

If the stream cannot be saved to the memory, *errstatus* has a non-zero value. The random stream can be read from the memory pointed by *memptr* using the `vslLoadStreamM` function.

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	Either *memptr* or *stream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is a `NULL` pointer.
`VSL_ERROR_BAD_STREAM`	*stream* is not a valid random stream.

vslLoadStreamM

Creates a new stream and reads stream descriptive data, including stream state, from the memory buffer.

Syntax

Fortran:

```
errstatus = vslloadstreamm( stream, memptr )
```

C:

```
errstatus = vslLoadStreamM( &stream, memptr );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
memptr	**FORTRAN 77:** `INTEGER*1` **Fortran 90:** `INTEGER(KIND=1), DIMENSION(*), INTENT(IN)` **C:** `const char*`	**Fortran:** Memory buffer to load random stream descriptive data from **C:** Memory buffer to load random stream descriptive data from

Output Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(OUT)` **C:** `VSLStreamStatePtr*`	**Fortran:** Descriptor of a new random stream **C:** Pointer to a new random stream
errstatus	**Fortran:** `INTEGER` **C:** `int`	Error status of the operation

Description

The `vslLoadStreamM` function creates a new stream and reads stream descriptive data, including the stream state, from the memory buffer. A new random stream is created using the stream descriptive data from the memory pointer by *memptr*. If the stream cannot be read (for example, *memptr* is invalid), *errstatus* has a non-zero value. To save random stream to the memory, use `vslSaveStreamM` function. Use the service routine `vslGetStreamSize` to determine the amount of memory sufficient to hold the random stream.

CAUTION Calling `LoadStreamM` with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamM`, you should call the `vslDeleteStream` function first to deallocate the resources.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*memptr* is a NULL pointer.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_RNG_ERROR_BAD_MEM_FORMAT	Descriptive random stream format is unknown.

vslGetStreamSize

Computes size of memory necessary to hold the random stream.

Syntax

Fortran:

```
memsize = vslgetstreamsize( stream )
```

C:

```
memsize = vslGetStreamSize( stream );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE(VSL_STREAM_STATE), INTENT(IN) **C:** const VSLStreamStatePtr	Random stream

Output Parameters

Name	Type	Description
memsize	**Fortran:** INTEGER **C:** int	Amount of memory in bytes necessary to hold descriptive data of random stream *stream*

Description

The vslGetStreamSize function returns the size of memory in bytes which is necessary to hold the given random stream. Use the output of the function to allocate the buffer to which you will save the random stream by means of the vslSaveStreamM function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_BAD_STREAM	*stream* is a NULL pointer.

VSL_ERROR_BAD_STREAM	*stream* is not a valid random stream.

vslLeapfrogStream

Initializes a stream using the leapfrog method.

Syntax

Fortran:

```
status = vslleapfrogstream( stream, k, nstreams )
```

C:

```
status = vslLeapfrogStream( stream, k, nstreams );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

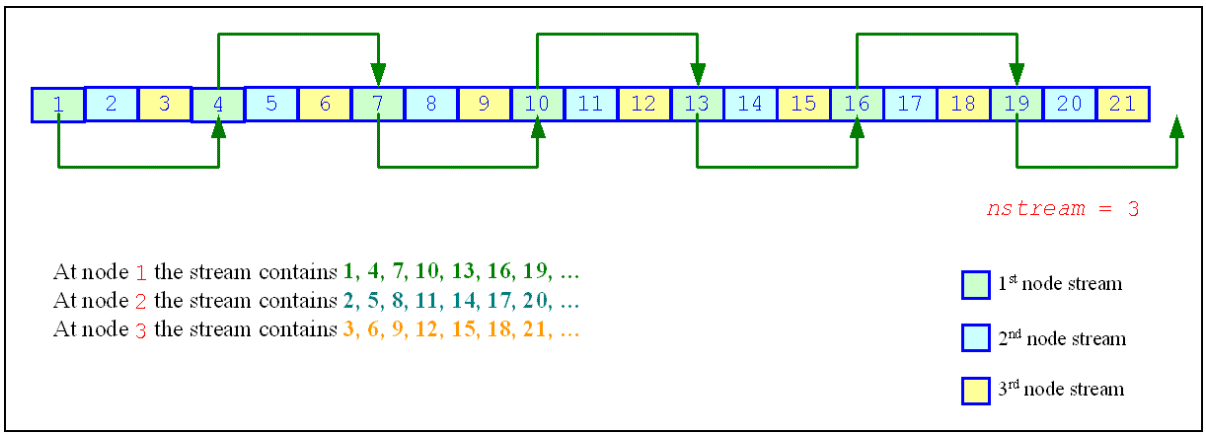
Name	Type	Description
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE(VSL_STREAM_STATE), INTENT(IN) **C:** VSLStreamStatePtr	**Fortran:** Descriptor of the stream to which leapfrog method is applied **C:** Pointer to the stream state structure to which leapfrog method is applied
k	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Index of the computational node, or stream number
nstreams	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Largest number of computational nodes, or stride

Description

The vslLeapfrogStream function generates random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the *nstreams* buffers without generating the original random sequence with subsequent manual distribution.

One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across *nstreams* computational nodes. The function initializes the original random stream (see Figure "Leapfrog Method") to generate random numbers for the computational node k, $0 \le k < nstreams$, where *nstreams* is the largest number of computational nodes used.

Leapfrog Method



The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See VSL Notes for details.

For quasi-random basic generators, the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case *nstreams* parameter should be equal to the dimension of the quasi-random vector while *k* parameter should be the index of a component to be generated ($0 \le k < nstreams$). Other parameters values are not allowed.

The following code examples illustrate the initialization of three independent streams using the leapfrog method:

Fortran 90 Code for Leapfrog Method

```
...
TYPE(VSL_STREAM_STATE)   ::stream1
TYPE(VSL_STREAM_STATE)   ::stream2
TYPE(VSL_STREAM_STATE)   ::stream3

! Creating 3 identical streams
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)
status = vslcopystream(stream2, stream1)
status = vslcopystream(stream3, stream1)

! Leapfrogging the streams
status = vslleapfrogstream(stream1, 0, 3)
status = vslleapfrogstream(stream2, 1, 3)
status = vslleapfrogstream(stream3, 2, 3)

! Generating random numbers
...
! Deleting the streams
status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

C Code for Leapfrog Method

```
...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);

/* Leapfrogging the streams
*/
status = vslLeapfrogStream(stream1, 0, 3);
status = vslLeapfrogStream(stream2, 1, 3);
status = vslLeapfrogStream(stream3, 2, 3);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.

vslSkipAheadStream

Initializes a stream using the block-splitting method.

Syntax

Fortran:

```
status = vslskipaheadstream( stream, nskip )
```

C:

```
status = vslSkipAheadStream( stream, nskip);
```

Include Files

- FORTRAN 77: mkl_vsl.f77

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

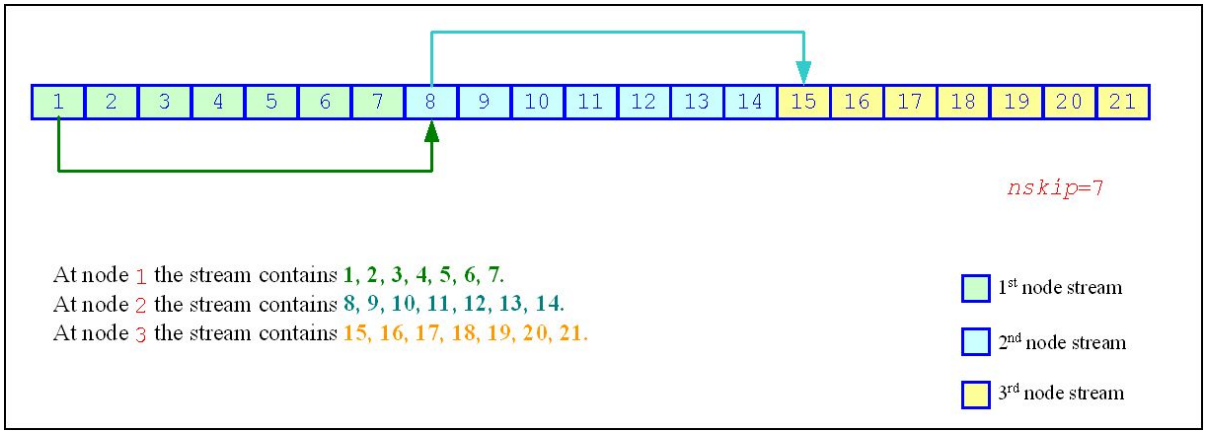
Input Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), INTENT(IN)` **C:** `VSLStreamStatePtr`	**Fortran:** Descriptor of the stream to which block-splitting method is applied **C:** Pointer to the stream state structure to which block-splitting method is applied
nskip	**FORTRAN 77:** `INTEGER*4 nskip(2)` **Fortran 90:** `INTEGER(KIND=8), INTENT(IN)` **C:** `const long long int`	Number of skipped elements

Description

The `vslSkipAheadStream` function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is *nskip*, then the original random sequence may be split by `vslSkipAheadStream` into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see Figure "Block-Splitting Method").

Block-Splitting Method



The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See VSL Notes for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Therefore, to skip NS quasi-random vectors, set the *nskip* parameter equal to the NS*DIMEN, where DIMEN is the dimension of the quasi-random vector. If this operation results in exceeding the period of the quasi-random number generator, which is 2^{32}-1, the library returns the VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED error code.

The following code examples illustrate how to initialize three independent streams using the vslSkipAheadStream function:

Fortran 90 Code for Block-Splitting Method

```
...
type(VSL_STREAM_STATE)  ::stream1
type(VSL_STREAM_STATE)  ::stream2
type(VSL_STREAM_STATE)  ::stream3

! Creating the 1st stream
status = vslnewstream(stream1, VSL_BRNG_MCG31, 174)

! Skipping ahead by 7 elements the 2nd stream
status = vslcopystream(stream2, stream1);
status = vslskipaheadstream(stream2, 7);

! Skipping ahead by 7 elements the 3rd stream
status = vslcopystream(stream3, stream2);
status = vslskipaheadstream(stream3, 7);

! Generating random numbers
...
! Deleting the streams
status = vsldeletestream(stream1)
status = vsldeletestream(stream2)
status = vsldeletestream(stream3)
...
```

C Code for Block-Splitting Method

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);

/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);

/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	BRNG does not support the Skip-Ahead method.

vslGetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

Syntax

Fortran:

```
brng = vslgetstreamstatebrng( stream )
```

C:

```
brng = vslGetStreamStateBrng( stream );
```

Include Files

- FORTRAN 77: mkl_vsl.f77

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE(VSL_STREAM_STATE), TINTENT(IN)` **C:** `const VSLStreamStatePtr`	**Fortran:** Descriptor of the stream state **C:** Pointer to the stream state structure

Output Parameters

Name	Type	Description
brng	**Fortran:** `INTEGER` **C:** `int`	Index of the basic generator assigned for the generation of *stream* ; negative in case of an error

Description

The `vslGetStreamStateBrng` function retrieves the index of a basic generator used for generation of a given random stream.

Return Values

`VSL_ERROR_NULL_PTR`	*stream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.

vslGetNumRegBrngs

Obtains the number of currently registered basic generators.

Syntax

Fortran:

```
nregbrngs = vslgetnumregbrngs( )
```

C:

```
nregbrngs = vslGetNumRegBrngs( void );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Output Parameters

Name	Type	Description
nregbrngs	**Fortran:** `INTEGER`	Number of basic generators registered at the moment of the function call

Name	Type	Description
	C: int	

Description

The vslGetNumRegBrngs function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by the VSL_MAX_REG_BRNGS parameter.

Distribution Generators

Intel MKL VSL routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence for both Fortran and C-interface and the explanation of input and output parameters. Table "Continuous Distribution Generators" and Table "Discrete Distribution Generators" list the random number generator routines with data types and output distributions, and sets correspondence between data types of the generator routines and the basic random number generators.

Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
vRngUniform	s, d	s, d	Uniform continuous distribution on the interval [*a*,*b*]
vRngGaussian	s, d	s, d	Normal (Gaussian) distribution
vRngGaussianMV	s, d	s, d	Multivariate normal (Gaussian) distribution
vRngExponential	s, d	s, d	Exponential distribution
vRngLaplace	s, d	s, d	Laplace distribution (double exponential distribution)
vRngWeibull	s, d	s, d	Weibull distribution
vRngCauchy	s, d	s, d	Cauchy distribution
vRngRayleigh	s, d	s, d	Rayleigh distribution
vRngLognormal	s, d	s, d	Lognormal distribution
vRngGumbel	s, d	s, d	Gumbel (extreme value) distribution
vRngGamma	s, d	s, d	Gamma distribution
vRngBeta	s, d	s, d	Beta distribution

Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
vRngUniform	i	d	Uniform discrete distribution on the interval [*a*,*b*)
vRngUniformBits	i	i	Underlying BRNG integer recurrence

Type of Distribution	Data Types	BRNG Data Type	Description
vRngUniformBits32	i	i	Uniformly distributed bits in 32-bit chunks
vRngUniformBits64	i	i	Uniformly distributed bits in 64-bit chunks
vRngBernoulli	i	s	Bernoulli distribution
vRngGeometric	i	s	Geometric distribution
vRngBinomial	i	d	Binomial distribution
vRngHypergeometric	i	d	Hypergeometric distribution
vRngPoisson	i	s (for VSL_RNG_METHOD_POISSON_POISNORM) s (for distribution parameter $\lambda \geq 27$) and d (for $\lambda < 27$) (for VSL_RNG_METHOD_POISSON_PTPE)	Poisson distribution
vRngPoissonV	i	s	Poisson distribution with varying mean
vRngNegBinomial	i	d	Negative binomial distribution, or Pascal distribution

Modes of random number generation

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval [*a*,*b*] belong to this interval irrespective of what *a* and *b* values may be. Fast mode provides high performance of generation and also guaranties that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
vRngUniform	s, d
vRngExponential	s, d
vRngWeibull	s, d
vRngRayleigh	s, d
vRngLognormal	s, d
vRngGamma	s, d
vRngBeta	s, d

See additional details about accurate and fast mode of random number generation in VSL Notes.

New method names

The current version of Intel MKL has a modified structure of VSL RNG method names. (See RNG Naming Conventions for details.) The old names are kept for backward compatibility. The set correspondence between the new and legacy method names for VSL random number generators.

Method Names for Continuous Distribution Generators

RNG	Legacy Method Name	New Method Name
vRngUniform	VSL_METHOD_SUNIFORM_STD, VSL_METHOD_DUNIFORM_STD, VSL_METHOD_SUNIFORM_STD_ACCURATE, VSL_METHOD_DUNIFORM_STD_ACCURATE	VSL_RNG_METHOD_UNIFORM_STD, VSL_RNG_METHOD_UNIFORM_STD_ACCURATE
vRngGaussian	VSL_METHOD_SGAUSSIAN_BOXMULLER, VSL_METHOD_SGAUSSIAN_BOXMULLER2, VSL_METHOD_SGAUSSIAN_ICDF, VSL_METHOD_DGAUSSIAN_BOXMULLER, VSL_METHOD_DGAUSSIAN_BOXMULLER2, VSL_METHOD_DGAUSSIAN_ICDF	VSL_RNG_METHOD_GAUSSIAN_BOXMULLER, VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2, VSL_RNG_METHOD_GAUSSIAN_ICDF
vRngGaussianMV	VSL_METHOD_SGAUSSIANMV_BOXMULLER, VSL_METHOD_SGAUSSIANMV_BOXMULLER2, VSL_METHOD_SGAUSSIANMV_ICDF, VSL_METHOD_DGAUSSIANMV_BOXMULLER, VSL_METHOD_DGAUSSIANMV_BOXMULLER2, VSL_METHOD_DGAUSSIANMV_ICDF	VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER, VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER2, VSL_RNG_METHOD_GAUSSIANMV_ICDF
vRngExponential	VSL_METHOD_SEXPONENTIAL_ICDF, VSL_METHOD_DEXPONENTIAL_ICDF, VSL_METHOD_SEXPONENTIAL_ICDF_ACCURATE, VSL_METHOD_DEXPONENTIAL_ICDF_ACCURATE	VSL_RNG_METHOD_EXPONENTIAL_ICDF, VSL_RNG_METHOD_EXPONENTIAL_ICDF_ACCURATE
vRngLaplace	VSL_METHOD_SLAPLACE_ICDF, VSL_METHOD_DLAPLACEL_ICDF	VSL_RNG_METHOD_LAPLACE_ICDF
vRngWeibull	VSL_METHOD_SWEIBULL_ICDF, VSL_METHOD_DWEIBULL_ICDF, VSL_METHOD_SWEIBULL_ICDF_ACCURATE, VSL_METHOD_DWEIBULL_ICDF_ACCURATE	VSL_RNG_METHOD_WEIBULL_ICDF, VSL_RNG_METHOD_WEIBULL_ICDF_ACCURATE
vRngCauchy	VSL_METHOD_SCAUCHY_ICDF, VSL_METHOD_DCAUCHY_ICDF	VSL_RNG_METHOD_CAUCHY_ICDF
vRngRayleigh	VSL_METHOD_SRAYLEIGH_ICDF, VSL_METHOD_DRAYLEIGH_ICDF, VSL_METHOD_SRAYLEIGH_ICDF_ACCURATE, VSL_METHOD_DRAYLEIGH_ICDF_ACCURATE	VSL_RNG_METHOD_RAYLEIGH_ICDF, VSL_RNG_METHOD_RAYLEIGH_ICDF_ACCURATE
vRngLognormal	VSL_METHOD_SLOGNORMAL_BOXMULLER2, VSL_METHOD_DLOGNORMAL_BOXMULLER2, VSL_METHOD_SLOGNORMAL_BOXMULLER2_ACCURATE, VSL_METHOD_DLOGNORMAL_BOXMULLER2_ACCURATE	VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2, VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2_ACCURATE
vRngGumbel	VSL_METHOD_SGUMBEL_ICDF, VSL_METHOD_DGUMBEL_ICDF	VSL_RNG_METHOD_GUMBEL_ICDF

vRngBeta	VSL_METHOD_SBETA_CJA, VSL_METHOD_DBETA_CJA, VSL_METHOD_SBETA_CJA_ACCURATE, VSL_METHOD_DBETA_CJA_ACCURATE	VSL_RNG_METHOD_BETA_CJA, VSL_RNG_METHOD_BETA_CJA_ACCURATE

Method Names for Discrete Distribution Generators

RNG	Legacy Method Name	New Method Name
vRngUniform	VSL_METHOD_IUNIFORM_STD	VSL_RNG_METHOD_UNIFORM_STD
vRngUniformBits	VSL_METHOD_IUNIFORMBITS_STD	VSL_RNG_METHOD_UNIFORMBITS_STD
vRngBernoulli	VSL_METHOD_IBERNOULLI_ICDF	VSL_RNG_METHOD_BERNOULLI_ICDF
vRngGeometric	VSL_METHOD_IGEOMETRIC_ICDF	VSL_RNG_METHOD_GEOMETRIC_ICDF
vRngBinomial	VSL_METHOD_IBINOMIAL_BTPE	VSL_RNG_METHOD_BINOMIAL_BTPE
vRngHypergeometric	VSL_METHOD_IHYPERGEOMETRIC_H2PE	VSL_RNG_METHOD_HYPERGEOMETRIC_H2PE
vRngPoisson	VSL_METHOD_IPOISSON_PTPE, VSL_METHOD_IPOISSON_POISNORM	VSL_RNG_METHOD_POISSON_PTPE, VSL_RNG_METHOD_POISSON_POISNORM
vRngPoissonV	VSL_METHOD_IPOISSONV_POISNORM	VSL_RNG_METHOD_POISSONV_POISNORM
vRngNegBinomial	VSL_METHOD_INEGBINOMIAL_NBAR	VSL_RNG_METHOD_NEGBINOMIAL_NBAR

Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

vRngUniform

Generates random numbers with uniform distribution.

Syntax

Fortran:

```
status = vsrnguniform( method, stream, n, r, a, b )
status = vdrnguniform( method, stream, n, r, a, b )
```

C:

```
status = vsRngUniform( method, stream, n, r, a, b );
status = vdRngUniform( method, stream, n, r, a, b );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Generation method; the specific values are as follows: `VSL_RNG_METHOD_UNIFORM_STD` `VSL_RNG_METHOD_UNIFORM_STD_ACCURATE` Standard method.
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE (VSL_STREAM_STATE), INTENT(IN)` **C:** `VSLStreamStatePtr`	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Number of random values to be generated
a	**FORTRAN 77:** `REAL` for `vsrnguniform` `DOUBLE PRECISION` for `vdrnguniform` **Fortran 90:** `REAL(KIND=4), INTENT(IN)` for `vsrnguniform` `REAL(KIND=8), INTENT(IN)` for `vdrnguniform` **C:** `const float` for `vsRngUniform` `const double` for `vdRngUniform`	Left bound `a`
b	**FORTRAN 77:** `REAL` for `vsrnguniform` `DOUBLE PRECISION` for `vdrnguniform` **Fortran 90:** `REAL(KIND=4), INTENT(IN)` for `vsrnguniform` `REAL(KIND=8), INTENT(IN)` for `vdrnguniform`	Right bound `b`

Name	Type	Description
	C: `const float` for `vsRngUniform` `const double` for `vdRngUniform`	

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `REAL` for `vsrnguniform` `DOUBLE PRECISION` for `vdrnguniform` **Fortran 90:** `REAL(KIND=4), INTENT(OUT)` for `vsrnguniform` `REAL(KIND=8), INTENT(OUT)` for `vdrnguniform` **C:** `float*` for `vsRngUniform` `double*` for `vdRngUniform`	Vector of `n` random numbers uniformly distributed over the interval `[a,b]`

Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval `[a, b]`, where `a, b` are the left and right bounds of the interval, respectively, and `a, b ∈ R ; a < b`.

The probability density function is given by:

$$f_{a,b}(x) = \begin{cases} \dfrac{1}{b-a}, & x \in [a,b] \\ 0, & x \notin [a,b] \end{cases}, \quad -\infty < x < +\infty$$

The cumulative distribution function is as follows:

$$f_{a,b}(x) = \begin{cases} 0, & x < a \\ \dfrac{x-a}{b-a}, & a \le x \le b, \\ 1, & x \ge b \end{cases} \quad -\infty < x < +\infty .$$

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*stream* is a `NULL` pointer.

VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngGaussian

Generates normally distributed random numbers.

Syntax

Fortran:

```
status = vsrnggaussian( method, stream, n, r, a, sigma )
status = vdrnggaussian( method, stream, n, r, a, sigma )
```

C:

```
status = vsRngGaussian( method, stream, n, r, a, sigma );
status = vdRngGaussian( method, stream, n, r, a, sigma );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAUSSIAN_BOXMULLER VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2 VSL_RNG_METHOD_GAUSSIAN_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in Table "Values of <*method*> in *method* parameter"
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE (VSL_STREAM_STATE), INTENT(IN) **C:** VSLStreamStatePtr	**Fortran:** Descriptor of the stream state structure **C:** Pointer to the stream state structure
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Number of random values to be generated

Name	Type	Description
a	**FORTRAN 77:** REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian **Fortran 90:** REAL(KIND=4), INTENT(IN) for vsrnggaussian REAL(KIND=8), INTENT(IN) for vdrnggaussian **C:** const float for vsRngGaussian const double for vdRngGaussian	Mean value *a*.
sigma	**FORTRAN 77:** REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian **Fortran 90:** REAL(KIND=4), INTENT(IN) for vsrnggaussian REAL(KIND=8), INTENT(IN) for vdrnggaussian **C:** const float for vsRngGaussian const double for vdRngGaussian	Standard deviation σ.

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** REAL for vsrnggaussian DOUBLE PRECISION for vdrnggaussian **Fortran 90:** REAL(KIND=4), INTENT(OUT) for vsrnggaussian REAL(KIND=8), INTENT(OUT) for vdrnggaussian **C:** float* for vsRngGaussian double* for vdRngGaussian	Vector of n normally distributed random numbers

Description

The vRngGaussian function generates random numbers with normal (Gaussian) distribution with mean value a and standard deviation σ, where

$a, \sigma \in R ; \sigma > 0.$

The probability density function is given by:

$$f_{a,\sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\sigma}(x) = \int_{-\infty}^{x} \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y-a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function $F_{a,\sigma}(x)$ can be expressed in terms of standard normal distribution $\Phi(x)$ as

$F_{a,\sigma}(x) = \Phi((x - a)/\sigma)$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngGaussianMV

Generates random numbers from multivariate normal distribution.

Syntax

Fortran:

```
status = vsrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
status = vdrnggaussianmv( method, stream, n, r, dimen, mstorage, a, t )
```

C:

```
status = vsRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
status = vdRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

Include Files

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** REAL for vsrnggaussianmv DOUBLE PRECISION for vdrnggaussianmv **Fortran 90:** REAL(KIND=4), INTENT(OUT) for vsrnggaussianmv	Array of *n* random vectors of dimension *dimen*

Name	Type	Description
	REAL(KIND=8), INTENT(OUT) for vdrnggaussianmv **C:** float* for vsRngGaussianMV double* for vdRngGaussianMV	

Description

The vRngGaussianMV function generates random numbers with d-variate normal (Gaussian) distribution with mean value a and variance-covariance matrix C, where $a \in R^d$; C is a $d \times d$ symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp\left(-1/2(x-a)^T C^{-1}(x-a)\right),$$

where $x \in R^d$.

Matrix C can be represented as $C = TT^T$, where T is a lower triangular matrix - Cholesky factor of C.

Instead of variance-covariance matrix C the generation routines require Cholesky factor of C in input. To compute Cholesky factor of matrix C, the user may call MKL LAPACK routines for matrix factorization: ?potrf or ?pptrf for v?RngGaussianMV/v?rnggaussianmv routines (? means either s or d for single and double precision respectively). See Application Notes for more details.

Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of MKL factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VSL example file.

Using Cholesky Factorization Routines in Fortran

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in Fortran two-dimensional array	spotrf for vsrnggaussianmv dpotrf for vdrnggaussianmv	'U'	Upper triangle of T^T. Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsrnggaussianmv dpptrf for vdrnggaussianmv	'L'	Upper triangle of T^T packed by rows into one-dimensional array.

Using Cholesky Factorization Routines in C

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	*C* in C two-dimensional array	spotrf for vsRngGaussianMV dpotrf for vdRngGaussianMV	'U'	Upper triangle of T^T. Lower triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of *C* packed by columns into one-dimensional array	spptrf for vsRngGaussianMV dpptrf for vdRngGaussianMV	'L'	Upper triangle of T^T packed by rows into one-dimensional array.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngExponential

Generates exponentially distributed random numbers.

Syntax

Fortran:

```
status = vsrngexponential( method, stream, n, r, a, beta )
status = vdrngexponential( method, stream, n, r, a, beta )
```

C:

```
status = vsRngExponential( method, stream, n, r, a, beta );
status = vdRngExponential( method, stream, n, r, a, beta );
```

Name	Type	Description
	`const double` for `vdRngExponential`	

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `REAL` for `vsrngexponential` `DOUBLE PRECISION` for `vdrngexponential` **Fortran 90:** `REAL(KIND=4), INTENT(OUT)` for `vsrngexponential` `REAL(KIND=8), INTENT(OUT)` for `vdrngexponential` **C:** `float*` for `vsRngExponential` `double*` for `vdRngExponential`	Vector of *n* exponentially distributed random numbers

Description

The `vRngExponential` function generates random numbers with exponential distribution that has displacement `a` and scalefactor β, where *a*, β∈*R* ; β > 0.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp\left((-(x-a)) / \beta \right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left((-(x-a)) / \beta \right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*stream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.
`VSL_RNG_ERROR_BAD_UPDATE`	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, `< 0` or `> nmax`.

VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngLaplace

Generates random numbers with Laplace distribution.

Syntax

Fortran:

```
status = vsrnglaplace( method, stream, n, r, a, beta )
status = vdrnglaplace( method, stream, n, r, a, beta )
```

C:

```
status = vsRngLaplace( method, stream, n, r, a, beta );
status = vdRngLaplace( method, stream, n, r, a, beta );
```

Include Files

Name	Type	Description
	`REAL(KIND=8), INTENT(IN)` for `vdrnglaplace` **C:** `const float` for `vsRngLaplace` `const double` for `vdRngLaplace`	
beta	**FORTRAN 77:** `REAL` for `vsrnglaplace` `DOUBLE PRECISION` for `vdrnglaplace` **Fortran 90:** `REAL(KIND=4), INTENT(IN)` for `vsrnglaplace` `REAL(KIND=8), INTENT(IN)` for `vdrnglaplace` **C:** `const float` for `vsRngLaplace` `const double` for `vdRngLaplace`	Scalefactor β.

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `REAL` for `vsrnglaplace` `DOUBLE PRECISION` for `vdrnglaplace` **Fortran 90:** `REAL(KIND=4), INTENT(OUT)` for `vsrnglaplace` `REAL(KIND=8), INTENT(OUT)` for `vdrnglaplace` **C:** `float*` for `vsRngLaplace` `double*` for `vdRngLaplace`	Vector of *n* Laplace distributed random numbers

Description

The `vRngLaplace` function generates random numbers with Laplace distribution with mean value (or average) *a* and scalefactor β, where *a*, $\beta \in R$; $\beta > 0$. The scalefactor value determines the standard deviation as

$\sqrt{2}\beta$

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2\beta}} \exp\left(-\frac{|x-a|}{\beta}\right), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{2}\exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2}\exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngWeibull

Generates Weibull distributed random numbers.

Syntax

Fortran:

```
status = vsrngweibull( method, stream, n, r, alpha, a, beta )
status = vdrngweibull( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngWeibull( method, stream, n, r, alpha, a, beta );
status = vdRngWeibull( method, stream, n, r, alpha, a, beta );
```

Include Files

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** REAL for vsrngweibull DOUBLE PRECISION for vdrngweibull **Fortran 90:** REAL(KIND=4), INTENT(OUT) for vsrngweibull REAL(KIND=8), INTENT(OUT) for vdrngweibull **C:** float* for vsRngWeibull double* for vdRngWeibull	Vector of *n* Weibull distributed random numbers

Description

The vRngWeibull function generates Weibull distributed random numbers with displacement *a*, scalefactor β, and shape α, where α, β, *a*∈*R* ; α > 0, β > 0.

The probability density function is given by:

$$f_{a,\alpha,\beta}(x) = \begin{cases} \frac{\alpha}{\beta^{\alpha}}(x-a)^{\alpha-1}\exp\left(-\left(\frac{x-a}{\beta}\right)^{\alpha}\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x-a}{\beta}\right)^{\alpha}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngCauchy

Generates Cauchy distributed random values.

Syntax

Fortran:

```
status = vsrngcauchy( method, stream, n, r, a, beta )
status = vdrngcauchy( method, stream, n, r, a, beta )
```

C:

```
status = vsRngCauchy( method, stream, n, r, a, beta );
status = vdRngCauchy( method, stream, n, r, a, beta );
```

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** REAL for vsrngcauchy DOUBLE PRECISION for vdrngcauchy **Fortran 90:** REAL(KIND=4), INTENT(OUT) for vsrngcauchy	Vector of *n* Cauchy distributed random numbers

Name	Type	Description
	REAL(KIND=8), INTENT(OUT) for vdrngcauchy **C:** float* for vsRngCauchy double* for vdRngCauchy	

Description

The function generates Cauchy distributed random numbers with displacement *a* and scalefactor β, where *a*, β∈*R* ; β > 0.

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta\left(1+\left(\frac{x-a}{\beta}\right)^2\right)}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \frac{1}{2} + \frac{1}{\pi}\arctan\left(\frac{x-a}{\beta}\right), -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngRayleigh

Generates Rayleigh distributed random values.

Syntax

Fortran:

```
status = vsrngrayleigh( method, stream, n, r, a, beta )
status = vdrngrayleigh( method, stream, n, r, a, beta )
```

C:

```
status = vsRngRayleigh( method, stream, n, r, a, beta );
```

```
status = vdRngRayleigh( method, stream, n, r, a, beta );
```

Description

The `vRngRayleigh` function generates Rayleigh distributed random numbers with displacement *a* and scalefactor β, where *a*, $\beta \in R$; $\beta > 0$.

The Rayleigh distribution is a special case of the `Weibull` distribution, where the shape parameter $\alpha = 2$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngLognormal

Generates lognormally distributed random numbers.

Syntax

Fortran:

```
status = vsrnglognormal( method, stream, n, r, a, sigma, b, beta )
status = vdrnglognormal( method, stream, n, r, a, sigma, b, beta )
```

C:

```
status = vsRngLognormal( method, stream, n, r, a, sigma, b, beta );
status = vdRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

Description

The vRngLognormal function generates lognormally distributed random numbers with average of distribution *a* and standard deviation σ of subject normal distribution, displacement *b*, and scalefactor β, where *a*, σ, *b*, β∈*R* ; σ > 0 , β > 0.

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \dfrac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\dfrac{\left[\ln((x-b)/\beta) - a\right]^2}{2\sigma^2}\right), & x > b \\ 0, & x \le b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi(\ (\ln(\ (x-b)/\beta) - a)/\sigma), & x > b \\ 0, & x \le b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngGumbel

Generates Gumbel distributed random values.

Syntax

Fortran:

```
status = vsrnggumbel( method, stream, n, r, a, beta )
status = vdrnggumbel( method, stream, n, r, a, beta )
```

C:

```
status = vsRngGumbel( method, stream, n, r, a, beta );
status = vdRngGumbel( method, stream, n, r, a, beta );
```

	DOUBLE PRECISION for vdrnggumbel	
	Fortran 90: REAL(KIND=4), INTENT(OUT) for vsrnggumbel	
	REAL(KIND=8), INTENT(OUT) for vdrnggumbel	
	C: float* for vsRngGumbel	
	double* for vdRngGumbel	

Description

The vRngGumbel function generates Gumbel distributed random numbers with displacement a and scalefactor β, where a, $\beta \in R$; β > 0.

The probability density function is given by:

$$f_{a,\beta}(x) = \left\{ \frac{1}{\beta} \exp\left(\frac{x-a}{\beta} \right) \exp\left(-\exp\left((x-a)/\beta\right)\right), -\infty < x < +\infty \right.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = 1 - \exp\left(-\exp\left((x-a)/\beta\right)\right), -\infty < x < +\infty$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngGamma

Generates gamma distributed random values.

Syntax

Fortran:

```
status = vsrnggamma( method, stream, n, r, alpha, a, beta )
status = vdrnggamma( method, stream, n, r, alpha, a, beta )
```

C:

```
status = vsRngGamma( method, stream, n, r, alpha, a, beta );
status = vdRngGamma( method, stream, n, r, alpha, a, beta );
```

Name	Type	Description
beta	**FORTRAN 77:** `REAL` for `vsrnggamma` `DOUBLE PRECISION` for `vdrnggamma` **Fortran 90:** `REAL(KIND=4), INTENT(IN)` for `vsrnggamma` `REAL(KIND=8), INTENT(IN)` for `vdrnggamma` **C:** `const float` for `vsRngGamma` `const double` for `vdRngGamma`	Scalefactor β.

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `REAL` for `vsrnggamma` `DOUBLE PRECISION` for `vdrnggamma` **Fortran 90:** `REAL(KIND=4), INTENT(OUT)` for `vsrnggamma` `REAL(KIND=8), INTENT(OUT)` for `vdrnggamma` **C:** `float*` for `vsRngGamma` `double*` for `vdRngGamma`	Vector of *n* random numbers with gamma distribution

Description

The `vRngGamma` function generates random numbers with gamma distribution that has shape parameter α, displacement *a*, and scale parameter β, where α, β, and $a \in R$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{\alpha,a,\beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^{\alpha}}(x-a)^{\alpha-1}e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

where Γ(α) is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha,a,\beta}(x) = \begin{cases} \int_{a}^{x} \frac{1}{\Gamma(\alpha)\beta^{\alpha}}(y-a)^{\alpha-1}e^{-(y-a)/\beta}dy, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngBeta

Generates beta distributed random values.

Syntax

Fortran:

```
status = vsrngbeta( method, stream, n, r, p, q, a, beta )
status = vdrngbeta( method, stream, n, r, p, q, a, beta )
```

C:

```
status = vsRngBeta( method, stream, n, r, p, q, a, beta );
status = vdRngBeta( method, stream, n, r, p, q, a, beta );
```

Name	Type	Description
	`REAL(KIND=8), INTENT(IN)` for `vdrngbeta` **C:** `const float` for `vsRngBeta` `const double` for `vdRngBeta`	

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `REAL` for `vsrngbeta` `DOUBLE PRECISION` for `vdrngbeta` **Fortran 90:** `REAL(KIND=4), INTENT(OUT)` for `vsrngbeta` `REAL(KIND=8), INTENT(OUT)` for `vdrngbeta` **C:** `float*` for `vsRngBeta` `double*` for `vdRngBeta`	Vector of *n* random numbers with beta distribution

Description

The `vRngBeta` function generates random numbers with beta distribution that has shape parameters `p` and *q*, displacement *a*, and scale parameter β, where *p*, *q*, *a*, and β∈R ; $p > 0$, $q > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p,q)\beta^{p+q-1}}(x-a)^{p-1}(\beta+a-x)^{q-1}, & a \le x < a+\beta \\ 0, & x < a, x \ge a+\beta \end{cases}, -\infty < x < \infty,$$

where $B(p, q)$ is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p,q)\beta^{p+q-1}}(y-a)^{p-1}(\beta+a-y)^{q-1}dy, & a \le x < a+\beta \\ 1, & x \ge a+\beta \end{cases}, -\infty < x < \infty.$$

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*stream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.

VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

vRngUniform

Generates random numbers uniformly distributed over the interval [a, b).

Syntax

Fortran:

```
status = virnguniform( method, stream, n, r, a, b )
```

C:

```
status = viRngUniform( method, stream, n, r, a, b );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Generation method; the specific value is as follows: VSL_RNG_METHOD_UNIFORM_STD Standard method. Currently there is only one method for this distribution generator.
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE (VSL_STREAM_STATE), INTENT(IN) **C:** VSLStreamStatePtr	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Number of random values to be generated
a	**FORTRAN 77:** INTEGER*4	Left interval bound a

Name	Type	Description
	Fortran 90: INTEGER(KIND=4), INTENT(IN) **C:** const int	
b	**FORTRAN 77:** INTEGER*4 **Fortran 90:** INTEGER(KIND=4), INTENT(IN) **C:** const int	Right interval bound b

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** INTEGER*4 **Fortran 90:** INTEGER(KIND=4), INTENT(OUT) **C:** int*	Vector of *n* random numbers uniformly distributed over the interval [*a*,*b*)

Description

The vRngUniform function generates random numbers uniformly distributed over the interval [*a*, *b*), where *a*, *b* are the left and right bounds of the interval respectively, and *a*, *b*∈*Z*; *a* < *b*.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b-a}, k \in \{a, a+1, \ldots, b-1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \dfrac{\lfloor x - a + 1 \rfloor}{b-a}, & a \le x < b, x \in R. \\ 1, & x \ge b \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.

VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngUniformBits

Generates bits of underlying BRNG integer recurrence.

Syntax

Fortran:

```
status = virnguniformbits( method, stream, n, r )
```

C:

```
status = viRngUniformBits( method, stream, n, r );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Generation method; the specific value is VSL_RNG_METHOD_UNIFORMBITS_STD
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE (VSL_STREAM_STATE), INTENT(IN) **C:** VSLStreamStatePtr	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Number of random values to be generated

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** INTEGER*4 **Fortran 90:** INTEGER(KIND=4), INTENT(OUT) **C:** unsigned int*	**Fortran:** Vector of *n* random integer numbers. If the *stream* was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of *r* respectively. The number of bytes occupied by each integer is contained in the field *wordsize* of the structure VSL_BRNG_PROPERTIES. The total number of bits that are

Name	Type	Description
		actually used to store the value are contained in the field *nbits* of the same structure. See Advanced Service Routines for a more detailed discussion of VSLBRngProperties. **C:** Vector of *n* random integer numbers. If the *stream* was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of *r* respectively. The number of bytes occupied by each integer is contained in the field *WordSize* of the structure VSLBRngProperties. The total number of bits that are actually used to store the value are contained in the field *NBits* of the same structure.See Advanced Service Routines for a more detailed discussion of VSLBRngProperties.

Description

The vRngUniformBits function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit *LCG* only 24 higher bits of an integer value can be considered random. See VSL Notes for details.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngUniformBits32

Generates uniformly distributed bits in 32-bit chunks.

Syntax

Fortran:

```
status = virnguniformbits32( method, stream, n, r )
```

C:

```
status = viRngUniformBits32( method, stream, n, r );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90

- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Generation method; the specific value is `VSL_RNG_METHOD_UNIFORMBITS32_STD`
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE (VSL_STREAM_STATE), INTENT(IN)` **C:** `VSLStreamStatePtr`	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Number of random values to be generated

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `INTEGER*4` **Fortran 90:** `INTEGER (KIND=4), INTENT(OUT)` **C:** `unsigned int*`	**Fortran:** Vector of *n* 32-bit random integer numbers with uniform bit distribution. **C:** Vector of *n* 32-bit random integer numbers with uniform bit distribution.

Description

The `vRngUniformBits32` function generates uniformly distributed bits in 32-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits32` is designed to ensure each bit in the 32-bit chunk is uniformly distributed. See VSL Notes for details.

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*stream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.
`VSL_RNG_ERROR_BRNG_NOT_SUPPORTED`	BRNG is not supported by the function.
`VSL_RNG_ERROR_NO_NUMBERS`	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
`VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED`	Period of the generator has been exceeded.

vRngUniformBits64

Generates uniformly distributed bits in 64-bit chunks.

Syntax

Fortran:

```
status = virnguniformbits64( method, stream, n, r )
```

C:

```
status = viRngUniformBits64( method, stream, n, r );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Generation method; the specific value is `VSL_RNG_METHOD_UNIFORMBITS64_STD`
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE (VSL_STREAM_STATE), INTENT(IN)` **C:** `VSLStreamStatePtr`	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Number of random values to be generated

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `INTEGER*8` **Fortran 90:** `INTEGER (KIND=8), INTENT(OUT)` **C:** `unsigned long long*`	**Fortran:** Vector of *n* 64-bit random integer numbers with uniform bit distribution. **C:** Vector of *n* 64-bit random integer numbers with uniform bit distribution.

Description

The `vRngUniformBits64` function generates uniformly distributed bits in 64-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits64` is designed to ensure each bit in the 64-bit chunk is uniformly distributed. See VSL Notes for details.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngBernoulli

Generates Bernoulli distributed random values.

Syntax

Fortran:

```
status = virngbernoulli( method, stream, n, r, p )
```

C:

```
status = viRngBernoulli( method, stream, n, r, p );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Generation method. The specific value is as follows: VSL_RNG_METHOD_BERNOULLI_ICDF Inverse cumulative distribution function method.
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE (VSL_STREAM_STATE), INTENT(IN) **C:** VSLStreamStatePtr	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Number of random values to be generated
p	**FORTRAN 77:** DOUBLE PRECISION	Success probability *p* of a trial

Name	Type	Description
	Fortran 90: REAL(KIND=8), INTENT(IN) **C:** const double	

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** INTEGER*4 **Fortran 90:** INTEGER(KIND=4), INTENT(OUT) **C:** int*	Vector of *n* Bernoulli distributed random values

Description

The vRngBernoulli function generates Bernoulli distributed random numbers with probability *p* of a single trial success, where

$p \in R;\ 0 \le p \le 1.$

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success *p*, and to 0 with probability 1 - *p*.

The probability distribution is given by:

$P(X = 1) = p$

$P(X = 0) = 1 - p$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, x < 0 \\ 1 - p, 0 \le x < 1, x \in R. \\ 1, x \ge 1 \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngGeometric

Generates geometrically distributed random values.

Syntax

Fortran:

```
status = virnggeometric( method, stream, n, r, p )
```

C:

```
status = viRngGeometric( method, stream, n, r, p );
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Generation method. The specific value is as follows: `VSL_RNG_METHOD_GEOMETRIC_ICDF` Inverse cumulative distribution function method.
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE (VSL_STREAM_STATE), INTENT(IN)` **C:** `VSLStreamStatePtr`	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Number of random values to be generated
p	**FORTRAN 77:** `DOUBLE PRECISION` **Fortran 90:** `REAL(KIND=8), INTENT(IN)` **C:** `const double`	Success probability *p* of a trial

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `INTEGER*4` **Fortran 90:** `INTEGER(KIND=4), INTENT(OUT)` **C:** `int*`	Vector of *n* geometrically distributed random values

Description

The vRngGeometric function generates geometrically distributed random numbers with probability p of a single trial success, where $p \in R;\ 0 < p < 1$.

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is p.

The probability distribution is given by:

$P(X = k) = p \cdot (1 - p)^k$, $k \in \{0,1,2, \ldots\}$.

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \geq x \end{cases} \qquad x \in R.$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngBinomial

Generates binomially distributed random numbers.

Syntax

Fortran:

```
status = virngbinomial( method, stream, n, r, ntrial, p )
```

C:

```
status = viRngBinomial( method, stream, n, r, ntrial, p );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Generation method. The specific value is as follows: VSL_RNG_METHOD_BINOMIAL_BTPE See brief description of the BTPE method in Table "Values of <*method*> in *method* parameter".
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE (VSL_STREAM_STATE), INTENT(IN) **C:** VSLStreamStatePtr	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Number of random values to be generated
ntrial	**FORTRAN 77:** INTEGER*4 **Fortran 90:** INTEGER(KIND=4), INTENT(IN) **C:** const int	Number of independent trials m
p	**FORTRAN 77:** DOUBLE PRECISION **Fortran 90:** REAL(KIND=8), INTENT(IN) **C:** const double	Success probability p of a single trial

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** INTEGER*4 **Fortran 90:** INTEGER(KIND=4), INTENT(OUT) **C:** int*	Vector of n binomially distributed random values

Description

The vRngBinomial function generates binomially distributed random numbers with number of independent Bernoulli trials m, and with probability p of a single trial success, where $p \in R;\ 0 \le p \le 1,\ m \in N$.

A binomially distributed variate represents the number of successes in m independent Bernoulli trials with probability of a single trial success p.

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \ldots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1 - p)^{m-k}, & 0 \le x < m, x \in R \\ 1, & x \ge m \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngHypergeometric

Generates hypergeometrically distributed random values.

Syntax

Fortran:

```
status = virnghypergeometric( method, stream, n, r, l, s, m )
```

C:

```
status = viRngHypergeometric( method, stream, n, r, l, s, m );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER	Generation method. The specific value is as follows: VSL_RNG_METHOD_HYPERGEOMETRIC_H2PE

Name	Type	Description
	Fortran 90: `INTEGER, INTENT(IN)` **C:** `const int`	See brief description of the `H2PE` method in Table "Values of <*method*> in *method* parameter"
stream	**FORTRAN 77:** `INTEGER*4 stream(2)` **Fortran 90:** `TYPE (VSL_STREAM_STATE), INTENT(IN)` **C:** `VSLStreamStatePtr`	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, INTENT(IN)` **C:** `const int`	Number of random values to be generated
l	**FORTRAN 77:** `INTEGER*4` **Fortran 90:** `INTEGER(KIND=4), INTENT(IN)` **C:** `const int`	Lot size `l`
s	**FORTRAN 77:** `INTEGER*4` **Fortran 90:** `INTEGER(KIND=4), INTENT(IN)` **C:** `const int`	Size of sampling without replacement `s`
m	**FORTRAN 77:** `INTEGER*4` **Fortran 90:** `INTEGER(KIND=4), INTENT(IN)` **C:** `const int`	Number of marked elements `m`

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `INTEGER*4` **Fortran 90:** `INTEGER(KIND=4), INTENT(OUT)` **C:** `int*`	Vector of *n* hypergeometrically distributed random values

Description

The `vRngHypergeometric` function generates hypergeometrically distributed random values with lot size *l*, size of sampling *s*, and number of marked elements in the lot *m*, where $l,\ m,\ s \in N \cup \{0\};\ l \geq \max(s,\ m)$.

Consider a lot of *l* elements comprising *m* "marked" and *l*-*m* "unmarked" elements. A trial sampling without replacement of exactly *s* elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of *s* elements contains exactly *k* marked elements.

The probability distribution is given by:)

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}$$

, $k \in$ {max(0, s + m - l), ..., min(s, m)}

The cumulative distribution function is as follows:

$$F_{l,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - l) \\ \sum_{k=\max(0,s+m-l)}^{\lfloor x \rfloor} \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, & \max(0, s + m - l) \le x \le \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngPoisson

Generates Poisson distributed random values.

Syntax

Fortran:

```
status = virngpoisson( method, stream, n, r, lambda )
```

C:

```
status = viRngPoisson( method, stream, n, r, lambda );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Generation method. The specific values are as follows: VSL_RNG_METHOD_POISSON_PTPE VSL_RNG_METHOD_POISSON_POISNORM See brief description of the PTPE and POISNORM methods in Table "Values of <method> in method parameter".
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE (VSL_STREAM_STATE), INTENT(IN) **C:** VSLStreamStatePtr	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Number of random values to be generated
lambda	**FORTRAN 77:** DOUBLE PRECISION **Fortran 90:** REAL(KIND=8), INTENT(IN) **C:** const double	Distribution parameter λ.

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** INTEGER*4 **Fortran 90:** INTEGER(KIND=4), INTENT(OUT) **C:** int*	Vector of *n* Poisson distributed random values

Description

The vRng"Poisson function generates Poisson distributed random numbers with distribution parameter λ, where $\lambda \in R;\ \lambda > 0$.

The probability distribution is given by:

$k \in \{0, 1, 2, \ldots\}$.

The cumulative distribution function is as follows:

$$F_\lambda(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngPoissonV

Generates Poisson distributed random values with varying mean.

Syntax

Fortran:

```
status = virngpoissonv( method, stream, n, r, lambda )
```

C:

```
status = viRngPoissonV( method, stream, n, r, lambda );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Generation method. The specific value is as follows: VSL_RNG_METHOD_POISSONV_POISNORM See brief description of the POISNORM method in Table "Values of <*method*> in *method* parameter"
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE (VSL_STREAM_STATE), INTENT(IN)	**Fortran:** Descriptor of the stream state structure. **C:** Pointer to the stream state structure

Name	Type	Description
	C: `VSLStreamStatePtr`	
n	**FORTRAN 77:** `INTEGER`	Number of random values to be generated
	Fortran 90: `INTEGER, INTENT(IN)`	
	C: `const int`	
lambda	**FORTRAN 77:** `DOUBLE PRECISION`	Array of *n* distribution parameters λ_i.
	Fortran 90: `REAL(KIND=8), INTENT(IN)`	
	C: `const double*`	

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** `INTEGER*4`	Vector of *n* Poisson distributed random values
	Fortran 90: `INTEGER(KIND=4), INTENT(OUT)`	
	C: `int*`	

Description

The `vRngPoissonV` function generates *n* Poisson distributed random numbers $x_i (i = 1, ..., n)$ with distribution parameter λ_i, where $\lambda_i \in R$; $\lambda_i > 0$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, k \in \{0, 1, 2, ...\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_ERROR_NULL_PTR`	*stream* is a `NULL` pointer.
`VSL_RNG_ERROR_BAD_STREAM`	*stream* is not a valid random stream.

VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

vRngNegBinomial

Generates random numbers with negative binomial distribution.

Syntax

Fortran:

```
status = virngnegbinomial( method, stream, n, r, a, p )
```

C:

```
status = viRngNegbinomial( method, stream, n, r, a, p );
```

Include Files

- FORTRAN 77: mkl_vsl.f77
- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
method	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Generation method. The specific value is: VSL_RNG_METHOD_NEGBINOMIAL_NBAR See brief description of the NBAR method in Table "Values of <*method*> in *method* parameter"
stream	**FORTRAN 77:** INTEGER*4 stream(2) **Fortran 90:** TYPE (VSL_STREAM_STATE), INTENT(IN) **C:** VSLStreamStatePtr	**Fortran:** descriptor of the stream state structure. **C:** pointer to the stream state structure
n	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER, INTENT(IN) **C:** const int	Number of random values to be generated
a	**FORTRAN 77:** DOUBLE PRECISION **Fortran 90:** REAL(KIND=8), INTENT(IN) **C:** const double	The first distribution parameter *a*

Name	Type	Description
p	**FORTRAN 77:** DOUBLE PRECISION **Fortran 90:** REAL(KIND=8), INTENT(IN) **C:** const double	The second distribution parameter p

Output Parameters

Name	Type	Description
r	**FORTRAN 77:** INTEGER*4 **Fortran 90:** INTEGER(KIND=4), INTENT(OUT) **C:** int*	Vector of *n* random values with negative binomial distribution.

Description

The vRngNegBinomial function generates random numbers with negative binomial distribution and distribution parameters *a* and *p*, where *p*, *a*∈*R*; 0 < *p* < 1; *a* > 0.

If the first distribution parameter *a*∈*N*, this distribution is the same as Pascal distribution. If *a*∈*N*, the distribution can be interpreted as the expected time of *a*-th success in a sequence of Bernoulli trials, when the probability of success is *p*.

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^{k} p^{a}(1-p)^{k}, k \in \{0, 1, 2, \ldots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^{k} p^{a}(1-p)^{k}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	*stream* is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	*stream* is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

Advanced Service Routines

This section describes service routines for registering a user-designed basic generator (vslRegisterBrng) and for obtaining properties of the previously registered basic generators (vslGetBrngProperties). See VSL Notes ("Basic Generators" section of VSL Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

Data types

The Advanced Service routines refer to a structure defining the properties of the basic generator. This structure is described in Fortran 90 as follows:

```
TYPE VSL_BRNG_PROPERTIES
    INTEGER streamstatesize
    INTEGER nseeds
    INTEGER includeszero
    INTEGER wordsize
    INTEGER nbits
    INTEGER nitstream
    INTEGER sbrng
    INTEGER dbrng
    INTEGER ibrng
END TYPE VSL_BRNG_PROPERTIES
```

The C version is as follows:

```
typedef struct _VSLBRngProperties {
       int StreamStateSize;
       int NSeeds;
       int IncludesZero;
       int WordSize;
       int NBits;
       InitStreamPtr InitStream;
       sBRngPtr sBRng;
       dBRngPtr dBRng;
       iBRngPtr iBRng;
} VSLBRngProperties;
```

The following table provides brief descriptions of the fields engaged in the above structure:

Field Descriptions

Field	Short Description
Fortran: `streamstatesize` **C:** `StreamStateSize`	The size, in bytes, of the stream state structure for a given basic generator.
Fortran: `nseeds` **C:** `NSeeds`	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.

Field	Short Description
Fortran: includeszero **C:** IncludesZero	Flag value indicating whether the generator can produce a random 0.
Fortran: wordsize **C:** WordSize	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
Fortran: nbits **C:** NBits	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, wordsize/WordSize is equal to 8 (number of bytes used to store the random value), while nbits/NBits contains the actual number of bits occupied by the value (in this example, 48).
Fortran: initstream **C:** InitStream	Contains the pointer to the initialization routine of a given basic generator.
Fortran: sbrng **C:** sBRng	Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval (*a*,*b*) (real in Fortran and float in C).
Fortran: dbrng **C:** dBRng	Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval (*a*,*b*) (double PRECISION in Fortran and double in C).
Fortran: ibrng **C:** iBRng	Contains the pointer to the basic generator of integer numbers with uniform bit distribution[1] (INTEGER in Fortran and unsigned int in C).

[1]A specific generator that permits operations over single bits and bit groups of random numbers.

vslRegisterBrng

Registers user-defined basic generator.

Syntax

Fortran:

```
brng = vslregisterbrng( properties )
```

C:

```
brng = vslRegisterBrng( &properties );
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
properties	**Fortran:** TYPE(VSL_BRNG_PROPERTIES), INTENT(IN) **C:** const VSLBRngProperties*	Pointer to the structure containing properties of the basic generator to be registered

NOTE FORTRAN 77 support is unavailable for this function.

Output Parameters

Name	Type	Description
brng	**Fortran:** INTEGER, INTENT(OUT) **C:** int	Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error.

Description

An example of a registration procedure can be found in the respective directory of the VSL examples.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	Bad value in StreamStateSize field.
VSL_RNG_ERROR_BAD_WORD_SIZE	Bad value in WordSize field.
VSL_RNG_ERROR_BAD_NSEEDS	Bad value in NSeeds field.
VSL_RNG_ERROR_BAD_NBITS	Bad value in NBits field.
VSL_ERROR_NULL_PTR	At least one of the fields iBrng, dBrng, sBrng or InitStream is a NULL pointer.

vslGetBrngProperties

Returns structure with properties of a given basic generator.

Syntax

Fortran:

```
status = vslgetbrngproperties( brng, properties )
```

C:

```
status = vslGetBrngProperties( brng, &properties );
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
brng	**Fortran:** INTEGER(KIND=4), INTENT(IN) **C:** const int	Number (index) of the registered basic generator; used for identification. See specific values in Table "Values of *brng* parameter". Negative values indicate the registration error.

NOTE FORTRAN 77 support is unavailable for this function.

Output Parameters

Name	Type	Description
properties	**Fortran:** `TYPE(VSL_BRNG_PROPERTIES), INTENT(OUT)` **C:** `VSLBRngProperties*`	Pointer to the structure containing properties of the generator with number *brng*

Description

The `vslGetBrngProperties` function returns a structure with properties of a given basic generator.

Return Values

`VSL_ERROR_OK`, `VSL_STATUS_OK`	Indicates no error, execution is successful.
`VSL_RNG_ERROR_INVALID_BRNG_INDEX`	BRNG index is invalid.

Formats for User-Designed Generators

To register a user-designed basic generator using `vslRegisterBrng` function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See below recommendations on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VSL examples.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] );
typedef int(*sBRngPtr)( VSLStreamStatePtr stream, int n, float r[], float a, float b );
typedef int(*dBRngPtr)( VSLStreamStatePtr stream, int n, double r[], double a, double b );
typedef int(*iBRngPtr)( VSLStreamStatePtr stream, int n, unsigned int r[] );
```

InitStream

C:

```
int MyBrngInitStream( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] )
{
      /* Initialize the stream */
      ...
} /* MyBrngInitStream */
```

Description

The initialization routine of a user-designed generator must initialize *stream* according to the specified initialization *method*, initial conditions *params* and the argument *n*. The value of *method* determines the initialization method to be used.

- If *method* is equal to `1`, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the *stream* structure was not previously initialized. The value of *n* is used as the actual number of 32-bit values passed as initial conditions

through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.

- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code VSL_ERROR_LEAPFROG_UNSUPPORTED.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code VSL_ERROR_SKIPAHEAD_UNSUPPORTED.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of vslLeapfrogStream and vslSkipAheadStream, respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

C:

```
typedef struct
{
    unsigned int Reserved1[2];
    unsigned int Reserved2[2];
    [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;
- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in *LCG*(*a*, *c*, *m*), apart from the initial conditions, two more fields should be specified: the value of the multiplier a^k and the value of the increment $(a^k-1)c/(a-1)$.

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VSL examples.

iBRng

C:

```
int iMyBrng( VSLStreamStatePtr stream, int n, unsigned int r[] )
{
    int i; /* Loop variable */
    /* Generating integer random numbers */
    /* Pay attention to word size needed to
    store only random number */
    for( i = 0; i < n; i++)
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* iMyBrng */
```

NOTE When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector *r* correctly. For example, storing one 64-bit value requires two elements of *r*, the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of *r* to store a 128-bit value.

sBRng

C:

```
int sMyBrng( VSLStreamStatePtr stream, int n, float r[], float a, float b )
{
    int   i;    /* Loop variable */
    /* Generating float (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* sMyBrng */
```

dBRng

C:

```
int dMyBrng( VSLStreamStatePtr stream, int n, double r[], double a, double b )
{
    int i;   /* Loop variable */
    /* Generating double (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* dMyBrng */
```

Convolution and Correlation

Intel MKL VSL provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see the Mathematical Notation and Definitions section.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM* ESSL library:

```
SCONF, SCORF
SCOND, SCORD
SDCON, SDCOR
DDCON, DDCOR
SDDCON, SDDCOR.
```

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources for Fortran and C. To reuse them, use the following directories:

```
${MKL}/examples/vslc/essl/vsl_wrappers
${MKL}/examples/vslf/essl/vsl_wrappers
```

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers. You can find the examples in the following directories:

```
${MKL}/examples/vslc/essl
${MKL}/examples/vslf/essl
```

Convolution and correlation API provides interfaces for FORTRAN 77, Fortran 90 and C/89 languages. You may use the C/89 interface also with later versions of C or C++, or Fortran 90 interface with programs written in Fortran 95.

For users of the C/C++ and Fortran languages, the `mkl_vsl.h`, `mkl_vsl.f90`, and `mkl_vsl.f77` headers are provided. All header files are found under the directory:

`${MKL}/include`

See more details about the Fortran header in Random Number Generators section of this chapter.

Convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All the Intel MKL VSL convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

Task Constructors - routines that create a new task object descriptor and set up most common parameters.

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Execution Routines - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

Task Copy - routines used to make several copies of the task descriptor.

Task Destructors - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

Naming Conventions

The names of Fortran routines in the convolution and correlation API are written in lowercase (`vslsconvexec`), while the names of Fortran types and constants are written in uppercase. The names are not case-sensitive.

In C, the names of routines, types, and constants are case-sensitive and can be lowercase and uppercase (`vslsConvExec`).

The names of routines have the following structure:

`vsl[`*`datatype`*`]{Conv|Corr}<base name>` for the C interface

`vsl[`*`datatype`*`]{conv|corr}<base name>` for the Fortran interface

where

- `vsl` is a prefix indicating that the routine belongs to Vector Statistical Library of Intel® MKL.
- `[`*`datatype`*`]` is optional. If present, the symbol specifies the type of the input and output data and can be `s` (for single precision real type), `d` (for double precision real type), `c` (for single precision complex type), or `z` (for double precision complex type).
- `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.
- `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
FORTRAN 77: `INTEGER*4 task(2)`	Pointer to a task descriptor for convolution

Type	Data Object
Fortran 90: `TYPE(VSL_CONV_TASK)` **C:** `VSLConvTaskPtr`	
FORTRAN 77: `INTEGER*4 task(2)` **Fortran 90:** `TYPE(VSL_CORR_TASK)` **C:** `VSLCorrTaskPtr`	Pointer to a task descriptor for correlation
FORTRAN 77: `REAL*4` **Fortran 90:** `REAL(KIND=4)` **C:** `float`	Input/output user real data in single precision
FORTRAN 77: `REAL*8` **Fortran 90:** `REAL(KIND=8)` **C:** `double`	Input/output user real data in double precision
FORTRAN 77: `COMLEX*8` **Fortran 90:** `COMPLEX(KIND=4)` **C:** `MKL_Complex8`	Input/output user complex data in single precision
FORTRAN 77: `COMPLEX*16` **Fortran 90:** `COMPLEX(KIND=8)` **C:** `MKL_Complex16`	Input/output user complex data in double precision
FORTRAN 77: `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	All other data

Generic integer type (without specifying the byte size) is used for all integer data.

NOTE The actual size of the generic integer type is platform-dependent. Before you compile your application, set an appropriate byte size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel© MKL User's Guide*.

Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel MKL convolution and correlation API.

Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
job	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation
type	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
precision	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays *x*,*y*,*z*.
mode	explicit	integer	None	Specifies whether the convolution/ correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See SetMode for the list of named constants for this parameter.
method	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given *mode*. Setting this parameter to "auto" means that software will choose the best available method.
internal_precision	optional	integer	Set equal to the value of *precision*	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See SetInternalPrecision for the list of named constants for this parameter.
dims	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays *x*,*y*,*z*. Can be in the range from 1 to 7.
x,*y*	explicit	real arrays	None	Specify input data arrays. See Data Allocation for more information.
z	explicit	real array	None	Specifies output data array. See Data Allocation for more information.
xshape, *yshape*, *zshape*	explicit	integer arrays	None	Define shapes of the arrays *x*, *y*, *z*. See Data Allocation for more information.
xstride, *ystride*, *zstride*	explicit	integer arrays	None	Define strides within arrays *x*, *y*, *z*, that is specify the physical location of the input and output data in these arrays. See Data Allocation for more information.
start	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array *z*. See SetStart and Data Allocation for more information.

Name	Category	Type	Default Value Label	Description
decimation	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array *z*. See SetDecimation and Data Allocation for more information.

Users of the C or C++ language may pass the NULL pointer instead of either or all of the parameters *xstride*, *ystride*, or *zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x*, *y*, or *z* due to the Fortran-style "by columns" representation of multi-dimensional arrays.

Task Status and Error Reporting

The task status is an integer value, which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings.

An error can be caused by invalid parameter values, a system fault like a memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, the constructor assigns the VSL_STATUS_OK status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation, which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor is terminated and the task keeps the same error code.

Normally, every convolution or correlation function (except DeleteTask) returns the status assigned to the task while performing the function operation.

The status codes are given symbolic names defined in the respective header files. For the C/C++ interface, these names are defined as macros via the #define statements, and for the Fortran interface as integer constants via the PARAMETER operators.

If there is no error, the VSL_STATUS_OK status is returned, which is defined as zero:

```
C/C++:          #define VSL_STATUS_OK 0
F90/F95:        INTEGER(KIND=4) VSL_STATUS_OK
                PARAMETER(VSL_STATUS_OK = 0)

F77:            INTEGER*4 VSL_STATUS_OK
                PARAMETER(VSL_STATUS_OK = 0)
```

In case of an error, a non-zero error code is returned, which indicates the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files for both C/C++ and Fortran languages.

Convolution/Correlation Status Codes

Status Code	Description
VSL_CC_ERROR_NOT_IMPLEMENTED	Requested functionality is not implemented.
VSL_CC_ERROR_ALLOCATION_FAILURE	Memory allocation failure.
VSL_CC_ERROR_BAD_DESCRIPTOR	Task descriptor is corrupted.

Status Code	Description
VSL_CC_ERROR_SERVICE_FAILURE	A service function has failed.
VSL_CC_ERROR_EDIT_FAILURE	Failure while editing the task.
VSL_CC_ERROR_EDIT_PROHIBITED	You cannot edit this parameter.
VSL_CC_ERROR_COMMIT_FAILURE	Task commitment has failed.
VSL_CC_ERROR_COPY_FAILURE	Failure while copying the task.
VSL_CC_ERROR_DELETE_FAILURE	Failure while deleting the task.
VSL_CC_ERROR_BAD_ARGUMENT	Bad argument or task parameter.
VSL_CC_ERROR_JOB	Bad parameter: *job*.
SL_CC_ERROR_KIND	Bad parameter: *kind*.
VSL_CC_ERROR_MODE	Bad parameter: *mode*.
VSL_CC_ERROR_METHOD	Bad parameter: *method*.
VSL_CC_ERROR_TYPE	Bad parameter: *type*.
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: *external_precision*.
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: *internal_precision*.
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: *dims*.
VSL_CC_ERROR_XSHAPE	Bad parameter: *xshape*.
VSL_CC_ERROR_YSHAPE	Bad parameter: *yshape*.
	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or >nmax.
VSL_CC_ERROR_ZSHAPE	Bad parameter: *zshape*.
VSL_CC_ERROR_XSTRIDE	Bad parameter: *xstride*.
VSL_CC_ERROR_YSTRIDE	Bad parameter: *ystride*.
VSL_CC_ERROR_ZSTRIDE	Bad parameter: *zstride*.
VSL_CC_ERROR_X	Bad parameter: *x*.
VSL_CC_ERROR_Y	Bad parameter: *y*.
VSL_CC_ERROR_Z	Bad parameter: *z*.
VSL_CC_ERROR_START	Bad parameter: *start*.
VSL_CC_ERROR_DECIMATION	Bad parameter: *decimation*.
VSL_CC_ERROR_OTHER	Another error.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. No additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form constructors but also assign particular data to the first operand vector used in the convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Each constructor routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

The Table "Task Constructors" lists available task constructors:

Task Constructors

Routine	Description
vslConvNewTask/vslCorrNewTask	Creates a new convolution or correlation task descriptor for a multidimensional case.
vslConvNewTask1D/ vslCorrNewTask1D	Creates a new convolution or correlation task descriptor for a one-dimensional case.
vslConvNewTaskX/vslCorrNewTaskX	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
vslConvNewTaskX1D/ vslCorrNewTaskX1D	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

vslConvNewTask/vslCorrNewTask

Creates a new convolution or correlation task descriptor for multidimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslcconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzconvnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslscorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vsldcorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslccorrnewtask(task, mode, dims, xshape, yshape, zshape)
status = vslzcorrnewtask(task, mode, dims, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vsldConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslsCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

Input Parameters

Name	Type	Description
mode	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `const int`	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
dims	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `const int`	Rank of user data. Specifies number of dimensions for the input and output arrays *x*, *y*, and *z* used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
xshape	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, DIMENSION(*)` **C:** `const int[]`	Defines the shape of the input data for the source array *x*. See Data Allocation for more information.
yshape	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, DIMENSION(*)` **C:** `const int[]`	Defines the shape of the input data for the source array *y*. See Data Allocation for more information.
zshape	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, DIMENSION(*)` **C:** `const int[]`	Defines the shape of the output data to be stored in array *z*. See Data Allocation for more information.

Output Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslsconvnewtask`, `vsldconvnewtask`, `vslcconvnewtask`, `vslzconvnewtask` `INTEGER*4 task(2)` for `vslscorrnewtask`, `vsldcorrnewtask`, `vslccorrnewtask`, `vslzcorrnewtask` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslsconvnewtask`, `vsldconvnewtask`, `vslcconvnewtask`, `vslzconvnewtask` `TYPE(VSL_CORR_TASK)` for `vslscorrnewtask`, `vsldcorrnewtask`, `vslccorrnewtask`, `vslzcorrnewtask` **C:** `VSLConvTaskPtr*` for `vslsConvNewTask`, `vsldConvNewTask`, `vslcConvNewTask`, `vslzConvNewTask` `VSLCorrTaskPtr*` for `vslsCorrNewTask`, `vsldCorrNewTask`, `vslcConvNewTask`, `vslzConvNewTask`	Pointer to the task descriptor if created successfully or `NULL` pointer otherwise.
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Set to `VSL_STATUS_OK` if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTask`/`vslCorrNewTask` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see Table "Convolution and Correlation Task Parameters").

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a NULL task pointer.

vslConvNewTask1D/vslCorrNewTask1D

Creates a new convolution or correlation task descriptor for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslcconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzconvnewtask1d(task, mode, xshape, yshape, zshape)
status = vslscorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vsldcorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslccorrnewtask1d(task, mode, xshape, yshape, zshape)
status = vslzcorrnewtask1d(task, mode, xshape, yshape, zshape)
```

C:

```
status = vslsConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vslsCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vsldCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslcCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vslzCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

Description

Each `vslConvNewTask1D`/`vslCorrNewTask1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see Table "Convolution and Correlation Task Parameters"). Unlike `vslConvNewTask`/`vslCorrNewTask`, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter *dims* is 1. The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

vslConvNewTaskX/vslCorrNewTaskX

Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslcconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslzconvnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslscorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vsldcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslccorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
status = vslzcorrnewtaskx(task, mode, dims, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
```

Description

Each vslConvNewTaskX/vslCorrNewTaskX constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see Table "Convolution and Correlation Task Parameters").

Unlike vslConvNewTask/vslCorrNewTask, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the vslConvNewTaskX/vslCorrNewTaskX constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see vslConvDeleteTask/ vslCorrDeleteTask).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

The stride parameter *xstride* specifies the physical location of the input data in the array *x*. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is s, then only every s^{th} element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

vslConvNewTaskX1D/vslCorrNewTaskX1D

Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.

Syntax

Fortran:

```
status = vslsconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vsldconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslcconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslzconvnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

```
status = vslscorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vsldcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslccorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
status = vslzcorrnewtaskx1d(task, mode, xshape, yshape, zshape, x, xstride)
```

C:

```
status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
```

x	**FORTRAN 77:** `REAL*4` for real data in single precision flavors, `REAL*8` for real data in double precision flavors, `COMPLEX*8` for complex data in single precision flavors,	Pointer to the array containing input data for the first operand vector. See Data Allocation for more information.

Name	Type	Description
	`COMPLEX*16` for complex data in double precision flavors **Fortran 90:** `REAL(KIND=4), DIMENSION (*)` for real data in single precision flavors, `REAL(KIND=8), DIMENSION (*)` for real data in double precision flavors, `COMPLEX(KIND=4), DIMENSION (*)` for complex data in single precision flavors, `COMPLEX(KIND=8), DIMENSION (*)` for complex data in double precision flavors **C:** `const float[]` for real data in single precision flavors, `const double[]` for real data in double precision flavors, `const MKL_Complex8[]` for complex data in single precision flavors, `const MKL_Complex16[]` for complex data in double precision flavors	
xstride	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `const int`	Stride for input data sequence in the array *x*.

Output Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslsconvnewtaskx1d`, `vsldconvnewtaskx1d`, `vslcconvnewtaskx1d`, `vslzconvnewtaskx1d` `INTEGER*4 task(2)` for `vslscorrnewtaskx1d`, `vsldcorrnewtaskx1d`, `vslccorrnewtaskx1d`, `vslzcorrnewtaskx1d` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslsconvnewtaskx1d`,	Pointer to the task descriptor if created successfully or `NULL` pointer otherwise.

Name	Type	Description
	`vsldconvnewtaskx1d`, `vslcconvnewtaskx1d`, `vslzconvnewtaskx1d` `TYPE(VSL_CORR_TASK)` for `vslscorrnewtaskx1d`, `vsldcorrnewtaskx1d`, `vslccorrnewtaskx1d`, `vslzcorrnewtaskx1d` **C:** `VSLConvTaskPtr*` for `vslsConvNewTaskX1D`, `vsldConvNewTaskX1D`, `vslcConvNewTaskX1D`, `vslzConvNewTaskX1D` `VSLCorrTaskPtr*` for `vslsCorrNewTaskX1D`, `vsldCorrNewTaskX1D`, `vslcCorrNewTaskX1D`, `vslzCorrNewTaskX1D`	
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Set to `VSL_STATUS_OK` if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTaskX1D`/`vslCorrNewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see Table "Convolution and Correlation Task Parameters").

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter *dims* is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX1D`/`vslCorrNewTaskX1D` constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see `vslConvDeleteTask`/`vslCorrDeleteTask`).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

The stride parameters *xstride* specifies the physical location of the input data in the array *x* and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is `s`, then only every s^{th} element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

Task Editors

Task editors in convolution and correlation API of Intel MKL are routines intended for setting up or changing the following task parameters (see Table "Convolution and Correlation Task Parameters"):

- *mode*
- *internal_precision*
- *start*
- *decimation*

For setting up or changing each of the above parameters, a separate routine exists.

NOTE Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

The work data computed during the last commitment process may become invalid with respect to new parameter settings. That is why after applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and goes through the full commitment process again during the next execution or copy operation. For more information on task commitment, see the Introduction to Convolution and Correlation.

Table "Task Editors" lists available task editors.

Task Editors

Routine	Description
vslConvSetMode/vslCorrSetMode	Changes the value of the parameter *mode* for the operation of convolution or correlation.
vslConvSetInternalPrecision/ vslCorrSetInternalPrecision	Changes the value of the parameter *internal_precision* for the operation of convolution or correlation.
vslConvSetStart/vslCorrSetStart	Sets the value of the parameter *start* for the operation of convolution or correlation.
vslConvSetDecimation/ vslCorrSetDecimation	Sets the value of the parameter *decimation* for the operation of convolution or correlation.

NOTE You can use the NULL task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslConvSetMode/vslCorrSetMode

Changes the value of the parameter mode in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetmode(task, newmode)
status = vslcorrsetmode(task, newmode)
```

C:

```
status = vslConvSetMode(task, newmode);
status = vslCorrSetMode(task, newmode);
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslconvsetmode` `INTEGER*4 task(2)` for `vslcorrsetmode` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslconvsetmode` `TYPE(VSL_CORR_TASK)` for `vslcorrsetmode` **C:** `VSLConvTaskPtr` for `vslConvSetMode` `VSLCorrTaskPtr` for `vslCorrSetMode`	Pointer to the task descriptor.
newmode	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `const int`	New value of the parameter `mode`.

Output Parameters

Name	Type	Description
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Current status of the task.

Description

This function is declared in `mkl_vsl.f77` for FORTRAN 77 interface, in `mkl_vsl.f90` for Fortran 90 interface, and in `mkl_vsl_functions.h` for C interface.

The function routine changes the value of the parameter `mode` for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for `mode` is assigned by a task constructor.

Predefined values for the `mode` parameter are as follows:

Values of *mode* parameter

Value	Purpose
`VSL_CONV_MODE_FFT`	Compute convolution by using fast Fourier transform.
`VSL_CORR_MODE_FFT`	Compute correlation by using fast Fourier transform.

Value	Purpose
VSL_CONV_MODE_DIRECT	Compute convolution directly.
VSL_CORR_MODE_DIRECT	Compute correlation directly.
VSL_CONV_MODE_AUTO	Automatically choose direct or Fourier mode for convolution.
VSL_CORR_MODE_AUTO	Automatically choose direct or Fourier mode for correlation.

vslConvSetInternalPrecision/vslCorrSetInternalPrecision

Changes the value of the parameter `internal_precision` *in the convolution or correlation task descriptor.*

Syntax

Fortran:

```
status = vslconvsetinternalprecision(task, precision)
status = vslcorrsetinternalprecision(task, precision)
```

C:

```
status = vslConvSetInternalPrecision(task, precision);
status = vslCorrSetInternalPrecision(task, precision);
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslconvsetinternalprecision` `INTEGER*4 task(2)` for `vslcorrsetinternalprecision` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslconvsetinternalprecision` `TYPE(VSL_CORR_TASK)` for `vslcorrsetinternalprecision` **C:** `VSLConvTaskPtr` for `vslConvSetInternalPrecision`	Pointer to the task descriptor.

Name	Type	Description
	`VSLCorrTaskPtr` for `vslCorrSetInternalPrecision`	
precision	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `const int`	New value of the parameter *internal_precision*.

Output Parameters

Name	Type	Description
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Current status of the task.

Description

The `vslConvSetInternalPrecision`/`vslCorrSetInternalPrecision` routine changes the value of the parameter *internal_precision* for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for *internal_precision* is assigned by a task constructor and set to either "single" or "double" according to the particular flavor of the constructor used.

Changing the *internal_precision* can be useful if the default setting of this parameter was "single" but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the *internal_precision* input parameter are as follows:

Values of *internal_precision* Parameter

Value	Purpose
`VSL_CONV_PRECISION_SINGLE`	Compute convolution with single precision.
`VSL_CORR_PRECISION_SINGLE`	Compute correlation with single precision.
`VSL_CONV_PRECISION_DOUBLE`	Compute convolution with double precision.
`VSL_CORR_PRECISION_DOUBLE`	Compute correlation with double precision.

vslConvSetStart/vslCorrSetStart

Changes the value of the parameter `start` in the convolution or correlation task descriptor.

Syntax

Fortran:

```
status = vslconvsetstart(task, start)
status = vslcorrsetstart(task, start)
```

C:

```
status = vslConvSetStart(task, start);
```

```
status = vslCorrSetStart(task, start);
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslconvsetstart` `INTEGER*4 task(2)` for `vslcorrsetstart` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslconvsetstart` `TYPE(VSL_CORR_TASK)` for `vslcorrsetstart` **C:** `VSLConvTaskPtr` for `vslConvSetStart` `VSLCorrTaskPtr` for `vslCorrSetStart`	Pointer to the task descriptor.
start	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, DIMENSION (*)` **C:** `const int[]`	New value of the parameter *start*.

Output Parameters

Name	Type	Description
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Current status of the task.

Description

The `vslConvSetStart`/`vslCorrSetStart` routine sets the value of the parameter *start* for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, *start* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see Data Allocation.

During the initial task descriptor construction, the default value for *start* is undefined and this parameter is not used. Therefore the only way to set and use the *start* parameter is via assigning it some value by one of the `vslConvSetStart`/`vslCorrSetStart` routines.

vslConvSetDecimation/vslCorrSetDecimation

Changes the value of the parameter `decimation` *in the convolution or correlation task descriptor.*

Syntax

Fortran:

```
status = vslconvsetdecimation(task, decimation)
status = vslcorrsetdecimation(task, decimation)
```

C:

```
status = vslConvSetDecimation(task, decimation);
status = vslCorrSetDecimation(task, decimation);
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslconvsetdecimation` `INTEGER*4 task(2)` for `vslcorrsetdecimation` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslconvsetdecimation` `TYPE(VSL_CORR_TASK)` for `vslcorrsetdecimation` **C:** `VSLConvTaskPtr` for `vslConvSetDecimation` `VSLCorrTaskPtr` for `vslCorrSetDecimation`	Pointer to the task descriptor.
decimation	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, DIMENSION (*)` **C:** `const int[]`	New value of the parameter *decimation*.

Output Parameters

Name	Type	Description
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER`	Current status of the task.

Name	Type	Description
	C: `int`	

Description

The routine sets the value of the parameter *decimation* for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if *decimation* = *d* > 1, only every *d*-th element of the mathematical result is written to the output array *z*. In a multidimensional case, *decimation* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see Data Allocation.

During the initial task descriptor construction, the default value for *decimation* is undefined and this parameter is not used. Therefore the only way to set and use the *decimation* parameter is via assigning it some value by one of the `vslSetDecimation` routines.

Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the user data supplied for input vectors.

After you create and adjust a task, you can execute it multiple times by applying to different input/output data of the same type, precision, and shape.

Intel MKL provides the following forms of convolution/correlation execution routines:

- **General form** executors that use the task descriptor created by the general form constructor and expect to get two source data arrays *x* and *y* on input
- **X-form** executors that use the task descriptor created by the X-form constructor and expect to get only one source data array *y* on input because the first array *x* has been already specified on the construction stage

When the task is executed for the first time, the execution routine includes a task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

Each execution routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE You can use the `NULL` task pointer in calls to execution routines. In this case, the routine is terminated and no system crash occurs.

If the task is executed successfully, the execution routine returns the zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`
- if the task descriptor is corrupted
- if calculation has failed for some other reason.

NOTE Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

Task Execution Routines

Routine	Description
vslConvExec/vslCorrExec	Computes convolution or correlation for a multidimensional case.
vslConvExec1D/vslCorrExec1D	Computes convolution or correlation for a one-dimensional case.
vslConvExecX/vslCorrExecX	Computes convolution or correlation as X-form for a multidimensional case.
vslConvExecX1D/vslCorrExecX1D	Computes convolution or correlation as X-form for a one-dimensional case.

vslConvExec/vslCorrExec

Computes convolution or correlation for multidimensional case.

Syntax

Fortran:

```
status = vslsconvexec(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec(task, x, xstride, y, ystride, z, zstride);
```

Include Files

Name	Type	Description
z	**FORTRAN 77:** `REAL*4` for `vslsconvexec` and `vslscorrexec`, `REAL*8` for `vsldconvexec` and `vsldcorrexec`, `COMPLEX*8` for`vslcconvexec` and `vslccorrexec`, `COMPLEX*16` for`vslzconvexec` and `vslzcorrexec` **Fortran 90:** `REAL(KIND=4), DIMENSION(*)` for `vslsconvexec` and `vslscorrexec`, `REAL(KIND=8), DIMENSION(*)` for `vsldconvexec` and `vsldcorrexec`, `COMPLEX(KIND=4), DIMENSION (*)` for`vslcconvexec` and `vslccorrexec`, `COMPLEX(KIND=8), DIMENSION (*)` for `vslzconvexec` and `vslzcorrexec`	Pointer to the array that stores output data. See Data Allocation for more information.

Name	Type	Description
	C: `const float[]` for `vslsConvExec` and `vslsCorrExec`, `const double[]` for `vsldConvExec` and `vsldCorrExec`, `const MKL_Complex8[]` for `vslcConvExec` and `vslcCorrExec`, `const MKL_Complex16[]` for `vslzConvExec` and `vslzCorrExec`	
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Set to `VSL_STATUS_OK` if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExec`/`vslCorrExec` routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask`/`vslCorrNewTask` constructor and pointed to by *task*. If *task* is `NULL`, no operation is done.

The stride parameters *xstride*, *ystride*, and *zstride* specify the physical location of the input and output data in the arrays *x*, *y*, and *z*, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *zstride* is `s`, then only every s^{th} element of the array *z* will be used to store the output data. The stride value must be positive or negative but not zero.

vslConvExec1D/vslCorrExec1D

Computes convolution or correlation for one-dimensional case.

Syntax

Fortran:

```
status = vslsconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslcconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslzconvexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslscorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vsldcorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslccorrexec1d(task, x, xstride, y, ystride, z, zstride)
status = vslzcorrexec1d(task, x, xstride, y, ystride, z, zstride)
```

C:

```
status = vslsConvExec1D(task, x, xstride, y, ystride, z, zstride);
```

```
status = vsldConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec1D(task, x, xstride, y, ystride, z, zstride);
```

Description

Each of the vslConvExec1D/vslCorrExec1D routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter *dims* is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding vslConvNewTask1D/vslCorrNewTask1D constructor and pointed to by *task*. If *task* is NULL, no operation is done.

vslConvExecX/vslCorrExecX

Computes convolution or correlation for multidimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexecx(task, y, ystride, z, zstride)
status = vsldconvexecx(task, y, ystride, z, zstride)
status = vslcconvexecx(task, y, ystride, z, zstride)
status = vslzconvexecx(task, y, ystride, z, zstride)
status = vslscorrexecx(task, y, ystride, z, zstride)
status = vsldcorrexecx(task, y, ystride, z, zstride)
status = vslccorrexecx(task, y, ystride, z, zstride)
status = vslzcorrexecx(task, y, ystride, z, zstride)
```

C:

```
status = vslsConvExecX(task, y, ystride, z, zstride);
status = vsldConvExecX(task, y, ystride, z, zstride);
status = vslcConvExecX(task, y, ystride, z, zstride);
status = vslzConvExecX(task, y, ystride, z, zstride);
status = vslsCorrExecX(task, y, ystride, z, zstride);
status = vslcCorrExecX(task, y, ystride, z, zstride);
status = vslzCorrExecX(task, y, ystride, z, zstride);
status = vsldCorrExecX(task, y, ystride, z, zstride);
```

Input Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslsconvexecx`, `vsldconvexecx`, `vslcconvexecx`, `vslzconvexecx` `INTEGER*4 task(2)` for `vslscorrexecx`, `vsldcorrexecx`, `vslccorrexecx`, `vslzcorrexecx` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslsconvexecx`, `vsldconvexecx`, `vslcconvexecx`, `vslzconvexecx` `TYPE(VSL_CORR_TASK)` for `vslscorrexecx`, `vsldcorrexecx`, `vslccorrexecx`, `vslzcorrexecx` **C:** `VSLConvTaskPtr` for `vslsConvExecX`, `vsldConvExecX`, `vslcConvExecX`, `vslzConvExecX` `VSLCorrTaskPtr` for `vslsCorrExecX`, `vsldCorrExecX`, `vslcCorrExecX`, `vslzCorrExecX`	Pointer to the task descriptor.
x ,*y*	**FORTRAN 77:** `REAL*4` for `vslsconvexecx` and `vslscorrexecx`, `REAL*8` for `vsldconvexecx` and `vsldcorrexecx`, `COMPLEX*8` for`vslcconvexecx` and `vslccorrexecx`, `COMPLEX*16` for`vslzconvexecx` and `vslzcorrexecx` **Fortran 90:** `REAL(KIND=4), DIMENSION(*)` for `vslsconvexecx` and `vslscorrexecx`,	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.

Name	Type	Description
	`REAL(KIND=8), DIMENSION(*)` for `vsldconvexecx` and `vsldcorrexecx`, `COMPLEX(KIND=4), DIMENSION (*)` for`vslcconvexecx` and `vslccorrexecx`, `COMPLEX(KIND=8), DIMENSION (*)` for `vslzconvexecx` and `vslzcorrexecx` **C:** `const float[]` for `vslsConvExecX` and `vslsCorrExecX`, `const double[]` for `vsldConvExecX` and `vsldCorrExecX`, `const MKL_Complex8[]` for `vslcConvExecX` and `vslcCorrExecX`, `const MKL_Complex16[]` for `vslzConvExecX` and `vslzCorrExecX`	
ystride ,*z stride*	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER, DIMENSION (*)` **C:** `const int[]`	Strides for input and output data. For more information, see stride parameters.

Output Parameters

Name	Type	Description
z	**FORTRAN 77:** `REAL*4` for `vslsconvexecx` and `vslscorrexecx`, `REAL*8` for `vsldconvexecx` and `vsldcorrexecx`, `COMPLEX*8` for`vslcconvexecx` and `vslccorrexecx`, `COMPLEX*16` for`vslzconvexecx` and `vslzcorrexecx` **Fortran 90:** `REAL(KIND=4), DIMENSION(*)` for `vslsconvexecx` and `vslscorrexecx`,	Pointer to the array that stores output data. See Data Allocation for more information.

Name	Type	Description
	`REAL(KIND=8), DIMENSION(*)` for `vsldconvexecx` and `vsldcorrexecx`, `COMPLEX(KIND=4), DIMENSION (*)` for`vslcconvexecx` and `vslccorrexecx`, `COMPLEX(KIND=8), DIMENSION (*)` for `vslzconvexecx` and `vslzcorrexecx` **C:** `const float[]` for `vslsConvExecX` and `vslsCorrExecX`, `const double[]` for `vsldConvExecX` and `vsldCorrExecX`, `const MKL_Complex8[]` for `vslcConvExecX` and `vslcCorrExecX`, `const MKL_Complex16[]` for `vslzConvExecX` and `vslzCorrExecX`	
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Set to `VSL_STATUS_OK` if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExecX`/`vslCorrExecX` routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array *x*.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX`/`vslCorrNewTaskX` constructor and pointed to by *task*. If *task* is `NULL`, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

vslConvExecX1D/vslCorrExecX1D

Computes convolution or correlation for one-dimensional case with the fixed first operand vector.

Syntax

Fortran:

```
status = vslsconvexecx1d(task, y, ystride, z, zstride)
```

```
status = vsldconvexecx1d(task, y, ystride, z, zstride)
status = vslcconvexecx1d(task, y, ystride, z, zstride)
status = vslzconvexecx1d(task, y, ystride, z, zstride)
status = vslscorrexecx1d(task, y, ystride, z, zstride)
status = vsldcorrexecx1d(task, y, ystride, z, zstride)
status = vslccorrexecx1d(task, y, ystride, z, zstride)
status = vslzcorrexecx1d(task, y, ystride, z, zstride)
```

C:

```
status = vslsConvExecX1D(task, y, ystride, z, zstride);
status = vsldConvExecX1D(task, y, ystride, z, zstride);
status = vslcConvExecX1D(task, y, ystride, z, zstride);
status = vslzConvExecX1D(task, y, ystride, z, zstride);
status = vslsCorrExecX1D(task, y, ystride, z, zstride);
status = vslcCorrExecX1D(task, y, ystride, z, zstride);
status = vslzCorrExecX1D(task, y, ystride, z, zstride);
status = vsldCorrExecX1D(task, y, ystride, z, zstride);
```

Input Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslsconvexecx1d`, `vsldconvexecx1d`, `vslcconvexecx1d`, `vslzconvexecx1d` `INTEGER*4 task(2)` for `vslscorrexecx1d`, `vsldcorrexecx1d`, `vslccorrexecx1d`, `vslzcorrexecx1d` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslsconvexecx1d`, `vsldconvexecx1d`, `vslcconvexecx1d`, `vslzconvexecx1d`	Pointer to the task descriptor.

Name	Type	Description
	`TYPE(VSL_CORR_TASK)` for `vslscorrexecx1d`, `vsldcorrexecx1d`, `vslccorrexecx1d`, `vslzcorrexecx1d` **C:** `VSLConvTaskPtr` for `vslsConvExecX1D`, `vsldConvExecX1D`, `vslcConvExecX1D`, `vslzConvExecX1D` `VSLCorrTaskPtr` for `vslsCorrExecX1D`, `vsldCorrExecX1D`, `vslcCorrExecX1D`, `vslzCorrExecX1D`	
x, *y*	**FORTRAN 77:** `REAL*4` for `vslsconvexecx1d` and `vslscorrexecx1d`, `REAL*8` for `vsldconvexecx1d` and `vsldcorrexecx1d`, `COMPLEX*8` for`vslcconvexecx1d` and `vslccorrexecx1d`, `COMPLEX*16` for`vslzconvexecx1d` and `vslzcorrexecx1d` **Fortran 90:** `REAL(KIND=4), DIMENSION(*)` for `vslsconvexecx1d` and `vslscorrexecx1d`, `REAL(KIND=8), DIMENSION(*)` for `vsldconvexecx1d` and `vsldcorrexecx1d`, `COMPLEX(KIND=4), DIMENSION(*)` for`vslcconvexecx1d` and `vslccorrexecx1d`, `COMPLEX(KIND=8), DIMENSION(*)` for `vslzconvexecx1d` and `vslzcorrexecx1d` **C:** `const float[]` for `vslsConvExecX1D` and `vslsCorrExecX1D`, `const double[]` for `vsldConvExecX1D` and `vsldCorrExecX1D`,	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.

Name	Type	Description
	`const MKL_Complex8[]` for `vslcConvExecX1D` and `vslcCorrExecX1D`, `const MKL_Complex16[]` for `vslzConvExecX1D` and `vslzCorrExecX1D`	
ystride, *zstride*	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `const int`	Strides for input and output data. For more information, see stride parameters.

Output Parameters

Name	Type	Description
z	**FORTRAN 77:** `REAL*4` for `vslsconvexecx1d` and `vslscorrexecx1d`, `REAL*8` for `vsldconvexecx1d` and `vsldcorrexecx1d`, `COMPLEX*8` for`vslcconvexecx1d` and `vslccorrexecx1d`, `COMPLEX*16` for`vslzconvexecx1d` and `vslzcorrexecx1d` **Fortran 90:** `REAL(KIND=4), DIMENSION(*)` for `vslsconvexecx1d` and `vslscorrexecx1d`, `REAL(KIND=8), DIMENSION(*)` for `vsldconvexecx1d` and `vsldcorrexecx1d`, `COMPLEX(KIND=4), DIMENSION(*)` for`vslcconvexecx1d` and `vslccorrexecx1d`, `COMPLEX(KIND=8), DIMENSION(*)` for `vslzconvexecx1d` and `vslzcorrexecx1d` **C:** `const float[]` for `vslsConvExecX1D` and `vslsCorrExecX1D`, `const double[]` for `vsldConvExecX1D` and `vsldCorrExecX1D`,	Pointer to the array that stores output data. See Data Allocation for more information.

Name	Type	Description
	`const MKL_Complex8[]` for `vslcConvExecX1D` and `vslcCorrExecX1D`, `const MKL_Complex16[]` for `vslzConvExecX1D` and `vslzCorrExecX1D`	
status	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Set to `VSL_STATUS_OK` if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExecX1D`/`vslCorrExecX1D` routines computes convolution or correlation of one-dimensional (assuming that *dims* =1) data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX1D`/`vslCorrNewTaskX1D` constructor and pointed to by *task*. If *task* is `NULL`, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

vslConvDeleteTask/vslCorrDeleteTask

Destroys the task object and frees the memory.

Syntax

Fortran:

```
errcode = vslconvdeletetask(task)
errcode = vslcorrdeletetask(task)
```

C:

```
errcode = vslConvDeleteTask(task);
errcode = vslCorrDeleteTask(task);
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**FORTRAN 77:** `INTEGER*4 task(2)` for `vslconvdeletetask` `INTEGER*4 task(2)` for `vslcorrdeletetask` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslconvdeletetask` `TYPE(VSL_CORR_TASK)` for `vslcorrdeletetask` **C:** `VSLConvTaskPtr*` for `vslConvDeleteTask` `VSLCorrTaskPtr*` for `vslCorrDeleteTask`	Pointer to the task descriptor.

Output Parameters

Name	Type	Description
errcode	**FORTRAN 77:** `INTEGER` **Fortran 90:** `INTEGER` **C:** `int`	Contains 0 if the task object is deleted successfully. Contains an error code if an error occurred.

Description

The `vslConvDeleteTask`/`vslCorrvDeleteTask` routine deletes the task descriptor object and frees any working memory and the memory allocated for the data structure. The task pointer is set to `NULL`.

Note that if the `vslConvDeleteTask`/`vslCorrvDeleteTask` routine does not delete the task successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

NOTE You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine terminates with no system crash.

Task Copy

The routines are designed for copying convolution and correlation task descriptors.

vslConvCopyTask/vslCorrCopyTask

Copies a descriptor for convolution or correlation task.

Syntax

Fortran:

```
status = vslconvcopytask(newtask, srctask)
```

```
status = vslcorrcopytask(newtask, srctask)
```

C:

```
status = vslConvCopyTask(newtask, srctask);
status = vslCorrCopyTask(newtask, srctask);
```

Include Files

- FORTRAN 77: `mkl_vsl.f77`
- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
srctask	**FORTRAN 77:** `INTEGER*4 srctask(2)` for `vslconvcopytask` `INTEGER*4 srctask(2)` for `vslcorrcopytask` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslconvcopytask` `TYPE(VSL_CORR_TASK)` for `vslcorrcopytask` **C:** `const VSLConvTaskPtr` for `vslConvCopyTask` `const VSLCorrTaskPtr` for `vslCorrCopyTask`	Pointer to the source task descriptor.

Output Parameters

Name	Type	Description
newtask	**FORTRAN 77:** `INTEGER*4 srctask(2)` for `vslconvcopytask` `INTEGER*4 srctask(2)` for `vslcorrcopytask` **Fortran 90:** `TYPE(VSL_CONV_TASK)` for `vslconvcopytask` `TYPE(VSL_CORR_TASK)` for `vslcorrcopytask` **C:** `VSLConvTaskPtr*` for `vslConvCopyTask` `VSLCorrTaskPtr*` for `vslCorrCopyTask`	Pointer to the new task descriptor.

Name	Type	Description
status	**FORTRAN 77:** INTEGER **Fortran 90:** INTEGER **C:** int	Current status of the source task.

Description

If a task object *srctask* already exists, you can use an appropriate vslConvCopyTask/vslCorrCopyTask routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see Introduction to Convolution and Correlation for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a NULL pointer instead of a reference to a new task object.

Usage Examples

This section demonstrates how you can use the Intel MKL routines to perform some common convolution and correlation operations both for single-threaded and multithreaded calculations. The following two sample functions scond1 and sconf1 simulate the convolution and correlation functions SCOND and SCONF found in IBM ESSL* library. The functions assume single-threaded calculations and can be used with C or C++ compilers.

Function scond1 for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int scond1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task,VSL_CONV_MODE_DIRECT,nh,nx,ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h,inch, x,incx, y,incy);
    vslConvDeleteTask(&task);
    return status;
}
```

Function sconf1 for Single-Threaded Calculations

```
#include "mkl_vsl.h"
int sconf1(
    int init,
    float h[], int inc1h,
    float x[], int inc1x, int inc2x,
    float y[], int inc1y, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)
{
    int status;
    /* assume that aux1!=0 and naux1 is big enough */
    VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;
    if (init != 0)
        /* initialization: */
        status = vslsConvNewTaskX1D(task,VSL_CONV_MODE_FFT,
         nh,nx,ny, h,inc1h);
    if (init == 0) {
        /* calculations: */
        int i;
        vslConvSetStart(*task, &iy0);
        for (i=0; i<m; i++) {
         float* xi = &x[inc2x * i];
         float* yi = &y[inc2y * i];
         /* task is implicitly committed at i==0 */
         status = vslsConvExecX1D(*task, xi, inc1x, yi, inc1y);
        };
    };
    vslConvDeleteTask(task);
    return status;
}
```

Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If `m>1`, you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create `m` copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using Task Editors) before copying it.

The sample code in this case may look as follows:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    . . .
    vslConvSetStart(*task, &iy0);
    . . .
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i],*task);
    . . .
```

Then, `m` threads may be started to execute different copies of the task:

```
. . .
        float* xi = &x[inc2x * i];
        float* yi = &y[inc2y * i];
        ss[i]=vslsConvExecX1D(tasks[i], xi,inc1x, yi,inc1y);
    . . .
```

And finally, after all threads have finished the calculations, overall status should be collected from all task objects. The following code signals the first error found, if any:

```
    . . .
    for (i=0; i<m; i++) {
        status = ss[i];
        if (status != 0) /* 0 means "OK" */
            break;
    };
    return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. That is why different threads must use different copies of the task.

Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$R = (-\infty, +\infty)$	The set of real numbers.
$Z = \{0, \pm1, \pm2, \ldots\}$	The set of integer numbers.
$Z^N = Z\times \ldots \times Z$	The set of N-dimensional series of integer numbers.
$p = (p_1, \ldots, p_N) \in Z^N$	N-dimensional series of integers.
u:$\mathbf{Z}^N \rightarrow \mathbf{R}$	Function u with arguments from $\mathbf{Z}^N$ and values from **R**.
$u(p) = u(p_1, \ldots, p_N)$	The value of the function u for the argument $(p_1, \ldots, p_N)$.
$w = u*v$	Function w is the convolution of the functions u, v.

$w = u \bullet v$	Function w is the correlation of the functions u, v.

Given series $p, q \in \mathbf{Z}^N$:

- series $r = p + q$ is defined as $r^n = p^n + q^n$ for every $n=1,\ldots,N$
- series $r = p - q$ is defined as $r^n = p^n - q^n$ for every $n=1,\ldots,N$
- series $r = \sup\{p, q\}$ is defines as $r^n = \max\{p^n, q^n\}$ for every $n=1,\ldots,N$
- series $r = \inf\{p, q\}$ is defined as $r^n = \min\{p^n, q^n\}$ for every $n=1,\ldots,N$
- inequality $p \le q$ means that $p^n \le q^n$ for every $n=1,\ldots,N$.

A function $u(p)$ is called a finite function if there exist series P^{min}, $P^{max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0$$

implies

$$P^{min} \le p \le P^{max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions u, v and series P^{min}, $P^{max}Q^{min}$, $Q^{max} \in \mathbf{Z}^N$ such that:

$u(p) \neq 0$ implies $P^{min} \le p \le P^{max}$.
$v(q) \neq 0$ implies $Q^{min} \le q \le Q^{max}$.

Definitions of linear correlation and linear convolution for functions u and v are given below.

Linear Convolution

If function $w = u*v$ is the convolution of u and v, then:

$w(r) \neq 0$ implies $R^{min} \le r \le R^{max}$,
where $R^{min} = P^{min} + Q^{min}$ and $R^{max} = P^{max} + Q^{max}$.

If $R^{min} \le r \le R^{max}$, then:

$w(r) = \sum u(t) \cdot v(r-t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $T^{min} \le t \le T^{max}$,
where $T^{min} = \sup\{P^{min}, r - Q^{max}\}$ and $T^{max} = \inf\{P^{max}, r - Q^{min}\}$.

Linear Correlation

If function $w = u \bullet v$ is the correlation of u and v, then:

$w(r) \neq 0$ implies $R^{min} \le r \le R^{max}$,
where $R^{min} = Q^{min} - P^{max}$ and $R^{max} = Q^{max} - P^{min}$.

If $R^{min} \le r \le R^{max}$, then:

$w(r) = \sum u(t) \cdot v(r+t)$ is the sum for all $t \in Z^N$ such that $T^{min} \le t \le T^{max}$,
where $T^{min} = \sup\{P^{min}, Q^{min} - r\}$ and $T^{max} = \inf\{P^{max}, Q^{max} - r\}$.

Representation of the functions u, v, w as the input/output data for the Intel MKL convolution and correlation functions is described in the Data Allocation section below.

Data Allocation

This section explains the relation between:

- mathematical finite functions u, v, w introduced in the section Mathematical Notation and Definitions;
- multi-dimensional input and output data vectors representing the functions u, v, w;
- arrays u, v, w used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays x, y, z

- Shape arrays *xshape*, *yshape*, *zshape*
- Strides within arrays *xstride*, *ystride*, *zstride*
- Parameters *start*, *decimation*

Finite Functions and Data Vectors

The finite functions *u(p)*, *v(q)*, and *w(r)* introduced above are represented as multi-dimensional vectors of input and output data:

inputu(i_1,...,i_{dims}) for *u*(p_1,...,p_N)

inputv(j_1,...,j_{dims}) for *v*(q_1,...,q_N)

output(k_1,...,k_{dims}) for *w*(r_1,...,r_N).

Parameter *dims* represents the number of dimensions and is equal to N.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of input/output vectors:

inputu(i_1,...,i_{dims}) is defined if $1 \le i_n \le xshape(n)$ for every n=1,...,*dims*

inputv(j_1,...,j_{dims}) is defined if $1 \le j_n \le yshape(n)$ for every n=1,...,*dims*

output(k_1,...,k_{dims}) is defined if $1 \le k_n \le zshape(n)$ for every n=1,...,*dims*.

Relation between the input vectors and the functions *u* and *v* is defined by the following formulas:

inputu(i_1,...,i_{dims})= *u*(p_1,...,p_N), where $p_n = P_n^{min} + (i_n-1)$ for every n

inputv(j_1,...,j_{dims})= *v*(q_1,...,q_N), where $q_n=Q_n^{min} + (j_n-1)$ for every n.

The relation between the output vector and the function *w(r)* is similar (but only in the case when parameters *start* and *decimation* are not defined):

output(k_1,...,k_{dims})= w(r_1,...,r_N), where $r_n=R_n^{min} + (k_n-1)$ for every n.

If the parameter *start* is defined, it must belong to the interval $R_n^{min} \le start(n) \le R_n^{max}$. If defined, the *start* parameter replaces R^{min} in the formula:

output(k_1,...,k_{dims})=w(r_1,...,r_N), where r_n=start(n) + (k_n-1)

If the parameter *decimation* is defined, it changes the relation according to the following formula:

output(k_1,...,k_{dims})=w(r_1,...,r_N), where $r_n= R_n^{min} + (k_n-1)$*decimation(n)

If both parameters *start* and *decimation* are defined, the formula is as follows:

output(k_1,...,k_{dims})=w(r_1,...,r_N), where r_n=start(n) + (k_n-1)*decimation(n)

The convolution and correlation software checks the values of *zshape*, *start*, and *decimation* during task commitment. If r_n exceeds R_n^{max} for some k_n,n=1,...,dims, an error is raised.

Allocation of Data Vectors

Both parameter arrays *x* and *y* contain input data vectors in memory, while array *z* is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters *x*, *y*, and *z*, you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays *x*, *y*, and *z* is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices $i, j, k \in \mathbf{Z}^N$, one-dimensional indices $e, f, g \in \mathbf{Z}$ are defined such that:

inputu(i_1,...,i_{dims}) is allocated at *x(e)*

inputv(j_1,...,j_{dims}) is allocated at *y(f)*

output(k_1,...,k_{dims}) is allocated at *z(g)*.

The indices *e*, *f*, and *g* are defined as follows:

e = 1 + ∑*xstride*(n)·*dx*(n) (the sum is for all n=1,...,dims)

f = 1 + ∑*ystride*(n)·*dy*(n) (the sum is for all n=1,...,dims)

g = 1 + ∑*zstride*(n)·*dz*(n) (the sum is for all n=1,...,dims)

The distances dx(n), dy(n), and dz(n) depend on the signum of the stride:

dx(n) = i_n-1 if xstride(n)>0, or dx(n) = i_n-xshape(n) if xstride(n)<0

dy(n) = j_n-1 if ystride(n)>0, or dy(n) = j_n-yshape(n) if ystride(n)<0

dz(n) = k_n-1 if zstride(n)>0, or dz(n) = k_n-zshape(n) if zstride(n)<0

The definitions of indices *e*, *f*, and *g* assume that indexes for arrays *x*, *y*, and *z* are started from unity:

x(e) is defined for e=1,...,length(x)

y(f) is defined for f=1,...,length(y)

z(g) is defined for g=1,...,length(z)

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array *z* for one-dimensional and two-dimensional cases.

One-dimensional case. If *dims*=1, then *zshape* is the number of the output values to be stored in the array *z*. The actual length of array *z* may be greater than *zshape* elements.

If zstride>1, output values are stored with the stride: output(1) is stored to z(1), output(2) is stored to z(1+zstride), and so on. Hence, the actual length of *z* must be at least 1+zstride*(zshape-1) elements or more.

If zstride<0, it still defines the stride between elements of array *z*. However, the order of the used elements is the opposite. For the *k*-th output value, output(k) is stored in z(1+|zstride|*(zshape-k)), where |zstride| is the absolute value of zstride. The actual length of the array *z* must be at least 1+|zstride|*(zshape - 1) elements.

Two-dimensional case. If *dims*=2, the output data is a two-dimensional matrix. The value zstride(1) defines the stride inside matrix columns, that is, the stride between the output(k_1, k_2) and output(k_1+1, k_2) for every pair of indices k_1, k_2. On the other hand, zstride(2) defines the stride between columns, that is, the stride between output(k_1,k_2) and output(k_1,k_2+1).

If zstride(2) is greater than zshape(1), this causes sparse allocation of columns. If the value of zstride(2) is smaller than zshape(1), this may result in the transposition of the output matrix. For example, if zshape = (2,3), you can define zstride = (3,1) to allocate output values like transposed matrix of the shape 3x2.

Whether zstride assumes this kind of transformations or not, you need to ensure that different elements output (k_1, ...,k_{dims}) will be stored in different locations *z(g)*.

VSL Summary Statistics

The VSL Summary Statistics domain comprises a set of routines that compute basic statistical estimates for single and double precision multi-dimensional datasets.

See the definition of the supported operations in the Mathematical Notation and Definitions section.

The VSL Summary Statistics routines calculate:

- raw and central moments up to the fourth order
- skewness and excess kurtosis (further referred to as *kurtosis* for brevity)

- variation coefficient
- quantiles and order statistics
- minimum and maximum
- variance-covariance/correlation matrix
- pooled/group variance-covariance matrix and mean
- partial variance-covariance/correlation matrix
- robust estimators for variance-covariance matrix and mean in presence of outliers

The library also contains functions to perform the following tasks:

- Detect outliers in datasets
- Support missing values in datasets
- Parameterize correlation matrices
- Compute quantiles for streaming data

You can access the VSL Summary Statistics routines through the Fortran 90 and C89 language interfaces. You can also use the C89 interface with later versions of the C/C++, or Fortran 90 interface with programs written in Fortran 95.

For users of the C/C++ and Fortran languages, Intel MKL provides the `mkl_vsl.h`, `mkl_vsl.f90`, and `mkl_vsl.f77` header files. All the header files are in the directory

```
${MKL}/include
```

See more details about the Fortran header in the Random Number Generators section of this chapter.

You can find examples that demonstrate calculation of the VSL Summary Statistics estimates in the following directories:

```
${MKL}/examples/vslc
```

```
${MKL}/examples/vslf
```

The VSL Summary Statistics API is implemented through task objects, or tasks. A task object is a data structure, or a descriptor, holding parameters that determine a specific VSL Summary Statistics operation. For example, such parameters may be precision, dimensions of user data, the matrix of the observations, or shapes of data arrays.

All the VSL Summary Statistics routines process a task object as follows:

1. Create a task.
2. Modify settings of the task parameters.
3. Compute statistical estimates.
4. Destroy the task.

The VSL Summary Statistics functions fall into the following categories:

Task Constructors - routines that create a new task object descriptor and set up most common parameters (dimension, number of observations, and matrix of the observations).

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Computation Routine - a routine that computes specified statistical estimates.

Task Destructor - a routine that deletes the task object and frees the memory.

A VSL Summary Statistics task object contains a series of pointers to the input and output data arrays. You can read and modify the datasets and estimates at any time but you should allocate and release memory for such data.

See detailed information on the algorithms, API, and their usage in the *Intel® MKL Summary Statistics Library Application Notes* on the Intel® MKL web page.

Naming Conventions

The names of the Fortran routines in the VSL Summary Statistics are in lowercase (`vslsseditquantiles`), while the names of types and constants are in uppercase. The names are not case-sensitive.

In C, the names of the routines, types, and constants are case-sensitive and can be lowercase and uppercase (`vslsSSEditQuantiles`).

The names of routines have the following structure:

`vsl[datatype]SS<base name>` for the C interface

`vsl[datatype]ss<base name>` for the Fortran interface

where

- `vsl` is a prefix indicating that the routine belongs to the Vector Statistical Library of Intel MKL.
- `[datatype]` specifies the type of the input and/or output data and can be `s` (single precision real type), `d` (double precision real type), or `i` (integer type).
- `SS`/`ss` indicates that the routine is intended for calculations of the VSL Summary Statistics estimates.
- `<base name>` specifies a particular functionality that the routine is designed for, for example, `NewTask`, `Compute`, `DeleteTask`.

NOTE The VSL Summary Statistics routine `vslDeleteTask` for deletion of the task is independent of the data type and its name omits the `[datatype]` field.

Data Types

The VSL Summary Statistics routines use the following data types for the calculations:

Type	Data Object
Fortran 90: `TYPE(VSL_SS_TASK)` **C:** `VSLSSTaskPtr`	Pointer to a VSL Summary Statistics task
Fortran 90: `REAL(KIND=4)` **C:** `float`	Input/output user data in single precision
Fortran 90: `REAL(KIND=8)` **C:** `double`	Input/output user data in double precision
Fortran 90: `INTEGER` or `INTEGER(KIND=8)` **C:** `MKL_INT` or `long long`	Other data

NOTE The actual size of the generic integer type is platform-specific and can be 32 or 64 bits in length. Before you compile your application, set an appropriate size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL User's Guide*.

Parameters

The basic parameters in the task descriptor (addresses of dimensions, number of observations, and datasets) are assigned values when the task editors create or modify the task object. Other parameters are determined by the specific task and changed by the task editors.

Task Status and Error Reporting

The task status is an integer value, which is zero if no error is detected, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names defined in the respective header files. For the C/C++ interface, these names are defined as macros via the `#define` statements, and for the Fortran interface as integer constants via the `PARAMETER` operators.

If no error is detected, the function returns the `VSL_STATUS_OK` code, which is defined as zero:

```
C/C++:          #define VSL_STATUS_OK 0
F90/F95:        INTEGER, PARAMETER::VSL_STATUS_OK = 0
```

In the case of an error, the function returns a non-zero error code that specifies the origin of the failure. The header files for both C/C++ and Fortran languages define the following status codes for the VSL Summary Statistics error codes:

VSL Summary Statistics Status Codes

Status Code	Description
VSL_STATUS_OK	Operation is successfully completed.
VSL_SS_ERROR_ALLOCATION_FAILURE	Memory allocation has failed.
VSL_SS_ERROR_BAD_DIMEN	Dimension value is invalid.
VSL_SS_ERROR_BAD_OBSERV_N	Invalid number (zero or negative) of observations was obtained.
VSL_SS_ERROR_STORAGE_NOT_SUPPORTED	Storage format is not supported.
VSL_SS_ERROR_BAD_INDC_ADDR	Array of indices is not defined.
VSL_SS_ERROR_BAD_WEIGHTS	Array of weights contains negative values.
VSL_SS_ERROR_BAD_MEAN_ADDR	Array of means is not defined.
VSL_SS_ERROR_BAD_2R_MOM_ADDR	Array of the second order raw moments is not defined.
VSL_SS_ERROR_BAD_3R_MOM_ADDR	Array of the third order raw moments is not defined.
VSL_SS_ERROR_BAD_4R_MOM_ADDR	Array of the fourth order raw moments is not defined.
VSL_SS_ERROR_BAD_2C_MOM_ADDR	Array of the second order central moments is not defined.
VSL_SS_ERROR_BAD_3C_MOM_ADDR	Array of the third order central moments is not defined.
VSL_SS_ERROR_BAD_4C_MOM_ADDR	Array of the fourth order central moments is not defined.
VSL_SS_ERROR_BAD_KURTOSIS_ADDR	Array of kurtosis values is not defined.
VSL_SS_ERROR_BAD_SKEWNESS_ADDR	Array of skewness values is not defined.
VSL_SS_ERROR_BAD_MIN_ADDR	Array of minimum values is not defined.
VSL_SS_ERROR_BAD_MAX_ADDR	Array of maximum values is not defined.
VSL_SS_ERROR_BAD_VARIATION_ADDR	Array of variation coefficients is not defined.
VSL_SS_ERROR_BAD_COV_ADDR	Covariance matrix is not defined.
VSL_SS_ERROR_BAD_COR_ADDR	Correlation matrix is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER_ADDR	Array of quantile orders is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_QUANT_ORDER	Quantile order value is invalid.
VSL_SS_ERROR_BAD_QUANT_ADDR	Array of quantiles is not defined.
VSL_SS_ERROR_BAD_ORDER_STATS_ADDR	Array of order statistics is not defined.
VSL_SS_ERROR_MOMORDER_NOT_SUPPORTED	Moment of requested order is not supported.
VSL_SS_NOT_FULL_RANK_MATRIX	Correlation matrix is not of full rank.
VSL_SS_ERROR_ALL_OBSERVS_OUTLIERS	All observations are outliers. (At least one observation must not be an outlier.)
VSL_SS_ERROR_BAD_ROBUST_COV_ADDR	Robust covariance matrix is not defined.
VSL_SS_ERROR_BAD_ROBUST_MEAN_ADDR	Array of robust means is not defined.
VSL_SS_ERROR_METHOD_NOT_SUPPORTED	Requested method is not supported.
VSL_SS_ERROR_NULL_TASK_DESCRIPTOR	Task descriptor is null.
VSL_SS_ERROR_BAD_OBSERV_ADDR	Dataset matrix is not defined.
VSL_SS_ERROR_BAD_ACCUM_WEIGHT_ADDR	Pointer to the variable that holds the value of accumulated weight is not defined.
VSL_SS_ERROR_SINGULAR_COV	Covariance matrix is singular.
VSL_SS_ERROR_BAD_POOLED_COV_ADDR	Pooled covariance matrix is not defined.
VSL_SS_ERROR_BAD_POOLED_MEAN_ADDR	Array of pooled means is not defined.
VSL_SS_ERROR_BAD_GROUP_COV_ADDR	Group covariance matrix is not defined.
VSL_SS_ERROR_BAD_GROUP_MEAN_ADDR	Array of group means is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC_ADDR	Array of group indices is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC	Group indices have improper values.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_ADDR	Array of parameters for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_N_ADDR	Pointer to size of the parameter array for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_WEIGHTS_ADDR	Output of the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_ADDR	Array of parameters of the robust covariance estimation algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_N_ADDR	Pointer to the number of parameters of the algorithm for robust covariance is not defined.
VSL_SS_ERROR_BAD_STORAGE_ADDR	Pointer to the variable that holds the storage format is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX_ADDR	Array that encodes sub-components of a random vector for the partial covariance algorithm is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX	Array that encodes sub-components of a random vector for partial covariance has improper values.
VSL_SS_ERROR_BAD_PARTIAL_COV_ADDR	Partial covariance matrix is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COR_ADDR	Partial correlation matrix is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_ADDR	Array of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_N_ADDR	Pointer to number of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_BAD_PARAMS_N	Size of the parameter array of the Multiple Imputation method is invalid.
VSL_SS_ERROR_BAD_MI_PARAMS	Parameters of the Multiple Imputation method are invalid.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_N_ADDR	Pointer to the number of initial estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_ADDR	Array of initial estimates for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_ADDR	Array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N_ADDR	Pointer to the size of the array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N_ADDR	Pointer to the number of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_ADDR	Array of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N	Invalid size of the array of simulated values in the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N	Invalid size of an array to hold parameter estimates obtained using the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_OUTPUT_PARAMS	Array of output parameters in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_N_ADDR	Pointer to the number of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_ADDR	Array of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_MISSING_VALS_N	Invalid number of missing values was obtained.
VSL_SS_SEMIDEFINITE_COR	Correlation matrix passed into the parameterization function is semi-definite.
VSL_SS_ERROR_BAD_PARAMTR_COR_ADDR	Correlation matrix to be parameterized is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_COR	All eigenvalues of the correlation matrix to be parameterized are non-positive.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N_ADDR	Pointer to the number of parameters for the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_ADDR	Array of parameters of the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N	Invalid number of parameters of the quantile computation algorithm for streaming data has been obtained.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS	Invalid parameters of the quantile computation algorithm for streaming data have been passed.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER_ADDR	Array of the quantile orders for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER	Invalid quantile order for streaming data is defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ADDR	Array of quantiles for streaming data is not defined.

Routines for robust covariance estimation, outlier detection, partial covariance estimation, multiple imputation, and parameterization of a correlation matrix can return internal error codes that are related to a specific implementation. Such error codes indicate invalid input data or other bugs in the Intel MKL routines other than the VSL Summary Statistics routines.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters.

NOTE If the constructor fails to create a task descriptor, it returns the NULL task pointer.

vslSSNewTask

Creates and initializes a new summary statistics task descriptor.

Syntax

Fortran:

```
status = vslsssnewtask(task, p, n, xstorage, x, w, indices)
status = vsldssnewtask(task, p, n, xstorage, x, w, indices)
```

C:

```
status = vslsSSNewTask(&task, p, n, xstorage, x, w, indices);
status = vsldSSNewTask(&task, p, n, xstorage, x, w, indices);
```

Include Files

- Fortran 90: mkl_vsl.f90

- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
p	**Fortran:** INTEGER **C:** MKL_INT	Dimension of the task, number of variables
n	**Fortran:** INTEGER **C:** MKL_INT	Number of observations
xstorage	**Fortran:** INTEGER **C:** MKL_INT	Storage format of matrix of observations
x	**Fortran:** REAL(KIND=4) DIMENSION(*) for vslsssnewtask REAL(KIND=8) DIMENSION(*) for vsldssnewtask **C:** float* for vslsSSNewTask double* for vsldSSNewTask	Matrix of observations
w	**Fortran:** REAL(KIND=4) DIMENSION(*) for vslsssnewtask REAL(KIND=8) DIMENSION(*) for vsldssnewtask **C:** float* for vslsSSNewTask double* for vsldSSNewTask	Array of weights of size *n*. Elements of the arrays are non-negative numbers. If a NULL pointer is passed, each observation is assigned weight equal to 1.
indices	**Fortran:** INTEGER, DIMENSION(*) **C:** MKL_INT*	Array of vector components that will be processed. Size of array is *p*. If a NULL pointer is passed, all components of random vector are processed.

Output Parameters

Name	Type	Description
task	**Fortran:** TYPE(VSL_SS_TASK) **C:** VSLSSTaskPtr*	Descriptor of the task
status	**Fortran:** INTEGER **C:** int	Set to VSL_STATUS_OK if the task is created successfully, otherwise a non-zero error code is returned.

Description

Each vslSSNewTask constructor routine creates a new summary statistics task descriptor with the user-specified value for a required parameter, dimension of the task. The optional parameters (matrix of observations, its storage format, number of observations, weights of observations, and indices of the random vector components) are set to their default values.

The observations of random p-dimensional vector $\xi = (\xi_1, ..., \xi_i, ..., \xi_p)$, which are n vectors of dimension p, are passed as a one-dimensional array x. The parameter *xstorage* defines the storage format of the observations and takes one of the possible values listed in Table "Storage format of matrix of observations and order statistics".

NOTE Since matrices in Fortran are stored by columns while in C they are stored by rows, initialization of the *xstorage* variable in Fortran is opposite to that in C. Set *xstorage* to VSL_SS_MATRIX_STORAGE_COLS, if the dataset is stored as a two-dimensional matrix that consists of p rows and n columns; otherwise, use the VSL_SS_MATRIX_STORAGE_ROWS constant.

Storage format of matrix of observations and order statistics

Parameter	Description
VSL_SS_MATRIX_STORAGE_ROWS	The observations of random vector ξ are packed by rows: n data points for the vector component ξ_1 come first, n data points for the vector component ξ_2 come second, and so forth.
VSL_SS_MATRIX_STORAGE_COLS	The observations of random vector ξ are packed by columns: the first p-dimensional observation of the vector ξ comes first, the second p-dimensional observation of the vector comes second, and so forth.

A one-dimensional array w of size n contains non-negative weights assigned to the observations. You can pass a NULL array into the constructor. In this case, each observation is assigned the default value of the weight.

You can choose vector components for which you wish to compute statistical estimates. If an element of the vector indices of size p contains 0, the observations that correspond to this component are excluded from the calculations. If you pass the NULL value of the parameter into the constructor, statistical estimates for all random variables are computed.

If the constructor fails to create a task descriptor, it returns the NULL task pointer.

Task Editors

Task editors are intended to set up or change the task parameters listed in Table "Parameters of VSL Summary Statistics Task to Be Initialized or Modified". As an example, to compute the sample mean for a one-dimensional dataset, initialize a variable for the mean value, and pass its address into the task as shown in the example below:

```
#define DIM    1
#define N   1000

int main()
{
     VSLSSTaskPtr task;
     double x[N];
     double mean;
     MKL_INT p, n, xstorage;
     int status;
     /* initialize variables used in the computations of sample mean */
     p = DIM;
     n = N;
     xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
     mean = 0.0;

     /* create task */
     status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, 0 );

     /* initialize task parameters */
```

```
    status = vsldSSEditTask( task, VSL_SS_ED_MEAN, &mean );

    /* compute mean using SS fast method */
    status = vsldSSCompute(task, VSL_SS_MEAN, VSL_SS_METHOD_FAST );

    /* deallocate task resources */
    status = vslSSDeleteTask( &task );

    return 0;
}
```

Use the single (`vslsssedittask`) or double (`vsldsedittask`) version of an editor, to initialize single or double precision version task parameters, respectively. Use an integer version of an editor (`vslisseditask`) to initialize parameters of the integer type.

Table "VSL Summary Statistics Task Editors" lists the task editors for VSL Summary Statistics. Each of them initializes and/or modifies a respective group of related parameters.

VSL Summary Statistics Task Editors

Editor	Description
vslSSEditTask	Changes a pointer in the task descriptor.
vslSSEditMoments	Changes pointers to arrays associated with raw and central moments.
vslSSEditCovCor	Changes pointers to arrays associated with covariance and/or correlation matrices.
vslSSEditPartialCovCor	Changes pointers to arrays associated with partial covariance and/or correlation matrices.
vslSSEditQuantiles	Changes pointers to arrays associated with quantile/order statistics calculations.
vslSSEditStreamQuantiles	Changes pointers to arrays for quantile related calculations for streaming data.
vslSSEditPooledCovariance	Changes pointers to arrays associated with algorithms related to a pooled covariance matrix.
vslSSEditRobustCovariance	Changes pointers to arrays for robust estimation of a covariance matrix and mean.
vslSSEditOutliersDetection	Changes pointers to arrays for detection of outliers.
vslSSEditMissingValues	Changes pointers to arrays associated with the method of supporting missing values in a dataset.
vslSSEditCorParameterization	Changes pointers to arrays associated with the algorithm for parameterization of a correlation matrix.

NOTE You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslSSEditTask

Modifies address of an input/output parameter in the task descriptor.

Syntax

Fortran:

```
status = vslsssedittask(task, parameter, par_addr)
```

```
status = vsldssedittask(task, parameter, par_addr)
status = vslissedittask(task, parameter, par_addr)
```

C:

```
status = vslsSSEditTask(task, parameter, par_addr);
status = vsldSSEditTask(task, parameter, par_addr);
status = vsliSSEditTask(task, parameter, par_addr);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(VSL_SS_TASK)` **C:** `VSLSSTaskPtr`	Descriptor of the task
parameter	**Fortran:** `INTEGER` **C:** `MKL_INT`	Parameter to change
par_addr	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssedittask` `REAL(KIND=8) DIMENSION(*)` for `vsldssedittask` `INTEGER DIMENSION(*)` for `vslissedittask` **C:** `float*` for `vslsSSEditTask` `double*` for `vsldSSEditTask` `MKL_INT*` for `vsliSSEditTask`	Address of the new parameter

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditTask` routine replaces the pointer to the parameter stored in the VSL Summary Statistics task descriptor with the *par_addr* pointer. If you pass the `NULL` pointer to the editor, no changes take place in the task and a corresponding error code is returned. See Table "Parameters of VSL Summary Statistics Task to Be Initialized or Modified" for the predefined values of the parameter.

Use the single (`vslsssedittask`) or double (`vsldssedittask`) version of the editor, to initialize single or double precision version task parameters, respectively. Use an integer version of the editor (`vslissedittask`) to initialize parameters of the integer type.

Parameters of VSL Summary Statistics Task to Be Initialized or Modified

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_DIMEN	i	Address of a variable that holds the task dimension	Required. Positive integer value.
VSL_SS_ED_OBSERV_N	i	Address of a variable that holds the number of observations	Required. Positive integer value.
VSL_SS_ED_OBSERV	d, s	Address of the observation matrix	Required. Provide the matrix containing your observations.
VSL_SS_ED_OBSERV_STORAGE	i	Address of a variable that holds the storage format for the observation matrix	Required. Provide a storage format supported by the library whenever you pass a matrix of observations.[1]
VSL_SS_ED_INDC	i	Address of the array of indices	Optional. Provide this array if you need to process individual components of the random vector. Set entry *i* of the array to one to include the *i*th coordinate in the analysis. Set entry *i* of the array to zero to exclude the *i*th coordinate from the analysis.
VSL_SS_ED_WEIGHTS	d, s	Address of the array of observation weights	Optional. If the observations have weights different from the default weight (one), set entries of the array to non-negative floating point values.
VSL_SS_ED_MEAN	d, s	Address of the array of means	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_MOM	d, s	Address of an array of raw moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_MOM	d, s	Address of an array of raw moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4R_MOM	d, s	Address of an array of raw moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_2C_MOM	d, s	Address of an array of central moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_3C_MOM	d, s	Address of an array of central moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_4C_MOM	d, s	Address of an array of central moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_KURTOSIS	d, s	Address of the array of kurtosis estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_SKEWNESS	d, s	Address of the array of skewness estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_MIN	d, s	Address of the array of minimum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_MAX	d, s	Address of the array of maximum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_VARIATION	d, s	Address of the array of variation coefficients	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_COV	d, s	Address of a covariance matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Make sure you also provide an array for the mean.
VSL_SS_ED_COV_STORAGE	i	Address of the variable that holds the storage format for a covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute the covariance matrix.[2]
VSL_SS_ED_COR	d, s	Address of a correlation matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. If you initialize the matrix in non-trivial way, make sure that the main diagonal contains variance values. Also, provide an array for the mean.
VSL_SS_ED_COR_STORAGE	i	Address of the variable that holds the correlation storage format for a correlation matrix	Required. Provide a storage format supported by the library whenever you intend to compute the correlation matrix.[2]
VSL_SS_ED_ACCUM_WEIGHT	d, s	Address of the array of size 2 that holds the accumulated weight (sum of weights) in the first position and the sum of weights squared in the second position	Optional. Set the entries of the matrix to meaningful values (typically zero) if you intend to do progressive processing of the dataset or need the sum of weights and sum of squared weights assigned to observations.
VSL_SS_ED_QUANT_ORDER_N	i	Address of the variable that holds the number of quantile orders	Required. Positive integer value. Provide the number of quantile orders whenever you compute quantiles.
VSL_SS_ED_QUANT_ORDER	d, s	Address of the array of quantile orders	Required. Set entries of array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_QUANT_QUANTILES	d, s	Address of the array of quantiles	None.
VSL_SS_ED_ORDER_STATS	d, s	Address of the array of order statistics	None.
VSL_SS_ED_GROUP_INDC	i	Address of the array of group indices used in computation of a pooled covariance matrix	Required. Set entry i to integer value k if the observation belongs to group k. Values of k take values in the range [0, g-1], where g is the number of groups.
VSL_SS_ED_POOLED_COV_STORAGE	i	Address of a variable that holds the storage format for a pooled covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute pooled covariance.[2]
VSL_SS_ED_POOLED_MEAN	i	Address of an array of pooled means	None.
VSL_SS_ED_POOLED_COV	d, s	Address of pooled covariance matrices	None.
VSL_SS_ED_GROUP_COV_INDC	d, s	Address of an array of indices for which covariance/means should be computed	Optional. Set the kth entry of the array to 1 if you need group covariance and mean for group k; otherwise set it to zero.
VSL_SS_ED_GROUP_MEANS	i	Address of an array of group means	None.
VSL_SS_ED_GROUP_COV_STORAGE	d, s	Address of a variable that holds the storage format for a group covariance matrix	Required. Provide a storage format supported by the library whenever you intend to get group covariance.[2]
VSL_SS_ED_GROUP_COV	i	Address of group covariance matrices	None.
VSL_SS_ED_ROBUST_COV_STORAGE	d, s	Address of a variable that holds the storage format for a robust covariance matrix	Required. Provide a storage format supported by the library whenever you compute robust covariance[2].
VSL_SS_ED_ROBUST_COV_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters of the method for robust covariance estimation	Required. Set to the number of TBS parameters, *VSL_SS_TBS_PARAMS_N*.
VSL_SS_ED_ROBUST_COV_PARAMS	d, s	Address of an array of parameters of the method for robust estimation of a covariance	Required. Set the entries of the array according to the description in EditRobustCovariance.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_ROBUST_MEAN	i	Address of an array of robust means	None.
VSL_SS_ED_ROBUST_COV	d, s	Address of a robust covariance matrix	None.
VSL_SS_ED_OUTLIERS_PARAMS_N	d, s	Address of a variable that holds the number of parameters of the outlier detection method	Required. Set to the number of outlier detection parameters, *VSL_SS_BACON_PARAMS_N*.
VSL_SS_ED_OUTLIERS_PARAMS	i	Address of an array of algorithmic parameters for the outlier detection method	Required. Set the entries of the array according to the description in EditOutliersDetection.
VSL_SS_ED_OUTLIERS_WEIGHT	d, s	Address of an array of weights assigned to observations by the outlier detection method	None.
VSL_SS_ED_ORDER_STATS_STORAGE	d, s	Address of a variable that holds the storage format of an order statistics matrix	Required. Provide a storage format supported by the library whenever you compute a matrix of order statistics.[1]
VSL_SS_ED_PARTIAL_COV_IDX	i	Address of an array that encodes subcomponents of a random vector	Required. Set the entries of the array according to the description in EditPartialCovCor.
VSL_SS_ED_PARTIAL_COV	d, s	Address of a partial covariance matrix	None.
VSL_SS_ED_PARTIAL_COV_STORAGE	i	Address of a variable that holds the storage format of a partial covariance matrix	Required. Provide a storage format supported by the library whenever you compute the partial covariance.[2]
VSL_SS_ED_PARTIAL_COR	d, s	Address of a partial correlation matrix	None.
VSL_SS_ED_PARTIAL_COR_STORAGE	i	Address of a variable that holds the storage format for a partial correlation matrix	Required. Provide a storage format supported by the library whenever you compute the partial correlation.[2]
VSL_SS_ED_MI_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters for the Multiple Imputation method	Required. Set to the number of MI parameters, *VSL_SS_MI_PARAMS_SIZE*.
VSL_SS_ED_MI_PARAMS	d, s	Address of an array of algorithmic parameters for the Multiple Imputation method	Required. Set entries of the array according to the description in EditMissingValues.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_MI_INIT_ESTIMATES_N	i	Address of a variable that holds the number of initial estimates for the Multiple Imputation method	Optional. Set to $p+p*(p+1)/2$, where p is the task dimension.
VSL_SS_ED_MI_INIT_ESTIMATES	d, s	Address of an array of initial estimates for the Multiple Imputation method	Optional. Set the values of the array according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the *Intel® MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.
VSL_SS_ED_MI_SIMUL_VALS_N	i	Address of a variable that holds the number of simulated values in the Multiple Imputation method	Optional. Positive integer indicating the number of missing points in the observation matrix.
VSL_SS_ED_MI_SIMUL_VALS	d, s	Address of an array of simulated values in the Multiple Imputation method	None.
VSL_SS_ED_MI_ESTIMATES_N	i	Address of a variable that holds the number of estimates obtained as a result of the Multiple Imputation method	Optional. Positive integer number defined according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the *Intel® MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.
VSL_SS_ED_MI_ESTIMATES	d, s	Address of an array of estimates obtained as a result of the Multiple Imputation method	None.
VSL_SS_ED_MI_PRIOR_N	i	Address of a variable that holds the number of prior parameters for the Multiple Imputation method	Optional. If you pass a user-defined array of prior parameters, set this parameter to $(p^2+3*p+4)/2$, where p is the task dimension.
VSL_SS_ED_MI_PRIOR	d, s	Address of an array of prior parameters for the Multiple Imputation method	Optional. Set entries of the array of prior parameters according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics Library" in the *Intel® MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_PARAMTR_COR	d, s	Address of a parameterized correlation matrix	None.
VSL_SS_ED_PARAMTR_COR_STORAGE	i	Address of a variable that holds the storage format of a parameterized correlation matrix	Required. Provide a storage format supported by the library whenever you compute the parameterized correlation matrix.[2]
VSL_SS_ED_STREAM_QUANT_PARAMS_N	i	Address of a variable that holds the number of parameters of a quantile computation method for streaming data	Required. Set to the number of quantile computation parameters, *VSL_SS_SQUANTS_ZW_PARAMS_N*.
VSL_SS_ED_STREAM_QUANT_PARAMS	d, s	Address of an array of parameters of a quantile computation method for streaming data	Required. Set the entries of the array according to the description in "Computing Quantiles for Streaming Data" in the *Intel® MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.
VSL_SS_ED_STREAM_QUANT_ORDER_N	i	Address of a variable that holds the number of quantile orders for streaming data	Required. Positive integer value.
VSL_SS_ED_STREAM_QUANT_ORDER	d, s	Address of an array of quantile orders for streaming data	Required. Set entries of the array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_STREAM_QUANT_QUANTILES	d, s	Address of an array of quantiles for streaming data	None.

1. See Table: "Storage format of matrix of observations and order statistics" for storage formats.
2. See Table: "Storage formats of a variance-covariance/correlation matrix" for storage formats.

vslSSEditMoments

Modifies the pointers to arrays that hold moment estimates.

Syntax

Fortran:

```
status = vslssseditmoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m)
status = vsldsseditmoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m)
```

C:

```
status = vslsSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
status = vsldSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(VSL_SS_TASK)` **C:** `VSLSSTaskPtr`	Descriptor of the task
mean	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditmoments` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditmoments` **C:** `float*` for `vslsSSEditMoments` `double*` for `vsldSSEditMoments`	Pointer to the array of means
r2m	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditmoments` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditmoments` **C:** `float*` for `vslsSSEditMoments` `double*` for `vsldSSEditMoments`	Pointer to the array of raw moments of the 2nd order
r3m	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditmoments` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditmoments` **C:** `float*` for `vslsSSEditMoments` `double*` for `vsldSSEditMoments`	Pointer to the array of raw moments of the 3rd order
r4m	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditmoments` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditmoments` **C:** `float*` for `vslsSSEditMoments` `double*` for `vsldSSEditMoments`	Pointer to the array of raw moments of the 4th order
c2m	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditmoments` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditmoments` **C:** `float*` for `vslsSSEditMoments` `double*` for `vsldSSEditMoments`	Pointer to the array of central moments of the 2nd order
c3m	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditmoments`	Pointer to the array of central moments of the 3rd order

Name	Type	Description
	`REAL(KIND=8) DIMENSION(*)` for `vsldsseditmoments` **C:** `float*` for `vslsSSEditMoments` `double*` for `vsldSSEditMoments`	
c4m	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditmoments` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditmoments` **C:** `float*` for `vslsSSEditMoments` `double*` for `vsldSSEditMoments`	Pointer to the array of central moments of the 4th order

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditMoments` routine replaces pointers to the arrays that hold estimates of raw and central moments with values passed as corresponding parameters of the routine. If an input parameter is `NULL`, the value of the relevant parameter remains unchanged.

vslSSEditCovCor

Modifies the pointers to covariance/correlation parameters.

Syntax

Fortran:

```
status = vslsssseditcovcor(task, mean, cov, cov_storage, cor, cor_storage)
status = vsldsseditcovcor(task, mean, cov, cov_storage, cor, cor_storage)
```

C:

```
status = vslsSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
status = vsldSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(VSL_SS_TASK)`	Descriptor of the task

Name	Type	Description
	C: `VSLSSTaskPtr`	
mean	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsseditcovcor` `REAL(KIND=8) DIMENSION(*)` for `vsldseditcovcor` **C:** `float*` for `vslsSSEditCovCor` `double*` for `vsldSSEditCovCor`	Pointer to the array of means
cov	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsseditcovcor` `REAL(KIND=8) DIMENSION(*)` for `vsldseditcovcor` **C:** `float*` for `vslsSSEditCovCor` `double*` for `vsldSSEditCovCor`	Pointer to a covariance matrix
cov_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of the covariance matrix
cor	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsseditcovcor` `REAL(KIND=8) DIMENSION(*)` for `vsldseditcovcor` **C:** `float*` for `vslsSSEditCovCor` `double*` for `vsldSSEditCovCor`	Pointer to a correlation matrix
cor_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of the correlation matrix

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditCovCor` routine replaces pointers to the array of means, covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See Table "Storage formats of a variance-covariance/correlation matrix" for possible values of the *cov_storage* and *cor_storage* parameters. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the VSL Summary Statistics task descriptor.

Storage formats of a variance-covariance/correlation matrix

Parameter	Description
VSL_SS_MATRIX_STORAGE_FULL	A symmetric variance-covariance/correlation matrix is a one-dimensional array with elements $c(i,j)$ stored as $cp(i*p + j)$. The size of the array is $p*p$.
VSL_SS_MATRIX_STORAGE_L_PACKED	A symmetric variance-covariance/correlation matrix with elements $c(i,j)$ is packed as a one-dimensional array $cp(i + (2n - j)*(j - 1)/2)$ for $j \le i$. The size of the array is $p*(p+ 1)/2$.
VSL_SS_MATRIX_STORAGE_U_PACKED	A symmetric variance-covariance/correlation matrix with elements $c(i,j)$ is packed as a one-dimensional array $cp(i + j*(j - 1)/2)$ for $i \le j$. The size of the array is $p*(p+ 1)/2$.

vslSSEditPartialCovCor

Modifies the pointers to partial covariance/correlation parameters.

Syntax

Fortran:

```
status = vslssseditpartialcovcor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage)
```

```
status = vsldsseditpartialcovcor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage)
```

C:

```
status = vslsSSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage);
```

```
status = vsldSSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(VSL_SS_TASK) **C:** VSLSSTaskPtr	Descriptor of the task
p_idx_array	**Fortran:** INTEGER **C:** MKL_INT*	Pointer to the array that encodes indices of subcomponents z and Y of the random vector as described in section Mathematical Notation and Definitions. *p_idx_array[i]* equals to

Name	Type	Description
		-1 if the *i*-th component of the random vector belongs to *Z* 1, if the *i*-th component of the random vector belongs to *Y*.
cov	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditpartialcovcor` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpartialcovcor` **C:** `float*` for `vslsSSEditPartialCovCor` `double*` for `vsldSSEditPartialCovCor`	Pointer to a covariance matrix
cov_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of the covariance matrix
cor	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditpartialcovcor` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpartialcovcor` **C:** `float*` for `vslsSSEditPartialCovCor` `double*` for `vsldSSEditPartialCovCor`	Pointer to a correlation matrix
cor_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of the correlation matrix
p_cov	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditpartialcovcor` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpartialcovcor` **C:** `float*` for `vslsSSEditPartialCovCor` `double*` for `vsldSSEditPartialCovCor`	Pointer to a partial covariance matrix
p_cov_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of the partial covariance matrix
p_cor	**Fortran:** `REAL(KIND=4) DIMENSION(*)`	Pointer to a partial correlation matrix

Name	Type	Description
	for `vslsssEditPartialCovCor` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpartialcovcor` **C:** `float*` for `vslsSSEditPartialCovCor` `double*` for `vsldSSEditPartialCovCor`	
p_cor_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of the partial correlation matrix

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditPartialCovCor` routine replaces pointers to covariance/correlation arrays, partial covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See Table "Storage formats of a variance-covariance/correlation matrix" for possible values of the *cov_storage*, *cor_storage*, *p_cov_storage*, and *p_cor_storage* parameters. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the VSL Summary Statistics task descriptor.

vslSSEditQuantiles

Modifies the pointers to parameters related to quantile computations.

Syntax

Fortran:

```
status = vslsssEditQuantiles(task, quant_order_n, quant_order, quants, order_stats, order_stats_storage)
status = vsldsseditquantiles(task, quant_order_n, quant_order, quants, order_stats, order_stats_storage)
```

C:

```
status = vslsSSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats, order_stats_storage);
status = vsldSSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats, order_stats_storage);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(VSL_SS_TASK) **C:** VSLSSTaskPtr	Descriptor of the task
quant_order_n	**Fortran:** INTEGER **C:** MKL_INT*	Pointer to the number of quantile orders
quant_order	**Fortran:** REAL(KIND=4) DIMENSION(*) for vslssseditquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditquantiles **C:** float* for vslsSSEditQuantiles double* for vsldSSEditQuantiles	Pointer to the array of quantile orders
quants	**Fortran:** REAL(KIND=4) DIMENSION(*) for vslssseditquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditquantiles **C:** float* for vslsSSEditQuantiles double* for vsldSSEditQuantiles	Pointer to the array of quantiles
order_stats	**Fortran:** REAL(KIND=4) DIMENSION(*) for vslssseditquantiles REAL(KIND=8) DIMENSION(*) for vsldsseditquantiles **C:** float* for vslsSSEditQuantiles double* for vsldSSEditQuantiles	Pointer to the array of order statistics
order_stats_storage	**Fortran:** INTEGER **C:** MKL_INT*	Pointer to the storage format of the order statistics array

Output Parameters

Name	Type	Description
status	**Fortran:** INTEGER	Current status of the task

Name	Type	Description
	C: `int`	

Description

The `vslSSEditQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the array that holds order statistics, and the storage format for the order statistics with values passed into the routine. See Table "Storage format of matrix of observations and order statistics" for possible values of the *order_statistics_storage* parameter. If an input parameter is `NULL`, the corresponding parameter in the VSL Summary Statistics task descriptor remains unchanged.

vslSSEditStreamQuantiles

Modifies the pointers to parameters related to quantile computations for streaming data.

Syntax

Fortran:

status = vslsssseditstreamquantiles(*task*, *quant_order_n*, *quant_order*, *quants*, *nparams*, *params*)

status = vsldsseditstreamquantiles(*task*, *quant_order_n*, *quant_order*, *quants*, *nparams*, *params*)

C:

status = vslsSSEditStreamQuantiles(*task*, *quant_order_n*, *quant_order*, *quants*, *nparams*, *params*);

status = vsldSSEditStreamQuantiles(*task*, *quant_order_n*, *quant_order*, *quants*, *nparams*, *params*);

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(VSL_SS_TASK)`	Descriptor of the task
	C: `VSLSSTaskPtr`	
quant_order_n	**Fortran:** `INTEGER`	Pointer to the number of quantile orders
	C: `MKL_INT*`	
quant_order	**Fortran:** `REAL(KIND=4) DIMENSION(*)`	Pointer to the array of quantile orders
	for `vslsssseditstreamquantiles`	
	`REAL(KIND=8) DIMENSION(*)`	
	for `vsldsseditstreamquantiles`	
	C: `float*`	
	for `vslsSSEditStreamQuantiles`	

Name	Type	Description
	`double*` for `vsldSSEditStreamQuantiles`	
quants	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditstreamquantiles` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditstreamquantiles` **C:** `float*` for `vslsSSEditStreamQuantiles` `double*` for `vsldSSEditStreamQuantiles`	Pointer to the array of quantiles
nparams	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the number of the algorithm parameters
params	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditstreamquantiles` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditstreamquantiles` **C:** `float*` for `vslsSSEditStreamQuantiles` `double*` for `vsldSSEditStreamQuantiles`	Pointer to the array of the algorithm parameters

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditStreamQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the number of the algorithm parameters, and the array of the algorithm parameters with values passed into the routine. If an input parameter is `NULL`, the corresponding parameter in the VSL Summary Statistics task descriptor remains unchanged.

vslSSEditPooledCovariance

Modifies pooled/group covariance matrix array pointers.

Syntax

Fortran:

```
status = vslsssEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
grp_cov_indices, grp_means, grp_cov)
status = vsldsseditpooledcovariance(task, grp_indices, pld_mean, pld_cov,
grp_cov_indices, grp_means, grp_cov)
```

C:

```
status = vslsSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
grp_cov_indices, grp_means, grp_cov);
status = vsldSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
grp_cov_indices, grp_means, grp_cov);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(VSL_SS_TASK)` **C:** `VSLSSTaskPtr`	Descriptor of the task
grp_indices	**Fortran:** `INTEGER DIMENSION(*)` **C:** `MKL_INT*`	Pointer to an array of size *n*. The *i*-th element of the array contains the number of the group the observation belongs to.
pld_mean	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssEditPooledCovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpooledcovariance` **C:** `float*` for `vslsSSEditPooledCovariance` `double*` for `vsldSSEditPooledCovariance`	Pointer to the array of pooled means
pld_cov	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssEditPooledCovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpooledcovariance` **C:** `float*` for `vslsSSEditPooledCovariance` `double*` for	Pointer to the array that holds a pooled covariance matrix

Name	Type	Description
	`vsldSSEditPooledCovariance`	
grp_cov_indices	**Fortran:** `INTEGER DIMENSION(*)` **C:** `MKL_INT*`	Pointer to the array that contains indices of group covariance matrices to return
grp_means	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditpooledcovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpooledcovariance` **C:** `float*` for `vslsSSEditPooledCovariance` `double*` for `vsldSSEditPooledCovariance`	Pointer to the array of group means
grp_cov	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditpooledcovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditpooledcovariance` **C:** `float*` for `vslsSSEditPooledCovariance` `double*` for `vsldSSEditPooledCovariance`	Pointer to the array that holds group covariance matrices

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditPooledCovariance` routine replaces pointers to the array of group indices, the array of pooled means, the array for a pooled covariance matrix, and pointers to the array of indices of group matrices, the array of group means, and the array for group covariance matrices with values passed in the editors. If an input parameter is `NULL`, the corresponding parameter in the VSL Summary Statistics task descriptor remains unchanged. Use the `vslSSEditTask` routine to replace the storage format for pooled and group covariance matrices.

vslSSEditRobustCovariance

Modifies pointers to arrays related to a robust covariance matrix.

Syntax

Fortran:

```
status = vslsssEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov)
status = vsldsseditrobustcovariance(task, rcov_storage, nparams, params, rmean, rcov)
```

C:

```
status = vslsSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
status = vsldSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(VSL_SS_TASK)` **C:** `VSLSSTaskPtr`	Descriptor of the task
rcov_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of a robust covariance matrix
nparams	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the number of method parameters
params	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssEditRobustCovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditrobustcovariance` **C:** `float*` for `vslsSSEditRobustCovariance` `double*` for `vsldSSEditRobustCovariance`	Pointer to the array of method parameters
rmean	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssEditRobustCovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditrobustcovariance` **C:** `float*` for `vslsSSEditRobustCovariance` `double*` for	Pointer to the array of robust means

Name	Type	Description
	`vsldSSEditRobustCovariance`	
rcov	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsssseditrobustcovariance` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditrobustcovariance` **C:** `float*` for `vslsSSEditRobustCovariance` `double*` for `vsldSSEditRobustCovariance`	Pointer to a robust covariance matrix

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditRobustCovariance` routine uses values passed as parameters of the routine to replace:

- pointers to covariance matrix storage
- pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- pointers to the arrays that hold robust means and covariance

See Table "Storage formats of a variance-covariance/correlation matrix" for possible values of the *rcov_storage* parameter. If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Intel MKL provides a Translated Biweight S-estimator (TBS) for robust estimation of a variance-covariance matrix and mean [Rocke96]. Use one iteration of the Maronna algorithm with the reweighting step [Maronna02] to compute the initial point of the algorithm. Pack the parameters of the TBS algorithm into the *params* array and pass them into the editor. Table "Structure of the Array of TBS Parameters" describes the *params* structure.

Structure of the Array of TBS Parameters

Array Position	Algorithm Parameter	Description
0	ε	Breakdown point, the number of outliers the algorithm can hold. By default, the value is $(n-p)/(2n)$.
1	α	Asymptotic rejection probability, see details in [Rocke96]. By default, the value is 0.001.
2	δ	Stopping criterion: the algorithm is terminated if weights are changed less than δ. By default, the value is 0.001.
3	`max_iter`	Maximum number of iterations. The algorithm terminates after `max_iter` iterations. By default, the value is 10.

Array Position	Algorithm Parameter	Description
		If you set this parameter to zero, the function returns a robust estimate of the variance-covariance matrix computed using the Maronna method [Maronna02] only.

See additional details of the algorithm usage model in the *Intel© MKL Summary Statistics Library Application Notes* document on the Intel© MKL web page.

vslSSEditOutliersDetection

Modifies array pointers related to multivariate outliers detection.

Syntax

Fortran:

```
status = vslssseditoutliersdetection(task, nparams, params, w)
status = vsldsseditoutliersdetection(task, nparams, params, w)
```

C:

```
status = vslsSSEditOutliersDetection(task, nparams, params, w);
status = vsldSSEditOutliersDetection(task, nparams, params, w);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(VSL_SS_TASK)` **C:** `VSLSSTaskPtr`	Descriptor of the task
nparams	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the number of method parameters
params	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslssseditoutliersdetection` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditoutliersdetection` **C:** `float*` for `vslsSSEditOutliersDetection` `double*` for `vsldSSEditOutliersDetection`	Pointer to the array of method parameters

Name	Type	Description
w	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslssseditoutliersdetection` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditoutliersdetection` **C:** `float*` for `vslsSSEditOutliersDetection` `double*` for `vsldSSEditOutliersDetection`	Pointer to an array of size *n*. The array holds the weights of observations to be marked as outliers.

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditOutliersDetection` routine uses the parameters passed to replace

- the pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- the pointer to the array that holds the calculated weights of the observations

If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Intel MKL provides the BACON algorithm ([Billor00]) for the detection of multivariate outliers. Pack the parameters of the BACON algorithm into the *params* array and pass them into the editor. Table "Structure of the Array of BACON Parameters" describes the *params* structure.

Structure of the Array of BACON Parameters

Array Position	Algorithm Parameter	Description
0	Method to start the algorithm	The parameter takes one of the following possible values: `VSL_SS_METHOD_BACON_MEDIAN_INIT`, if the algorithm is started using the median estimate. This is the default value of the parameter. `VSL_SS_METHOD_BACON_MAHALANOBIS_INIT`, if the algorithm is started using the Mahalanobis distances.
1	α	One-tailed probability that defines the $(1 - \alpha)$ quantile of χ^2 distribution with p degrees of freedom. The recommended value is α / n, where n is the number of observations. By default, the value is 0.05.
2	δ	Stopping criterion; the algorithm is terminated if the size of the basic subset is changed less than δ. By default, the value is 0.005.

Output of the algorithm is the vector of weights, `BaconWeights`, such that `BaconWeights(i)` = 0 if *i*-th observation is detected as an outlier. Otherwise `BaconWeights(i)` = *w*(*i*), where *w* is the vector of input weights. If you do not provide the vector of input weights, `BaconWeights(i)` is set to 1 if the *i*-th observation is not detected as an outlier.

See additional details about usage model of the algorithm in the *Intel(R) MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.

vslSSEditMissingValues

Modifies pointers to arrays associated with the method of supporting missing values in a dataset.

Syntax

Fortran:

```
status = vslssseditmissingvalues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates)
```

```
status = vsldsseditmissingvalues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates)
```

C:

```
status = vslsSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

```
status = vsldSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

Include Files

- Fortran 90: `mkl_vsl.f90`
- C: `mkl_vsl_functions.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(VSL_SS_TASK)` **C:** `VSLSSTaskPtr`	Descriptor of the task
nparams	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the number of method parameters
params	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslssseditmissingvalues` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditmissingvalues` **C:** `float*` for	Pointer to the array of method parameters

Name	Type	Description
	vslsSSEditMissingValues double* for vsldSSEditMissingValues	
init_estimates_n	**Fortran:** INTEGER **C:** MKL_INT*	Pointer to the number of initial estimates for mean and a variance-covariance matrix
init_estimates	**Fortran:** REAL(KIND=4) DIMENSION(*) for vslsssseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues **C:** float* for vslsSSEditMissingValues double* for vsldSSEditMissingValues	Pointer to the array that holds initial estimates for mean and a variance-covariance matrix
prior_n	**Fortran:** INTEGER **C:** MKL_INT*	Pointer to the number of prior parameters
prior	**Fortran:** REAL(KIND=4) DIMENSION(*) for vslsssseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues **C:** float* for vslsSSEditMissingValues double* for vsldSSEditMissingValues	Pointer to the array of prior parameters
simul_missing_vals_n	**Fortran:** INTEGER **C:** MKL_INT*	Pointer to the size of the array that holds output of the Multiple Imputation method
simul_missing_vals	**Fortran:** REAL(KIND=4) DIMENSION(*) for vslsssseditmissingvalues REAL(KIND=8) DIMENSION(*) for vsldsseditmissingvalues **C:** float* for vslsSSEditMissingValues	Pointer to the array of size $k*m$, where k is the total number of missing values, and m is number of copies of missing values. The array holds m sets of simulated missing values for the matrix of observations.

Name	Type	Description
	`double*` for `vsldSSEditMissingValues`	
estimates_n	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the number of estimates to be returned by the routine
estimates	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsseditmissingvalues` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditmissingvalues` **C:** `float*` for `vslsSSEditMissingValues` `double*` for `vsldSSEditMissingValues`	Pointer to the array that holds estimates of the mean and a variance-covariance matrix.

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditMissingValues` routine uses values passed as parameters of the routine to replace pointers to the number and the array of the method parameters, pointers to the number and the array of initial mean/variance-covariance estimates, the pointer to the number and the array of prior parameters, pointers to the number and the array of simulated missing values, and pointers to the number and the array of the intermediate mean/covariance estimates. If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Before you call the VSL Summary Statistics routines to process missing values, preprocess the dataset and denote missing observations with one of the following predefined constants:

- `VSL_SS_SNAN`, if the dataset is stored in single precision floating-point arithmetic
- `VSL_SS_DNAN`, if the dataset is stored in double precision floating-point arithmetic

Intel MKL provides the `VSL_SS_METHOD_MI` method to support missing values in the dataset based on the Multiple Imputation (MI) approach described in [Schafer97]. The following components support Multiple Imputation:

- Expectation Maximization (EM) algorithm to compute the start point for the Data Augmentation (DA) procedure
- DA function

NOTE The DA component of the MI procedure is simulation-based and uses the `VSL_BRNG_MCG59` basic random number generator with predefined *seed* = 2^{50} and the Gaussian distribution generator (`ICDF` method) available in Intel MKL [Gaussian].

Pack the parameters of the MI algorithm into the *params* array. Table "Structure of the Array of MI Parameters" describes the *params* structure.

Structure of the Array of MI Parameters

Array Position	Algorithm Parameter	Description
0	em_iter_num	Maximal number of iterations for the EM algorithm. By default, this value is 50.
1	da_iter_num	Maximal number of iterations for the DA algorithm. By default, this value is 30.
2	ε	Stopping criterion for the EM algorithm. The algorithm terminates if the maximal module of the element-wise difference between the previous and current parameter values is less than ε. By default, this value is 0.001.
3	m	Number of sets to impute
4	missing_vals_num	Total number of missing values in the datasets

You can also pass initial estimates into the EM algorithm by packing both the vector of means and the variance-covariance matrix as a one-dimensional array *init_estimates*. The size of the array should be at least $p + p(p + 1)/2$. For i=0, .., p-1, the *init_estimates*[i] array contains the initial estimate of means. The remaining positions of the array are occupied by the upper triangular part of the variance-covariance matrix.

If you provide no initial estimates for the EM algorithm, the editor uses the default values, that is, the vector of zero means and the unitary matrix as a variance-covariance matrix. You can also pass *prior* parameters for μ and Σ into the library: μ_0, τ, m, and Λ^{-1}. Pack these parameters as a one-dimensional array *prior* with a size of at least

$(p^2 + 3p + 4)/2$.

The storage format is as follows:

- *prior*[0], ..., *prior*[p–1] contain the elements of the vector μ_0.
- *prior*[p] contains the parameter τ.
- *prior*[p+1] contains the parameter m.
- The remaining positions are occupied by the upper-triangular part of the inverted matrix Λ^{-1}.

If you provide no *prior* parameters, the editor uses their default values:

- The array of p zeros is used as μ_0.
- τ is set to 0.
- m is set to p.
- The zero matrix is used as an initial approximate of Λ^{-1}.

The EditMissingValues editor returns m sets of imputed values and/or a sequence of parameter estimates drawn during the DA procedure.

The editor returns the imputed values as the *simul_missing_vals* array. The size of the array should be sufficient to hold m sets each of the missing_vals_num size, that is, at least m*missing_vals_num in total. The editor packs the imputed values one by one in the order of their appearance in the matrix of observations.

For example, consider a task of dimension 4. The total number of observations n is 10. The second observation vector misses variables 1 and 2, and the seventh observation vector lacks variable 1. The number of sets to impute is m=2. Then, *simul_missing_vals*[0] and *simul_missing_vals*[1] contains the first and the second points for the second observation vector, and *simul_missing_vals*[2] holds the first point for the seventh observation. Positions 3, 4, and 5 are formed similarly.

To estimate convergence of the DA algorithm and choose a proper value of the number of DA iterations, request the sequence of parameter estimates that are produced during the DA procedure. The editor returns the sequence of parameters as a single array. The size of the array is

m*da_iter_num*(p+(p^2+p)/2)

where

- m is the number of sets of values to impute.
- da_iter_num is the number of DA iterations.
- The value p+(p^2+p)/2 determines the size of the memory to hold one set of the parameter estimates.

In each set of the parameters, the vector of means occupies the first p positions and the remaining (p^2+p)/2 positions are intended for the upper triangular part of the variance-covariance matrix.

Upon successful generation of m sets of imputed values, you can place them in cells of the data matrix with missing values and use the VSL Summary Statistics routines to analyze and get estimates for each of the m complete datasets.

NOTE Intel MKL implementation of the MI algorithm rewrites cells of the dataset that contain the VSL_SS_SNAN/VSL_SS_DNAN values. If you want to use the VSL Summary Statistics routines to process the data with missing values again, mask the positions of the empty cells.

See additional details of the algorithm usage model in the *Intel© MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page.

vslSSEditCorParameterization

Modifies pointers to arrays related to the algorithm of correlation matrix parameterization.

Syntax

Fortran:

```
status = vslsssseditcorparameterization(task, cor, cor_storage, pcor, pcor_storage)
status = vsldsseditcorparameterization(task, cor, cor_storage, pcor, pcor_storage)
```

C:

```
status = vslsSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
status = vsldSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(VSL_SS_TASK)	Descriptor of the task

Name	Type	Description
	C: `VSLSSTaskPtr`	
cor	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsseditcorparameterization` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditcorparameterization` **C:** `float*` for `vslsSSEditCorParameterization` `double*` for `vsldSSEditCorParameterization`	Pointer to the correlation matrix
cor_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of the correlation matrix
pcor	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `vslsseditcorparameterization` `REAL(KIND=8) DIMENSION(*)` for `vsldsseditcorparameterization` **C:** `float*` for `vslsSSEditCorParameterization` `double*` for `vsldSSEditCorParameterization`	Pointer to the parameterized correlation matrix
por_storage	**Fortran:** `INTEGER` **C:** `MKL_INT*`	Pointer to the storage format of the parameterized correlation matrix

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Current status of the task

Description

The `vslSSEditCorParameterization` routine uses values passed as parameters of the routine to replace pointers to the correlation matrix, pointers to the correlation matrix storage format, a pointer to the parameterized correlation matrix, and a pointer to the parameterized correlation matrix storage format. See Table "Storage formats of a variance-covariance/correlation matrix" for possible values of the *cor_storage* and *pcor_storage* parameters. If an input parameter is `NULL`, the corresponding parameter in the VSL Summary Statistics task descriptor remains unchanged.

Task Computation Routines

Task computation routines calculate statistical estimates on the data provided and parameters held in the task descriptor. After you create the task and initialize its parameters, you can call the computation routines as many times as necessary. Table "VSL Summary Statistics Estimates Obtained with `vslSSCompute` Routine" lists the statistical estimates that you can obtain using the `vslSSCompute` routine.

NOTE The VSL Summary Statistics computation routines do not signal floating-point errors, such as overflow or gradual underflow, or operations with `NaNs` (except for the missing values in the observations).

VSL Summary Statistics Estimates Obtained with vslSSCompute Routine

Estimate	Support of Observations Available in Blocks	Description
`VSL_SS_MEAN`	Yes	Computes the array of means.
`VSL_SS_2R_MOM`	Yes	Computes the array of the 2nd order raw moments.
`VSL_SS_3R_MOM`	Yes	Computes the array of the 3rd order raw moments.
`VSL_SS_4R_MOM`	Yes	Computes the array of the 4th order raw moments.
`VSL_SS_2C_MOM`	Yes	Computes the array of the 2nd order central moments.
`VSL_SS_3C_MOM`	Yes	Computes the array of the 3rd order central moments.
`VSL_SS_4C_MOM`	Yes	Computes the array of the 4th order central moments.
`VSL_SS_KURTOSIS`	Yes	Computes the array of kurtosis values.
`VSL_SS_SKEWNESS`	Yes	Computes the array of skewness values.
`VSL_SS_MIN`	Yes	Computes the array of minimum values.
`VSL_SS_MAX`	Yes	Computes the array of maximum values.
`VSL_SS_VARIATION`	Yes	Computes the array of variation coefficients.
`VSL_SS_COV`	Yes	Computes a covariance matrix.
`VSL_SS_COR`	Yes	Computes a correlation matrix.
`VSL_SS_POOLED_COV`	No	Computes a pooled covariance matrix.
`VSL_SS_GROUP_COV`	No	Computes group covariance matrices.
`VSL_SS_QUANTS`	No	Computes quantiles.
`VSL_SS_ORDER_STATS`	No	Computes order statistics.
`VSL_SS_ROBUST_COV`	No	Computes a robust covariance matrix.
`VSL_SS_OUTLIERS`	No	Detects outliers in the dataset.

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_PARTIAL_COV	No	Computes a partial covariance matrix.
VSL_SS_PARTIAL_COR	No	Computes a partial correlation matrix.
VSL_SS_MISSING_VALS	No	Supports missing values in datasets.
VSL_SS_PARAMTR_COR	No	Computes a parameterized correlation matrix.
VSL_SS_STREAM_QUANTS	Yes	Computes quantiles for streaming data.

Table "VSL Summary Statistics Computation Methods" lists estimate calculation methods supported by Intel MKL. See the *Intel(R) MKL Summary Statistics Library Application Notes* document on the Intel® MKL web page for a detailed description of the methods.

VSL Summary Statistics Computation Method

Method	Description
VSL_SS_METHOD_FAST	Fast method for calculation of the estimates
VSL_SS_METHOD_1PASS	One-pass method for calculation of estimates
VSL_SS_METHOD_TBS	TBS method for robust estimation of covariance and mean
VSL_SS_METHOD_BACON	BACON method for detection of multivariate outliers
VSL_SS_METHOD_MI	Multiple imputation method for support of missing values
VSL_SS_METHOD_SD	Spectral decomposition method for parameterization of a correlation matrix
VSL_SS_METHOD_SQUANTS_ZW	Zhang-Wang (ZW) method for quantile estimation for streaming data
VSL_SS_METHOD_SQUANTS_ZW_FAST	Fast ZW method for quantile estimation for streaming data

You can calculate all requested estimates in one call of the routine. For example, to compute a kurtosis and covariance matrix using a fast method, pass a combination of the pre-defined parameters into the `Compute` routine as shown in the example below:

```
...
method = VSL_SS_METHOD_FAST;
task_params = VSL_SS_KURTOSIS|VSL_SS_COV;
…
status = vsldSSCompute( task, task_params, method );
```

To compute statistical estimates for the next block of observations, you can do one of the following:

- copy the observations to memory, starting with the address available to the task
- use one of the appropriate Editors to modify the pointer to the new dataset in the task.

The library does not detect your changes of the dataset and computed statistical estimates. To obtain statistical estimates for a new matrix, change the observations and initialize relevant arrays. You can follow this procedure to compute statistical estimates for observations that come in portions. See Table "VSL Summary Statistics Estimates Obtained with `vslSSCompute` Routine" for information on such observations supported by the Intel MKL VSL Summary Statistics estimators.

To modify parameters of the task using the Task Editors, set the address of the targeted matrix of the observations or change the respective vector component indices. After you complete editing the task parameters, you can compute statistical estimates in the modified environment.

If the task completes successfully, the computation routine returns the zero status code. If an error is detected, the computation routine returns an error code. In particular, an error status code is returned in the following cases:

- the task pointer is NULL
- memory allocation has failed
- the calculation has failed for some other reason

NOTE You can use the NULL task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslSSCompute

Computes VSL Summary Statistics estimates.

Syntax

Fortran:

```
status = vslssscompute(task, estimates, method)
status = vsldsscompute(task, estimates, method)
```

C:

```
status = vslsSSCompute(task, estimates, method);
status = vsldSSCompute(task, estimates, method);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(VSL_SS_TASK) **C:** VSLSSTaskPtr	Descriptor of the task
estimates	**Fortran:** INTEGER (KIND=8) **C:** unsigned long long	List of statistical estimates to compute
method	**Fortran:** INTEGER **C:** MKL_INT	Method to be used in calculations

Output Parameters

Name	Type	Description
status	**Fortran:** INTEGER **C:** int	Current status of the task

Description

The vslSSCompute routine calculates statistical estimates passed as the *estimates* parameter using the algorithms passed as the *method* parameter of the routine. The computations are done in the context of the task descriptor that contains pointers to all required and optional, if necessary, properly initialized arrays. In

one call of the function, you can compute several estimates using proper methods for their calculation. See Table "VSL Summary Statistics Estimates Obtained with Compute Routine" for the list of the estimates that you can calculate with the vslSSCompute routine. See Table "VSL Summary Statistics Computation Methods" for the list of possible values of the *method* parameter.

To initialize single or double precision version task parameters, use the single (vslssscompute) or double (vsldsscompute) version of the editor, respectively. To initialize parameters of the integer type, use an integer version of the editor (vslisscompute).

NOTE Requesting a combination of the VSL_SS_MISSING_VALS value and any other estimate parameter in the Compute function results in processing only the missing values.

Task Destructor

Task destructor is the vslSSDeleteTask routine intended to delete task objects and release memory.

vslSSDeleteTask

Destroys the task object and releases the memory.

Syntax

Fortran:

```
status = vslssdeletetask(task)
```

C:

```
status = vslSSDeleteTask(&task);
```

Include Files

- Fortran 90: mkl_vsl.f90
- C: mkl_vsl_functions.h

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(VSL_SS_TASK) **C:** VSLSSTaskPtr*	Descriptor of the task to destroy

Output Parameters

Name	Type	Description
status	**Fortran:** INTEGER **C:** int	Sets to VSL_STATUS_OK if the task is deleted; otherwise a non-zero code is returned.

Description

The vslSSDeleteTask routine deletes the task descriptor object, releases the memory allocated for the structure, and sets the task pointer to NULL. If vslSSDeleteTask fails to delete the task successfully, it returns an error code.

NOTE Call of the destructor with the `NULL` pointer as the parameter results in termination of the function with no system crash.

Usage Examples

The following examples show various standard operations with Summary Statistics routines.

Calculating Fixed Estimates for Fixed Data

The example shows recurrent calculation of the same estimates with a given set of variables for the complete life cycle of the task in the case of a variance-covariance matrix. The set of vector components to process remains unchanged, and the data comes in blocks. Before you call the `vslSSCompute` routine, initialize pointers to arrays for mean and covariance and set buffers.

```
….
double w[2];
double indices[DIM] = {1, 0, 1};

/* calculating mean for 1st and 3d random vector components */

/* Initialize parameters of the task */
p = DIM;
n = N;

xstorage   = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, indices );

status = vsldSSEditTask  ( task, VSL_SS_ED_ACCUM_WEIGHT, w    );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );
```

You can process data arrays that come in blocks as follows:

```
for ( i = 0; i < num_of_blocks; i++ )
{
    status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );
    /* Read new data block into array x */
}
…
```

Calculating Different Estimates for Variable Data

The context of your calculation may change in the process of data analysis. The example below shows the data that comes in two blocks. You need to estimate a covariance matrix for the complete data, and the third central moment for the second block of the data using the weights that were accumulated for the previous datasets. The second block of the data is stored in another array. You can proceed as follows:

```
/* Set parameters for the task */
p = DIM;
n = N;
xstorage   = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

/* Create task */
status = vsldSSNewTask( &task, &p, &n, &xstorage, x1, 0, indices );
```

```
/* Initialize the task parameters */
status = vsldSSEditTask( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );

/* Calculate covariance for the x1 data */
status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );

/* Initialize array of the 3d central moments and pass the pointer to the task */
for ( i = 0; i < p; i++ ) c3_m[i] = 0.0;

/* Modify task context */
status = vsldSSEditTask( task, VSL_SS_ED_3C_MOM, c3_m );
status = vsldSSEditTask( task, VSL_SS_ED_OBSERV, x2 );

/* Calculate covariance for the x1 & x2 data block */
/* Calculate the 3d central moment for the 2nd data block using earlier accumulated weight */
status = vsldSSCompute(task, VSL_SS_COV|VSL_SS_3C_MOM, VSL_SS_METHOD_FAST );
…
status = vslSSDeleteTask( &task );
```

Similarly, you can modify indices of the variables to be processed for the next data block.

Mathematical Notation and Definitions

The following notations are used in the mathematical definitions and the description of the Intel MKL VSL Summary Statistics functions.

Matrix and Weights of Observations

For a random p-dimensional vector $\xi = (\xi_1,..., \xi_i,..., \xi_p)$, this manual denotes the following:

- $(X)_i=(x_{ij})_{j=1..n}$ is the result of n independent observations for the i-th component ξ_i of the vector ξ.
- The two-dimensional array $X=(x_{ij})_{p \times n}$ is the matrix of observations.
- The column $[X]_j=(x_{ij})_{i=1..p}$ of the matrix X is the j-th observation of the random vector ξ.

Each observation $[X]_j$ is assigned a non-negative weight w_j , where

- The vector $(w_j)_{j=1..n}$ is a vector of weights corresponding to n observations of the random vector ξ.
-

$$W = \sum_{i=1}^{n} w_i$$

  is the accumulated weight corresponding to observations X.

Vector of sample means

$$M(X) = (M_1(X),\ldots,M_p(X)) \text{ with } M_i(X) = \frac{1}{w}\sum_{j=1}^{n} w_j x_{ij}$$

for all i = 1, ..., p.

Vector of sample variances

$$V(X) = (V_1(X),\ldots,V_p(X)) \text{ with } V_i(X) = \frac{1}{\mathrm{B}}\sum_{j=1}^{n} w_j (x_{ij} - M_i(X))^2,\ \mathrm{B} = W - \sum_{j=1}^{n} w_j^2 / W$$

for all $i = 1, \ldots, p$.

Vector of sample raw/algebraic moments of k-th order, $k \geq 1$

$$R^{(k)}(X) = (R_1^{(k)}(X), \ldots, R_p^{(k)}(X)) \text{ with } R_i^{(k)}(X) = \frac{1}{W}\sum_{j=1}^{n} w_j x_{ij}^k$$

for all $i = 1, \ldots, p$.

Vector of sample central moments of the third and the fourth order

$$C^{(k)}(X) = (C_1^{(k)}(X), \ldots, C_p^{(k)}(X)) \text{ with } C_i^{(k)}(X) = \frac{1}{B}\sum_{j=1}^{n} w_j (x_{ij} - M_i(X))^k,\ B = \sum_{j=1}^{n} w_j$$

for all $i = 1, \ldots, p$ and $k = 3, 4$.

Vector of sample excess kurtosis values

$$\mathrm{B}(X) = (\mathrm{B}_1(X), \ldots, \mathrm{B}_p(X)) \text{ with } \mathrm{B}_i(X) = \frac{C_i^{(4)}(X)}{V_i^2(X)} - 3$$

for all $i = 1, \ldots, p$.

Vector of sample skewness values

$$\Gamma(X) = (\Gamma_1(X), \ldots, \Gamma_p(X)) \text{ with } \Gamma_i(X) = \frac{C_i^{(3)}(X)}{V_i^{1.5}(X)}$$

for all $i = 1, \ldots, p$.

Vector of sample variation coefficients

$$VC(X) = (VC_1(X), \ldots, VC_p(X)) \text{ with } VC_i(X) = \frac{V_i^{0.5}(X)}{M_i(X)}$$

for all $i = 1, \ldots, p$.

Matrix of order statistics

Matrix $Y = (y_{ij})_{pxn}$, in which the i-th row $(Y)_i = (y_{ij})_{j=1..n}$ is obtained as a result of sorting in the ascending order of row $(X)_i = (x_{ij})_{j=1..n}$ in the original matrix of observations.

Vector of sample minimum values

$$Min(X) = (Min_1(X), \ldots, Min_p(X)), \text{ where } Min_i(X) = y_{i1}$$

for all i = 1, ..., p.

Vector of sample maximum values

$$Max(X) = (Max_1(X), \ldots, Max_p(X)), \text{ where } Max_i(X) = y_{in}$$

for all i = 1, ..., p.

Vector of sample median values

$$Med(X) = (Med_1(X), \ldots, Med_p(X)), \text{ where } Med_i(X) = \begin{cases} y_{i,(n+1)/2}, & \text{if } n \text{ is odd} \\ \left(y_{i,n/2} + y_{i,n/2+1}\right)/2, & \text{if } n \text{ is even} \end{cases}$$

for all i = 1, ..., p.

Vector of sample quantile values

For a positive integer number q and k belonging to the interval [0, q-1], point z_i is the k-th q quantile of the random variable ξ_i if $P\{\xi_i \le z_i\} \ge \beta$ and $P\{\xi_i \le z_i\} \ge 1 - \beta$, where

- P is the probability measure.
- $\beta = k/n$ is the quantile order.

The calculation of quantiles is as follows:

$j = [(n\text{-}1)\beta]$ and $f = \{(n\text{-}1)\beta\}$ as integer and fractional parts of the number $(n\text{-}1)\beta$, respectively, and the vector of sample quantile values is

$Q(X,\beta) = (Q_1(X,\beta), \ldots, Q_p(X,\beta))$

where

$(Q_i(X,\beta) = y_{i,j+1} + f(y_{i,j+2} - y_{i,j+1})$

for all i = 1, ..., p.

Variance-covariance matrix

$C(X) = (c_{ij}(X))_{p \times p}$

where

$$c_{ij}(X) = \frac{1}{B}\sum_{k=1}^{n} w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X)), B = W - \sum_{j=1}^{n} w_j^2 / W$$

Pooled and group variance-covariance matrices

The set $N = \{1, ..., n\}$ is partitioned into non-intersecting subsets

$$G_i, i = 1..g, N = \bigcup_{i=1}^{g} G_i$$

The observation $[X]_j = (x_{ij})_{i=1..p}$ belongs to the group r if $j \in G_r$. One observation belongs to one group only. The group mean and variance-covariance matrices are calculated similarly to the formulas above:

$$M^{(r)}(X) = (M_1^{(r)}(X), \ldots, M_p^{(r)}(X)) \text{ with } M_i^{(r)}(X) = \frac{1}{W^{(r)}} \sum_{j \in G_r} w_j x_{ij}, W^{(r)} = \sum_{j \in G_r} w_j$$

for all $i = 1, ..., p$,

$$C^{(r)}(X) = (c_{ij}^{(r)}(X))_{p \times p}$$

where

$$c_{ij}^{(r)}(X) = \frac{1}{B^{(r)}} \sum_{k \in G_r} w_k (x_{ik} - M_i^{(r)}(X))(x_{jk} - M_j^{(r)}(X)), \; B^{(r)} = W^{(r)} - \sum_{j \in G_r} w_j^2 / W^{(r)}$$

for all $i = 1, ..., p$ and $j = 1, ..., p$.

A pooled variance-covariance matrix and a pooled mean are computed as weighted mean over group covariance matrices and group means, correspondingly:

$$M^{pooled}(X) = (M_1^{pooled}(X), \ldots, M_p^{pooled}(X)) \text{ with } M_i^{pooled}(X) = \frac{1}{W^{(1)} + \ldots + W^{(g)}} \sum_{r=1}^{g} W^{(r)} M_i^{(r)}(X)$$

for all $i = 1, ..., p$,

$$C^{pooled}(X) = (c_{ij}^{pooled}(X))_{p \times p}, c_{ij}^{pooled}(X) = \frac{1}{B^{(1)} + \ldots + B^{(g)}} \sum_{r=1}^{g} B^{(r)} c_{ij}^{(r)}(X)$$

for all $i = 1, ..., p$ and $j = 1, ..., p$.

Correlation matrix

$$R(X) = (r_{ij}(X))_{p \times p}, \text{ where } r_{ij}(X) = \frac{c_{ij}}{\sqrt{c_{ii} c_{jj}}}$$

for all i = 1, ..., p and j = 1, ..., p.

Partial variance-covariance matrix

For a random vector ξ partitioned into two components Z and Y, a variance-covariance matrix C describes the structure of dependencies in the vector ξ:

$$C(X)=\begin{bmatrix} C_Z(X) & C_{ZY}(X) \\ C_{YZ}(X) & C_Y(X) \end{bmatrix}.$$

The partial covariance matrix $P(X) = (p_{ij}(X))_{kxk}$ is defined as

$$P(X) = C_Y(X) - C_{YZ}(X)C_Z^{-1}(X)C_{ZY}(X).$$

where k is the dimension of Y.

Partial correlation matrix

The following is a partial correlation matrix for all i = 1, ..., k and j = 1, ..., k:

$$RP(X) = (rp_{ij}(X))_{kxk}, \text{ where } rp_{ij}(X) = \frac{p_{ij}(X)}{\sqrt{p_{ii}(X)p_{jj}(X)}}$$

where

- k is the dimension of Y.
- $p_{ij}(X)$ are elements of the partial variance-covariance matrix.

11 Fourier Transform Functions

The general form of the discrete Fourier transform is

$$Z_{k_1,k_2,\ldots,k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \ldots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1,j_2,\ldots,j_d} \exp\left(\delta i 2\pi \sum_{l=1}^{d} j_l k_l / n_l\right)$$

for $k_l = 0, \ldots n_l-1$ $(l = 1, \ldots, d)$, where σ is a scale factor, $\delta = -1$ for the forward transform, and $\delta = +1$ for the inverse (backward) transform. In the forward transform, the input (periodic) sequence $\{w_{j_1, j_2, \ldots, j_d}\}$ typically belongs to the set of complex-valued sequences and real-valued sequences (forward domain). Respective domains for the backward transform, or backward domains, are represented by complex-valued sequences and complex-valued conjugate-even sequences.

Math Kernel Library (Intel® MKL) provides an interface for computing a discrete Fourier transform through the fast Fourier transform algorithm. This chapter describes the following implementations of the fast Fourier transform functions available in Intel MKL:

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see FFT Functions below)
- Cluster FFT functions for distributed-memory architectures (available with Intel® MKL for the Linux* and Windows* operating systems only).

NOTE Intel MKL also supports the FFTW3* interfaces to the fast Fourier transform functionality for symmetric multiprocessing (SMP) systems.

Both FFT and Cluster FFT functions support a five-stage usage model for computing an FFT:

1. Allocate a fresh descriptor for the problem with a call to the `DftiCreateDescriptor` or `DftiCreateDescriptorDM` function. The descriptor captures the configuration of the transform, such as the dimensionality (or rank), sizes, number of transforms, memory layout of the input/output data (defined by strides), and scaling factors. Many of the configuration settings are assigned default values in this call and may need modification depending on your application.
2. Optionally adjust the descriptor configuration with a call to the `DftiSetValue` or `DftiSetValueDM` function as needed. Typically, you must carefully define the data storage layout for an FFT or the data distribution among processes for a Cluster FFT. The configuration settings of the descriptor, such as the default values, can be obtained with the `DftiGetValue` or `DftiGetValueDM` function.
3. Commit the descriptor with a call to the `DftiCommitDescriptor` or `DftiCommitDescriptorDM` function, that is, make the descriptor ready for the transform computation. Once the descriptor is committed, the parameters of the transform, such as the type and number of transforms, strides and distances, the type and storage layout of the data, and so on, are "frozen" in the descriptor.
4. Compute the transform with a call to the `DftiComputeForward`/`DftiComputeBackward` or `DftiComputeForwardDM`/`DftiComputeBackwardDM` functions as many times as needed. With the committed descriptor, the compute functions only accept pointers to the input/output data and compute the transform as defined. To modify any configuration parameters later on, use `DftiSetValue` followed by `DftiCommitDescriptor` (`DftiSetValueDM` followed by `DftiCommitDescriptorDM`) or create and commit another descriptor.
5. Deallocate the descriptor with a call to the `DftiFreeDescriptor` or `DftiFreeDescriptorDM` function. This will return the memory internally consumed by the descriptor to the operating system.

All the above functions return an integer status value, which is zero upon successful completion of the operation. You can interpret a non-zero status with the help of the `DftiErrorClass` or `DftiErrorMessage` function.

The FFT functions support lengths with arbitrary factors. You can improve performance of the Intel MKL FFT if the length of your data vector permits factorization into powers of optimized radices. See the *Intel MKL User's Guide* for specific radices supported efficiently and the length constraints.

NOTE The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel MKL Vector Mathematical Functions provide an efficient tool for conversion to and from the polar representation (see Example "Conversion from Cartesian to polar representation of complex data" and Example "Conversion from polar to Cartesian representation of complex data").

FFT Functions

The fast Fourier transform function library of Intel MKL provides one-dimensional, two-dimensional, and multi-dimensional transforms (of up to seven dimensions); and both Fortran and C interfaces for all transform functions.

Table "FFT Functions in Intel MKL" lists FFT functions implemented in Intel MKL:

FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptor	Allocates the descriptor data structure and initializes it with default configuration values.
DftiCommitDescriptor	Performs all initialization for the actual FFT computation.
DftiFreeDescriptor	Frees memory allocated for a descriptor.
DftiCopyDescriptor	Makes a copy of an existing descriptor.
FFT Computation Functions	
DftiComputeForward	Computes the forward FFT.
DftiComputeBackward	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValue	Sets one particular configuration parameter with the specified configuration value.
DftiGetValue	Gets the value of one particular configuration parameter.
Status Checking Functions	
DftiErrorClass	Checks if the status reflects an error of a predefined class.
DftiErrorMessage	Translates the numeric value of an error status into a message.

Computing an FFT

The FFT functions described later in this chapter are provided with the Fortran and C interfaces. Fortran 95 is required because it offers features that have no counterpart in FORTRAN 77.

NOTE The Fortran interface of the FFT computation functions requires one-dimensional data arrays for any dimension of FFT problem. For multidimensional transforms, you can pass the address of the first column of the multidimensional data to the computation functions.

The materials presented in this chapter assume the availability of native complex types in C as they are specified in C9X.

You can find code examples that use FFT interface functions to compute transform results in the Fourier Transform Functions Code Examples section in the Appendix C.

For most common situations, an FFT computation can be effected by four function calls (refer to the usage model for details). A single data structure, the descriptor, stores configuration parameters that can be changed independently.

The descriptor data structure, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of several configuration parameters. Default settings for some of these parameters are as follows:

- The FFT to be computed does not have a scale factor;
- There is only one set of data to be transformed;
- The data is stored contiguously in memory;
- The computed result overwrites the input data (the transform is in-place);

The default settings can be changed one-at-a-time through the function `DftiSetValue` as illustrated in the Example "Changing Default Settings (Fortran)" and Example "Changing Default Settings (C)".

FFT Interface

To use the FFT functions, you need to access the module `MKL_DFTI` through the "`use`" statement in Fortran; or include the header file `mkl_dfti.h` in C.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR`, named constants representing various names of configuration parameters and their possible values, and overloaded functions through the generic functionality of Fortran 95.

The C interface provides the `DFTI_DESCRIPTOR_HANDLE` type, named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`, and functions, some of which accept different numbers of input arguments.

NOTE The current version of the library may not support some of the FFT functions or functionality described in the subsequent sections of this chapter. You can find the complete list of the implementation-specific exceptions in the Intel MKL Release Notes.

For the main categories of Intel MKL FFT functions, see FFT Functions.

Descriptor Manipulation Functions

There are four functions in this category: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

DftiCreateDescriptor

Allocates the descriptor data structure and initializes it with default configuration values.

Syntax

Fortran:

```
status = DftiCreateDescriptor( desc_handle, precision, forward_domain, dimension,
length )
```

C:

```
status = DftiCreateDescriptor(&desc_handle, precision, forward_domain, dimension,
length);
```

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl_dfti.h`

Input Parameters

Name	Type	Description
precision	**FORTRAN:** `INTEGER` **C:** `enum`	Precision of the transform: `DFTI_SINGLE` or `DFTI_DOUBLE`.
forward_domain	**FORTRAN:** `INTEGER` **C:** `enum`	Forward domain of the transform: `DFTI_COMPLEX` or `DFTI_REAL`.
dimension	**FORTRAN:** `INTEGER` **C:** `MKL_LONG`	Dimension of the transform.
length	**FORTRAN:** `INTEGER` if *dimension* = 1. Array `INTEGER, DIMENSION(*)` otherwise. **C:** `MKL_LONG` if *dimension* == 1. Array of type `MKL_LONG` otherwise.	Length of the transform for a one-dimensional transform. Lengths of each dimension for a multi-dimensional transform.

Output Parameters

Name	Type	Description
desc_handle	**FORTRAN:** `DFTI_DESCRIPTOR` **C:** `DFTI_DESCRIPTOR_HANDLE`	FFT descriptor.
status	**FORTRAN:** `INTEGER` **C:** `MKL_LONG`	Function completion status.

Description

This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings with respect to the precision, forward domain, dimension, and length of the desired transform. Because memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function that can be found in software packages or libraries that implement more traditional algorithms for computing FFT. This function does not perform any significant computational work such as computation of twiddle factors. The function `DftiCommitDescriptor` does this work after the function `DftiSetValue` has set values of all needed parameters.

The function returns the zero status when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface and Prototype

```
! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.

  INTERFACE DftiCreateDescriptor

     FUNCTION some_actual_function_1d(desc, precision, domain, dim, length)
       INTEGER :: some_actual_function_1d
       ...
       INTEGER, INTENT(IN) :: length
     END FUNCTION some_actual_function_1d

     FUNCTION some_actual_function_md(desc, precision, domain, dim, lengths)
       INTEGER :: some_actual_function_md
       ...
       INTEGER, INTENT(IN), DIMENSION(*) :: lengths
     END FUNCTION some_actual_function_md

     ...

  END INTERFACE DftiCreateDescriptor
```

Note that the function is overloaded, because the actual parameter for the formal parameter *length* can be a scalar or a rank-one array.

The function is also overloaded with respect to the type of the *precision* parameter to provide an option of using a precision-specific function for the generic name. Using more specific functions can reduce the size of statically linked executable for the applications using only single-precision FFTs or only double-precision FFTs. To use this option, change the "`USE MKL_DFTI`" statement in your program unit to one of the following:

```
USE MKL_DFTI, FORGET=>DFTI_SINGLE, DFTI_SINGLE=>DFTI_SINGLE_R
```

```
USE MKL_DFTI, FORGET=>DFTI_DOUBLE, DFTI_DOUBLE=>DFTI_DOUBLE_R
```

where the name "`FORGET`" can be replaced with any name that is not used in the program unit.

```
/* C prototype.
 * Note that the preprocessor definition provided below only illustrates
 * that the actual function called may be determined at compile time.
 * You can rely only on the declaration of the function.
 * For precise definition of the preprocessor macro, see the include/mkl_dfti.h
 * file in the Intel MKL directory.
 */
MKL_LONG DftiCreateDescriptor(DFTI_DESCRIPTOR_HANDLE * pHandle,
     enum DFTI_CONFIG_VALUE precision,
     enum DFTI_CONFIG_VALUE domain,
     MKL_LONG dimension, ... /* length/lengths */ );
```

```
#define DftiCreateDescriptor(desc,prec,domain,dim,sizes) \
     ((prec)==DFTI_SINGLE && (dim)==1) ? \
     some_actual_function_s1d((desc),(domain),(MKL_LONG)(sizes)) : \
     ...
```

Variable *length/lengths* is interpreted as a scalar (MKL_LONG) or an array (MKL_LONG*), depending on the value of parameter *dimension*. If the value of parameter *precision* is known at compile time, an optimizing compiler retains only the call to the respective specific function, thereby reducing the size of the statically linked application. Avoid direct calls to the specific functions used in the preprocessor macro definition, because their interface may change in future releases of the library. If the use of the macro is undesirable, you can safely undefine it after inclusion of the Intel MKL FFT header file, as follows:

```
#include "mkl_dfti.h"
#undef DftiCreateDescriptor
```

Configuration Parameters

DftiCommitDescriptor

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
status = DftiCommitDescriptor( desc_handle )
```

C:

```
status = DftiCommitDescriptor(desc_handle);
```

Include Files

- FORTRAN 90: mkl_dfti.f90
- C: mkl_dfti.h

Input Parameters

Name	Type	Description
desc_handle	**FORTRAN:** DFTI_DESCRIPTOR **C:** DFTI_DESCRIPTOR_HANDLE	FFT descriptor.

Output Parameters

Name	Type	Description
desc_handle	**FORTRAN:** DFTI_DESCRIPTOR **C:** DFTI_DESCRIPTOR_HANDLE	Updated FFT descriptor.
status	**FORTRAN:** INTEGER **C:** MKL_LONG	Function completion status.

Description

This function completes initialization of a previously created descriptor, which is required before the descriptor can be used for FFT computations. Typically, this committal performs all initialization that facilitates the actual FFT computation. This initialization may involve exploring many different factorizations of the input length to find the optimal computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see Descriptor Configuration) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function call is immediately followed by a computation function call (see FFT Computation).

The function returns the zero status when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCommitDescriptor
!Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE
 FUNCTION some_actual function_1 ( Desc_Handle )
 INTEGER :: some_actual function_1
 TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
 END FUNCTION some_actual function_1
END INTERFACE DftiCommitDescriptor
```

```
/* C prototype */
MKL_LONG DftiCommitDescriptor( DFTI_DESCRIPTOR_HANDLE );
```

DftiFreeDescriptor

Frees the memory allocated for a descriptor.

Syntax

Fortran:

```
status = DftiFreeDescriptor( desc_handle )
```

C:

```
status = DftiFreeDescriptor(&desc_handle);
```

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl_dfti.h`

Input Parameters

Name	Type	Description
desc_handle	**FORTRAN:** DESCRIPTOR_HANDLE **C:** DFTI_DESCRIPTOR_HANDLE	FFT descriptor.

Output Parameters

Name	Type	Description
desc_handle	**FORTRAN:** DESCRIPTOR_HANDLE **C:** DFTI_DESCRIPTOR_HANDLE	Memory for the FFT descriptor is released.
status	**FORTRAN:** INTEGER **C:** MKL_LONG	Function completion status.

Description

This function frees all memory allocated for a descriptor.

NOTE Memory allocation/deallocation inside Intel MKL is managed by Intel MKL memory management software. So, even after successful completion of FreeDescriptor, the memory space may continue being allocated for the application because the memory management software sometimes does not return the memory space to the OS, but considers the space free and can reuse it for future memory allocation. See Example "mkl_free_buffers Usage with FFT Functions" in the description of the service function FreeBuffers on how to use Intel MKL memory management software and release memory to the OS.

The function returns the zero status when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiFreeDescriptor
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
 FUNCTION some_actual_function_3( Desc_Handle )
 INTEGER :: some_actual_function_3
 TYPE(DFTI_DESCRIPTOR), POINTER :: Desc_Handle
 END FUNCTION some_actual_function_3
END INTERFACE DftiFreeDescriptor
```

```
/* C prototype */
MKL_LONG DftiFreeDescriptor( DFTI_DESCRIPTOR_HANDLE * );
```

DftiCopyDescriptor

Makes a copy of an existing descriptor.

Syntax

Fortran:

```
status = DftiCopyDescriptor( desc_handle_original, desc_handle_copy )
```

C:

```
status = DftiCopyDescriptor(desc_handle_original, &desc_handle_copy);
```

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl_dfti.h`

Input Parameters

Name	Type	Description
desc_handle_original	**FORTRAN:** DESCRIPTOR_HANDLE **C:** DFTI_DESCRIPTOR_HANDLE	The FFT descriptor to make a copy of.

Output Parameters

Name	Type	Description
desc_handle_copy	**FORTRAN:** DESCRIPTOR_HANDLE **C:** DFTI_DESCRIPTOR_HANDLE	The copy of the FFT descriptor.
status	**FORTRAN:** INTEGER **C:** MKL_LONG	Function completion status.

Description

This function makes a copy of an existing descriptor and provides a pointer to it. The purpose is that all information of the original descriptor will be maintained even if the original is destroyed via the free descriptor function `DftiFreeDescriptor`.

The function returns the zero status when it completes successfully. See Status Checking Functions for more information on the returned status.

Interface and Prototype

```
! Fortran interface
INTERFACE DftiCopyDescriptor
! Note that the body provided here is to illustrate the different
!argument list and types of dummy arguments. The interface
!does not guarantee what the actual function names are.
!Users can only rely on the function name following the
!keyword INTERFACE

```

```
/* C prototype */
MKL_LONG DftiCopyDescriptor( DFTI_DESCRIPTOR_HANLDE, DFTI_DESCRIPTOR_HANDLE * );
```

FFT Computation Functions

There are two functions in this category: compute the forward transform, and compute the backward transform.

DftiComputeForward

Computes the forward FFT.

Syntax

Fortran:

```
status = DftiComputeForward( desc_handle, x_inout )
status = DftiComputeForward( desc_handle, x_in, y_out )
status = DftiComputeForward( desc_handle, xre_inout, xim_inout )
status = DftiComputeForward( desc_handle, xre_in, xim_in, yre_out, yim_out )
```

C:

```
status = DftiComputeForward(desc_handle, x_inout);
status = DftiComputeForward(desc_handle, x_in, y_out);
status = DftiComputeForward(desc_handle, xre_inout, xim_inout);
status = DftiComputeForward(desc_handle, xre_in, xim_in, yre_out, yim_out);
```

Input Parameters

Name	Type	Description
desc_handle	**FORTRAN:** DFTI_DESCRIPTOR **C:** DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
x_inout, x_in	**FORTRAN:** Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. **C:** Array of type float or double depending on the precision of the transform, specified in the DFTI_PRECISION configuration setting.	Data to be transformed in case of a real forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.
xre_inout, xim_inout, xre_in, xim_in	**FORTRAN:** Array REAL(KIND=WP) or COMPLEX(KIND=WP), DIMENSION(*), where type and working precision WP must be consistent with the forward domain and precision specified in the descriptor. **C:** Array of type float or double depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in case of a complex forward domain, specified in the DFTI_FORWARD_DOMAIN configuration setting.

The suffix in parameter names corresponds to the value of the configuration parameter DFTI_PLACEMENT as follows:

- *_inout* to DFTI_INPLACE
- *_in* or *_out* to DFTI_NOT_INPLACE

Output Parameters

Name	Type	Description
y_out	**FORTRAN:** Array `REAL(KIND=WP)` or `COMPLEX(KIND=WP), DIMENSION(*)`, where type and working precision `WP` must be consistent with the forward domain and precision specified in the descriptor. **C:** Array of type `float` or `double` depending on the precision of the transform.	The transformed data in case of a real backward domain, determined by the `DFTI_FORWARD_DOMAIN` configuration setting.
xre_inout, *xim_inout*, *yre_out*, *yim_out*	**FORTRAN:** Array `REAL(KIND=WP)` or `COMPLEX(KIND=WP), DIMENSION(*)`, where type and working precision `WP` must be consistent with the forward domain and precision specified in the descriptor. **C:** Array of type `float` or `double` depending on the precision of the transform.	Real and imaginary parts of the transformed data in case of a complex backward domain, determined by the `DFTI_FORWARD_DOMAIN` configuration setting.
status	**FORTRAN:** `INTEGER` **C:** `MKL_LONG`	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- *_inout* to `DFTI_INPLACE`
- *_in* or *_out* to `DFTI_NOT_INPLACE`

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl_dfti.h`

Description

The `DftiComputeForward` function accepts the descriptor handle parameter and one or more data parameters. Provided the descriptor is configured and committed successfully, this function computes the forward FFT, that is, the transform with the minus sign in the exponent, $\delta = -1$.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters in C and the generic interface in Fortran. The generic Fortran interface to the function is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters `FTI_FORWARD_DOMAIN`, `DFTI_INPUT_STRIDES`, `DFTI_INPUT_DISTANCE`, and so on.

The function returns the zero status when completes successfully. See Status Checking Functions for more information on the returned status.

Interface and Prototype

```
! Fortran interface.
! Note that the body provided below only illustrates the list of different
! parameters and the types of dummy parameters. You can rely only on the function
```

```
! name following keyword INTERFACE. For the precise definition of the
! interface, see the include/mkl_dfti.f90 file in the Intel MKL directory.
INTERFACE DftiComputeForward

  FUNCTION some_actual_function_1(desc,sSrcDst)
    INTEGER some_actual_function_1
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDst
    ...
  END FUNCTION some_actual_function_1

  FUNCTION some_actual_function_2(desc,cSrcDst)
    INTEGER some_actual_function_2
    COMPLEX(8), INTENT(INOUT), DIMENSION(*) :: cSrcDst
    ...
  END FUNCTION some_actual_function_2

  FUNCTION some_actual_function_3(desc,sSrcDstRe,sSrcDstIm)
    INTEGER some_actual_function_3
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstRe
    REAL(4), INTENT(INOUT), DIMENSION(*) :: sSrcDstIm
    ...
  END FUNCTION some_actual_function_3
  ...
END INTERFACE DftiComputeForward
```

The Fortran interface requires that the data parameters have the type of assumed-size rank-1 array, even for multidimensional transforms. The implementations of the FFT interface require the data stored linearly in memory with a regular "stride" pattern capable of describing multidimensional array layout (discussed more fully in `DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES`, see also [3]), and the function requires that the data parameters refer to the first element of the data. Consequently, the data arrays should be specified with the `DIMENSION(*)` attribute and the storage associated with the actual multidimensional arrays via the `EQUIVALENCE` statement.

- C: `mkl_dfti.h`

Description

The function accepts the descriptor handle parameter and one or more data parameters. Provided the descriptor is configured and committed successfully, the `DftiComputeBackward` function computes the inverse FFT, that is, the transform with the plus sign in the exponent, $\delta = +1$.

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters in C and the generic interface in Fortran. The generic Fortran interface to the computation function is based on a set of specific functions. These functions can check for inconsistency between the required and actual number of parameters. However, the specific functions disregard the type of the actual parameters and instead use the interpretation defined in the descriptor by configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_INPUT_STRIDES`, `DFTI_INPUT_DISTANCE`, and so on.

The function returns the zero status when completes successfully. See Status Checking Functions for more information on the returned status.

Descriptor Configuration Functions

There are two functions in this category: the value setting function DftiSetValue sets one particular configuration parameter to an appropriate value, and the value getting function DftiGetValue reads the value of one particular configuration parameter. While all configuration parameters are readable, you cannot set a few of them. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, which is derived by the implementation during execution of one of the functions. See Configuration Settings for details.

DftiSetValue

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
status = DftiSetValue( desc_handle, config_param, config_val )
```

C:

```
status = DftiSetValue(desc_handle, config_param, config_val);
```

Include Files

- FORTRAN 90: mkl_dfti.f90
- C: mkl_dfti.h

Input Parameters

Name	Type	Description
desc_handle	**FORTRAN:** DFTI_DESCRIPTOR **C:** DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
config_param	**FORTRAN:** INTEGER **C:** enum	Configuration parameter.
config_val	Depends on the configuration parameter.	Configuration value.

Output Parameters

Name	Type	Description
desc_handle	**FORTRAN:** DFTI_DESCRIPTOR **C:** DFTI_DESCRIPTOR_HANDLE	Updated FFT descriptor.
status	**FORTRAN:** INTEGER **C:** MKL_LONG	Function completion status.

Description

This function sets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- DFTI_PRECISION
- DFTI_FORWARD_DOMAIN
- DFTI_DIMENSION, DFTI_LENGTH
- DFTI_PLACEMENT
- DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE
- DFTI_NUMBER_OF_USER_THREADS
- DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES
- DFTI_NUMBER_OF_TRANSFORMS
- DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE
- DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, DFTI_CONJUGATE_EVEN_STORAGE
- DFTI_PACKED_FORMAT
- DFTI_WORKSPACE
- DFTI_ORDERING

The DftiSetValue function cannot be used to change configuration parameters DFTI_FORWARD_DOMAIN, DFTI_PRECISION, DFTI_DIMENSION, and DFTI_LENGTHS. Use the DftiCreateDescriptor function to set them.

The function returns the zero status when it completes successfully. See Status Checking Functions for more information on the returned status.

Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. Two functions serve to check the status. The first function is a logical function that checks if the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

DftiErrorClass

Checks whether the status reflects an error of a predefined class.

Syntax

Fortran:

```
predicate = DftiErrorClass( status, error_class )
```

C:

```
predicate = DftiErrorClass(status, error_class);
```

Include Files

- FORTRAN 90: `mkl_dfti.f90`
- C: `mkl_dfti.h`

Input Parameters

Name	Type	Description
status	**FORTRAN:** `INTEGER` **C:** `MKL_LONG`	Completion status of an FFT function.
error_class	**FORTRAN:** `INTEGER` **C:** `MKL_LONG`	Predefined error class.

Output Parameters

Name	Type	Description
predicate	**FORTRAN:** `LOGICAL` **C:** `MKL_LONG`	Result of checking.

Description

The FFT interface in Intel MKL provides a set of predefined error classes listed in Table "Predefined Error Classes". They are named constants and have the type `INTEGER` in Fortran and `MKL_LONG` in C.

Predefined Error Classes

Named Constants	Comments
`DFTI_NO_ERROR`	No error. The zero status belongs to this class.
`DFTI_MEMORY_ERROR`	Usually associated with memory allocation
`DFTI_INVALID_CONFIGURATION`	Invalid settings of one or more configuration parameters
`DFTI_INCONSISTENT_CONFIGURATION`	Inconsistent configuration or input parameters
`DFTI_NUMBER_OF_THREADS_ERROR`	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function)
`DFTI_MULTITHREADED_ERROR`	Usually associated with a value that OMP routines return in case of errors
`DFTI_BAD_DESCRIPTOR`	Descriptor is unusable for computation
`DFTI_UNIMPLEMENTED`	Unimplemented legitimate settings; implementation dependent
`DFTI_MKL_INTERNAL_ERROR`	Internal library error
`DFTI_1D_LENGTH_EXCEEDS_INT32`	Length of one of dimensions exceeds 2^{32} -1 (4 bytes).

The DftiErrorClass function returns a non-zero value in C or the value of .TRUE. in Fortran if the status belongs to a predefined error class. To check whether a function call was successful, call DftiErrorClass with a specific error class. However, the zero value of the status belongs to the DFTI_NO_ERROR class and thus the zero status indicates successful completion of an operation. See Example "Using Status Checking Functions" for an illustration of correct use of the status checking functions.

NOTE It is incorrect to directly compare a status with a predefined class.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorClass
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
 FUNCTION some_actual_function_8( Status, Error_Class )
 LOGICAL some_actual_function_8
 INTEGER, INTENT(IN) :: Status, Error_Class
 END FUNCTION some_actual_function_8
END INTERFACE DftiErrorClass
```

```
/* C prototype */
MKL_LONG DftiErrorClass( MKL_LONG , MKL_LONG );
```

DftiErrorMessage

Generates an error message.

Syntax

Fortran:

```
error_message = DftiErrorMessage( status )
```

C:

```
error_message = DftiErrorMessage(status);
```

Include Files

- FORTRAN 90: mkl_dfti.f90
- C: mkl_dfti.h

Input Parameters

Name	Type	Description
status	**FORTRAN:** INTEGER **C:** MKL_LONG	Completion status of a function.

Output Parameters

Name	Type	Description
error_message	**FORTRAN:** CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH) **C:** Array of char	The character string with the error message.

Description

The error message function generates an error message character string. In Fortran, use a character string of length DFTI_MAX_MESSAGE_LENGTH as a target for the error message. In C, the function returns a pointer to a constant character string, that is, a character array with terminating '\0' character, and you do not need to free this pointer.

Example "Using Status Checking Function" shows how this function can be used.

Interface and Prototype

```
//Fortran interface
INTERFACE DftiErrorMessage
//Note that the body provided here is to illustrate the different
//argument list and types of dummy arguments. The interface
//does not guarantee what the actual function names are.
//Users can only rely on the function name following the
//keyword INTERFACE
 FUNCTION some_actual_function_9( Status )
 CHARACTER(LEN=DFTI_MAX_MESSAGE_LENGTH) some_actual_function_9( Status )
 INTEGER, INTENT(IN) :: Status
 END FUNCTION some_actual_function_9
END INTERFACE DftiErrorMessage
```

```
/* C prototype */
char *DftiErrorMessage( MKL_LONG );
```

Configuration Settings

Each of the configuration parameters is identified by a named constant in the MKL_DFTI module. In C, these named constants have the enumeration type DFTI_CONFIG_PARAM.

All the Intel MKL FFT configuration parameters are readable. Some of them are read-only, while others can be set using the DftiCreateDescriptor or DftiSetValue function.

Values of the configuration parameters fall into the following groups:

- Values that have native data types. For example, the number of simultaneous transforms requested has an integer value, while the scale factor for a forward transform is a single-precision number.
- Values that are discrete in nature and are provided in the MKL_DFTI module as named constants. For example, the domain of the forward transform requires values to be named constants. In C, the named constants for configuration values have the enumeration type DFTI_CONFIG_VALUE.

Table "Configuration Parameters" summarises the information on configuration parameters, along with their types and values. For more details of each configuration parameter, see the subsection describing this parameter.

Configuration Parameters

Configuration Parameter	Type/Value	Comments
Most common configuration parameters, no default, must be set explicitly by `DftiCreateDescriptor`		
`DFTI_PRECISION`	Named constant `DFTI_SINGLE` or `DFTI_DOUBLE`	Precision of the computation.
`DFTI_FORWARD_DOMAIN`	Named constant `DFTI_COMPLEX` or `DFTI_REAL`	Type of the transform.
`DFTI_DIMENSION`	Integer scalar	Dimension of the transform.
`DFTI_LENGTH`	Integer scalar/array	Lengths of each dimension.
Common configuration parameters, settable by `DftiSetValue`		
`DFTI_PLACEMENT`	Named constant `DFTI_INPLACE` or `DFTI_NOT_INPLACE`	Defines whether the result overwrites the input data. Default value: `DFTI_INPLACE`.
`DFTI_FORWARD_SCALE`	Floating-point scalar	Scale factor for the forward transform. Default value: 1.0. Precision of the value should be the same as defined by `DFTI_PRECISION`.
`DFTI_BACKWARD_SCALE`	Floating-point scalar	Scale factor for the backward transform. Default value: 1.0. Precision of the value should be the same as defined by `DFTI_PRECISION`.
`DFTI_NUMBER_OF_USER_THREADS`	Integer scalar	Number of threads that concurrently use the same descriptor to compute FFT.
`DFTI_DESCRIPTOR_NAME`	Character string	Assigns a name to a descriptor. Assumed length of the string is `DFTI_MAX_NAME_LENGTH`. Default value: empty string.
Data layout configuration parameters for single and multiple transforms. Settable by `DftiSetValue`		
`DFTI_INPUT_STRIDES`	Integer array	Defines the input data layout.
`DFTI_OUTPUT_STRIDES`	Integer array	Defines the output data layout.
`DFTI_NUMBER_OF_TRANSFORMS`	Integer scalar	Number of transforms. Default value: 1.
`DFTI_INPUT_DISTANCE`	Integer scalar	Defines the distance between input data sets for multiple transforms. Default value: 0.
`DFTI_OUTPUT_DISTANCE`	Integer scalar	Defines the distance between output data sets for multiple transforms. Default value: 0.

Configuration Parameter	Type/Value	Comments
DFTI_COMPLEX_STORAGE	Named constant DFTI_COMPLEX_COMPLEX or DFTI_REAL_REAL	Defines whether the real and imaginary parts of data for a complex transform are interleaved in one array or split in two arrays. Default value: DFTI_COMPLEX_COMPLEX.
DFTI_REAL_STORAGE	Named constant DFTI_REAL_REAL	Defines how real data for a real transform is stored. Only the DFTI_REAL_REAL value is supported.
DFTI_CONJUGATE_EVEN_STORAGE	Named constant DFTI_COMPLEX_COMPLEX or DFTI_COMPLEX_REAL	Defines whether the complex data in the backward domain of a real transform is stored as complex elements or as real elements. For the default value, see the detailed description.
DFTI_PACKED_FORMAT	Named constant DFTI_CCE_FORMAT, DFTI_CCS_FORMAT, DFTI_PACK_FORMAT, or DFTI_PERM_FORMAT	Defines the layout of real elements in the backward domain of a one-dimensional or two-dimensional real transform.
Advanced configuration parameters, settable by DftiSetValue		
DFTI_WORKSPACE	Named constant DFTI_ALLOW or DFTI_AVOID	Defines whether the library should prefer algorithms using additional memory. Default value: DFTI_ALLOW.
DFTI_ORDERING	Named constant DFTI_ORDERED or DFTI_BACKWARD_SCRAMBLED	Defines whether the result of a complex transform is ordered or permuted. Default value: DFTI_ORDERED.
Read-Only configuration parameters		
DFTI_COMMIT_STATUS	Named constant DFTI_UNCOMMITTED or DFTI_COMMITTED	Readiness of the descriptor for computation.
DFTI_VERSION	String	Version of Intel MKL. Assumed length of the string is DFTI_VERSION_LENGTH.

DFTI_PRECISION

The configuration parameter DFTI_PRECISION denotes the floating-point precision in which the transform is to be carried out. A setting of DFTI_SINGLE stands for single precision, and a setting of DFTI_DOUBLE stands for double precision. The data must be presented in this precision, the computation is carried out in this precision, and the result is delivered in this precision.

DFTI_PRECISION does not have a default value. Set it explicitly by calling the DftiCreateDescriptor function.

NOTE Fortran module MKL_DFTI also defines named constants DFTI_SINGLE_R and DFTI_DOUBLE_R, with the same semantics as DFTI_SINGLE and DFTI_DOUBLE, respectively. Do not use these constants to set the DFTI_PRECISION configuration parameter. Use them only as described in section DftiCreateDescriptor.

DFTI_FORWARD_DOMAIN

The general form of a discrete Fourier transform is

$$Z_{k_1,k_2,\ldots,k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \cdots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1,j_2,\ldots,j_d} \exp\left(\delta i 2\pi \sum_{l=1}^{d} j_l k_l / n_l\right)$$

where w is the input sequence, z is the output sequence, both indexed by $k_l = 0, \ldots n_l-1$, for $l = 1, \ldots, d$, scale factor σ is an arbitrary real number with the default value of 1.0, δ is the sign in the exponent, and $\delta = -1$ for the forward transform and $\delta = +1$ for the backward transform.

The Intel MKL implementation of the FFT algorithm, used for fast computation of discrete Fourier transforms, supports forward transforms on input sequences of two domains, as specified by configuration parameter DFTI_FORWARD_DOMAIN: general complex-valued sequences (DFTI_COMPLEX domain) and general real-valued sequences (DFTI_REAL domain). The forward transform maps the forward domain to the corresponding backward domain, as shown in Table "Correspondence of Forward and Backward Domain".

The conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x(k_1, k_2, \ldots, k_d) = conjugate(x(n_1 - k_1, n_2 - k_2, \ldots, n_d - k_d)),$$

where the index arithmetic is performed modulo respective size, that is,

$$x(\ldots, expr_s, \ldots) \equiv x(\ldots, \mathrm{mod}(expr_s, n_s), \ldots),$$

and therefore

$$x(\ldots, n_s, \ldots) \equiv x(\ldots, 0, \ldots).$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in DFTI_CONJUGATE_EVEN_STORAGE.

Correspondence of Forward and Backward Domain

Forward Domain	Implied Backward Domain
Complex (DFTI_COMPLEX)	Complex (DFTI_COMPLEX)
Real (DFTI_REAL)	Conjugate-even

DFTI_FORWARD_DOMAIN does not have a default value. Set it explicitly by calling the DftiCreateDescriptor function.

DFTI_PRECISION
DFTI_DIMENSION, DFTI_LENGTHS
DftiCreateDescriptor

DFTI_DIMENSION, DFTI_LENGTHS

The dimension of the transform is a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For a one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `Integer` data type in Fortran and `MKL_LONG` data type in C. For multi-dimensional (≥ 2) transform, the lengths of each of the dimensions are supplied in an integer array (`Integer` data type in Fortran and `MKL_LONG` data type in C).

`DFTI_DIMENSION` and `DFTI_LENGTHS` do not have a default value. To set them, use the `DftiCreateDescriptor` function and not the `DftiSetValue` function.

DftiSetValue

DFTI_PLACEMENT

By default, the computational functions overwrite the input data with the output result. That is, the default setting of the configuration parameter `DFTI_PLACEMENT` is `DFTI_INPLACE`. You can change that by setting it to `DFTI_NOT_INPLACE`.

NOTE The data sets have no common elements.

See Also

DftiSetValue

DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE

The forward transform and backward transform are each associated with a scale factor σ of its own having the default value of 1. You can specify the scale factors using one or both of the configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length n, you can use the default scale of 1 for the forward transform and set the scale factor for the backward transform to be $1/n$, thus making the backward transform the inverse of the forward transform.

Set the scale factor configuration parameter using a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

NOTE For inquiry of the scale factor with the `DftiGetValue` function in C, the *`config_val`* parameter must have the same floating-point precision as the descriptor.

DFTI_NUMBER_OF_USER_THREADS

Use one of the following techniques to parallelize your application:

a. You specify the parallel mode within the FFT module of Intel MKL instead of creating threads in your application. See *Intel MKL User's Guide* for more information on how to do this. See also Example "Using Intel MKL Internal Threading Mode".

b. You create threads in the application yourself and have each thread perform all stages of FFT implementation, including descriptor initialization, FFT computation, and descriptor deallocation. In this case, each descriptor is used only within its corresponding thread. In this case, set single-threaded mode for Intel MKL. See Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region".

c. You create threads in the application yourself after initializing all FFT descriptors. This implies that threading is employed for parallel FFT computation only, and the descriptors are released upon return from the parallel region. In this case, each descriptor is used only within its corresponding thread. You must explicitly set the single-threaded mode for Intel MKL, otherwise, the actual number of threads may differ from one, because the `DftiCommitDescriptor` function is not in a parallel region. See Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread".

d. You create threads in the application yourself after initializing the only FFT descriptor. This implies that threading is employed for parallel FFT computation only, and the descriptor is released upon return from the parallel region. In this case, each thread uses the same descriptor. See Example "Using Parallel Mode with a Common Descriptor".

In cases "a", "b", and "c", listed above, set the parameter `DFTI_NUMBER_OF_USER_THREADS` to 1 (its default value), since each particular descriptor instance is used only in a single thread.

In case "d", use the `DftiSetValue()` function to set the `DFTI_NUMBER_OF_USER_THREADS` to the actual number of FFT computation threads, because multiple threads will be using the same descriptor. If this setting is not done, your program will work incorrectly or fail, since the descriptor contains individual data for each thread.

WARNING

- Avoid parallelizing your program and employing the Intel MKL internal threading simultaneously because this will slow down the performance. Note that in case "d" above, FFT computation is automatically initiated in a single-threading mode.
- Do not change the number of threads after the `DftiCommitDescriptor()` function completes FFT initialization.

DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES

The FFT interface provides configuration parameters that define the layout of multidimensional data in the computer memory. For d-dimensional data set X defined by dimensions N_1 x N_2 x ... x N_d, the layout describes where a particular element $X(k_1, k_2, ..., k_d)$ of the data set is located. The memory address of the element $X(k_1, k_2, ..., k_d)$ is expressed by the formula

$$\text{address of } X(k_1, k_2, ..., k_d) = \text{address of } X(0, 0, ..., 0) + \text{offset}$$

$$= \text{address of } X(0, 0, ..., 0) + s_0 + k_1*s_1 + k_2*s_2 + ...+ k_d*s_d,$$

where s_0 is the displacement and s_1, ..., s_d are generalized strides. The configuration parameters `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` enable you to get and set these values. The configuration value is an array of values (s_0, s_1, ..., s_d) of `INTEGER` data type in Fortran and `MKL_LONG` data type in C.

The offset is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the `DFTI_FORWARD_DOMAIN`, `DFTI_COMPLEX_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the type of the elements as shown in Table "Assumed Element Types of the Input/Output Data":

Assumed Element Types of the Input/Output Data

Descriptor Configuration	Element Type in the Forward Domain	Element Type in the Backward Domain
DFTI_FORWARD_DOMAIN=DFTI_COMPLEX DFTI_COMPLEX_STORAGE=DFTI_COMPLEX_COMPLEX	Complex	Complex
DFTI_FORWARD_DOMAIN=DFTI_COMPLEX DFTI_COMPLEX_STORAGE=DFTI_REAL_REAL	Real	Real
DFTI_FORWARD_DOMAIN=DFTI_REAL DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL	Real	Real
DFTI_FORWARD_DOMAIN=DFTI_REAL DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX	Real	Complex

The DFTI_INPUT_STRIDES configuration parameter describes the layout of the input data, and the element type is defined by the forward domain for the DftiComputeForward function, and by the backward domain for the DftiComputeBackward function. The DFTI_OUTPUT_STRIDES configuration parameter describes the layout of the output data, and the element type is defined by the backward domain for the DftiComputeForward function, and by the forward domain for DftiComputeBackward function.

For in-place transforms, the configuration set by DFTI_OUTPUT_STRIDES is ignored except when the element types in forward and backward domains are different. If they are different, set DFTI_OUTPUT_STRIDES explicitly (even though the transform is in-place). For in-place transforms, the configuration must be consistent, that is, the locations of the first elements in input and output must coincide in each dimension. The DFTI_PLACEMENT configuration parameter defines whether the transform is in-place or out-of-place.

The configuration parameters define the layout of input and output data, and not the forward-domain and backward-domain data. If the data layouts in forward domain and backward domain differ, set DFTI_INPUT_STRIDES and DFTI_OUTPUT_STRIDES explicitly and then commit the descriptor before calling computation functions.

The FFT interface supports both positive and negative stride values. If you use negative strides, set the displacement of the data as follows:

$$s_0 = \sum_{i=1}^{d} (N_i - 1) \cdot \max(-s_i, 0).$$

The default setting of strides in a general multi-dimensional case assumes that the array that contains the data has no padding. The order of the strides depends on the programming language. For example:

```
/* C/C++ */
MKL_LONG dims[] = { nd, …, n2, n1 };
DftiCreateDescriptor( &hand, precision, domain, d, dims );
// The above call assumes data declaration:  type X[nd]…[n2][n1]
// Default strides are { 0, nd*…*n2*n1, …,  n2*n1, n1, 1 }

! Fortran
INTEGER :: dims(d) = [n1, n2, …, nd]
status = DftiCreateDescriptor( hand, precision, domain, d, dims)
! The above call assumes data declaration:  type X(n1,n2,…,nd)
! Default strides are [ 0, 1, n1, n1*n2, …, n1*n2*…*nd]
```

Note that in case of a real FFT (DFTI_DOMAIN=DFTI_REAL), where different data layouts in the backward domain are available (see DFTI_PACKED_FORMAT), the default value of the strides is not intuitive for the recommended CCE format (configuration setting DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX). In case of an *in-place* real transform with the CCE format, set the strides explicitly, as follows:

```
/* C/C++ */
MKL_LONG dims[] = { nd, …, n2, n1 };
MKL_LONG rstrides[] = { 0, nd*…*n2*(n1/2+1), …, 2*n2*(n1/2+1), 2*(n1/2+1), 1 };
MKL_LONG cstrides[] = { 0, nd*…*n2*(n1/2+1), …, n2*(n1/2+1), (n1/2+1), 1 };
DftiCreateDescriptor( &hand, precision,  DFTI_REAL, d, dims );
DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
// Set the strides appropriately for forward/backward transform

! Fortran
INTEGER :: dims(d) = [n1, n2, …, nd]
INTEGER :: rstrides(1+d) = [0, 1, 2*(n1/2+1), 2*(n1/2+1)*n2, … ]
INTEGER :: cstrides(1+d) = [0, 1, (n1/2+1), (n1/2+1)*n2, … ]
status = DftiCreateDescriptor( hand, precision, domain, d, dims)
status = DftiSetValue( hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
! Set the strides appropriately for forward/backward transform
```

DFTI_NUMBER_OF_TRANSFORMS

In some situations, you may need to perform a number of FFTs of the same dimension and lengths. For example, you may need to transform a number of one-dimensional data sets of the same length. To specify this number, use the DFTI_NUMBER_OF_TRANSFORMS parameter, which has the default value of 1. You can set this parameter to a positive integer value using the Integer data type in Fortran and MKL_LONG data type in C.

NOTE The data sets to be transformed must not have common elements. Therefore one (or both) of the configuration parameters DFTI_INPUT_DISTANCE and DFTI_OUTPUT_DISTANCE is required if DFTI_NUMBER_OF_TRANSFORMS is greater than one.

See Also

DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE
DftiSetValue

DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE

The FFT interface in Intel MKL enables computation of multiple transforms. To compute multiple transforms, you need to specify the data distribution of the multiple sets of data. The distance between the first data elements of consecutive data sets, DFTI_INPUT_DISTANCE for input data or DFTI_OUTPUT_DISTANCE for output data, specifies the distribution. The configuration setting is a value of INTEGER data type in Fortran and MKL_LONG data type in C.

The default value for both configuration settings is one. You must set this parameter explicitly if the number of transforms is greater than one (see DFTI_NUMBER_OF_TRANSFORMS).

The distance is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the DFTI_FORWARD_DOMAIN, DFTI_COMPLEX_STORAGE, and DFTI_CONJUGATE_EVEN_STORAGE configuration parameters define the type of the elements as shown in Table "Assumed Element Types of the Input/Output Data".

For in-place transforms, the configuration set by DFTI_OUTPUT_DISTANCE is ignored except when the element types in forward and backward domains are different. If they are different, set DFTI_OUTPUT_DISTANCE explicitly (even though the transform is in-place). For in-place transforms, the configuration must be consistent, that is, the locations of the data sets on input and output must coincide. The DFTI_PLACEMENT configuration parameter defines whether the transform is in-place or out-of-place.

The configuration parameters define the distance within input and output data, and not within the forward-domain and backward-domain data. If the distances in the forward and backward domains differ, set DFTI_INPUT_DISTANCE and DFTI_OUTPUT_DISTANCE explicitly and then commit the descriptor before calling computation functions.

The following examples illustrate setting of the DFTI_INPUT_DISTANCE configuration parameter:

```
MKL_LONG dims[] = { nd, …, n2, n1 };
MKL_LONG distance = nd*…*n2*n1;
DftiCreateDescriptor( &hand, precision,  DFTI_COMPLEX, d, dims );
DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, (MLK_LONG)howmany );
DftiSetValue( hand, DFTI_INPUT_DISTANCE,  distance );

! Fortran
INTEGER :: dims(d) = [n1, n2, …, nd]
INTEGER :: distance = n1*n2*…*nd
status = DftiCreateDescriptor( hand, precision, DFTI_COMPLEX, d, dims)
status = DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, howmany )
status = DftiSetValue( hand, DFTI_INPUT_DISTANCE,  distance );
```

DFTI_COMPLEX_STORAGE, DFTI_REAL_STORAGE, DFTI_CONJUGATE_EVEN_STORAGE

Depending on the value of configuration parameter DFTI_FORWARD_DOMAIN, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined with generalized strides (see DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES). For multiple transforms, each nth set of data (where nth≥0) should be located within the same memory block, and the data sets should be placed at a distance from each other (see DFTI_NUMBER_OF_TRANSFORMS and DFTI_INPUT_DISTANCE, DFTI_OUTPUT_DISTANCE).

NOTE In C/C++, avoid setting up multidimensional arrays with lists of pointers to one-dimensional arrays. Instead use a one-dimensional array with the explicit indexing to access the data elements.

C notation is used in this section to describe association of mathematical entities with the data elements stored in memory. FFT Examples demonstrate the usage of storage formats in both C and Fortran.

Storage schemes for complex domain. For the DFTI_COMPLEX forward domain, both input and output sequences belong to the complex domain. In this case, the configuration parameter DFTI_COMPLEX_STORAGE can have one of the two values: DFTI_COMPLEX_COMPLEX (default) or DFTI_REAL_REAL.

NOTE In the Intel MKL FFT implementation, storage schemes for a forward complex domain and the respective backward complex domain are the same.

With DFTI_COMPLEX_COMPLEX storage, the complex-valued data sequence is referenced by a single complex parameter Z so that complex-valued element $z_{k_1, k_2, \ldots, k_d}$ of the sequence is located at Z[nth*distance + $stride_0$ + k_1*$stride_1$ + k_2*$stride_2$+ ... k_d*$stride_d$] as a structure consisting of the real and imaginary parts.

The following example illustrates a typical usage of the DFTI_COMPLEX_COMPLEX storage:

```
complex :: x(n)
...
! on input, for i=1,...,N: x(i) = r_{i-1}
status = DftiComputeForward( desc_handle, x )
! on output, for i=1,...,N: x(i) = z_{i-1}
```

With the DFTI_REAL_REAL storage, the complex-valued data sequence is referenced by two real parameters ZRe and ZIm so that complex-valued element $z_{k_1, k_2, \ldots, k_d}$ of the sequence is computed as ZRe[nth*distance + stride$_0$ + k_1*stride$_1$ + k_2*stride$_2$+ ... k_d*stride$_d$] + √(-1) × ZIm[nth*distance + stride$_0$ + k_1*stride$_1$ + k_2*stride$_2$+ ... k_d*stride$_d$].

A typical usage of the DFTI_REAL_REAL storage is illustrated by the following example:

```
real :: xre(n), xim(n)
...
status = DftiSetValue( desc_handle, DFTI_COMPLEX_STORAGE, DFTI_REAL_REAL)
! on input, for i=1,...,N: cmplx(xre(i),xim(i)) = r_{i-1}
status = DftiComputeForward( desc_handle, xre, xim )
! on output, for i=1,...,N: cmplx(xre(i),xim(i)) = z_{i-1}
```

Storage scheme for the real and conjugate-even domains. The setting for the storage schemes for real and conjugate-even domains is recorded in the configuration parameters DFTI_REAL_STORAGE and DFTI_CONJUGATE_EVEN_STORAGE. Since a forward real domain corresponds to a conjugate-even backward domain, they are considered together. The example below uses one-, two- and three-dimensional real to conjugate-even transforms. In-place computation is assumed whenever possible (that is, when the input data type matches the output data type).

One-Dimensional Transform

Consider a one-dimensional n-length transform of the form

$$z_k = \sum_{j=0}^{n-1} r_j e^{-i2\pi jk/n}, \qquad r_j \in R, z_k \in C.$$

There is a symmetry:

For even n: z(n/2+i) = conjg(z(n/2-i)), $1 \le i \le n/2-1$, and moreover z(0) and z(n/2) are real values.

For odd n: z(m+i) = conjg(z(m-i+1)), m = floor($n/2$), $1 \le i \le m$, and moreover z(0) is real value.

Assume that the stride has the default value of one.

This complex conjugate symmetric vector can be stored in the complex array of size m+1 or in the real array of size 2m+2 or 2m depending on which packed format is used.

Two-Dimensional Transform

Each of the real-to-complex functions computes the forward FFT of a two-dimensional real matrix according to the mathematical equation

$$z_{j,p} = \sum_{k=0}^{m-1} \sum_{l=0}^{n-1} r_{k,l} * e^{-i2\pi jk/m} * e^{-i2\pi pl/n},$$

$$0 \le j \le m\text{-}1, 0 \le p \le n\text{-}1$$

The mathematical result $z_{j,p}$, $0 \le j \le m-1$, $0 \le p \le n-1$, is the complex matrix of size `(m,n)`.

This mathematical result can be stored in the real two-dimensional array of size:

`(m+2,n+2)` (`CCS` format), or
`(m,n)` (`Pack` or `Perm` formats), or
`(2*(m/2+1), n)` (`CCE` format, Fortran interface),
`(m, 2*(n/2+1))` (`CCE` format, C interface)

or in the complex two-dimensional array of size:

`(m/2+1, n)` (`CCE` format, Fortran interface),
`(m, n/2+1)` (`CCE` format, C interface)

Since the multidimensional array data are arranged differently in Fortran and C (see `DFTI_INPUT_STRIDES`, `DFTI_OUTPUT_STRIDES`), the output array that holds the computational result contains complex conjugate-symmetric columns (for Fortran) or complex conjugate-symmetric rows (for C).

The following tables give examples of output data layout in `Pack` format for a forward two-dimensional real-to-complex FFT of a 6-by-4 real matrix. Note that the same layout is used for the input data of the corresponding backward complex-to-real FFT.

Fortran-interface Data Layout for a 6-by-4 Matrix

z(1,1)	Re z(1,2)	Im z(1,2)	z(1,3)
Re z(2,1)	Re z(2,2)	Re z(2,3)	Re z(2,4)
Im z(2,1)	Im z(2,2)	Im z(2,3)	Im z(2,4)
Re z(3,1)	Re z(3,2)	Re z(3,3)	Re z(3,4)
Im z(3,1)	Im z(3,2)	Im z(3,3)	Im z(3,4)
z(4,1)	Re z(4,2)	Im z(4,2)	z(4,3)

For the above example, the stride array is (0, 1, 6).

C-interface Data Layout for a 6-by-4 Matrix

z(1,1)	Re z(1,2)	Im z(1,2)	z(1,3)
Re z(2,1)	Re z(2,2)	Im z(2,2)	Re z(2,3)
Im z(2,1)	Re z(3,2)	Im z(3,2)	Im z(2,3)
Re z(3,1)	Re z(4,2)	Im z(4,2)	Re z(3,3)
Im z(3,1)	Re z(5,2)	Im z(5,2)	Im z(3,3)
z(4,1)	Re z(6,2)	Im z(6,2)	z(4,3)

For the second example, the stride array is (0, 4, 1). See `DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES` for details.

See also `DFTI_PACKED_FORMAT`.

Three-Dimensional Transform

Each of the real-to-complex functions computes the forward FFT of a three-dimensional real matrix according to the mathematical equation

$$z_{j,t,q} = \sum_{p=0}^{m-1} \sum_{l=0}^{n-1} \sum_{s=0}^{k-1} r_{p,l,s} * e^{-i2\pi jp/m} * e^{-i2\pi tl/n} * e^{-i2\pi qs/k},$$

$$0 \le j \le m\text{-}1, 0 \le t \le n\text{-}1, 0 \le q \le k\text{-}1$$

The mathematical result $z_{j,t,q}$, $0 \le j \le m-1$, $0 \le t \le n-1$, $0 \le q \le k-1$ is the complex matrix of size (m,n,k), which is a complex conjugate-symmetric, or conjugate-even, matrix as follows:

$z_{m1,n1,k1} = conjg(z_{m-m1,n-n1,k-k1})$, where each dimension is periodic.

This mathematical result can be stored in the real three-dimensional array of size:

(m/2+1,n,k) (CCE format, Fortran interface),
(m,n,k/2+1) (CCE format, C interface).

Since the multidimensional array data are arranged differently in Fortran and C (see DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES), the output array that holds the computational result contains complex conjugate-symmetric columns (for Fortran) or complex conjugate-symmetric rows (for C).

NOTE CCE is the only packed format for a three-dimensional real FFT. In both in-place and out-of-place REAL FFT, for real data, the stride and distance parameters are in REAL units and for complex data, they are in COMPLEX units. So elements of the input and output data can be placed in different elements of input-output array of the in-place FFT.

1. DFTI_REAL_REAL for real domain, DFTI_COMPLEX_REAL for conjugate-even domain (by default). It is used for 1D and 2D REAL FFT.
   - A typical usage of in-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:2*m+1)
...some other code...
...assuming inplace transform...
Status = DftiComputeForward( Desc_Handle, X )
```

   On input,

   X(p) = r_p, p = 0,1,...,n-1.

   On output,

   Output data stored in one of formats: Pack, Perm or CCS (see DFTI_PACKED_FORMAT).

   CCS format: X(2*k) = Re(z_k), X(2*k+1) = Im(z_k), k = 0,1,...,m.

   Pack format:

   even n: X(0) = Re(z_0), X(2*k-1) = Re(z_k), X(2*k) = Im(z_k), k = 1,...,m-1, and X(n-1) = Re(z_m)

   odd n: X(0) = Re(z_0), X(2*k-1) = Re(z_k), X(2*k) = Im(z_k), k = 1,...,m

   Perm format:

   even n: X(0) = Re(z_0), X(1) = Re(z_m), X(2*k) = Re(z_k), X(2*k+1) = Im(z_k), k = 1,...,m-1,

odd n: $X(0) = Re(z_0), X(2*k-1) = Re(z_k), X(2*k) = Im(z_k), k = 1,...,m$.

See Example "One-dimensional In-place FFT (Fortran Interface)", Example "One-dimensional In-place FFT (C Interface)", Example "Two-dimensional FFT (Fortran Interface)", and Example "Two-dimensional FFT (C Interface)".

Input and output data exchange roles in the backward transform.

- A typical usage of out-of-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:n-1)
REAL :: Y(0:2*m+1)
...some other code...
...assuming out-of-place transform...
Status = DftiComputeForward( Desc_Handle, X, Y )
```

On input, $X(p) = r_p, p = 0,1,...,n-1$.

On output,

Output data stored in one of formats: `Pack`, `Perm` or `CCS` (see `DFTI_PACKED_FORMAT`).

CCS format: $Y(2*k) = Re(z_k), Y(2*k+1) = Im(z_k), k = 0,1,...,m$.

Pack format:

even n: $Y(0) = Re(z_0), Y(2*k-1) = Re(z_k), Y(2*k) = Im(z_k), k = 1,...,m-1,$ and $Y(n-1) = Re(z_m)$

odd n: $Y(0) = Re(z_0), Y(2*k-1) = Re(z_k), Y(2*k) = Im(z_k), k = 1,...,m$

Perm format:

even n: $Y(0) = Re(z_0), Y(1) = Re(z_m), Y(2*k) = Re(z_k)$, $Y(2*k+1) = Im(z_k), k = 1,...,m-1,$

odd n: $Y(0) = Re(z_0), Y(2*k-1) = Re(z_k), Y(2*k) = Im(z_k), k = 1,...,m$.

Notice that if the stride of the output array is not set to the default value unit stride, the real and imaginary parts of one complex element will be placed with this stride.

For example:

CCS format: $Y(2*k*s) = Re(z_k), Y((2*k+1)*s) = Im(z_k), k = 0,1, ..., m,$ *s* - stride.

See Example "One-dimensional Out-of-place FFT (Fortran Interface)" and Example "One-dimensional Out-of-place FFT (C Interface)".

Input and output data exchange roles in the backward transform.

2. `DFTI_REAL_REAL` for real domain, `DFTI_COMPLEX_COMPLEX` for conjugate-even domain. It is used for 1D, 2D and 3D REAL FFT. The CCE format is set by default. You must explicitly set the storage scheme in this case, because its value is not the default one.

- A typical usage of in-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:m*2)
...some other code...
...assuming in-place transform...
Status = DftiSetValue( Desc_Handle,  DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
...
Status = DftiComputeForward( Desc_Handle, X)
```

  On input,

  $X(p) = r_p$, $p = 0,1,\ldots,n-1$.

  On output,

  $X(2*k) = Re(z_k)$, $X(2*k+1) = Im(z_k)$, $k = 0,1,\ldots,m$.

  See Example "Two-Dimensional REAL In-place FFT (Fortran Interface)".

  Input and output data exchange roles in the backward transform.

- A typical usage of out-of-place transform is as follows:

```
// m = floor( n/2 )
REAL :: X(0:n-1)
COMPLEX :: Y(0:m)
...some other code...
...assuming out-of-place transform...
Status = DftiSetValue( Desc_Handle,  DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
...
Status = DftiComputeForward( Desc_Handle, X, Y )
```

  On input,

  $X(p) = r_p$, $p = 0,1,\ldots,n-1$.

  On output,

  $Y(k) = z_k$, $k = 0,1,\ldots,m$.

  See Example "Two-Dimensional REAL Out-of-place FFT (Fortran Interface)" and Example "Three-Dimensional REAL FFT (C Interface)"

  Input and output data exchange roles in the backward transform.

DFTI_PACKED_FORMAT

The result of the forward transform (that is, in the frequency domain) of real data is represented in several possible packed formats: Pack, Perm, CCS, or CCE. The data can be packed due to the symmetry property of the FFT of real data.

Use the following non-default settings for real transforms of all ranks:

- The configuration parameter `DFTI_CONJUGATE_EVEN_STORAGE` has the value of `DFTI_COMPLEX_COMPLEX`.
- Elements of the result in the conjugate-even domain have a complex type.
- The configuration parameter `DFTI_PACKED_FORMAT` has the value of `DFTI_CCE_FORMAT`.

The following setting is the default for one-dimensional and two-dimensional real transforms:

- The configuration parameter `DFTI_CONJUGATE_EVEN_STORAGE` has the value of `DFTI_COMPLEX_REAL`.
- Data elements in the frequency domain have a real type.
- The value of `DFTI_PACKED_FORMAT` defines how real and imaginary parts of the data are laid out in the result.

NOTE This setting does not apply to three-dimensional and higher-rank transforms. Though not recommended, it is the default for backward compatibility.

The CCE format stores the values of the first half of the output complex conjugate-even signal resulting from the forward FFT. For a multi-dimensional real transform, `n1 * n2 * n3 * ... * nk` the size of complex matrix in CCE format is `(n1/2+1)* n2 * n3 * ... * nk` for Fortran and `n1 * n2 * ... * (nk/2+1)` for C.

The CCS format is similar to the CCE format and is the same format for one-dimensional transform. It differs slightly for multi-dimensional real transforms. In CCS format, the output samples of the FFT are arranged as shown in Table "Packed Format Output Samples" for a one-dimensional FFT and in Table "CCS Format Output Samples (Two-Dimensional Matrix (m+2)-by-(n+2))" for a two-dimensional FFT.

The Pack format is a compact representation of a complex conjugate-symmetric sequence, but the elements are arranged intuitively for complex FFT algorithms rather than for real FFTs. In the Pack format, the output samples of the FFT are arranged as shown in Table "Packed Format Output Samples" for one-dimensional FFT and in Table "Pack Format Output Samples (Two-Dimensional Matrix m-by-n)" for two-dimensional FFT.

The Perm format is a permutation of the Pack format for even lengths and is the same as the Pack format for odd lengths. In Perm format, the output samples of the FFT are arranged as shown in Table "Packed Format Output Samples" for a one-dimensional FFT and in Table "Perm Format Output Samples (Two-Dimensional Matrix m-by-n)" for a two-dimensional FFT.

Packed Format Output Samples

For n = 2*s

FFT Real	0	1	2	3	...	n-2	n-1	n	n+1
CCS	R_0	0	R_1	I_1	...	$R_{n/2-1}$	$I_{n/2-1}$	$R_{n/2}$	0
Pack	R_0	R_1	I_1	R_2	...	$I_{n/2-1}$	$R_{n/2}$		
Perm	R_0	$R_{n/2}$	R_1	I_1	...	$R_{n/2-1}$	$I_{n/2-1}$		

For n = 2*s + 1

FFT Real	0	1	2	3	...	n-4	n-3	n-2	n-1	n	n+1
CCS	R_0	0	R_1	I_1	...	I_{s-2}	R_{s-1}	I_{s-1}	R_s	I_s	
Pack	R_0	R_1	I_1	R_2	...	R_{s-1}	I_{s-1}	R_s	I_s		
Perm	R_0	R_1	I_1	R_2	...	R_{s-1}	I_{s-1}	R_s	I_s		

Note that Table "Packed Format Output Samples" uses the following notation for complex data entries:

R_j = Re z_j

I_j = Im z_j

See also Table "Comparison of the Storage Effects of Complex-to-Complex and Real-to-Complex FFTs for Forward Transform" and Table "Comparison of the Storage Effects of Complex-to-Complex and Complex-to-Real FFTs for Backward Transform".

DFTI_WORKSPACE

The computation step for some FFT algorithms requires a scratch space for permutation or other purposes. To manage the use of the auxiliary storage, Intel MKL enables you to set the configuration parameter `DFTI_WORKSPACE` with the following values:

DFTI_ALLOW	(default) Permits the use of the auxiliary storage.
DFTI_AVOID	Instructs Intel MKL to avoid using the auxiliary storage if possible.

See Also
DftiSetValue

DFTI_COMMIT_STATUS

The DFTI_COMMIT_STATUS configuration parameter indicates whether the descriptor is ready for computation. The parameter has two possible values:

DFTI_UNCOMMITTED	Default value, set after a successful call of DftiCreateDescriptor.
DFTI_COMMITTED	The value after a successful call to DftiCommitDescriptor.

A computation function called with an uncommitted descriptor returns an error.

You cannot directly set this configuration parameter in a call to DftiSetValue, but a change in the configuration of a committed descriptor may change the commit status of the descriptor to DFTI_UNCOMMITTED.

DFTI_ORDERING

Some FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying an FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus using scrambled data is acceptable if it leads to better performance. The following options are available in Intel MKL:

- DFTI_ORDERED: Forward transform data ordered, backward transform data ordered (default option).
- DFTI_BACKWARD_SCRAMBLED: Forward transform data ordered, backward transform data scrambled.

Table "Scrambled Order Transform" tabulates the effect of this configuration setting.

Scrambled Order Transform

	DftiComputeForward	DftiComputeBackward
DFTI_ORDERING	Input → Output	Input → Output
DFTI_ORDERED	ordered → ordered	ordered → ordered
DFTI_BACKWARD_SCRAMBLED	ordered → scrambled	scrambled → ordered

NOTE The word "scrambled" in this table means "permit scrambled order if possible". In some situations permitting out-of-order data gives no performance advantage and an implementation may choose to ignore the suggestion.

Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® MKL.

NOTE These functions are available only for the Linux* and Windows* operating systems.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel MKL provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel MKL cluster FFT functions are similar to the corresponding interfaces for the conventional Intel MKL FFT functions, described earlier in this chapter. Refer there for details not explained in this section.

Table "Cluster FFT Functions in Intel MKL" lists cluster FFT functions implemented in Intel MKL:

Cluster FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptorDM	Allocates memory for the descriptor data structure and preliminarily initializes it.
DftiCommitDescriptorDM	Performs all initialization for the actual FFT computation.
DftiFreeDescriptorDM	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForwardDM	Computes the forward FFT.
DftiComputeBackwardDM	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValueDM	Sets one particular configuration parameter with the specified configuration value.
DftiGetValueDM	Gets the value of one particular configuration parameter.

Computing Cluster FFT

The cluster FFT functions described later in this section are provided with Fortran and C interfaces. Fortran stands for Fortran 95.

Cluster FFT computation is performed by DftiComputeForwardDM and DftiComputeBackwardDM functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates local part of the input data, i.e. some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel MKL cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling MPI_Init in C/C++ or MPI_INIT in Fortran (the function must be called prior to calling any FFT function and any MPI function).

2. Allocate memory for the descriptor and create it by calling DftiCreateDescriptorDM.
3. Specify one of several values of configuration parameters by one or more calls to DftiSetValueDM.
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling DftiGetValueDM.
5. Initialize the descriptor for the FFT computation by calling DftiCommitDescriptorDM.
6. Create arrays for local parts of input and output data and fill the local part of input data with values. (For more information, see Distributing Data among Processes.)
7. Compute the transform by calling DftiComputeForwardDM or DftiComputeBackwardDM.
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling DftiFreeDescriptorDM.
10. Finalize communication through MPI by calling MPI_Finalize in C/C++ or MPI_FINALIZE in Fortran (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in the "Examples for Cluster FFT Functions" section in Appendix C illustrate cluster FFT computations.

Distributing Data among Processes

The Intel MKL cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order in C/C++ and in the column-major order in Fortran. For example, a two-dimensional matrix A of size (*m*,*n*) is stored in a vector B of size *m***n* so that

- B[i*n+j]=A[i][j] in C/C++ (*i=0, ..., m-1, j=0, ..., n-1*)
- B(j*m+i)=A(i,j) in Fortran (*i=1, ..., m, j=1, ..., n*).

NOTE Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with Lengths=(*m*,*n*,*1*) can be computed over an array Ar[m][n][l] in C/C++ or AR(m,n,l) in Fortran.

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able do this, see sections below on how the virtual global array is composed of the local ones.

Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in C and the last one in Fortran. If the global array is two-dimensional, in C, it gives each process several consecutive rows. The term "rows" will be used regardless of the array dimension and programming language. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size (11,15,12), the processes may store local arrays of sizes (6,15,12) and (5,15,12), respectively.

If p is the number of MPI processes and the matrix of a transform to be computed has size (*m*,*n*,*1*), in C, each MPI process works with local data array of size (m_q , *n*, *1*), where $\Sigma m_q=m$, $q=0, \ldots, p-1$. Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: CDFT_LOCAL_NX, CDFT_LOCAL_START_X, and CDFT_LOCAL_SIZE. To retrieve values of the parameters, use the DftiGetValueDM function:

- CDFT_LOCAL_NX specifies how many rows of the global array the current process receives.

- CDFT_LOCAL_START_X specifies which row of the global input or output array corresponds to the first row of the local input or output array. If A is a global array and L is the appropriate local array, then
  - L[i][j][k]=A[i+cdft_local_start_x][j][k], where *i=0, ..., m_q-1, j=0, ..., n-1, k=0, ..., l-1* for C/C++
  - L(i,j,k)=A(i,j,k+cdft_local_start_x-1), where *i=1, ..., m, j=1, ..., n, k=1, ..., l_q* for Fortran.

Example "2D Out-of-place Cluster FFT Computation" in Appendix C shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, *four* configuration parameters are needed: CDFT_LOCAL_NX, CDFT_LOCAL_START_X, CDFT_LOCAL_OUT_NX, and CDFT_LOCAL_OUT_START_X. Use the DftiGetValueDM function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in Table "Data Distribution Configuration Parameters for 1D Transforms":

Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	CDFT_LOCAL_NX	CDFT_LOCAL_OUT_NX
Elements shift in input array	CDFT_LOCAL_START_X	CDFT_LOCAL_OUT_START_X
Number of elements in output array	CDFT_LOCAL_OUT_NX	CDFT_LOCAL_NX
Elements shift in output array	CDFT_LOCAL_OUT_START_X	CDFT_LOCAL_START_X

Memory size for local data

The memory size needed for local arrays cannot be just calculated from CDFT_LOCAL_NX (CDFT_LOCAL_OUT_NX), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter CDFT_LOCAL_SIZE specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than CDFT_LOCAL_SIZE*size_of_element. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to Table "Settable configuration Parameters"), it must have the same size as the local arrays. Example "1D In-place Cluster FFT Computations" in Appendix C illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation effected with a user-defined workspace.

Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions MKL_CDFT_ScatterData and MKL_CDFT_GatherData to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel MKL and located in the following subdirectory of the Intel MKL installation directory: examples/cdftc/source/cdft_example_support.c for C/C++ and examples/cdftf/source/cdft_example_support.f90 for Fortran.

Restriction on Lengths of Transforms

The algorithm that the Intel MKL cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, lengths of the first two dimensions in C/C++ or of the last two dimensions in Fortran must be not less than the number of MPI processes.
- Length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to Error Codes for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

Cluster FFT Interface

To use the cluster FFT functions, you need to access the module `MKL_CDFT` through the "`use`" statement in Fortran; or access the header file `mkl_cdft.h` through "`include`" in C/C++.

The Fortran interface provides a derived type `DFTI_DESCRIPTOR_DM`; a number of named constants representing various names of configuration parameters and their possible values; and a number of overloaded functions through the generic functionality of Fortran 95.

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- Fortran:

  ```
  INCLUDE "mpif.h"
  ```

  (for some MPI versions, "`mpif90.h`" header may be used instead).
- C/C++:

  ```
  #include "mpi.h"
  ```

There are three main categories of the cluster FFT functions in Intel MKL:

1. **Descriptor Manipulation**. There are three functions in this category. The `DftiCreateDescriptorDM` function creates an FFT descriptor whose storage is allocated dynamically. The `DftiCommitDescriptorDM` function "commits" the descriptor to all its settings. The `DftiFreeDescriptorDM` function frees up the memory allocated for the descriptor.
2. **FFT Computation**. There are two functions in this category. The `DftiComputeForwardDM` function performs the forward FFT computation, and the `DftiComputeBackwardDM` function performs the backward FFT computation.
3. **Descriptor Configuration**. There are two functions in this category. The `DftiSetValueDM` function sets one specific configuration value to one of the many configuration parameters. The `DftiGetValueDM` function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

DftiCreateDescriptorDM

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

Fortran:

```
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, size)
Status = DftiCreateDescriptorDM(comm, handle, v1, v2, dim, sizes)
```

C:

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size );
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes );
```

Include Files

- FORTRAN 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

comm	MPI communicator, e.g. `MPI_COMM_WORLD`.
v1	Precision of the transform.
v2	Type of the forward domain. Must be `DFTI_COMPLEX` for complex-to-complex transforms or `DFTI_REAL` for real-to-complex transforms.
dim	Dimension of the transform.
size	Length of the transform in a one-dimensional case.
sizes	Lengths of the transform in a multi-dimensional case.

Output Parameters

handle	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.

Description

This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a pointer to the created descriptor. This function is slightly different from the "initialization" function `DftiCommitDescriptorDM` in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function `DftiSetValueDM`.

The value of the parameter *v1* is specified through named constants `DFTI_SINGLE` and `DFTI_DOUBLE`. It corresponds to precision of input data, output data, and computation. A setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The parameter *dim* is a simple positive integer indicating the dimension of the transform.

In C/C++, for one-dimensional transforms, length is a single integer value of the parameter *size* having type `MKL_LONG`; for multi-dimensional transforms, length is supplied with the parameter *sizes*, which is an array of integers having type `MKL_LONG`. In Fortran, length is an integer or an array of integers.

Return Values

The function returns DFTI_NO_ERROR when completes successfully. In this case, the pointer to the created descriptor handle is stored in *handle*. If the function fails, it returns a value of another error class constant

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCreateDescriptorDM
    INTEGER(4) FUNCTION DftiCreateDescriptorDMn(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L(*)
    END FUNCTION
    INTEGER(4) FUNCTION DftiCreateDescriptorDM1(C,H,P1,P2,D,L)
        TYPE(DFTI_DESCRIPTOR_DM), POINTER :: H
        INTEGER(4) C,P1,P2,D,L
    END FUNCTION
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiCreateDescriptorDM(MPI_Comm,DFTI_DESCRIPTOR_DM_HANDLE*,
   enum DFTI_CONFIG_VALUE,enum DFTI_CONFIG_VALUE,MKL_LONG,...);
```

DftiCommitDescriptorDM

Performs all initialization for the actual FFT computation.

Syntax

Fortran:

```
Status = DftiCommitDescriptorDM(handle)
```

C:

```
status = DftiCommitDescriptorDM(handle);
```

Include Files

- FORTRAN 90: mkl_cdft.f90
- C: mkl_cdft.h

Input Parameters

handle	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM.

Description

The cluster FFT interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations in a particular MPI process. The `DftiCommitDescriptorDM` function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see Descriptor Configuration) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see FFT Computation).

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the Error Codes section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiCommitDescriptorDM
   INTEGER(4) FUNCTION DftiCommitDescriptorDM(handle);
     TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
 END FUNCTION
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);
```

DftiFreeDescriptorDM

Frees memory allocated for a descriptor.

Syntax

Fortran:

```
Status = DftiFreeDescriptorDM(handle)
```

C:

```
status = DftiFreeDescriptorDM(&handle);
```

Include Files

- FORTRAN 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

handle	The descriptor handle. Must be valid, that is, created in a call to `DftiCreateDescriptorDM`.

Output Parameters

handle	The descriptor handle. Memory allocated for the handle is released on output.

Description

This function frees up all memory allocated for a descriptor in a particular MPI process. Call the DftiFreeDescriptorDM function to delete the descriptor handle. Upon successful completion of DftiFreeDescriptorDM the descriptor handle is no longer valid.

Return Values

The function returns DFTI_NO_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the Error Codes section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiFreeDescriptorDM
 INTEGER(4) FUNCTION DftiFreeDescriptorDM(handle)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: handle
   END FUNCTION
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE *handle);
```

FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

DftiComputeForwardDM

Computes the forward FFT.

Syntax

Fortran:

```
Status = DftiComputeForwardDM(handle, in_X, out_X)
Status = DftiComputeForwardDM(handle, in_out_X)
```

C:

```
status = DftiComputeForwardDM(handle, in_X, out_X);
status = DftiComputeForwardDM(handle, in_out_X);
```

Include Files

- FORTRAN 90: mkl_cdft.f90

- C: `mkl_cdft.h`

Input Parameters

handle	The descriptor handle.
in_X, in_out_X	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

out_X, in_out_X	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.

Description

The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor $e^{-i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the Distributing Data Among Processes section for details.

Refer to the Configuration Settings section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION Even in case of an out-of-place transform, local array of input data *in_X* may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the Error Codes section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiComputeForwardDM
   INTEGER(4) FUNCTION DftiComputeForwardDM(h, in_X, out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
   COMPLEX(8), DIMENSION(*) :: in_x, out_X
   END FUNCTION DftiComputeForwardDM
   INTEGER(4) FUNCTION DftiComputeForwardDMi(h, in_out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(8), DIMENSION(*) :: in_out_X
   END FUNCTION DftiComputeForwardDMi
   INTEGER(4) FUNCTION DftiComputeForwardDMs(h, in_X, out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(4), DIMENSION(*) :: in_x, out_X
   END FUNCTION DftiComputeForwardDMs
   INTEGER(4) FUNCTION DftiComputeForwardDMis(h, in_out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(4), DIMENSION(*) :: in_out_X
   END FUNCTION DftiComputeForwardDMis
END INTERFACE

/*   C/C++ prototype */
MKL_LONG DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

DftiComputeBackwardDM

Computes the backward FFT.

Syntax

Fortran:

```
Status = DftiComputeBackwardDM(handle, in_X, out_X)
Status = DftiComputeBackwardDM(handle, in_out_X)
```

C:

```
status = DftiComputeBackwardDM(handle, in_X, out_X);
status = DftiComputeBackwardDM(handle, in_out_X);
```

Include Files

- FORTRAN 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

handle	The descriptor handle.
in_X, in_out_X	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

out_X, in_out_X	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.

Description

The DftiComputeBackwardDM function computes the backward FFT. Backward FFT is the transform using the factor $e^{i2\pi/n}$.

Before you call the function, the valid descriptor, created by DftiCreateDescriptorDM, must be configured and committed using the DftiCommitDescriptorDM function.

The computation is carried out by calling the DftiComputeBackward function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of DftiComputeBackward.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the Distributing Data among Processes section for details.

Refer to the Configuration Settings section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter DFTI_PRECISION determines the precision of input data, output data, and transform: a setting of DFTI_SINGLE indicates single-precision floating-point data type and a setting of DFTI_DOUBLE indicates double-precision floating-point data type.

The configuration parameter DFTI_PLACEMENT informs the function whether the computation should be in-place. If the value of this parameter is DFTI_INPLACE (default), you must call the function with two parameters, otherwise you must supply three parameters. If DFTI_PLACEMENT = DFTI_INPLACE and three parameters are supplied, then the third parameter is ignored.

CAUTION Even in case of an out-of-place transform, local array of input data *in_X* may be changed. To save data, make its copy before calling DftiComputeBackwardDM.

In case of an in-place transform, DftiComputeBackwardDM dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE You can specify your own workspace of the same size through the configuration parameter CDFT_WORKSPACE to avoid redundant memory allocation.

Return Values

The function returns DFTI_NO_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the Error Codes section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiComputeBackwardDM
   INTEGER(4) FUNCTION DftiComputeBackwardDM(h, in_X, out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(8), DIMENSION(*) :: in_x, out_X
   END FUNCTION DftiComputeBackwardDM
   INTEGER(4) FUNCTION DftiComputeBackwardDMi(h, in_out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(8), DIMENSION(*) :: in_out_X
   END FUNCTION DftiComputeBackwardDMi
   INTEGER(4) FUNCTION DftiComputeBackwardDMs(h, in_X, out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(4), DIMENSION(*) :: in_x, out_X
   END FUNCTION DftiComputeBackwardDMs
   INTEGER(4) FUNCTION DftiComputeBackwardDMis(h, in_out_X)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      COMPLEX(4), DIMENSION(*) :: in_out_X
   END FUNCTION DftiComputeBackwardDMis
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

Descriptor Configuration Functions

There are two functions in this category: the value setting function `DftiSetValueDM` sets one particular configuration parameter to an appropriate value, the value getting function `DftiGetValueDM` reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see Configuration Settings subsection in the "FFT Functions" section for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `MKL_LONG` in C/C++ and `INTEGER(4)` in Fortran. The exact type of the configuration parameters being floating-point scalars is `float` or `double` in C/C++ and `REAL(4)` or `REAL(8)` in Fortran. The configuration parameters whose values are named constants have the `enum` type in C/C++ and `INTEGER` in Fortran. They are defined in the `mkl_cdft.h` header file in C/C++ and `MKL_CDFT` module in Fortran.

Names of the configuration parameters specific to the cluster FFT interface have prefix `CDFT`.

DftiSetValueDM

Sets one particular configuration parameter with the specified configuration value.

Syntax

Fortran:

```
Status = DftiSetValueDM (handle, param, value)
```

C:

```
status = DftiSetValueDM (handle, param, value);
```

Include Files

- FORTRAN 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

handle	The descriptor handle. Must be valid, that is, created in a call to `DftiCreateDescriptorDM`.
param	Name of a parameter to be set up in the descriptor handle. See Table "Settable Configuration Parameters" for the list of available parameters.
value	Value of the parameter.

Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See Configuration Settings for details of the meaning of each setting and for possible values of the parameters whose values are named constants.

Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
`DFTI_FORWARD_SCALE`	Floating-point scalar	Scale factor of forward transform.	1.0
`DFTI_BACKWARD_SCALE`	Floating-point scalar	Scale factor of backward transform.	1.0
`DFTI_PLACEMENT`	Named constant	Placement of the computation result.	`DFTI_INPLACE`
`DFTI_ORDERING`	Named constant	Scrambling of data order.	`DFTI_ORDERED`
`DFTI_WORKSPACE`	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	`NULL` (allocate workspace dynamically).
`DFTI_PACKED_FORMAT`	Named constant	Packed format, real data.	• `DFTI_PERM_FORMAT` — default and the only available value for one-dimensional transforms

Parameter Name	Data Type	Description	Default Value
			• DFTI_CCE_FORMAT — default and the only available value for multi-dimensional transforms
DFTI_TRANSPOSE	Named constant	This parameter determines how the output data is located for multi-dimensional transforms. If the parameter value is DFTI_NONE, the data is located in a usual manner described in this manual. If the value is DFTI_ALLOW, the last (first) global transposition is not performed for a forward (backward) transform.	DFTI_NONE

Return Values

The function returns DFTI_NO_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the Error Codes section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiSetValueDM

/* C/C++ prototype */
MKL_LONG DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

DftiGetValueDM

Gets the value of one particular configuration parameter.

Syntax

Fortran:

```
Status = DftiGetValueDM(handle, param, value)
```

C:

```
status = DftiGetValueDM(handle, param, &value);
```

Include Files

- FORTRAN 90: `mkl_cdft.f90`
- C: `mkl_cdft.h`

Input Parameters

handle	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM.
param	Name of a parameter to be retrieved from the descriptor. See Table "Retrievable Configuration Parameters" for the list of available parameters.

Output Parameters

value	Value of the parameter.

Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in Table "Configuration Parameters" and relevant subsections of the Configuration Settings section.

Retrievable Configuration Parameters

Parameter Name	Data Type	Description
DFTI_PRECISION	Named constant	Precision of computation, input data and output data.
DFTI_DIMENSION	Integer scalar	Dimension of the transform
DFTI_LENGTHS	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.
DFTI_PLACEMENT	Named constant	Placement of the computation result.
DFTI_COMMIT_STATUS	Named constant	Shows whether descriptor has been committed.
DFTI_FORWARD_DOMAIN	Named constant	Forward domain of transforms, has the value of DFTI_COMPLEX or DFTI_REAL.
DFTI_ORDERING	Named constant	Scrambling of data order.

Parameter Name	Data Type	Description
CDFT_MPI_COMM	Type of MPI communicator	MPI communicator used for transforms.
CDFT_LOCAL_SIZE	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
CDFT_LOCAL_X_START	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see Distributing Data among Processes.
CDFT_LOCAL_NX	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see Distributing Data among Processes.
CDFT_LOCAL_OUT_X_START	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see Distributing Data among Processes.
CDFT_LOCAL_OUT_NX	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see Distributing Data among Processes.

Return Values

The function returns DFTI_NO_ERROR when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the Error Codes section).

Interface and Prototype

```
! Fortran Interface
INTERFACE DftiGetValueDM
   INTEGER(4) FUNCTION DftiGetValueDM(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p, v
   END FUNCTION

      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p, v(*)
   END FUNCTION
   INTEGER(4) FUNCTION DftiGetValueDMd(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p
      REAL(8) :: v
   END FUNCTION
   INTEGER(4) FUNCTION DftiGetValueDMs(h, p, v)
      TYPE(DFTI_DESCRIPTOR_DM), POINTER :: h
      INTEGER(4) :: p
      REAL(4) :: v
   END FUNCTION
END INTERFACE

/* C/C++ prototype */
MKL_LONG DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns `DFTI_NO_ERROR` if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. Named constants specific to the cluster FFT interface have prefix "`CDFT`" in names. Table "Error Codes that Cluster FFT Functions Return" lists error codes that the cluster FFT functions may return.

Error Codes that Cluster FFT Functions Return

Named Constants	Comments
`DFTI_NO_ERROR`	No error.
`DFTI_MEMORY_ERROR`	Usually associated with memory allocation.

Named Constants	Comments
DFTI_INVALID_CONFIGURATION	Invalid settings of one or more configuration parameters.
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters.
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors.
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation.
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent.
DFTI_MKL_INTERNAL_ERROR	Internal library error.
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds 2^{32} -1 (4 bytes).
CDFT_SPREAD_ERROR	Data cannot be distributed (For more information, see Distributing Data among Processes.)
CDFT_MPI_ERROR	MPI error. Occurs when calling MPI.

PBLAS Routines

12

This chapter describes the Intel® Math Kernel Library implementation of the PBLAS (Parallel Basic Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using in vector-vector, matrix-vector, and matrix-matrix operations to simplify the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- PBLAS Level 1 Routines (distributed vector-vector operations)
- PBLAS Level 2 Routines (distributed matrix-vector operations)
- PBLAS Level 3 Routines (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by the routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to a character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see *Routine Naming Conventions*.

NOTE PBLAS routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. The Intel MKL version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on PBLAS routines and related information, see http://www.netlib.org/scalapack/html/pblas_qref.html.

Overview

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. Table "Content of the array descriptor for dense matrices" gives an example of an array descriptor structure.

Content of Array Descriptor for Dense Matrices

Array Element #	Name	Definition
1	*dtype*	Descriptor type (=1 for dense matrices)
2	*ctxt*	BLACS context handle for the process grid

Array Element #	Name	Definition
3	*m*	Number of rows in the global array
4	*n*	Number of columns in the global array
5	*mb*	Row blocking factor
6	*nb*	Column blocking factor
7	*rsrc*	Process row over which the first row of the global array is distributed
8	*csrc*	Process column over which the first column of the global array is distributed
9	*lld*	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by *LOCr*() and *LOCc*(), respectively. To compute these numbers, you can use the ScaLAPACK tool routine numroc.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray sub(*A*), defined by the following 6 values (for dense matrices):

m	The number of rows of sub(*A*)
n	The number of columns of sub(*A*)
a	A pointer to the local array containing the entire global array *A*
ia	The row index of sub(*A*) in the global array
ja	The column index of sub(*A*) in the global array
desca	The array descriptor for the global array *A*

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see http://www.netlib.org/scalapack/html/pblas_qref.html).

Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see Routine Naming Conventions in Chapter 2). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter p that stands for "parallel".

The Intel MKL PBLAS routine names have the following structure:

```
p <character> <name> <mod> ( )
```

The <*character*> field indicates the Fortran data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision
i	integer

Some routines and functions can have combined character codes, such as sc or dz.

For example, the function pscasum uses a complex input array and returns a real value.

The <*name*> field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines p?dot, p?swap, p?copy compute a vector dot product, vector swap, and a copy vector, respectively.

In PBLAS level 2 and 3, <*name*> reflects the matrix argument type:

ge	general matrix
sy	symmetric matrix
he	Hermitian matrix
tr	triangular matrix

In PBLAS level 3, the <*name*>=tran indicates the transposition of the matrix.

The <mod> field, if present, provides additional details of the operation. The PBLAS level 1 names can have the following characters in the <mod> field:

c	conjugated vector
u	unconjugated vector

The PBLAS level 2 names can have the following additional characters in the <mod> field:

mv	matrix-vector product
sv	solving a system of linear equations with matrix-vector operations
r	rank-1 update of a matrix
r2	rank-2 update of a matrix.

The PBLAS level 3 names can have the following additional characters in the <mod> field:

mm	matrix-matrix product
sm	solving a system of linear equations with matrix-matrix operations
rk	rank-*k* update of a matrix
r2k	rank-2*k* update of a matrix.

The examples below show how to interpret PBLAS routine names:

pddot	<p> <d> <dot>: double-precision real distributed vector-vector dot product
pcdotc	<p> <c> <dot> <c>: complex distributed vector-vector dot product, conjugated
pscasum	<p> <sc> <asum>: sum of magnitudes of distributed vector elements, single precision real output and single precision complex input
pcdotu	<p> <c> <dot> <u>: distributed vector-vector dot product, unconjugated, complex
psgemv	<p> <s> <ge> <mv>: distributed matrix-vector product, general matrix, single precision
pztrmm	<p> <z> <tr> <mm>: distributed matrix-matrix product, triangular matrix, double-precision complex.

PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions that perform distributed vector-vector operations. Table "PBLAS Level 1 Routine Groups and Their Data Types" lists the PBLAS Level 1 routine groups and the data types associated with them.

PBLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
p?amax	s, d, c, z	Calculates an index of the distributed vector element with maximum absolute value
p?asum	s, d, sc, dz	Calculates sum of magnitudes of a distributed vector
p?axpy	s, d, c, z	Calculates distributed vector-scalar product
p?copy	s, d, c, z	Copies a distributed vector
p?dot	s, d	Calculates a dot product of two distributed real vectors
p?dotc	c, z	Calculates a dot product of two distributed complex vectors, one of them is conjugated

Routine or Function Group	Data Types	Description
p?dotu	c, z	Calculates a dot product of two distributed complex vectors
p?nrm2	s, d, sc, dz	Calculates the 2-norm (Euclidean norm) of a distributed vector
p?scal	s, d, c, z, cs, zd	Calculates a product of a distributed vector by a scalar
p?swap	s, d, c, z	Swaps two distributed vectors

p?amax

Computes the global index of the element of a distributed vector with maximum absolute value.

Syntax

```
call psamax(n, amax, indx, x, ix, jx, descx, incx)
call pdamax(n, amax, indx, x, ix, jx, descx, incx)
call pcamax(n, amax, indx, x, ix, jx, descx, incx)
call pzamax(n, amax, indx, x, ix, jx, descx, incx)
```

Include Files

- C: `mkl_pblas.h`

Description

The functions `p?amax` compute global index of the maximum element in absolute value of a distributed vector `sub(x)`,

where `sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx=m_x`, and `X(ix: ix+n-1, jx)` if `incx= 1`.

Input Parameters

n	(global) `INTEGER`. The length of distributed vector `sub(x)`, *n*≥0.
x	(local) `REAL` for `psamax` `DOUBLE PRECISION` for `pdamax` `COMPLEX` for `pcamax` `DOUBLE COMPLEX` for `pzamax` Array, `DIMENSION (jx-1)*m_x + ix+(n-1)*abs(incx))`. This array contains the entries of the distributed vector `sub(x)`.
ix, *jx*	(global) `INTEGER`. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix `sub(X)`, respectively.
descx	(global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) `INTEGER`. Specifies the increment for the elements of `sub(x)`. Only two values are supported, namely 1 and `m_x`. *incx* must not be zero.

Output Parameters

amax	(global) `REAL` for `psamax`.

DOUBLE PRECISION for pdamax.
COMPLEX for pcamax.
DOUBLE COMPLEX for pzamax.
Maximum absolute value (magnitude) of elements of the distributed vector only in its scope.

indx (global) INTEGER. The global index of the maximum element in absolute value of the distributed vector sub(*x*) only in its scope.

p?asum

Computes the sum of magnitudes of elements of a distributed vector.

Syntax

```
call psasum(n, asum, x, ix, jx, descx, incx)
call pscasum(n, asum, x, ix, jx, descx, incx)
call pdasum(n, asum, x, ix, jx, descx, incx)
call pdzasum(n, asum, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The functions p?asum compute the sum of the magnitudes of elements of a distributed vector sub(*x*), where sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1.

Input Parameters

n (global) INTEGER. The length of distributed vector sub(*x*), *n*≥0.

x (local) REAL for psasum
DOUBLE PRECISION for pdasum
COMPLEX for pscasum
DOUBLE COMPLEX for pdzasum
Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).
This array contains the entries of the distributed vector sub(*x*).

ix, *jx* (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.

descx (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.

incx (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

asum (local) REAL for psasum and pscasum.
DOUBLE PRECISION for pdasum and pdzasum
Contains the sum of magnitudes of elements of the distributed vector only in its scope.

p?axpy

Computes a distributed vector-scalar product and adds the result to a distributed vector.

Syntax

```
call psaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzaxpy(n, a, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?axpy` routines perform the following operation with distributed vectors:

```
sub(y) := sub(y) + a*sub(x)
```

where:

a is a scalar;

`sub(x)` and `sub(y)` are *n*-element distributed vectors.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if *incx*=*m_x*, and `X(ix: ix+n-1, jx)` if *incx*= 1;

`sub(y)` denotes `Y(iy, jy:jy+n-1)` if *incy*=*m_y*, and `Y(iy: iy+n-1, jy)` if *incy*= 1.

Input Parameters

n	(global) `INTEGER`. The length of distributed vectors, *n*≥0.
a	(local) `REAL` for `psaxpy` `DOUBLE PRECISION` for `pdaxpy` `COMPLEX` for `pcaxpy` `DOUBLE COMPLEX` for `pzaxpy` Specifies the scalar *a*.
x	(local) `REAL` for `psaxpy` `DOUBLE PRECISION` for `pdaxpy` `COMPLEX` for `pcaxpy` `DOUBLE COMPLEX` for `pzaxpy` Array, `DIMENSION (jx-1)*m_x + ix+(n-1)*abs(incx))`. This array contains the entries of the distributed vector `sub(x)`.
ix, *jx*	(global) `INTEGER`. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix `sub(X)`, respectively.
descx	(global and local) `INTEGER` array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) `INTEGER`. Specifies the increment for the elements of `sub(x)`. Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) `REAL` for `psaxpy` `DOUBLE PRECISION` for `pdaxpy` `COMPLEX` for `pcaxpy`

	DOUBLE COMPLEX for pzaxpy Array, DIMENSION (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global)INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by sub(*y*) := sub(*y*) + *a**sub(*x*).

p?copy

Copies one distributed vector to another vector.

Syntax

```
call pscopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pccopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzcopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call picopy(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?copy routines perform a copy operation with distributed vectors defined as

```
sub(y) = sub(x),
```

where sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, *n*≥0.
x	(local) REAL for pscopy DOUBLE PRECISION for pdcopy COMPLEX for pccopy DOUBLE COMPLEX for pzcopy INTEGER for picopy Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).

ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) REAL for pscopy DOUBLE PRECISION for pdcopy COMPLEX for pccopy DOUBLE COMPLEX for pzcopy INTEGER for picopy Array, DIMENSION (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global)INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten with the distributed vector sub(*x*).

p?dot

Computes the dot product of two distributed real vectors.

Syntax

```
call psdot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pddot(n, dot, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The ?dot functions compute the dot product *dot* of two distributed real vectors defined as

```
dot  = sub(x)'*sub(y)
```

where sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, *n*≥0.
x	(local) REAL for psdot

DOUBLE PRECISION for pddot
Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).
This array contains the entries of the distributed vector sub(*x*).

ix, *jx* (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.

descx (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.

incx (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y (local) REAL for psdot
DOUBLE PRECISION for pddot
Array, DIMENSION (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)).
This array contains the entries of the distributed vector sub(*y*).

iy, *jy* (global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.

descy (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.

incy (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

dot (local) REAL for psdot
DOUBLE PRECISION for pddot
Dot product of sub(*x*) and sub(*y*) only in their scope.

p?dotc

Computes the dot product of two distributed complex vectors, one of them is conjugated.

Syntax

```
call pcdotc(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotc(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?dotu functions compute the dot product *dotc* of two distributed vectors one of them is conjugated:

```
dotc  = conjg(sub(x)')*sub(y)
```

where sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, *n*≥0.
x	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Array, DIMENSION (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

dotc	(local) COMPLEX for pcdotc DOUBLE COMPLEX for pzdotc Dot product of sub(*x*) and sub(*y*) only in their scope.

p?dotu

Computes the dot product of two distributed complex vectors.

Syntax

```
call pcdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzdotu(n, dotu, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?dotu functions compute the dot product *dotu* of two distributed vectors defined as

```
dotu  = sub(x)'*sub(y)
```

where sub(*x*) and sub(*y*) are *n*-element distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, $n \geq 0$.
x	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Array, DIMENSION (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

dotu	(local) COMPLEX for pcdotu DOUBLE COMPLEX for pzdotu Dot product of sub(*x*) and sub(*y*) only in their scope.

p?nrm2

Computes the Euclidean norm of a distributed vector.

Syntax

```
call psnrm2(n, norm2, x, ix, jx, descx, incx)
call pdnrm2(n, norm2, x, ix, jx, descx, incx)
call pscnrm2(n, norm2, x, ix, jx, descx, incx)
call pdznrm2(n, norm2, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The p?nrm2 functions compute the Euclidean norm of a distributed vector sub(*x*),

where sub(*x*) is an *n*-element distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vector sub(*x*), *n*≥0.
x	(local) REAL for psnrm2 DOUBLE PRECISION for pdnrm2 COMPLEX for pscnrm2 DOUBLE COMPLEX for pdznrm2 Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

norm2	(local) REAL for psnrm2 and pscnrm2. DOUBLE PRECISION for pdnrm2 and pdznrm2 Contains the Euclidean norm of a distributed vector only in its scope.

p?scal

Computes a product of a distributed vector by a scalar.

Syntax

```
call psscal(n, a, x, ix, jx, descx, incx)
call pdscal(n, a, x, ix, jx, descx, incx)
call pcscal(n, a, x, ix, jx, descx, incx)
call pzscal(n, a, x, ix, jx, descx, incx)
call pcsscal(n, a, x, ix, jx, descx, incx)
call pzdscal(n, a, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The p?scal routines multiplies a *n*-element distributed vector sub(*x*) by the scalar *a*:

```
sub(x) = a*sub(x),
```

where sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vector sub(*x*), *n*≥0.
a	(global) REAL for psscal and pcsscal DOUBLE PRECISION for pdscal and pzdscal

	COMPLEX for pcscal DOUBLE COMPLEX for pzscal Specifies the scalar *a*.
x	(local) REAL for psscal DOUBLE PRECISION for pdscal COMPLEX for pcscal and pcsscal DOUBLE COMPLEX for pzscal and pzdscal Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

x	Overwritten by the updated distributed vector sub(*x*)

p?swap

Swaps two distributed vectors.

Syntax

```
call psswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pdswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pcswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
call pzswap(n, x, ix, jx, descx, incx, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

Given two distributed vectors sub(*x*) and sub(*y*), the p?swap routines return vectors sub(*y*) and sub(*x*) swapped, each replacing the other.

Here sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx*=*m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx*= 1;

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy*=*m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy*= 1.

Input Parameters

n	(global) INTEGER. The length of distributed vectors, *n*≥0.
x	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).

ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*X*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) REAL for psswap DOUBLE PRECISION for pdswap COMPLEX for pcswap DOUBLE COMPLEX for pzswap Array, DIMENSION (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*Y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

x	Overwritten by distributed vector sub(*y*).
y	Overwritten by distributed vector sub(*x*).

PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. Table "PBLAS Level 2 Routine Groups and Their Data Types" lists the PBLAS Level 2 routine groups and the data types associated with them.

PBLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
p?gemv	s, d, c, z	Matrix-vector product using a distributed general matrix
p?agemv	s, d, c, z	Matrix-vector product using absolute values for a distributed general matrix
p?ger	s, d	Rank-1 update of a distributed general matrix
p?gerc	c, z	Rank-1 update (conjugated) of a distributed general matrix
p?geru	c, z	Rank-1 update (unconjugated) of a distributed general matrix
p?hemv	c, z	Matrix-vector product using a distributed Hermitian matrix
p?ahemv	c, z	Matrix-vector product using absolute values for a distributed Hermitian matrix
p?her	c, z	Rank-1 update of a distributed Hermitian matrix
p?her2	c, z	Rank-2 update of a distributed Hermitian matrix

Routine Groups	Data Types	Description
p?symv	s, d	Matrix-vector product using a distributed symmetric matrix
p?asymv	s, d	Matrix-vector product using absolute values for a distributed symmetric matrix
p?syr	s, d	Rank-1 update of a distributed symmetric matrix
p?syr2	s, d	Rank-2 update of a distributed symmetric matrix
p?trmv	s, d, c, z	Distributed matrix-vector product using a triangular matrix
p?atrmv	s, d, c, z	Distributed matrix-vector product using absolute values for a triangular matrix
p?trsv	s, d, c, z	Solves a system of linear equations whose coefficients are in a distributed triangular matrix

p?gemv

Computes a distributed matrix-vector product using a general matrix.

Syntax

```
call psgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pdgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pcgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pzgemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?gemv` routines perform a distributed matrix-vector operation defined as

```
sub(y)  := alpha*sub(A)*sub(x) + beta*sub(y),
```

or

```
sub(y)  := alpha*sub(A)'*sub(x) + beta*sub(y),
```

or

```
sub(y)  := alpha*conjg(sub(A)')*sub(x) + beta*sub(y),
```

where

alpha and *beta* are scalars,

sub(*A*) is a *m*-by-*n* submatrix, sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) and sub(*y*) are subvectors.

When *trans* = 'N' or 'n', sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1, sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*m*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*m*-1, *jy*) if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c', sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1, sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*m*-1, *jy*) if *incy* = 1.

Input Parameters

trans
(global) CHARACTER*1. Specifies the operation:
if *trans*= 'N' or 'n', then sub(*y*) := *alpha**sub(*A*)'*sub(*x*) + *beta**sub(*y*);
if *trans*= 'T' or 't', then sub(*y*) := *alpha**sub(*A*)'*sub(*x*) + *beta**sub(*y*);
if *trans*= 'C' or 'c', then sub(*y*) := *alpha**conjg(subA)')*sub(*x*) + *beta**sub(*y*).

m
(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), *m*≥0.

n
(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), *n*≥0.

alpha
(global) REAL for psgemv
DOUBLE PRECISION for pdgemv
COMPLEX for pcgemv
DOUBLE COMPLEX for pzgemv
Specifies the scalar *alpha*.

a
(local) REAL for psgemv
DOUBLE PRECISION for pdgemv
COMPLEX for pcgemv
DOUBLE COMPLEX for pzgemv
Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*A*).

ia, *ja*
(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca
(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

x
(local) REAL for psgemv
DOUBLE PRECISION for pdgemv
COMPLEX for pcgemv
DOUBLE COMPLEX for pzgemv
Array, DIMENSION (*jx*-1)**m_x* + *ix*+(*n*-1)*abs(*incx*)) when *trans* = 'N' or 'n', and (*jx*-1)**m_x* + *ix*+(*m*-1)*abs(*incx*)) otherwise.
This array contains the entries of the distributed vector sub(*x*).

ix, *jx*
(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx
(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.

incx
(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta
(global) REAL for psgemv

	DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.
y	(local) REAL for psgemv DOUBLE PRECISION for pdgemv COMPLEX for pcgemv DOUBLE COMPLEX for pzgemv Array, DIMENSION (*jy*-1)**m_y* + *iy*+(*m*-1)*abs(*incy*)) when *trans* = 'N' or 'n', and (*jy*-1)**m_y* + *iy*+(*n*-1)*abs(*incy*)) otherwise. This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by the updated distributed vector sub(*y*).

p?agemv

Computes a distributed matrix-vector product using absolute values for a general matrix.

Syntax

```
call psagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pdagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pcagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pzagemv(trans, m, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?agemv routines perform a distributed matrix-vector operation defined as

```
sub(y)  := abs(alpha)*abs(sub(A)')*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y)  := abs(alpha)*abs(sub(A)')*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y)  := abs(alpha)*abs(conjg(sub(A)'))*abs(sub(x)) + abs(beta*sub(y)),
```

where

alpha and *beta* are scalars,

sub(*A*) is a *m*-by-*n* submatrix, sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) and sub(*y*) are subvectors.

When *trans* = 'N' or 'n',

sub(*x*) denotes *X*(*ix*:*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and

X(*ix*:*ix*+*n*-1, *jx*:*jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*:*iy*, *jy*:*jy*+*m*-1) if *incy* = *m_y*, and

Y(*iy*:*iy*+*m*-1, *jy*:*jy*) if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c',

sub(*x*) denotes *X*(*ix*:*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and

X(*ix*:*ix*+*m*-1, *jx*:*jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*:*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and

Y(*iy*:*iy*+*m*-1, *jy*:*jy*) if *incy* = 1.

Input Parameters

trans	(global) CHARACTER*1. Specifies the operation: if *trans*= 'N' or 'n', then sub(*y*) := |*alpha*|*|sub(*A*)|*|sub(*x*)| + |*beta**sub(*y*)| if *trans*= 'T' or 't', then sub(*y*) := |*alpha*|*|sub(*A*)'|*|sub(*x*)| + |*beta**sub(*y*)| if *trans*= 'C' or 'c', then sub(*y*) := |*alpha*|*|sub(*A*)'|*|sub(*x*)| + |*beta**sub(*y*)|.
m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), *m*≥0.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), *n*≥0.
alpha	(global) REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Specifies the scalar *alpha*.
a	(local) REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
x	(local) REAL for psagemv DOUBLE PRECISION for pdagemv

	COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Array, DIMENSION (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)) when *trans* = 'N' or 'n', and (*jx*-1)*m_x + *ix*+(*m*-1)*abs(*incx*)) otherwise. This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
beta	(global) REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.
y	(local) REAL for psagemv DOUBLE PRECISION for pdagemv COMPLEX for pcagemv DOUBLE COMPLEX for pzagemv Array, DIMENSION (*jy*-1)*m_y + *iy*+(*m*-1)*abs(*incy*)) when *trans* = 'N' or 'n', and (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)) otherwise. This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by the updated distributed vector sub(*y*).

p?ger

Performs a rank-1 update of a distributed general matrix.

Syntax

```
call psger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

```
call pdger(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?ger routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *m*-by-*n* distributed general matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *m*-element distributed vector, sub(*y*) is an *n*-element distributed vector,

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), *m*≥0.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), *n*≥0.
alpha	(global) REAL for psger DOUBLE REAL for pdger Specifies the scalar *alpha*.
x	(local) REAL for psger DOUBLE REAL for pdger Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*m*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) REAL for psger DOUBLE REAL for pdger Array, DIMENSION at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.
a	(local) REAL for psger DOUBLE REAL for pdger Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). Before entry this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a	Overwritten by the updated distributed matrix sub(*A*).

p?gerc

Performs a rank-1 update (conjugated) of a distributed general matrix.

Syntax

```
call pcgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

```
call pzgerc(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?gerc routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conjg(sub(y)') + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *m*-by-*n* distributed general matrix, sub(*A*) = *A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *m*-element distributed vector, sub(*y*) is an *n*-element distributed vector,

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), $m \geq 0$.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), $n \geq 0$.
alpha	(global) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Specifies the scalar *alpha*.
x	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).

ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.
a	(local) COMPLEX for pcgerc DOUBLE COMPLEX for pzgerc Array, DIMENSION at least (*lld_a*, LOCq(*ja*+*n*-1)). Before entry this array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a	Overwritten by the updated distributed matrix sub(*A*).

p?geru

Performs a rank-1 update (unconjugated) of a distributed general matrix.

Syntax

```
call pcgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

```
call pzgeru(m, n, alpha, x, ix, jx, descx, incx, y, iy, jy, descy, incy, a, ia, ja, desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?geru routines perform a matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *m*-by-*n* distributed general matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *m*-element distributed vector, sub(*y*) is an *n*-element distributed vector,

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*m*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*m*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

m (global) INTEGER. Specifies the number of rows of the distributed matrix sub(*A*), $m \geq 0$.

n (global) INTEGER. Specifies the number of columns of the distributed matrix sub(*A*), $n \geq 0$.

alpha (global) COMPLEX for pcgeru
DOUBLE COMPLEX for pzgeru
Specifies the scalar *alpha*.

x (local) COMPLEX for pcgeru
DOUBLE COMPLEX for pzgeru
Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).

ix, *jx* (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.

incx (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y (local) COMPLEX for pcgeru
DOUBLE COMPLEX for pzgeru
Array, DIMENSION at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).

iy, *jy* (global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.

incy (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

a (local) COMPLEX for pcgeru
DOUBLE COMPLEX for pzgeru
Array, DIMENSION at least (*lld_a*, LOCq(*ja*+*n*-1)). Before entry this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a	Overwritten by the updated distributed matrix sub(*A*).

p?hemv

Computes a distributed matrix-vector product using a Hermitian matrix.

Syntax

call pchemv(*uplo*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pzhemv(*uplo*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

Include Files

- C: mkl_pblas.h

Description

The p?hemv routines perform a distributed matrix-vector operation defined as

sub(*y*) := *alpha**sub(*A*)*sub(*x*) + *beta**sub(*y*),

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* Hermitian distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*A*) is used: If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used. If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.
n	(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), $n \geq 0$.
alpha	(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar *alpha*.
a	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*). Before entry when *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *n*-by-*n* lower

	triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local)INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
x	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
beta	(global) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.
y	(local) COMPLEX for pchemv DOUBLE COMPLEX for pzhemv Array, DIMENSION at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by the updated distributed vector sub(*y*).

p?ahemv

Computes a distributed matrix-vector product using absolute values for a Hermitian matrix.

Syntax

```
call pcahemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

```
call pzahemv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?ahemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* Hermitian distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo
(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*A*) is used:
If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.
If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n
(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), $n \geq 0$.

alpha
(global) COMPLEX for pcahemv
DOUBLE COMPLEX for pzahemv
Specifies the scalar *alpha*.

a
(local) COMPLEX for pcahemv
DOUBLE COMPLEX for pzahemv
Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).
Before entry when *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja*
(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca
(global and local)INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

x
(local) COMPLEX for pcahemv
DOUBLE COMPLEX for pzahemv
Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).
This array contains the entries of the distributed vector sub(*x*).

ix, *jx*
(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
beta	(global) COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.
y	(local) COMPLEX for pcahemv DOUBLE COMPLEX for pzahemv Array, DIMENSION at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by the updated distributed vector sub(*y*).

p?her

Performs a rank-1 update of a distributed Hermitian matrix.

Syntax

```
call pcher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pzher(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?her routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*conjg(sub(x)') + sub(A),
```

where:

alpha is a real scalar,

sub(*A*) is a *n*-by-*n* distributed Hermitian matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

sub(*x*) is distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1.

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*A*) is used:

	If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used. If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.
n	(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), $n \geq 0$.
alpha	(global) REAL for pcher DOUBLE REAL for pzher Specifies the scalar *alpha*.
x	(local) COMPLEX for pcher DOUBLE COMPLEX for pzher Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
a	(local) COMPLEX for pcher DOUBLE COMPLEX for pzher Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*). Before entry with *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and with *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a	With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix sub(*A*). With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix sub(*A*).

p?her2

Performs a rank-2 update of a distributed Hermitian matrix.

Syntax

call pcher2(*uplo*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

call pzher2(*uplo*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

Include Files

- C: mkl_pblas.h

Description

The p?her2 routines perform a distributed matrix-vector operation defined as

sub(*A*) := *alpha**sub(*x*)*conj(sub(*y*)')+ conj(*alpha*)*sub(*y*)*conj(sub(*x*)') + sub(*A*),

where:

alpha is a scalar,

sub(*A*) is a *n*-by-*n* distributed Hermitian matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo — (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed Hermitian matrix sub(*A*) is used:
If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.
If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n — (global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n* ≥ 0.

alpha — (global) COMPLEX for pcher2
DOUBLE COMPLEX for pzher2
Specifies the scalar *alpha*.

x — (local) COMPLEX for pcher2
DOUBLE COMPLEX for pzher2
Array, DIMENSION at least (*jx*-1)**m_x* + *ix*+(*n*-1)*abs(*incx*)).
This array contains the entries of the distributed vector sub(*x*).

ix, *jx* — (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx — (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.

incx — (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

y — (local) COMPLEX for pcher2
DOUBLE COMPLEX for pzher2
Array, DIMENSION at least (*jy*-1)**m_y* + *iy*+(*n*-1)*abs(*incy*)).
This array contains the entries of the distributed vector sub(*y*).

iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.
a	(local) COMPLEX for pcher2 DOUBLE COMPLEX for pzher2 Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*). Before entry with *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and with *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a	With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix sub(*A*). With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix sub(*A*).

p?symv

Computes a distributed matrix-vector product using a symmetric matrix.

Syntax

call pssymv(*uplo*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

call pdsymv(*uplo*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

Include Files

- C: mkl_pblas.h

Description

The p?symv routines perform a distributed matrix-vector operation defined as

sub(*y*) := *alpha**sub(*A*)*sub(*x*) + *beta**sub(*y*),

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* symmetric distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*A*) is used:
If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used.
If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.

n (global) INTEGER. Specifies the order of the distributed matrix sub(*A*), $n \geq 0$.

alpha (global) REAL for pssymv
DOUBLE REAL for pdsymv
Specifies the scalar *alpha*.

a (local) REAL for pssymv
DOUBLE REAL for pdsymv
Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).
Before entry when *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local)INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

x (local) REAL for pssymv
DOUBLE REAL for pdsymv
Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).
This array contains the entries of the distributed vector sub(*x*).

ix, *jx* (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.

incx (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta (global) REAL for pssymv
DOUBLE REAL for pdsymv
Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.

y	(local) REAL for pssymv DOUBLE REAL for pdsymv Array, DIMENSION at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y	Overwritten by the updated distributed vector sub(*y*).

p?asymv

Computes a distributed matrix-vector product using absolute values for a symmetric matrix.

Syntax

```
call psasymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
call pdasymv(uplo, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

Include Files

- C: mkl_pblas.h

Description

The p?symv routines perform a distributed matrix-vector operation defined as

```
sub(y)  := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y)),
```

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* symmetric distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*A*) is used: If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used. If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.
n	(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n* ≥ 0.

alpha (global) REAL for psasymv
DOUBLE REAL for pdasymv
Specifies the scalar *alpha*.

a (local) REAL for psasymv
DOUBLE REAL for pdasymv
Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).
Before entry when *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local)INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

x (local) REAL for psasymv
DOUBLE PRECISION for pdasymv
Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)).
This array contains the entries of the distributed vector sub(*x*).

ix, *jx* (global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.

descx (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.

incx (global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

beta (global) REAL for psasymv
DOUBLE PRECISION for pdasymv
Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.

y (local) REAL for psasymv
DOUBLE PRECISION for pdasymv
Array, DIMENSION at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)).
This array contains the entries of the distributed vector sub(*y*).

iy, *jy* (global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.

descy (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.

incy (global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

y Overwritten by the updated distributed vector sub(*y*).

p?syr

Performs a rank-1 update of a distributed symmetric matrix.

Syntax

```
call pssyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
call pdsyr(uplo, n, alpha, x, ix, jx, descx, incx, a, ia, ja, desca)
```

Include Files

- C: mkl_pblas.h

Description

The p?syr routines perform a distributed matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(x)' + sub(A),
```

where:

alpha is a scalar,

sub(*A*) is a *n*-by-*n* distributed symmetric matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) is distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*A*) is used: If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used. If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.
n	(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n* ≥ 0.
alpha	(global) REAL for pssyr DOUBLE REAL for pdsyr Specifies the scalar *alpha*.
x	(local) REAL for pssyr DOUBLE REAL for pdsyr Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
a	(local) REAL for pssyr DOUBLE REAL for pdsyr Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

	Before entry with *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and with *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a	With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix sub(*A*). With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix sub(*A*).

p?syr2

Performs a rank-2 update of a distributed symmetric matrix.

Syntax

call pssyr2(*uplo*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

call pdsyr2(*uplo*, *n*, *alpha*, *x*, *ix*, *jx*, *descx*, *incx*, *y*, *iy*, *jy*, *descy*, *incy*, *a*, *ia*, *ja*, *desca*)

Include Files

- C: mkl_pblas.h

Description

The p?syr2 routines perform a distributed matrix-vector operation defined as

sub(*A*) := *alpha**sub(*x*)*sub(*y*)'+ *alpha**sub(*y*)*sub(*x*)' + sub(*A*),

where:

alpha is a scalar,

sub(*A*) is a *n*-by-*n* distributed symmetric matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(*x*) and sub(*y*) are distributed vectors.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(*y*) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the distributed symmetric matrix sub(*A*) is used: If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*A*) is used. If *uplo* = 'L' or 'l', then the low triangular part of the sub(*A*) is used.
n	(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), $n \geq 0$.
alpha	(global) REAL for pssyr2 DOUBLE REAL for pdsyr2 Specifies the scalar *alpha*.
x	(local) REAL for pssyr2 DOUBLE REAL for pdsyr2 Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
y	(local) REAL for pssyr2 DOUBLE REAL for pdsyr2 Array, DIMENSION at least (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)). This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.
a	(local) REAL for pssyr2 DOUBLE REAL for pdsyr2 Array, DIMENSION (*lld_a*, LOCq(*ja*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*A*). Before entry with *uplo* = 'U' or 'u', the *n*-by-*n* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of sub(*A*) is not referenced, and with *uplo* = 'L' or 'l', the *n*-by-*n* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of sub(*A*) is not referenced.
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local)INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

Output Parameters

a	With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix sub(*A*). With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix sub(*A*).

p?trmv

Computes a distributed matrix-vector product using a triangular matrix.

Syntax

```
call pstrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrmv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The p?trmv routines perform one of the following distributed matrix-vector operations defined as

sub(*x*) := sub(*A*)*sub(*x*), or sub(*x*) :=sub(*A*)'*sub(*x*), or sub(*x*) := conjg(sub(*A*)')*sub(*x*),

where:

sub(*A*) is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *n*-element distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular: if *uplo* = 'U' or 'u', then the matrix is upper triangular; if *uplo* = 'L' or 'l', then the matrix is low triangular.
trans	(global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix equation: if *transa* = 'N' or 'n', then sub(*x*) := sub(*A*)*sub(*x*); if *transa* = 'T' or 't', then sub(*x*) :=sub(*A*)'*sub(*x*); if *transa* = 'C' or 'c', then sub(*x*) := conjg(sub(*A*)')*sub(*x*).
diag	(global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular: if *diag* = 'U' or 'u' then the matrix is unit triangular; if *diag* = 'N' or 'n', then the matrix is not unit triangular.
n	(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n*≥0.

a	(local) REAL for pstrmv DOUBLE PRECISION for pdtrmv COMPLEX for pctrmv DOUBLE COMPLEX for pztrmv Array, DIMENSION at least (*lld_a*, LOCq(1, *ja*+*n*-1)). Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced. Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced . When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
x	(local) REAL for pstrmv DOUBLE PRECISION for pdtrmv COMPLEX for pctrmv DOUBLE COMPLEX for pztrmv Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

x	Overwritten by the transformed distributed vector sub(*x*).

p?atrmv

Computes a distributed matrix-vector product using absolute values for a triangular matrix.

Syntax

```
call psatrmv(uplo, trans, diag, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

```
call pdatrmv(uplo, trans, diag, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

```
call pcatrmv(uplo, trans, diag, n, alpha, a, ia, ja, desca, x, ix, jx, descx, incx, beta, y, iy, jy, descy, incy)
```

call pzatrmv(*uplo*, *trans*, *diag*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *x*, *ix*, *jx*, *descx*, *incx*, *beta*, *y*, *iy*, *jy*, *descy*, *incy*)

Include Files

- C: mkl_pblas.h

Description

The p?atrmv routines perform one of the following distributed matrix-vector operations defined as

sub(*y*) := abs(*alpha*)*abs(sub(*A*))*abs(sub(*x*))+ abs(*beta**sub(*y*)), or

sub(*y*) := abs(*alpha*)*abs(sub(*A*)')*abs(sub(*x*))+ abs(*beta**sub(*y*)), or

sub(*y*) := abs(*alpha*)*abs(conjg(sub(*A*)'))*abs(sub(*x*))+ abs(*beta**sub(*y*)),

where:

alpha and *beta* are scalars,

sub(*A*) is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

sub(*x*) is an *n*-element distributed vector.

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1.

Input Parameters

uplo — (global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular:
if *uplo* = 'U' or 'u', then the matrix is upper triangular;
if *uplo* = 'L' or 'l', then the matrix is low triangular.

trans — (global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix equation:
if *trans* = 'N' or 'n', then sub(*y*) := |*alpha*|*|sub(*A*)|*|sub(*x*)|+|*beta**sub(*y*)|;
if *trans* = 'T' or 't', then sub(*y*) := |*alpha*|*|sub(*A*)'|*|sub(*x*)|+|*beta**sub(*y*)|;
if *trans* = 'C' or 'c', then sub(*y*) := |*alpha*|*|conjg(sub(*A*)')|*|sub(*x*)|+|*beta**sub(*y*)|.

diag — (global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular:
if *diag* = 'U' or 'u' then the matrix is unit triangular;
if *diag* = 'N' or 'n', then the matrix is not unit triangular.

n — (global) INTEGER. Specifies the order of the distributed matrix sub(*A*), $n \geq 0$.

alpha — (global) REAL for psatrmv
DOUBLE PRECISION for pdatrmv
COMPLEX for pcatrmv
DOUBLE COMPLEX for pzatrmv
Specifies the scalar *alpha*.

a — (local) REAL for psatrmv
DOUBLE PRECISION for pdatrmv
COMPLEX for pcatrmv
DOUBLE COMPLEX for pzatrmv
Array, DIMENSION at least (*lld_a*, LOCq(1, *ja*+*n*-1)).

	Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced. Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced. When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
x	(local) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*).
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.
beta	(global) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Specifies the scalar *beta*. When *beta* is set to zero, then sub(*y*) need not be set on input.
y	(local) REAL for psatrmv DOUBLE PRECISION for pdatrmv COMPLEX for pcatrmv DOUBLE COMPLEX for pzatrmv Array, DIMENSION (*jy*-1)*m_y + *iy*+(*m*-1)*abs(*incy*)) when *trans* = 'N' or 'n', and (*jy*-1)*m_y + *iy*+(*n*-1)*abs(*incy*)) otherwise. This array contains the entries of the distributed vector sub(*y*).
iy, *jy*	(global) INTEGER. The row and column indices in the distributed matrix *Y* indicating the first row and the first column of the submatrix sub(*y*), respectively.
descy	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *Y*.
incy	(global) INTEGER. Specifies the increment for the elements of sub(*y*). Only two values are supported, namely 1 and *m_y*. *incy* must not be zero.

Output Parameters

x	Overwritten by the transformed distributed vector sub(*x*).

p?trsv

Solves a system of linear equations whose coefficients are in a distributed triangular matrix.

Syntax

```
call pstrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pdtrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pctrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
call pztrsv(uplo, trans, diag, n, a, ia, ja, desca, x, ix, jx, descx, incx)
```

Include Files

- C: mkl_pblas.h

Description

The p?trsv routines solve one of the systems of equations:

sub(*A*)*sub(*x*) = *b*, or sub(*A*)'*sub(*x*) = *b*, or conjg(sub(*A*)')*sub(*x*) = *b*,

where:

sub(*A*) is a *n*-by-*n* unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*) = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1),

b and sub(*x*) are *n*-element distributed vectors,

sub(*x*) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,.

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular: if *uplo* = 'U' or 'u', then the matrix is upper triangular; if *uplo* = 'L' or 'l', then the matrix is low triangular.
trans	(global) CHARACTER*1. Specifies the form of the system of equations: if *transa* = 'N' or 'n', then sub(*A*)*sub(*x*) = *b*; if *transa* = 'T' or 't', then sub(*A*)'*sub(*x*) = *b*; if *transa* = 'C' or 'c', then conjg(sub(*A*)')*sub(*x*) = *b*.
diag	(global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular: if *diag* = 'U' or 'u' then the matrix is unit triangular; if *diag* = 'N' or 'n', then the matrix is not unit triangular.
n	(global) INTEGER. Specifies the order of the distributed matrix sub(*A*), *n* ≥ 0.
a	(local) REAL for pstrsv DOUBLE PRECISION for pdtrsv COMPLEX for pctrsv

	DOUBLE COMPLEX for pztrsv Array, DIMENSION at least (*lld_a*, LOCq(1, *ja*+*n*-1)). Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced. Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced . When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
x	(local) REAL for pstrsv DOUBLE PRECISION for pdtrsv COMPLEX for pctrsv DOUBLE COMPLEX for pztrsv Array, DIMENSION at least (*jx*-1)*m_x + *ix*+(*n*-1)*abs(*incx*)). This array contains the entries of the distributed vector sub(*x*). Before entry, sub(*x*) must contain the *n*-element right-hand side distributed vector *b*.
ix, *jx*	(global) INTEGER. The row and column indices in the distributed matrix *X* indicating the first row and the first column of the submatrix sub(*x*), respectively.
descx	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *X*.
incx	(global) INTEGER. Specifies the increment for the elements of sub(*x*). Only two values are supported, namely 1 and *m_x*. *incx* must not be zero.

Output Parameters

x	Overwritten with the solution vector.

PBLAS Level 3 Routines

The PBLAS Level 3 routines perform distributed matrix-matrix operations. Table "PBLAS Level 3 Routine Groups and Their Data Types" lists the PBLAS Level 3 routine groups and the data types associated with them.

PBLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
p?geadd	s, d, c, z	Distributed matrix-matrix sum of general matrices
p?tradd	s, d, c, z	Distributed matrix-matrix sum of triangular matrices
p?gemm	s, d, c, z	Distributed matrix-matrix product of general matrices

Routine Group	Data Types	Description
p?hemm	c, z	Distributed matrix-matrix product, one matrix is Hermitian
p?herk	c, z	Rank-k update of a distributed Hermitian matrix
p?her2k	c, z	Rank-2k update of a distributed Hermitian matrix
p?symm	s, d, c, z	Matrix-matrix product of distributed symmetric matrices
p?syrk	s, d, c, z	Rank-k update of a distributed symmetric matrix
p?syr2k	s, d, c, z	Rank-2k update of a distributed symmetric matrix
p?tran	s, d	Transposition of a real distributed matrix
p?tranc	c, z	Transposition of a complex distributed matrix (conjugated)
p?tranu	c, z	Transposition of a complex distributed matrix
p?trmm	s, d, c, z	Distributed matrix-matrix product, one matrix is triangular
p?trsm	s, d, c, z	Solution of a distributed matrix equation, one matrix is triangular

p?geadd

Performs sum operation for two distributed general matrices.

Syntax

```
call psgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pcgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pzgeadd(trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?geadd` routines perform sum operation for two distributed general matrices. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*op(sub(A)),
```

where:

`op(x)` is one of `op(x) = x`, or `op(x) = x'`,

alpha and *beta* are scalars,

`sub(C)` is an *m*-by-*n* distributed matrix, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+m-1)`.

Input Parameters

trans (global) `CHARACTER*1`. Specifies the operation:

	if *trans* = 'N' or 'n', then op(sub(*A*)) := sub(*A*); if *trans* = 'T' or 't', then op(sub(*A*)) := sub(*A*)'; if *trans* = 'C' or 'c', then op(sub(*A*)) := sub(*A*)'.
m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*) and the number of columns of the submatrix sub(*A*), $m \geq 0$.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*) and the number of rows of the submatrix sub(*A*), $n \geq 0$.
alpha	(global) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Specifies the scalar *alpha*.
a	(local) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Array, DIMENSION (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
beta	(global) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local) REAL for psgeadd DOUBLE PRECISION for pdgeadd COMPLEX for pcgeadd DOUBLE COMPLEX for pzgeadd Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?tradd

Performs sum operation for two distributed triangular matrices.

Syntax

```
call pstradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdtradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pctradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pztradd(uplo, trans, m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?tradd` routines perform sum operation for two distributed triangular matrices. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*op(sub(A)),
```

where:

`op(x)` is one of `op(x) = x`, or `op(x) = x'`, or `op(x) = conjg(x')`.

alpha and *beta* are scalars,

`sub(C)` is an *m*-by-*n* distributed matrix, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A)=A(ia:ia+n-1, ja:ja+m-1)`.

Input Parameters

uplo
(global) `CHARACTER*1`. Specifies whether the distributed matrix `sub(C)` is upper or lower triangular:
if *uplo* = `'U'` or `'u'`, then the matrix is upper triangular;
if *uplo* = `'L'` or `'l'`, then the matrix is low triangular.

trans
(global) `CHARACTER*1`. Specifies the operation:
if *trans* = `'N'` or `'n'`, then `op(sub(A)) := sub(A)`;
if *trans* = `'T'` or `'t'`, then `op(sub(A)) := sub(A)'`;
if *trans* = `'C'` or `'c'`, then `op(sub(A)) := conjg(sub(A)')`.

m
(global) `INTEGER`. Specifies the number of rows of the distributed matrix `sub(C)` and the number of columns of the submatrix `sub(A)`, $m \geq 0$.

n
(global) `INTEGER`. Specifies the number of columns of the distributed matrix `sub(C)` and the number of rows of the submatrix `sub(A)`, $n \geq 0$.

alpha
(global) `REAL` for `pstradd`
`DOUBLE PRECISION` for `pdtradd`
`COMPLEX` for `pctradd`
`DOUBLE COMPLEX` for `pztradd`
Specifies the scalar *alpha*.

a
(local) `REAL` for `pstradd`
`DOUBLE PRECISION` for `pdtradd`
`COMPLEX` for `pctradd`
`DOUBLE COMPLEX` for `pztradd`
Array, `DIMENSION (lld_a, LOCq(ja+m-1))`. This array contains the local pieces of the distributed matrix `sub(A)`.

ia, *ja*
(global) `INTEGER`. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix `sub(A)`, respectively.

desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
beta	(global) REAL for pstradd DOUBLE PRECISION for pdtradd COMPLEX for pctradd DOUBLE COMPLEX for pztradd Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local) REAL for pstradd DOUBLE PRECISION for pdtradd COMPLEX for pctradd DOUBLE COMPLEX for pztradd Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.

Syntax

```
call psgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descc)
call pdgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descc)
call pcgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descc)
call pzgemm(transa, transb, m, n, k, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descc)
```

Include Files

- C: mkl_pblas.h

Description

The p?gemm routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

```
sub(C) := alpha*op(sub(A))*op(sub(B)) + beta*sub(C),
```

where:

op(*x*) is one of op(*x*) = *x*, or op(*x*) = *x*',

alpha and *beta* are scalars,

sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*k*-1), sub(*B*)=*B*(*ib*:*ib*+*k*-1, *jb*:*jb*+*n*-1), and sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1), are distributed matrices.

Input Parameters

transa (global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix multiplication:
if *transa* = 'N' or 'n', then op(sub(*A*)) = sub(*A*);
if *transa* = 'T' or 't', then op(sub(*A*)) = sub(*A*)';
if *transa* = 'C' or 'c', then op(sub(*A*)) = sub(*A*)'.

transb (global) CHARACTER*1. Specifies the form of op(sub(*B*)) used in the matrix multiplication:
if *transb* = 'N' or 'n', then op(sub(*B*)) = sub(*B*);
if *transb* = 'T' or 't', then op(sub(*B*)) = sub(*B*)';
if *transb* = 'C' or 'c', then op(sub(*B*)) = sub(*B*)'.

m (global) INTEGER. Specifies the number of rows of the distributed matrices op(sub(*A*)) and sub(*C*), $m \geq 0$.

n (global) INTEGER. Specifies the number of columns of the distributed matrices op(sub(*B*)) and sub(*C*), $n \geq 0$.
The value of *n* must be at least zero.

k (global) INTEGER. Specifies the number of columns of the distributed matrix op(sub(*A*)) and the number of rows of the distributed matrix op(sub(*B*)).
The value of *k* must be greater than or equal to 0.

alpha (global) REAL for psgemm
DOUBLE PRECISION for pdgemm
COMPLEX for pcgemm
DOUBLE COMPLEX for pzgemm
Specifies the scalar *alpha*.
When *alpha* is equal to zero, then the local entries of the arrays *a* and *b* corresponding to the entries of the submatrices sub(*A*) and sub(*B*) respectively need not be set on input.

a (local) REAL for psgemm
DOUBLE PRECISION for pdgemm
COMPLEX for pcgemm
DOUBLE COMPLEX for pzgemm
Array, DIMENSION (*lld_a*, *kla*), where *kla* is LOCc(*ja*+*k*-1) when *transa* = 'N' or 'n', and is LOCq(*ja*+*m*-1) otherwise. Before entry this array must contain the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b (local)REAL for psgemm
DOUBLE PRECISION for pdgemm
COMPLEX for pcgemm
DOUBLE COMPLEX for pzgemm
Array, DIMENSION (*lld_b*, *klb*), where *klb* is LOCc(*jb*+*n*-1) when *transb* = 'N' or 'n', and is LOCq(*jb*+*k*-1) otherwise. Before entry this array must contain the local pieces of the distributed matrix sub(*B*).

ib, *jb*	(global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively
descb	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.
beta	(global) REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local)REAL for psgemm DOUBLE PRECISION for pdgemm COMPLEX for pcgemm DOUBLE COMPLEX for pzgemm Array, DIMENSION (*lld_a*, LOCq(*jc*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the *m*-by-*n* distributed matrix *alpha**op(sub(*A*))*op(sub(*B*)) + *beta**sub(*C*).

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

call pchemm(*side*, *uplo*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pzhemm(*side*, *uplo*, *m*, *n*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

Include Files

- C: mkl_pblas.h

Description

The p?hemm routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

sub(*C*):=*alpha**sub(*A*)*sub(*B*)+ *beta**sub(*C*),

or

sub(*C*):=*alpha**sub(*B*)*sub(*A*)+ *beta**sub(*C*),

where:

alpha and *beta* are scalars,

sub(*A*) is a Hermitian distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1), if *side* = 'L', and sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), if *side* = 'R'.

sub(*B*) and sub(*C*) are *m*-by-*n* distributed matrices.

sub(*B*)=*B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*n*-1), sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

Input Parameters

side (global) CHARACTER*1. Specifies whether the Hermitian distributed matrix sub(*A*) appears on the left or right in the operation:
if *side* = 'L' or 'l', then sub(*C*) := *alpha**sub(*A*) *sub(*B*) + *beta**sub(*C*);
if *side* = 'R' or 'r', then sub(*C*) := *alpha**sub(*B*) *sub(*A*) + *beta**sub(*C*).

uplo (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*A*) is used:
if *uplo* = 'U' or 'u', then the upper triangular part is used;
if *uplo* = 'L' or 'l', then the lower triangular part is used.

m (global) INTEGER. Specifies the number of rows of the distribute submatrix sub(*C*), $m \geq 0$.

n (global) INTEGER. Specifies the number of columns of the distribute submatrix sub(*C*), $n \geq 0$.

alpha (global) COMPLEX for pchemm
DOUBLE COMPLEX for pzhemm
Specifies the scalar *alpha*.

a (local) COMPLEX for pchemm
DOUBLE COMPLEX for pzhemm
Array, DIMENSION (*lld_a*, LOCq(*ja*+*na*-1)).
Before entry this array must contain the local pieces of the symmetric distributed matrix sub(*A*), such that when *uplo* = 'U' or 'u', the *na*-by-*na* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *na*-by-*na* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b (local) COMPLEX for pchemm
DOUBLE COMPLEX for pzhemm
Array, DIMENSION (*lld_b*, LOCq(*jb*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*B*).

ib, *jb* (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.

beta (global) COMPLEX for pchemm

	DOUBLE COMPLEX for pzhemm Specifies the scalar *beta*. When *beta* is set to zero, then sub(*C*) need not be set on input.
c	(local) COMPLEX for pchemm DOUBLE COMPLEX for pzhemm Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively
descc	(global and local)INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the *m*-by-*n* updated distributed matrix.

p?herk

Performs a rank-k update of a distributed Hermitian matrix.

Syntax

```
call pcherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pzherk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- C: mkl_pblas.h

Description

The p?herk routines perform a distributed matrix-matrix operation defined as

```
sub(C):=alpha*sub(A)*conjg(sub(A)')+ beta*sub(C),
```

or

```
sub(C):=alpha*conjg(sub(A)')*sub(A)+ beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *n*-by-*n* Hermitian distributed matrix, sub(*C*)=C(*ic*:*ic*+*n*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*k*-1), if *trans* = 'N' or 'n', and sub(*A*)=*A*(*ia*:*ia*+*k*-1, *ja*:*ja*+*n*-1) otherwise.

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*C*) is used: If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*C*) is used. If *uplo* = 'L' or 'l', then the low triangular part of the sub(*C*) is used.
trans	(global) CHARACTER*1. Specifies the operation:

if *trans* = 'N' or 'n', then sub(*C*) := *alpha**sub(*A*)*conjg(sub(*A*)') + *beta**sub(*C*);
if *trans* = 'C' or 'c', then sub(*C*) := *alpha**conjg(sub(*A*)')*sub(*A*) + *beta**sub(*C*).

n (global) INTEGER. Specifies the order of the distributed matrix sub(*C*), $n \geq 0$.

k (global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrix sub(*A*) , and on entry with *trans* = 'T' or 't' or 'C' or 'c', *k* specifies the number of rows of the distributed matrix sub(*A*), $k \geq 0$.

alpha (global) REAL for pcherk
DOUBLE PRECISION for pzherk
Specifies the scalar *alpha*.

a (local) COMPLEX for pcherk
DOUBLE COMPLEX for pzherk
Array, DIMENSION (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

beta (global) REAL for pcherk
DOUBLE PRECISION for pzherk
Specifies the scalar *beta*.

c (local) COMPLEX for pcherk
DOUBLE COMPLEX for pzherk
Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)).
Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix sub(*C*) and its strictly lower triangular part is not referenced.
Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix sub(*C*) and its strictly upper triangular part is not referenced.

ic, *jc* (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.
With *uplo* = 'L' or 'l', the lower triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

Syntax

Fortran 77:

call pcher2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pzher2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

Include Files

- C: mkl_pblas.h

Description

The p?her2k routines perform a distributed matrix-matrix operation defined as

sub(*C*):=*alpha**sub(*A*)*conjg(sub(*B*)')+ conjg(*alpha*)*sub(*B*)*conjg(sub(*A*)')+*beta**sub(*C*),

or

sub(*C*):=*alpha**conjg(sub(*A*)')*sub(*A*)+ conjg(*alpha*)*conjg(sub(*B*)')*sub(*A*) + *beta**sub(*C*),

where:

alpha and *beta* are scalars,

sub(*C*) is an *n*-by-*n* Hermitian distributed matrix, sub(*C*) = C(*ic*:*ic*+*n*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*k*-1), if *trans* = 'N' or 'n', and sub(*A*) = *A*(*ia*:*ia*+*k*-1, *ja*:*ja*+*n*-1) otherwise.

sub(*B*) is a distributed matrix, sub(*B*) = *B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*k*-1), if *trans* = 'N' or 'n', and sub(*B*)=*B*(*ib*:*ib*+*k*-1, *jb*:*jb*+*n*-1) otherwise.

Input Parameters

uplo — (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the Hermitian distributed matrix sub(*C*) is used:
If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*C*) is used.
If *uplo* = 'L' or 'l', then the low triangular part of the sub(*C*) is used.

trans — (global) CHARACTER*1. Specifies the operation:
if *trans* = 'N' or 'n', then sub(*C*) := *alpha**sub(*A*)*conjg(sub(*B*)') + conjg(*alpha*)*sub(*B*)*conjg(sub(*A*)') + *beta**sub(*C*);
if *trans* = 'C' or 'c', then sub(*C*) := *alpha**conjg(sub(*A*)')*sub(*A*) + conjg(*alpha*)*conjg(sub(*B*)')*sub(*A*) + *beta**sub(*C*).

n — (global) INTEGER. Specifies the order of the distributed matrix sub(*C*), $n \geq 0$.

k — (global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrices sub(*A*) and sub(*B*), and on entry with *trans* = 'C' or 'c' , *k* specifies the number of rows of the distributed matrices sub(*A*) and sub(*B*), $k \geq 0$.

alpha — (global) COMPLEX for pcher2k

DOUBLE COMPLEX for pzher2k
Specifies the scalar *alpha*.

a (local) COMPLEX for pcher2k
DOUBLE COMPLEX for pzher2k
Array, DIMENSION (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b (local) COMPLEX for pcher2k
DOUBLE COMPLEX for pzher2k
Array, DIMENSION (*lld_b*, *klb*), where *klb* is LOCq(*jb*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*jb*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*B*).

ib, *jb* (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.

beta (global) REAL for pcher2k
DOUBLE PRECISION for pzher2k
Specifies the scalar *beta*.

c (local) COMPLEX for pcher2k
DOUBLE COMPLEX for pzher2k
Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)).
Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix sub(*C*) and its strictly lower triangular part is not referenced.
Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix sub(*C*) and its strictly upper triangular part is not referenced.

ic, *jc* (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.
With *uplo* = 'L' or 'l', the lower triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

p?symm

Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distribute matrices.

Syntax

Fortran 77:

```
call pssymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descc)
call pdsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descc)
call pcsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descc)
call pzsymm(side, uplo, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb, beta, c, ic, jc, descc)
```

Include Files

- C: `mkl_pblas.h`

Description

The `p?symm` routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

`sub(C):=alpha*sub(A)*sub(B)+ beta*sub(C),`

or

`sub(C):=alpha*sub(B)*sub(A)+ beta*sub(C),`

where:

alpha and *beta* are scalars,

`sub(A)` is a symmetric distributed matrix, `sub(A)=A(ia:ia+m-1, ja:ja+m-1)`, if *side* `='L'`, and `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`, if *side* `='R'`.

`sub(B)` and `sub(C)` are *m*-by-*n* distributed matrices.

`sub(B)=B(ib:ib+m-1, jb:jb+n-1)`, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

Input Parameters

side	(global) `CHARACTER*1`. Specifies whether the symmetric distributed matrix `sub(A)` appears on the left or right in the operation: if *side* `= 'L'` or `'l'`, then `sub(C) := alpha*sub(A) *sub(B) + beta*sub(C)`; if *side* `= 'R'` or `'r'`, then `sub(C) := alpha*sub(B) *sub(A) + beta*sub(C)`.
uplo	(global) `CHARACTER*1`. Specifies whether the upper or lower triangular part of the symmetric distributed matrix `sub(A)` is used: if *uplo* `= 'U'` or `'u'`, then the upper triangular part is used; if *uplo* `= 'L'` or `'l'`, then the lower triangular part is used.
m	(global) `INTEGER`. Specifies the number of rows of the distribute submatrix `sub(C)`, *m* ≥ 0.

n (global) INTEGER. Specifies the number of columns of the distribute submatrix sub(*C*), $m \geq 0$.

alpha (global) REAL for pssymm
DOUBLE PRECISION for pdsymm
COMPLEX for pcsymm
DOUBLE COMPLEX for pzsymm
Specifies the scalar *alpha*.

a (local) REAL for pssymm
DOUBLE PRECISION for pdsymm
COMPLEX for pcsymm
DOUBLE COMPLEX for pzsymm
Array, DIMENSION (*lld_a*, LOCq(*ja*+*na*-1)).
Before entry this array must contain the local pieces of the symmetric distributed matrix sub(*A*), such that when *uplo* = 'U' or 'u', the *na*-by-*na* upper triangular part of the distributed matrix sub(*A*) must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of sub(*A*) is not referenced, and when *uplo* = 'L' or 'l', the *na*-by-*na* lower triangular part of the distributed matrix sub(*A*) must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of sub(*A*) is not referenced.

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b (local) REAL for pssymm
DOUBLE PRECISION for pdsymm
COMPLEX for pcsymm
DOUBLE COMPLEX for pzsymm
Array, DIMENSION (*lld_b*, LOCq(*jb*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*B*).

ib, *jb* (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.

beta (global) REAL for pssymm
DOUBLE PRECISION for pdsymm
COMPLEX for pcsymm
DOUBLE COMPLEX for pzsymm
Specifies the scalar *beta*.
When *beta* is set to zero, then sub(*C*) need not be set on input.

c (local) REAL for pssymm
DOUBLE PRECISION for pdsymm
COMPLEX for pcsymm
DOUBLE COMPLEX for pzsymm
Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)). Before entry this array must contain the local pieces of the distributed matrix sub(*C*).

ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the *m*-by-*n* updated matrix.

p?syrk

Performs a rank-k update of a symmetric distributed matrix.

Syntax

```
call pssyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pcsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pzsyrk(uplo, trans, n, k, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- C: mkl_pblas.h

Description

The p?syrk routines perform a distributed matrix-matrix operation defined as

sub(*C*):=*alpha**sub(*A*)*sub(*A*)'+ *beta**sub(*C*),

or

sub(*C*):=*alpha**sub(*A*)'*sub(*A*)+ *beta**sub(*C*),

where:

alpha and *beta* are scalars,

sub(*C*) is an *n*-by-*n* symmetric distributed matrix, sub(*C*)=C(*ic*:*ic*+*n*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*k*-1), if *trans* = 'N' or 'n', and sub(*A*)=*A*(*ia*:*ia*+*k*-1, *ja*:*ja*+*n*-1) otherwise.

Input Parameters

uplo	(global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*C*) is used: If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*C*) is used. If *uplo* = 'L' or 'l', then the low triangular part of the sub(*C*) is used.
trans	(global) CHARACTER*1. Specifies the operation: if *trans* = 'N' or 'n', then sub(*C*) := *alpha**sub(*A*)*sub(*A*)' + *beta**sub(*C*); if *trans* = 'T' or 't', then sub(*C*) := *alpha**sub(*A*)'*sub(*A*) + *beta**sub(*C*).

n (global) INTEGER. Specifies the order of the distributed matrix sub(*C*), $n \geq 0$.

k (global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrix sub(*A*) , and on entry with *trans* = 'T' or 't' , *k* specifies the number of rows of the distributed matrix sub(*A*), $k \geq 0$.

alpha (global) REAL for pssyrk
DOUBLE PRECISION for pdsyrk
COMPLEX for pcsyrk
DOUBLE COMPLEX for pzsyrk
Specifies the scalar *alpha*.

a (local) REAL for pssyrk
DOUBLE PRECISION for pdsyrk
COMPLEX for pcsyrk
DOUBLE COMPLEX for pzsyrk
Array, DIMENSION (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

beta (global) REAL for pssyrk
DOUBLE PRECISION for pdsyrk
COMPLEX for pcsyrk
DOUBLE COMPLEX for pzsyrk
Specifies the scalar *beta*.

c (local) REAL for pssyrk
DOUBLE PRECISION for pdsyrk
COMPLEX for pcsyrk
DOUBLE COMPLEX for pzsyrk
Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)).
Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix sub(*C*) and its strictly lower triangular part is not referenced.
Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix sub(*C*) and its strictly upper triangular part is not referenced.

ic, *jc* (global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.

descc (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

With *uplo* = 'L' or 'l', the lower triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

p?syr2k

Performs a rank-2k update of a symmetric distributed matrix.

Syntax

call pssyr2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pdsyr2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pcsyr2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

call pzsyr2k(*uplo*, *trans*, *n*, *k*, *alpha*, *a*, *ia*, *ja*, *desca*, *b*, *ib*, *jb*, *descb*, *beta*, *c*, *ic*, *jc*, *descc*)

Include Files

- C: mkl_pblas.h

Description

The p?syr2k routines perform a distributed matrix-matrix operation defined as

sub(*C*):=*alpha**sub(*A*)*sub(*B*)'+*alpha**sub(*B*)*sub(*A*)'+ *beta**sub(*C*),

or

sub(*C*):=*alpha**sub(*A*)'*sub(*B*) +*alpha**sub(*B*)'*sub(*A*) + *beta**sub(*C*),

where:

alpha and *beta* are scalars,

sub(*C*) is an *n*-by-*n* symmetric distributed matrix, sub(*C*)=C(*ic*:*ic*+*n*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*k*-1), if *trans* = 'N' or 'n', and sub(*A*)=*A*(*ia*:*ia*+*k*-1, *ja*:*ja*+*n*-1) otherwise.

sub(*B*) is a distributed matrix, sub(*B*)=*B*(*ib*:*ib*+*n*-1, *jb*:*jb*+*k*-1), if *trans* = 'N' or 'n', and sub(*B*)=*B*(*ib*:*ib*+*k*-1, *jb*:*jb*+*n*-1) otherwise.

Input Parameters

uplo — (global) CHARACTER*1. Specifies whether the upper or lower triangular part of the symmetric distributed matrix sub(*C*) is used:
If *uplo* = 'U' or 'u', then the upper triangular part of the sub(*C*) is used.
If *uplo* = 'L' or 'l', then the low triangular part of the sub(*C*) is used.

trans — (global) CHARACTER*1. Specifies the operation:
if *trans* = 'N' or 'n', then sub(*C*) := *alpha**sub(*A*)*sub(*B*)' + *alpha**sub(*B*)*sub(*A*)' + *beta**sub(*C*);
if *trans* = 'T' or 't', then sub(*C*) := *alpha**sub(*B*)'*sub(*A*) + *alpha**sub(*A*)'*sub(*B*) + *beta**sub(*C*).

n — (global) INTEGER. Specifies the order of the distributed matrix sub(*C*), $n \geq 0$.

k (global) INTEGER. On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the distributed matrices sub(*A*) and sub(*B*), and on entry with *trans* = 'T' or 't' , *k* specifies the number of rows of the distributed matrices sub(*A*) and sub(*B*), $k \geq 0$.

alpha (global) REAL for pssyr2k
DOUBLE PRECISION for pdsyr2k
COMPLEX for pcsyr2k
DOUBLE COMPLEX for pzsyr2k
Specifies the scalar *alpha*.

a (local) REAL for pssyr2k
DOUBLE PRECISION for pdsyr2k
COMPLEX for pcsyr2k
DOUBLE COMPLEX for pzsyr2k
Array, DIMENSION (*lld_a*, *kla*), where *kla* is LOCq(*ja*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*ja*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja* (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b (local) REAL for pssyr2k
DOUBLE PRECISION for pdsyr2k
COMPLEX for pcsyr2k
DOUBLE COMPLEX for pzsyr2k
Array, DIMENSION (*lld_b*, *klb*), where *klb* is LOCq(*jb*+*k*-1) when *trans* = 'N' or 'n', and is LOCq(*jb*+*n*-1) otherwise. Before entry with *trans* = 'N' or 'n', this array contains the local pieces of the distributed matrix sub(*B*).

ib, *jb* (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.

beta (global) REAL for pssyr2k
DOUBLE PRECISION for pdsyr2k
COMPLEX for pcsyr2k
DOUBLE COMPLEX for pzsyr2k
Specifies the scalar *beta*.

c (local) REAL for pssyr2k
DOUBLE PRECISION for pdsyr2k
COMPLEX for pcsyr2k
DOUBLE COMPLEX for pzsyr2k
Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)).
Before entry with *uplo* = 'U' or 'u', this array contains *n*-by-*n* upper triangular part of the symmetric distributed matrix sub(*C*) and its strictly lower triangular part is not referenced.

	Before entry with *uplo* = 'L' or 'l', this array contains *n*-by-*n* lower triangular part of the symmetric distributed matrix sub(*C*) and its strictly upper triangular part is not referenced.
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	With *uplo* = 'U' or 'u', the upper triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix. With *uplo* = 'L' or 'l', the lower triangular part of sub(*C*) is overwritten by the upper triangular part of the updated distributed matrix.

p?tran

Transposes a real distributed matrix.

Syntax

```
call pstran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pdtran(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- C: mkl_pblas.h

Description

The p?tran routines transpose a real distributed matrix. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*sub(A)',
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*m*-1).

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*), $m \geq 0$.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*) , $n \geq 0$.
alpha	(global) REAL for pstran DOUBLE PRECISION for pdtran Specifies the scalar *alpha*.
a	(local) REAL for pstran DOUBLE PRECISION for pdtran Array, DIMENSION (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).

ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
beta	(global) REAL for pstran DOUBLE PRECISION for pdtran Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local) REAL for pstran DOUBLE PRECISION for pdtran Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?tranu

Transposes a distributed complex matrix.

Syntax

```
call pctranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pztranu(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- C: mkl_pblas.h

Description

The p?tranu routines transpose a complex distributed matrix. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*sub(A)',
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*m*-1).

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*), $m \geq 0$.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*) , $n \geq 0$.
alpha	(global) COMPLEX for pctranu

	DOUBLE COMPLEX for pztranu Specifies the scalar *alpha*.
a	(local) COMPLEX for pctranu DOUBLE COMPLEX for pztranu Array, DIMENSION (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
beta	(global) COMPLEX for pctranu DOUBLE COMPLEX for pztranu Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local) COMPLEX for pctranu DOUBLE COMPLEX for pztranu Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?tranc

Transposes a complex distributed matrix, conjugated.

Syntax

```
call pctranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
call pztranc(m, n, alpha, a, ia, ja, desca, beta, c, ic, jc, descc)
```

Include Files

- C: mkl_pblas.h

Description

The p?tranc routines transpose a complex distributed matrix. The operation is defined as

```
sub(C):=beta*sub(C) + alpha*conjg(sub(A)'),
```

where:

alpha and *beta* are scalars,

sub(*C*) is an *m*-by-*n* distributed matrix, sub(*C*)=*C*(*ic*:*ic*+*m*-1, *jc*:*jc*+*n*-1).

sub(*A*) is a distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*m*-1).

Input Parameters

m	(global) INTEGER. Specifies the number of rows of the distributed matrix sub(*C*), $m \geq 0$.
n	(global) INTEGER. Specifies the number of columns of the distributed matrix sub(*C*), $n \geq 0$.
alpha	(global) COMPLEX for pctranc DOUBLE COMPLEX for pztranc Specifies the scalar *alpha*.
a	(local) COMPLEX for pctranc DOUBLE COMPLEX for pztranc Array, DIMENSION (*lld_a*, LOCq(*ja*+*m*-1)). This array contains the local pieces of the distributed matrix sub(*A*).
ia, *ja*	(global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.
desca	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.
beta	(global) COMPLEX for pctranc DOUBLE COMPLEX for pztranc Specifies the scalar *beta*. When *beta* is equal to zero, then sub(*C*) need not be set on input.
c	(local) COMPLEX for pctranc DOUBLE COMPLEX for pztranc Array, DIMENSION (*lld_c*, LOCq(*jc*+*n*-1)). This array contains the local pieces of the distributed matrix sub(*C*).
ic, *jc*	(global) INTEGER. The row and column indices in the distributed matrix *C* indicating the first row and the first column of the submatrix sub(*C*), respectively.
descc	(global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *C*.

Output Parameters

c	Overwritten by the updated submatrix.

p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

Syntax

```
call pstrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pdtrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pctrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pztrmm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
```

Include Files

- C: mkl_pblas.h

Description

The p?trmm routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

```
sub(B) := alpha*op(sub(A))*sub(B)
```

or

```
sub(B) := alpha*sub(B)*op(sub(A))
```

where:

alpha is a scalar,

sub(*B*) is an *m*-by-*n* distributed matrix, sub(*B*)=*B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*n*-1).

A is a unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1), if *side* = 'L' or 'l', and sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), if *side* = 'R' or 'r'.

op(sub(*A*)) is one of op(sub(*A*)) = sub(*A*), or op(sub(*A*)) = sub(*A*)', or op(sub(*A*)) = conjg(sub(*A*)').

Input Parameters

side — (global)CHARACTER*1. Specifies whether op(sub(*A*)) appears on the left or right of sub(*B*) in the operation:
if *side* = 'L' or 'l', then sub(*B*) := *alpha**op(sub(*A*))*sub(*B*);
if *side* = 'R' or 'r', then sub(*B*) := *alpha**sub(*B*)*op(sub(*A*)).

uplo — (global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular:
if *uplo* = 'U' or 'u', then the matrix is upper triangular;
if *uplo* = 'L' or 'l', then the matrix is low triangular.

transa — (global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix multiplication:
if *transa* = 'N' or 'n', then op(sub(*A*)) = sub(*A*);
if *transa* = 'T' or 't', then op(sub(*A*)) = sub(*A*)' ;
if *transa* = 'C' or 'c', then op(sub(*A*)) = conjg(sub(*A*)').

diag — (global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular:
if *diag* = 'U' or 'u' then the matrix is unit triangular;
if *diag* = 'N' or 'n', then the matrix is not unit triangular.

m — (global) INTEGER. Specifies the number of rows of the distributed matrix sub(*B*), $m \geq 0$.

n — (global) INTEGER. Specifies the number of columns of the distributed matrix sub(*B*), $n \geq 0$.

alpha — (global) REAL for pstrmm
DOUBLE PRECISION for pdtrmm
COMPLEX for pctrmm
DOUBLE COMPLEX for pztrmm
Specifies the scalar *alpha*.
When *alpha* is zero, then the array*b* need not be set before entry.

a — (local) REAL for pstrmm
DOUBLE PRECISION for pdtrmm
COMPLEX for pctrmm
DOUBLE COMPLEX for pztrmm

Array, DIMENSION (*lld_a*,*ka*), where *ka* is at least LOCq(1, *ja*+*m*-1) when *side* = 'L' or 'l' and is at least LOCq(1, *ja*+*n*-1) when *side* = 'R' or 'r'.
Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced.
Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced .
When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.

ia, *ja* — (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca — (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b — (local) REAL for pstrmm
DOUBLE PRECISION for pdtrmm
COMPLEX for pctrmm
DOUBLE COMPLEX for pztrmm
Array, DIMENSION (*lld_b*, LOCq(1, *jb*+*n*-1)).
Before entry, this array contains the local pieces of the distributed matrix sub(*B*).

ib, *jb* — (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb — (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.

Output Parameters

b — Overwritten by the transformed distributed matrix.

p?trsm

Solves a distributed matrix equation (one matrix operand is triangular).

Syntax

```
call pstrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pdtrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pctrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
call pztrsm(side, uplo, transa, diag, m, n, alpha, a, ia, ja, desca, b, ib, jb, descb)
```

Include Files

- C: mkl_pblas.h

Description

The p?trsm routines solve one of the following distributed matrix equations:

op(sub(*A*))***X* = *alpha**sub(*B*),

or

*X**op(sub(*A*)) = *alpha**sub(*B*),

where:

alpha is a scalar,

X and sub(*B*) are *m*-by-*n* distributed matrices, sub(*B*)=*B*(*ib*:*ib*+*m*-1, *jb*:*jb*+*n*-1);

A is a unit, or non-unit, upper or lower triangular distributed matrix, sub(*A*)=*A*(*ia*:*ia*+*m*-1, *ja*:*ja*+*m*-1), if *side* = 'L' or 'l', and sub(*A*)=*A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1), if *side* = 'R' or 'r';

op(sub(*A*)) is one of op(sub(*A*)) = sub(*A*), or op(sub(*A*)) = sub(*A*)', or op(sub(*A*)) = conjg(sub(*A*)').

The distributed matrix sub(*B*) is overwritten by the solution matrix *X*.

Input Parameters

side (global)CHARACTER*1. Specifies whether op(sub(*A*)) appears on the left or right of *X* in the equation:
if *side* = 'L' or 'l', then op(sub(*A*))**X* = *alpha**sub(*B*);
if *side* = 'R' or 'r', then *X**op(sub(*A*)) = *alpha**sub(*B*).

uplo (global) CHARACTER*1. Specifies whether the distributed matrix sub(*A*) is upper or lower triangular:
if *uplo* = 'U' or 'u', then the matrix is upper triangular;
if *uplo* = 'L' or 'l', then the matrix is low triangular.

transa (global) CHARACTER*1. Specifies the form of op(sub(*A*)) used in the matrix equation:
if *transa* = 'N' or 'n', then op(sub(*A*)) = sub(*A*);
if *transa* = 'T' or 't', then op(sub(*A*)) = sub(*A*)';
if *transa* = 'C' or 'c', then op(sub(*A*)) = conjg(sub(*A*)').

diag (global) CHARACTER*1. Specifies whether the matrix sub(*A*) is unit triangular:
if *diag* = 'U' or 'u' then the matrix is unit triangular;
if *diag* = 'N' or 'n', then the matrix is not unit triangular.

m (global) INTEGER. Specifies the number of rows of the distributed matrix sub(*B*), $m \geq 0$.

n (global) INTEGER. Specifies the number of columns of the distributed matrix sub(*B*), $n \geq 0$.

alpha (global) REAL for pstrsm
DOUBLE PRECISION for pdtrsm
COMPLEX for pctrsm
DOUBLE COMPLEX for pztrsm
Specifies the scalar *alpha*.
When *alpha* is zero, then *a* is not referenced and *b* need not be set before entry.

a (local) REAL for pstrsm
DOUBLE PRECISION for pdtrsm
COMPLEX for pctrsm
DOUBLE COMPLEX for pztrsm

Array, DIMENSION (*lld_a*, *ka*), where *ka* is at least LOCq(1, *ja*+*m*-1) when *side* = 'L' or 'l' and is at least LOCq(1, *ja*+*n*-1) when *side* = 'R' or 'r'.
Before entry with *uplo* = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix sub(*A*) is not referenced.
Before entry with *uplo* = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix sub(*A*), and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix sub(*A*) is not referenced .
When *diag* = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix sub(*A*) are not referenced either, but are assumed to be unity.

ia, *ja* — (global) INTEGER. The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix sub(*A*), respectively.

desca — (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *A*.

b — (local) REAL for pstrsm
DOUBLE PRECISION for pdtrsm
COMPLEX for pctrsm
DOUBLE COMPLEX for pztrsm
Array, DIMENSION (*lld_b*, LOCq(1, *jb*+*n*-1)).
Before entry, this array contains the local pieces of the distributed matrix sub(*B*).

ib, *jb* — (global) INTEGER. The row and column indices in the distributed matrix *B* indicating the first row and the first column of the submatrix sub(*B*), respectively.

descb — (global and local) INTEGER array of dimension 8. The array descriptor of the distributed matrix *B*.

Output Parameters

b — Overwritten by the solution distributed matrix *X*.

Partial Differential Equations Support 13

The Intel® Math Kernel Library (Intel® MKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see Trigonometric Transform Routines) and Poisson Library (see Poisson Library Routines).

Poisson Library is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel MKL Fast Fourier Transform (FFT) interface (refer to Fourier Transform Functions), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the one that the Poisson Library provides. As it may be hard enough to modify the original code so as to make it work with Poisson Library, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Library routines can be called from C and Fortran 90, although the interfaces description uses C convention. Fortran 90 users can find routine calls specifics in the "Calling PDE Support Routines from Fortran 90" section.

Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in chapter "Fast Fourier Transforms", Intel® MKL supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this manual, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The current Intel MKL implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

To describe the Intel MKL TT interface, the C convention is used. Fortran users should refer to Calling PDE Support Routines from Fortran 90.

For the list of Trigonometric Transforms currently implemented in Intel MKL TT interface, see Transforms Implemented.

If you have got used to the FFTW interface (www.fftw.org), you can call the TT interface functions through real-to-real FFTW to Intel MKL wrappers without changing FFTW function calls in your code (refer to the "FFTW to Intel® MKL Wrappers for FFTW 3.x" section in Appendix F for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason why you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n}\sum_{i=1}^{n-1} f(i)\sin\frac{ki\pi}{n},\ k = 1,\ldots,n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k)\sin\frac{ki\pi}{n},\ i = 1,\ldots,n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n}\sin\frac{(2k-1)\pi}{2} f(n) + \frac{2}{n}\sum_{i=1}^{n-1} f(i)\sin\frac{(2k-1)i\pi}{2n},\ k = 1,\ldots,n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^{n} F(k)\sin\frac{(2k-1)i\pi}{2n},\ i = 1,\ldots,n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n}\sum_{i=1}^{n} f(i)\sin\frac{(2k-1)(2i-1)\pi}{4n},\ k = 1,\ldots,n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^{n} F(k)\sin\frac{(2k-1)(2i-1)\pi}{4n},\ i = 1,\ldots,n$$

Forward cosine transform

$$F(k) = \frac{1}{n}\left[f(0) + f(n)\cos k\pi\right] + \frac{2}{n}\sum_{i=1}^{n-1} f(i)\cos\frac{ki\pi}{n},\ k = 0,\ldots,n$$

Backward cosine transform

$$f(i)=\frac{1}{2}\left[F(0)+F(n)\cos i\pi\right]+\sum_{k=1}^{n-1}F(k)\cos\frac{ki\pi}{n},\ i=0,\ldots,n$$

Forward staggered cosine transform

$$F(k)=\frac{1}{n}f(0)+\frac{2}{n}\sum_{i=1}^{n-1}f(i)\cos\frac{(2k+1)i\pi}{2n},\ k=0,\ldots,n-1$$

Backward staggered cosine transform

$$f(i)=\sum_{k=0}^{n-1}F(k)\cos\frac{(2k+1)i\pi}{2n},\ i=0,\ldots,n-1$$

Forward staggered2 cosine transform

$$F(k)=\frac{2}{n}\sum_{i=1}^{n}f(i)\cos\frac{(2k-1)(2i-1)\pi}{4n},\ k=1,\ldots,n$$

Backward staggered2 cosine transform

$$f(i)=\sum_{k=1}^{n}F(k)\cos\frac{(2k-1)(2i-1)\pi}{4n},\ i=1,\ldots,n$$

NOTE The size of the transform n can be any integer greater or equal to 2.

Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. Table "TT Interface Routines" lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

TT Interface Routines

Routine	Description
?_init_trig_transform	Initializes basic data structures of Trigonometric Transforms.
?_commit_trig_transform	Checks consistency and correctness of user-defined data as well as creates a data structure to be used by Intel MKL FFT interface[1].

Routine	Description
?_forward_trig_transform ?_backward_trig_transform	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
free_trig_transform	Cleans the memory used by a data structure needed for calling FFT interface[1].

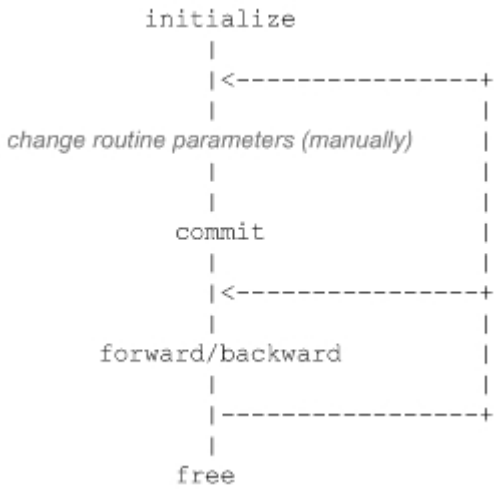
[1]TT routines call Intel MKL FFT interface for better performance.

To find a transformed vector for a particular input vector only once, the Intel MKL TT interface routines are normally invoked in the order in which they are listed in Table "TT Interface Routines".

NOTE Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in Figure "Typical Order of Invoking TT Interface Routines" indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

Typical Order of Invoking TT Interface Routines



A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```
...
    d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f ! If you want to preserve the data stored in f,
save them before this place in your code */
    d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
    d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
    d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
    free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...
```

You can find examples of Fortran 90 and C code that use TT interface routines to solve one-dimensional Helmholtz problem in the `examples\pdettf\source` and `examples\pdettc\source` folders of your Intel MKL directory.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the `examples\pdettf\source` and `examples\pdettc\source` folders of your Intel MKL directory).

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel MKL User's Guide*.

Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays *ipar*, *dpar* and *spar*. Values for these parameters should be specified very carefully (see Common Parameters). You can change these values during computations to meet your needs.

WARNING To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL TT routines do not make copies of user input arrays.

NOTE If you need a copy of your input data arrays, save them yourself.

TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel MKL FFT interface (described in section "FFT Functions" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_trig_transform

Initializes basic data structures of a Trigonometric Transform.

Syntax

```
void d_init_trig_transform(int *n, int *tt_type, int ipar[], double dpar[], int *stat);
void s_init_trig_transform(int *n, int *tt_type, int ipar[], float spar[], int *stat);
```

Include Files

- FORTRAN 90: `mkl_trig_transforms.f90`
- C: `mkl_trig_transforms.h`

Input Parameters

n	int*. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size *n*+1 for all but staggered2 transforms. Staggered2 transforms require the vector of size *n*.
tt_type	int*. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM; MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM.

Output Parameters

ipar	int array of size 128. Contains integer data needed for Trigonometric Transform computations.
dpar	double array of size 5*n*/2+2. Contains double-precision data needed for Trigonometric Transform computations.
spar	float array of size 5*n*/2+2. Contains single-precision data needed for Trigonometric Transform computations.
stat	int*. Contains the routine completion status, which is also written to *ipar[6]*. The status should be 0 to proceed to other TT routines.

Description

The ?_init_trig_transform routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to ?_init_trig_transform, all subsequently invoked TT routines use values of *ipar* and *dpar* (*spar*) array parameters returned by ?_init_trig_transform. The routine initializes the entire array *ipar*. In the *dpar* or *spar* array, ?_init_trig_transform initializes elements that do not depend upon the type of transform. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the Common Parameters section. You can skip calling the initialization routine in your code. For more information, see Caveat on Parameter Modifications.

Return Values

stat= 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this *stat* value.
stat= -99999	The routine failed to complete the task.

?_commit_trig_transform

Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.

Syntax

```
void d_commit_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[],
double dpar[], int *stat);
```

```
void s_commit_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[],
float spar[], int *stat);
```

Include Files

- FORTRAN 90: mkl_trig_transforms.f90

- C: `mkl_trig_transforms.h`

Input Parameters

f	`double` for `d_commit_trig_transform`, `float` for `s_commit_trig_transform`, array of size *n* for staggered2 transforms and of size *n*+1 for all other transforms, where *n* is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors: • *f*[0] and *f*[*n*] for sine transforms • *f*[*n*] for staggered cosine transforms • *f*[0] for staggered sine transforms. Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.
ipar	`int` array of size 128. Contains integer data needed for Trigonometric Transform computations.
dpar	`double` array of size 5*n*/2+2. Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.
spar	`float` array of size 5*n*/2+2. Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

Output Parameters

handle	`DFTI_DESCRIPTOR_HANDLE*`. The data structure used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms").
ipar	Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.
dpar	Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
spar	Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
stat	`int*`. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of `d_commit_trig_transform`, and *spar* in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the Common Parameters section. The routine performs only a basic check for correctness and

consistency of the parameters. If you are going to modify parameters of TT routines, see the Caveat on Parameter Modifications section. Unlike `?_init_trig_transform`, the `?_commit_trig_transform` routine is mandatory, and you cannot skip calling it in your code.

Return Values

stat= 11	The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.
stat= 10	The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.
stat= 1	The routine produced some warnings. You may proceed with computations by assigning *ipar[6]*=0 if you are sure that the parameters are correct.
stat= 0	The routine completed the task normally.
stat= -100	The routine stopped for any of the following reasons: • An error in the user's data was encountered. • Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.
stat= -1000	The routine stopped because of an FFT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar[0]* was altered by mistake.

NOTE Although positive values of *stat* usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve *stat*=0.

?_forward_trig_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_forward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], double dpar[], int *stat);
```

```
void s_forward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], float spar[], int *stat);
```

Include Files

- FORTRAN 90: `mkl_trig_transforms.f90`
- C: `mkl_trig_transforms.h`

Input Parameters

f	`double` for `d_forward_trig_transform`,

	`float` for `s_forward_trig_transform`, array of size *n* for staggered2 transforms and of size *n*+1 for all other transforms, where *n* is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors: • *f*[0] and *f*[*n*] for sine transforms • *f*[*n*] for staggered cosine transforms • *f*[0] for staggered sine transforms. Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.
handle	`DFTI_DESCRIPTOR_HANDLE*`. The data structure used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms").
ipar	`int` array of size 128. Contains integer data needed for Trigonometric Transform computations.
dpar	`double` array of size 5*n*/2+2. Contains double-precision data needed for Trigonometric Transform computations.
spar	`float` array of size 5*n*/2+2. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

f	Contains the transformed vector on output.
ipar	Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.
stat	`int*`. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The routine computes the forward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_forward_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the Common Parameters section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the Transforms Implemented section. The routine replaces the input vector *f* with the transformed vector.

NOTE If you need a copy of the data vector *f* to be transformed, make the copy before calling the `?_forward_trig_transform` routine.

Return Values

stat= 0	The routine completed the task normally.
stat= -100	The routine stopped for any of the following reasons: • An error in the user's data was encountered.

	• Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.
stat= -1000	The routine stopped because of an FFT interface error.
stat= -10000	The routine stopped because its commit step failed to complete or the parameter *ipar[0]* was altered by mistake.

?_backward_trig_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_backward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], double dpar[], int *stat);
```

```
void s_backward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], float spar[], int *stat);
```

Include Files

- FORTRAN 90: `mkl_trig_transforms.f90`
- C: `mkl_trig_transforms.h`

Input Parameters

f	`double` for `d_backward_trig_transform`, `float` for `s_backward_trig_transform`, array of size *n* for staggered2 transforms and of size *n*+1 for all other transforms, where *n* is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors: • *f*[0] and *f*[*n*] for sine transforms • *f*[*n*] for staggered cosine transforms • *f*[0] for staggered sine transforms. Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Poisson Library (described in the Poisson Library Routines section), which the TT interface is primarily designed for.
handle	`DFTI_DESCRIPTOR_HANDLE*`. The data structure used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms").
ipar	`int` array of size 128. Contains integer data needed for Trigonometric Transform computations.
dpar	`double` array of size 5*n*/2+2. Contains double-precision data needed for Trigonometric Transform computations.
spar	`float` array of size 5*n*/2+2. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

f	Contains the transformed vector on output.
ipar	Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.
stat	int*. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The routine computes the backward Trigonometric Transform of type defined in the ?_init_trig_transform routine and passed to ?_backward_trig_transform with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called ?_init_trig_transform routine. The other data that facilitates the computation is created by ?_commit_trig_transform and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the Common Parameters section. The routine has a commit step, which calls the ?_commit_trig_transform routine. The transform is computed according to formulas given in the Transforms Implemented section. The routine replaces the input vector *f* with the transformed vector.

NOTE If you need a copy of the data vector *f* to be transformed, make the copy before calling the ?_backward_trig_transform routine.

Return Values

stat= 0	The routine completed the task normally.
stat= -100	The routine stopped for any of the following reasons: • An error in the user's data was encountered. • Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.
stat= -1000	The routine stopped because of an FFT interface error.
stat= -10000	The routine stopped because its commit step failed to complete or the parameter *ipar[0]* was altered by mistake.

free_trig_transform

Cleans the memory allocated for the data structure used by the FFT interface.

Syntax

```
void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *handle, int ipar[], int *stat);
```

Include Files

- FORTRAN 90: mkl_trig_transforms.f90
- C: mkl_trig_transforms.h

Input Parameters

ipar	int array of size 128. Contains integer data needed for Trigonometric Transform computations.

handle	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms").

Output Parameters

handle	The data structure used by Intel MKL FFT interface. Memory allocated for the structure is released on output.
ipar	Contains integer data needed for Trigonometric Transform computations. On output, *ipar[6]* is updated with the *stat* value.
stat	int*. Contains the routine completion status, which is also written to *ipar[6]*.

Description

The free_trig_transform routine cleans the memory used by the *handle* structure, needed for Intel MKL FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

stat= 0	The routine completed the task normally.
stat= -1000	The routine stopped because of an FFT interface error.
stat= -99999	The routine failed to complete the task.

Common Parameters

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

NOTE Initial values are assigned to the array parameters by the appropriate ?_init_trig_transform and ?_commit_trig_transform routines.

ipar	int array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in Table "Elements of the ipar Array":

Elements of the ipar Array

Index	Description
0	Contains the size of the problem to solve. The ?_init_trig_transform routine sets *ipar[0]*=*n*, and all subsequently called TT routines use *ipar[0]* as the size of the transform.
1	Contains error messaging options: • *ipar[1]*=-1 indicates that all error messages will be printed to the file MKL_Trig_Transforms_log.txt in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • *ipar[1]*=0 indicates that no error messages will be printed. • *ipar[1]*=1 (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen). In case of errors, each TT routine assigns a non-zero value to *stat* regardless of the *ipar[1]* setting.

Index	Description
2	Contains warning messaging options: • *ipar[2]*=-1 indicates that all warning messages will be printed to the file MKL_Trig_Transforms_log.txt in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • *ipar[2]*=0 indicates that no warning messages will be printed. • *ipar[2]*=1 (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen). In case of warnings, the *stat* parameter will acquire a non-zero value regardless of the *ipar[2]* setting.
3 through 4	Reserved for future use.
5	Contains the type of the transform. The ?_init_trig_transform routine sets *ipar[5]*=*tt_type*, and all subsequently called TT routines use *ipar[5]* as the type of the transform.
6	Contains the *stat* value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with *stat*=0.
7	Informs the ?_commit_trig_transform routines whether to initialize data structures *dpar* (*spar*) and *handle*. *ipar[7]*=0 indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1. The possibility to check correctness and consistency of input data without initializing data structures *dpar*, *spar* and *handle* enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that *ipar[7]* gives only if you are sure to have supplied proper tolerance value in the *dpar* or *spar* array. Otherwise, avoid tuning this parameter.
8	Contains message style options for TT routines. If *ipar[8]*=0 then TT routines print all error and warning messages in Fortran-style notations. Otherwise, TT routines print the messages in C-style notations. The default value is 1. When selecting between these notations, mind that by default, numbering of elements in C arrays starts from 0 and in Fortran, it starts from 1. For example, for a C-style message "*parameter ipar[0]=3 should be an even integer*", the corresponding Fortran-style message will be "*parameter ipar(1)=3 should be an even integer*". The use of *ipar[8]* enables you to view messages in a more convenient style.
9	Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Poisson Library. The default value is 1. You are highly recommended not to alter this value. See also Caveat on Parameter Modifications.
10	Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in the "FFTW to Intel® MKL Wrappers for FFTW 3.x" section in Appendix F. See also Caveat on Parameter Modifications.
11 through 127	Reserved for future use.

NOTE You may declare the *ipar* array in your code as `int ipar[11]`. However, for compatibility with later versions of Intel MKL TT interface, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

dpar	`double` array of size 5*n*/2+2, holds data needed for double-precision routines to perform TT computations. This array is initialized in the `d_init_trig_transform` and `d_commit_trig_transform` routines.
spar	`float` array of size 5*n*/2+2, holds data needed for single-precision routines to perform TT computations. This array is initialized in the `s_init_trig_transform` and `s_commit_trig_transform` routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table "Elements of the dpar and spar Arrays":

Elements of the dpar and spar Arrays

Index	Description
0	Contains the first absolute tolerance used by the appropriate `?_commit_trig_transform` routine. For a staggered cosine or a sine transform, *f[n]* should be equal to 0.0 and for a staggered sine or a sine transform, *f[0]* should be equal to 0.0. The `?_commit_trig_transform` routine checks whether absolute values of these parameters are below *dpar[0]*n* or *spar[0]*n*, depending on the routine precision. To suppress warnings resulting from tolerance checks, set *dpar[0]* or *spar[0]* to a sufficiently large number.
1	Reserved for future use.
2 through 5*n*/2+1	Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform *tt_type*, set up in the `?_commit_trig_transform` routine: • If *tt_type*=MKL_SINE_TRANSFORM, the transform uses only the first *n*/2 array elements, which contain tabulated sine values. • If *tt_type*=MKL_STAGGERED_SINE_TRANSFORM, the transform uses only the first 3*n*/2 array elements, which contain tabulated sine and cosine values. • If *tt_type*=MKL_STAGGERED2_SINE_TRANSFORM, the transform uses all the 5*n*/2 array elements, which contain tabulated sine and cosine values. • If *tt_type*=MKL_COSINE_TRANSFORM, the transform uses only the first *n* array elements, which contain tabulated cosine values. • If *tt_type*=MKL_STAGGERED_COSINE_TRANSFORM, the transform uses only the first 3*n*/2 elements, which contain tabulated sine and cosine values. • If *tt_type*=MKL_STAGGERED2_COSINE_TRANSFORM, the transform uses all the 5*n*/2 elements, which contain tabulated sine and cosine values.

NOTE To save memory, you can define the array size depending upon the type of transform.

Caveat on Parameter Modifications

Flexibility of the TT interface enables you to skip calling the `?_init_trig_transform` routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_trig_transform` routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

NOTE To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at http://www.intel.com/software/products/support/ .

WARNING The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the TT language-specific header files to include in their code. Currently, the following of them are available:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`, for C programs.
- `mkl_trig_transforms.f90`, to be used together with `mkl_dfti.f90`, for Fortran 90 programs.

NOTE Use of the Intel MKL TT software without including one of the above header files is not supported.

C-specific Header File

The C-specific header file defines the following function prototypes:

```
void d_init_trig_transform(int *, int *, int *, double *, int *);
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, int *, double *, int *);

void s_init_trig_transform(int *, int *, int *, float *, int *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);
void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, int *, float *, int *);

void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, int *, int *);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes:

```
SUBROUTINE D_INIT_TRIG_TRANSFORM(n, tt_type, ipar, dpar, stat)
    INTEGER, INTENT(IN) :: n, tt_type
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_INIT_TRIG_TRANSFORM

SUBROUTINE D_COMMIT_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
    REAL(8), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_COMMIT_TRIG_TRANSFORM

SUBROUTINE D_FORWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
    REAL(8), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_FORWARD_TRIG_TRANSFORM

SUBROUTINE D_BACKWARD_TRIG_TRANSFORM(f, handle, ipar, dpar, stat)
    REAL(8), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(8), INTENT(INOUT) :: dpar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE D_BACKWARD_TRIG_TRANSFORM

SUBROUTINE S_INIT_TRIG_TRANSFORM(n, tt_type, ipar, spar, stat)
    INTEGER, INTENT(IN) :: n, tt_type
    INTEGER, INTENT(INOUT) :: ipar(*)
    REAL(4), INTENT(INOUT) :: spar(*)
    INTEGER, INTENT(OUT) :: stat
END SUBROUTINE S_INIT_TRIG_TRANSFORM

SUBROUTINE S_COMMIT_TRIG_TRANSFORM(f, handle, ipar, spar, stat)
    REAL(4), INTENT(INOUT) :: f(*)
    TYPE(DFTI_DESCRIPTOR), POINTER :: handle
```

Fortran 90 specifics of the TT routines usage are similar for all Intel MKL PDE support tools and described in the Calling PDE Support Routines from Fortran 90 section.

Poisson Library Routines

In addition to Real Discrete Trigonometric Transforms (TT) interface (refer to Trigonometric Transform Routines), Intel® MKL supports the Poisson Library interface, referred to as PL interface. The interface implements a group of routines (PL routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems being solved are defined more exactly in the Poisson Library Implemented subsection. The PL interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The interface can adjust style of error and warning messages to C or Fortran notations by setting up a dedicated parameter. This adds convenience to debugging, because users can read information in the way that is natural for their code. The Intel MKL PL interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

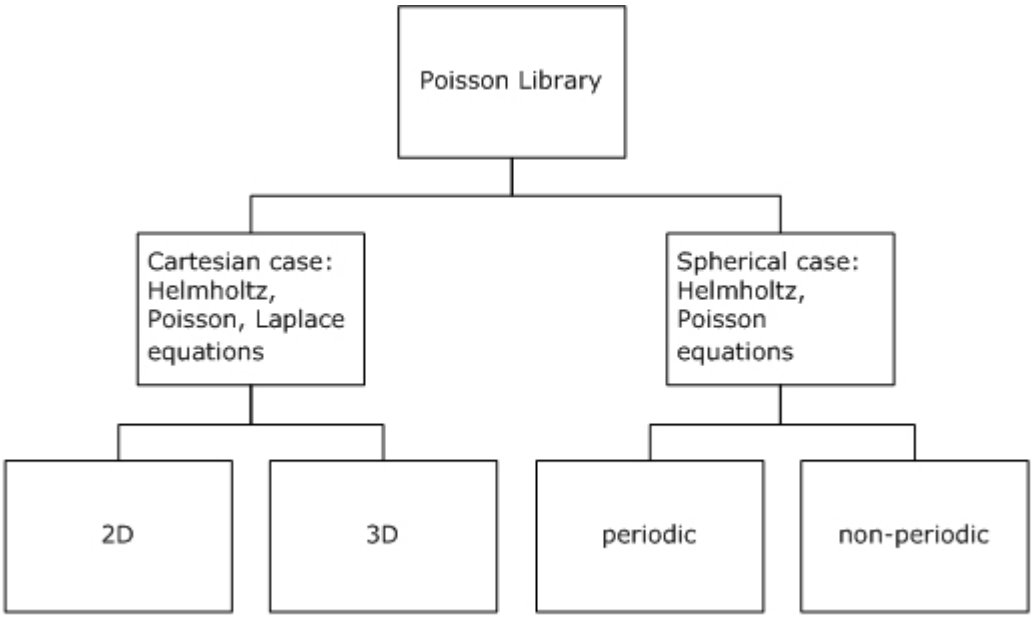
To describe the Intel MKL PL interface, the C convention is used. Fortran usage specifics can be found in the Calling PDE Support Routines from Fortran 90 section.

NOTE Fortran users should mind that respective array indices in Fortran increase by 1.

Poisson Library Implemented

PL routines enable approximate solving of certain two-dimensional and three-dimensional problems. Figure "Structure of the Poisson Library" shows the general structure of the Poisson Library.

Structure of the Poisson Library



Sections below provide details of the problems that can be solved using Intel MKL PL.

Two-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$ on a Cartesian plane:

$bd\_a_x = \{x = a_x, a_y \le y \le b_y\}$, $bd\_b_x = \{x = b_x, a_y \le y \le b_y\}$

$bd\_a_y = \{a_x \le x \le b_x, y = a_y\}$, $bd\_b_y = \{a_x \le x \le b_x, y = b_y\}$.

The wildcard "+" may stand for any of the symbols a_x, b_x, a_y, b_y, so that bd_+ denotes any of the above boundaries.

The PL interface description uses the following notation for boundaries of a rectangular domain $a_\varphi < \varphi < b_\varphi$, $a_\theta < \theta < b_\theta$ on a sphere $0 \le \varphi \le 2\pi$, $0 \le \theta \le \pi$:

$bd\_a_\varphi = \{\varphi = a_\varphi, a_\theta \le \theta \le b_\theta\}$, $bd\_b_\varphi = \{\varphi = b_\varphi, a_\theta \le \theta \le b_\theta\}$

$bd\_a_\theta = \{a_\varphi \le \varphi \le b_\varphi, \theta = a_\theta\}$, $bd\_b_\theta = \{a_\varphi \le \varphi \le b_\varphi, \theta = b_\theta\}$.

The wildcard "~" may stand for any of the symbols a_φ, b_φ, a_θ, b_θ, so that $bd\_\sim$ denotes any of the above boundaries.

Two-dimensional (2D) Helmholtz problem on a Cartesian plane

The 2D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2}-\frac{\partial^2 u}{\partial y^2}+qu=f(x,y), q=const \ge 0$$

in a rectangle, that is, a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$, with one of the following boundary conditions on each boundary bd_+:

- The Dirichlet boundary condition

$$u(x,y)=G(x,y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x,y)=g(x,y)$$

where

$n = -x$ on bd_a_x, $n = x$ on bd_b_x,

$n = -y$ on bd_a_y, $n = y$ on bd_b_y.

Two-dimensional (2D) Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when q=0. The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2}-\frac{\partial^2 u}{\partial y^2}=f(x,y)$$

in a rectangle $a_x < x < b_x$, $a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary `bd_+`. In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and `f(x, y)`=0. The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}=0$$

in a rectangle $a_x < x < b_x$, $a_y < y < b_y$ with the Dirichlet or Neumann boundary condition on each boundary `bd_+`.

Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u+qu=f,\ q=const\geq 0,$$
$$\Delta_s=\frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\varphi^2}+\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)$$

in a spherical rectangle that is, a domain bounded by angles $a_\varphi \leq \varphi \leq b_\varphi$, $a_\theta \leq \theta \leq b_\theta$, with boundary conditions for particular domains listed in Table "Details of Helmholtz Problem on a Sphere".

Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\varphi - a_\varphi < 2\pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary `bd_~`	*non-periodic*
Where $a_\varphi = 0$, $b_\varphi = 2\pi$, and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries `bd_`a_θ and `bd_`b_θ	*periodic*
Entire sphere, that is, $a_\varphi = 0$, $b_\varphi = 2\pi$, $a_\theta = 0$, and $b_\theta = \pi$	Boundary condition $\left(\sin\theta\frac{\partial u}{\partial\theta}\right)_{\substack{\theta\to 0\\ \theta\to\pi}}=0$ at the poles.	*periodic*

Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when q=0. The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f,\ \Delta_s = \frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\varphi^2} + \frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)$$

in a spherical rectangle $a_\varphi \le \varphi \le b_\varphi$, $a_\theta \le \theta \le b_\theta$ in cases listed in Table "Details of Helmholtz Problem on a Sphere". The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Library will compute the solution that provides the minimal Euclidean norm of a residual.

Approximation of 2D problems

To find an approximate solution for any of the 2D problems, a uniform mesh is built in the rectangular domain:

$$\left\{x_i = a_x + ih_x, y_j = a_y + jh_y\right\},$$
$$i = 0,\ldots,n_x, j = 0,\ldots,n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}$$

in the Cartesian case and

$$\left\{\varphi_i = a_\varphi + ih_\varphi, \theta_j = a_\theta + jh_\theta\right\},$$
$$i = 0,\ldots,n_\varphi, j = 0,\ldots,n_\theta, h_\varphi = \frac{b_\varphi - a_\varphi}{n_\varphi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta}$$

in the spherical case.

Poisson Library uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points (x_i , y_j) provided that the user knows the values of the right-hand side `f(x, y)` in these points and the values of the appropriate boundary functions `G(x, y)` and/or `g(x,y)` in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points (φ_i , θ_j) provided that the user knows the values of the right-hand side $f(\varphi, \theta)$ in these points.

NOTE The number of mesh intervals n_φ in the φ direction of a spherical mesh must be even in the periodic case. The current implementation of the Poisson Library does not support meshes with the number of intervals that does not meet this condition.

Three-Dimensional Problems

Notational Conventions

The PL interface description uses the following notation for boundaries of a parallelepiped domain $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$:

$bd\_a_x = \{x = a_x, a_y \le y \le b_y, a_z \le z \le b_z\}$, $bd\_b_x = \{x = b_x, a_y \le y \le b_y, a_z \le z \le b_z\}$

$bd\_a_y = \{a_x \le x \le b_x, y = a_y, a_z \le z \le b_z\}$, $bd\_b_y = \{a_x \le x \le b_x, y = b_y, a_z \le z \le b_z\}$

$bd\_a_z = \{a_x \le x \le b_x, a_y \le y \le b_y, z = a_z\}$, $bd\_b_x = \{a_x \le x \le b_x, a_y \le y \le b_y, z = b_z\}$.

The wildcard "+" may stand for any of the symbols a_x, b_x, a_y, b_y, a_z, b_z, so that bd_+ denotes any of the above boundaries.

Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2}-\frac{\partial^2 u}{\partial y^2}-\frac{\partial^2 u}{\partial z^2}+qu=f(x,y,z), q=const \ge 0$$

in a parallelepiped, that is, a parallelepiped domain $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$, with one of the following boundary conditions on each boundary bd_+:

- The Dirichlet boundary condition

$$u(x,y,z)=G(x,y,z)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x,y,z)=g(x,y,z)$$

where

$n = -x$ on bd_a_x, $n = x$ on bd_b_x,

$n = -y$ on bd_a_y, $n = y$ on bd_b_y,

$n = -z$ on bd_a_z, $n = z$ on bd_b_z.

Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2}-\frac{\partial^2 u}{\partial y^2}-\frac{\partial^2 u}{\partial z^2}=f(x,y,z)$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with Dirichlet or Neumann boundary condition on each boundary bd_+.

Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y, z)=0$. The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}+\frac{\partial^2 u}{\partial z^2}=0$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet or Neumann boundary condition on each boundary `bd_+`.

Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh is built in the parallelepiped domain

$$\left\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + kh_z\right\}$$

where

$$i = 0,\ldots,n_x, j = 0,\ldots,n_y, k = 0,\ldots,n_z$$

$$h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}, h_z = \frac{b_z - a_z}{n_z}$$

The Poisson Library uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points (x_i, y_j, z_k), provided that the user knows the values of the right-hand side `f(x, y, z)` in these points and the values of the appropriate boundary functions `G(x, y, z)` and/or `g(x, y, z)` in the mesh points laying on the boundary of the parallelepiped domain.

Sequence of Invoking PL Routines

NOTE This description always considers the solution process for the Helmholtz problem, because Fast Poisson Solver and Fast Laplace Solver are special cases of Fast Helmholtz Solver (see Poisson Library Implemented).

Computation of a solution of the Helmholtz problem using the PL interface is conceptually divided into four steps, each of which is performed via a dedicated routine. Table "PL Interface Routines" lists the routines and briefly describes their purpose.

Most PL routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "`s`" and "`d`". The wildcard "`?`" stands for either of these symbols in routine names. The routines for Cartesian coordinate system have 2D and 3D versions. Their names end respectively in "`2D`" and "`3D`". The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in "`p`" and "`np`"

PL Interface Routines

Routine	Description
?_init_Helmholtz_2D/?_init_Helmholtz_3D/ ?_init_sph_p/?_init_sph_np	Initializes basic data structures of Poisson Library for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.
?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/ ?_commit_sph_p/?_commit_sph_np	Checks consistency and correctness of user's data, creates and initializes data structures to be used by the Intel MKL FFT interface[1], as well as other data structures needed for the solver.
?_Helmholtz_2D/?_Helmholtz_3D/ ?_sph_p/?_sph_np	Computes an approximate solution of 2D/3D/periodic/non-periodic Helmholtz problem (see Poisson Library Implemented) specified by the parameters.
free_Helmholtz_2D/free_Helmholtz_3D/ free_sph_p/free_sph_np	Cleans the memory used by the data structures needed for calling the Intel MKL FFT interface[1].

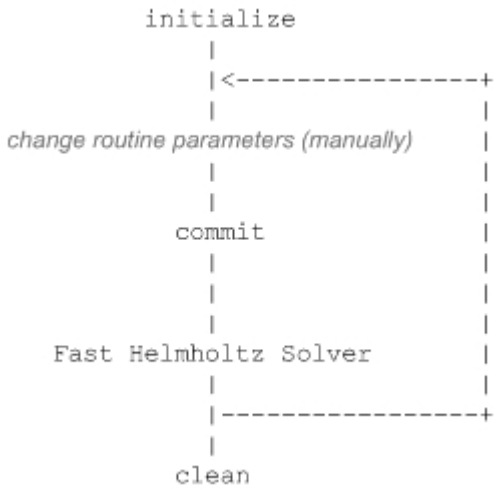
[1] PL routines call the Intel MKL FFT interface for better performance.

To find an approximate solution of Helmholtz problem only once, the Intel MKL PL interface routines are normally invoked in the order in which they are listed in Table "PL Interface Routines".

NOTE Though the order of invoking PL routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in Figure "Typical Order of Invoking PL Routines" indicates the typical order in which PL routines can be invoked in a general case.

Typical Order of Invoking PL Routines



A general scheme of using PL routines for double-precision computations in a 3D Cartesian case is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a 2D Cartesian case differs form the one below in the set of routine parameters and the ending of routine names: "2D" instead of "3D".

```
...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, BCtype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to keep the data stored
in f,
save it before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar, &stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

A general scheme of using PL routines for double-precision computations in a spherical periodic case is shown below. Similar scheme holds for single-precision computations with the only difference in the initial letter of routine names. The general scheme in a spherical non-periodic case differs from the one below in the set of routine parameters and the ending of routine names: "np" instead of "p".

```
...
d_init_sph_p(&ap,&bp,&at,&bt,&np,&nt,&q,ipar,dpar,&stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f! If you want to
keep the data stored in f, save it before the function call below */
d_commit_sph_p(f,&handle_s,&handle_c,ipar,dpar,&stat);
d_sph_p(f,&handle_s,&handle_c,ipar,dpar,&stat);
free_sph_p(&handle_s,&handle_c,ipar,&stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

You can find examples of Fortran 90 and C code that use PL routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the `examples\pdepoissonf\source` and `examples\pdepoissonc\source` folders of your Intel MKL directory.

Interface Description

All types in this documentation are standard C types: `int`, `float`, and `double`. Fortran 90 users can call the routines with `INTEGER`, `REAL`, and `DOUBLE PRECISION` Fortran types, respectively (see examples in the `examples\pdepoissonf\source` and `examples\pdepoissonc\source` folders of your Intel MKL directory.

The interface description uses the built-in type `int` for integer values. If you employ the ILP64 interface, read this type as `long long int` (or `INTEGER*8` for Fortran). For more information, refer to the *Intel(R) MKL User's Guide*.

Routine Options

All PL routines use parameters for passing various options to the routines. These parameters are arrays *ipar*, *dpar* and *spar*. Values for these parameters should be specified very carefully (see Common Parameters). You can change these values during computations to meet your needs.

WARNING To avoid failure or wrong results, you must provide correct and consistent parameters to the routines.

User Data Arrays

PL routines take arrays of user data as input. For example, user arrays are passed to the routine `d_Helmholtz_3D` to compute an approximate solution to 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL PL routines do not make copies of user input arrays.

NOTE If you need a copy of your input data arrays, save them yourself.

PL Routines for the Cartesian Solver

The section gives detailed description of Cartesian PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, 2D and 3D, are described together.

NOTE Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

PL routines call the Intel MKL FFT interface (described in section "FFT Functions" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_Helmholtz_2D/?_init_Helmholtz_3D

Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.

Syntax

```
void d_init_Helmholtz_2D(double* ax, double* bx, double* ay, double* by, int* nx, int* ny, char* BCtype, double* q, int* ipar, double* dpar, int* stat);
```

```
void s_init_Helmholtz_2D(float* ax, float* bx, float* ay, float* by, int* nx, int* ny, char* BCtype, float* q, int* ipar, float* spar, int* stat);
```

```
void d_init_Helmholtz_3D(double* ax, double* bx, double* ay, double* by, double* az, double* bz, int* nx, int* ny, int* nz, char* BCtype, double* q, int* ipar, double* dpar, int* stat);
```

```
void s_init_Helmholtz_3D(float* ax, float* bx, float* ay, float* by, float* az, float* bz, int* nx, int* ny, int* nz, char* BCtype, float* q, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl_poisson.h`

Input Parameters

ax	`double*` for `d_init_Helmholtz_2D/d_init_Helmholtz_3D`, `float*` for `s_init_Helmholtz_2D/s_init_Helmholtz_3D`. The coordinate of the leftmost boundary of the domain along x-axis.
bx	`double*` for `d_init_Helmholtz_2D/d_init_Helmholtz_3D`,

	float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along x-axis.
ay	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along y-axis.
by	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along y-axis.
az	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the leftmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
bz	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D. The coordinate of the rightmost boundary of the domain along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
nx	int*. The number of mesh intervals along x-axis.
ny	int*. The number of mesh intervals along y-axis.
nz	int*. The number of mesh intervals along z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
BCtype	char*. Contains the type of boundary conditions on each boundary. Must contain four characters for ?_init_Helmholtz_2D and six characters for ?_init_Helmholtz_3D. Each of the characters can be 'N' (Neumann boundary condition) or 'D' (Dirichlet boundary condition). Types of boundary conditions for the boundaries should be specified in the following order: bd_a_x, bd_b_x, bd_a_y, bd_b_y, bd_a_z, bd_b_z. Boundary condition types for the last two boundaries should be specified only in the 3D case.
q	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D . The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of *q* to 0.

Output Parameters

ipar	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
dpar	double array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
spar	float array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
stat	int*. Routine completion status, which is also written to *ipar[0]*. The status should be 0 to proceed to other PL routines.

Description

The ?_init_Helmholtz_2D/?_init_Helmholtz_3D routines initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a ?_init_Helmholtz_2D/?_init_Helmholtz_3D routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in Common Parameters.

WARNING Data structures initialized and created by 2D/3D flavors of the routine cannot be used by 3D/2D flavors of any PL routines, respectively.

You can skip calling this routine in your code. However, see Caveat on Parameter Modifications before doing so.

Return Values

stat= 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this *stat* value.
stat= -99999	The routine failed to complete the task because of a fatal error.

?_commit_Helmholtz_2D/?_commit_Helmholtz_3D

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve 2D/3D Helmholtz problem.

Syntax

```
void d_commit_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, double* dpar, int* stat);
```

```
void s_commit_Helmholtz_2D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float*
bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, float* spar, int* stat);
```

```
void d_commit_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay,
double* bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle,
DFTI_DESCRIPTOR_HANDLE* yhandle, int* ipar, double* dpar, int* stat);
```

```
void s_commit_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float*
bd_by, float* bd_az, float* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle,
DFTI_DESCRIPTOR_HANDLE* yhandle, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl_poisson.h`

Input Parameters

f	`double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`, `float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`. Contains the right-hand side of the problem packed in a single vector. The size of the vector for the 2D problem is (*nx*+1)*(*ny*+1). In this case, the value of the right-hand side in the mesh point (*i, j*) is stored in *f*[*i+j*(*nx*+1)] . The size of the vector for the 3D problem is (*nx*+1)*(*ny*+1)*(*nz*+1). In this case, value of the right-hand side in the mesh point (*i, j, k*) is stored in *f*[*i+j*(*nx*+1)+*k*(*nx*+1)*(*ny*+1)]. Note that to solve the Laplace problem, you should set all the elements of the array *f* to 0. Note also that the array *f* may be altered by the routine. To preserve the vector, save it in another memory location.
ipar	`int` array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

dpar — `double` array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

spar — `float` array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

bd_ax — `double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`, `float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along x-axis.
For `?_commit_Helmholtz_2D`, the size of the array is ny+1. In case of the Dirichlet boundary condition (value of *BCtype*[0] is 'D'), it contains values of the function $G(ax, y_j)$, j=0, ..., ny. In case of the Neumann boundary condition (value of *BCtype*[0] is 'N'), it contains values of the function $g(ax, y_j)$, j=0, ..., ny. The value corresponding to the index j is placed in *bd_ax*[j].
For `?_commit_Helmholtz_3D`, the size of the array is (ny+1)*(nz+1). In case of the Dirichlet boundary condition (value of *BCtype*[0] is 'D'), it contains values of the function $G(ax, y_j, z_k)$, j=0, ..., ny, k=0, ..., nz. In case of the Neumann boundary condition (value of *BCtype*[0] is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, j=0, ..., ny, k=0, ..., nz. The values are packed in the array so that the value corresponding to indices (j, k) is placed in *bd_ax*[j+k*(ny+1)].

bd_bx — `double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`, `float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along x-axis.
For `?_commit_Helmholtz_2D`, the size of the array is ny+1. In case of the Dirichlet boundary condition (value of *BCtype*[1] is 'D'), it contains values of the function $G(bx, y_j)$, j=0, ..., ny. In case of the Neumann boundary condition (value of *BCtype*[1] is 'N'), it contains values of the function $g(bx, y_j)$, j=0, ..., ny. The value corresponding to the index j is placed in *bd_bx*[j].
For `?_commit_Helmholtz_3D`, the size of the array is (ny+1)*(nz+1). In case of the Dirichlet boundary condition (value of *BCtype*[1] is 'D'), it contains values of the function $G(bx, y_j, z_k)$, j=0, ..., ny, k=0, ..., nz. In case of the Neumann boundary condition (value of *BCtype*[1] is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, j=0, ..., ny, k=0, ..., nz. The values are packed in the array so that the value corresponding to indices (j, k) is placed in *bd_bx*[j+k*(ny+1)].

bd_ay — `double*` for `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D`, `float*` for `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along y-axis.
For `?_commit_Helmholtz_2D`, the size of the array is nx+1. In case of the Dirichlet boundary condition (value of *BCtype*[2] is 'D'), it contains values of the function $G(x_i, ay)$, i=0, ..., nx. In case of the Neumann boundary condition (value of *BCtype*[2] is 'N'), it contains values of the function $g(x_i, ay)$, i=0, ..., nx. The value corresponding to the index i is placed in *bd_ay*[i].

For ?_commit_Helmholtz_3D, the size of the array is (*nx*+1)*(*nz*+1). In case of the Dirichlet boundary condition (value of *BCtype*[2] is 'D'), it contains values of the function $G(x_i, ay, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. In case of the Neumann boundary condition (value of *BCtype*[2] is 'N'), it contains the values of the function $g(x_i, ay, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. The values are packed in the array so that the value corresponding to indices *(i, k)* is placed in *bd_ay*[*i*+*k**(*nx*+1)].

bd_by — double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
Contains values of the boundary condition on the rightmost boundary of the domain along *y*-axis.
For ?_commit_Helmholtz_2D, the size of the array is *nx*+1. In case of the Dirichlet boundary condition (value of *BCtype*[3] is 'D'), it contains values of the function $G(x_i, by)$, i=0, ..., *nx*. In case of the Neumann boundary condition (value of *BCtype*[3] is 'N'), it contains values of the function $g(x_i, by)$, i=0, ..., *nx*. The value corresponding to the index *i* is placed in *bd_by*[*i*].
For ?_commit_Helmholtz_3D, the size of the array is (*nx*+1)*(*nz*+1). In case of the Dirichlet boundary condition (value of *BCtype*[3] is 'D'), it contains values of the function $G(x_i, by, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. In case of the Neumann boundary condition (value of *BCtype*[3] is 'N'), it contains the values of the function $g(x_i, by, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. The values are packed in the array so that the value corresponding to indices *(i, k)* is placed in *bd_by*[*i*+*k**(*nx*+1)].

bd_az — double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
This parameter is needed only for ?_commit_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along *z*-axis.
The size of the array is (*nx*+1)*(*ny*+1). In case of the Dirichlet boundary condition (value of *BCtype*[4] is 'D'), it contains values of the function $G(x_i, y_j, az)$, i=0, ..., *nx*, j=0, ..., *ny*. In case of the Neumann boundary condition (value of *BCtype*[4] is 'N'), it contains the values of the function $g(x_i, y_j, az)$, i=0, ..., *nx*, j=0, ..., *ny*. The values are packed in the array so that the value corresponding to indices *(i, j)* is placed in *bd_az*[*i*+*j**(*nx*+1)].

bd_bz — double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D.
This parameter is needed only for ?_commit_Helmholtz_3D. Contains values of the boundary condition on the rightmost boundary of the domain along *z*-axis.
The size of the array is (*nx*+1)*(*ny*+1). In case of the Dirichlet boundary condition (value of *BCtype*[5] is 'D'), it contains values of the function $G(x_i, y_j, bz)$, i=0, ..., *nx*, j=0, ..., *ny*. In case of the Neumann boundary condition (value of *BCtype*[5] is 'N'), it contains the values of the function $g(x_i, y_j, bz)$, i=0, ..., *nx*, j=0, ..., *ny*. The values are packed in the array so that the value corresponding to indices *(i, j)* is placed in *bd_bz*[*i*+*j**(*nx*+1)].

Output Parameters

f — Vector of the right-hand side of the problem. Possibly, altered on output.

ipar	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters.
dpar	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters.
spar	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters.
xhandle, yhandle	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). *yhandle* is used only by ?_commit_Helmholtz_3D.
stat	int*. Routine completion status, which is also written to *ipar[0]*. The status should be 0 to proceed to other PL routines.

Description

The ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routines check consistency and correctness of the parameters to be passed to the solver routines ?_Helmholtz_2D/?_Helmholtz_3D. They also initialize data structures *xhandle*, *yhandle* as well as arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to Common Parameters to find out which particular array elements the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the Caveat on Parameter Modifications section. Unlike ?_init_Helmholtz_2D/?_init_Helmholtz_3D, the routines ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D are mandatory, and you cannot skip calling them in your code. Values of *ax*, *bx*, *ay*, *by*, *az*, *bz*, *nx*, *ny*, *nz*, and *BCtype* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate ?_init_Helmholtz_2D/?_init_Helmholtz_3D routine.

Return Values

stat= 1	The routine completed without errors and produced some warnings.
stat= 0	The routine successfully completed the task.
stat= -100	The routine stopped because an error in the user's data was found or the data in the *dpar*, *spar* or *ipar* array was altered by mistake.
stat= -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.
stat= -99999	The routine failed to complete the task because of a fatal error.

?_Helmholtz_2D/?_Helmholtz_3D

Computes the solution of 2D/3D Helmholtz problem specified by the parameters.

Syntax

```
void d_Helmholtz_2D(double* f, double* bd_ax, double* bd_bx, double* bd_ay, double* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, double* dpar, int* stat);
```

```
void s_Helmholtz_2D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float* bd_by, DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, float* spar, int* stat);
```

```
void d_Helmholtz_3D(double* f, double* bd_ax, double* bd_bx, double* bd_ay, double*
bd_by, double* bd_az, double* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle,
DFTI_DESCRIPTOR_HANDLE* yhandle, int* ipar, double* dpar, int* stat);
```

```
void s_Helmholtz_3D(float* f, float* bd_ax, float* bd_bx, float* bd_ay, float* bd_by,
float* bd_az, float* bd_bz, DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE*
yhandle, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl_poisson.h`

Input Parameters

f	`double*` for `d_Helmholtz_2D/d_Helmholtz_3D`, `float*` for `s_Helmholtz_2D/s_Helmholtz_3D`. Contains the right-hand side of the problem packed in a single vector and modified by the appropriate `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector for the 2D problem is (nx+1)*(ny+1). In this case, value of the right-hand side in the mesh point (i, j) is stored in f[i+j*(nx+1)] . The size of the vector for the 3D problem is (nx+1)*(ny+1)*(nz+1). In this case, value of the right-hand side in the mesh point (i, j, k) is stored in f[i+j*(nx+1)+k*(nx+1)*(ny+1)].
xhandle, yhandle	`DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). *yhandle* is used only by `?_Helmholtz_3D`.
ipar	`int` array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
dpar	`double` array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer toCommon Parameters
spar	float array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).
bd_ax	`double*` for `d_Helmholtz_2D/d_Helmholtz_3D`, `float*` for `s_Helmholtz_2D/s_Helmholtz_3D`. Contains values of the boundary condition on the leftmost boundary of the domain along x-axis. For `?_Helmholtz_2D`, the size of the array is ny+1. In case of the the Dirichlet boundary condition (value of $BCtype$[0] is 'D'), it contains values of the function $G(ax, y_j)$, j=0, ..., ny. In case of the the Neumann boundary condition (value of $BCtype$[0] is 'N'), it contains values of the function $g(ax, y_j)$, j=0, ..., ny. The value corresponding to the index j is placed in bd_ax[j]. For `?_Helmholtz_3D`, the size of the array is (ny+1)*(nz+1). In case of the the Dirichlet boundary condition (value of $BCtype$[0] is 'D'), it contains values of the function $G(ax, y_j, z_k)$, j=0, ..., ny, k=0, ..., nz. In case of the Neumann boundary condition (value of $BCtype$[0] is 'N'), it contains the values of the function $g(ax, y_j, z_k)$, j=0, ..., ny, k=0, ..., nz. The values are packed in the array so that the value corresponding to indices (j, k) is placed in bd_ax[j+k*(ny+1)].

bd_bx

double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.
Contains values of the boundary condition on the rightmost boundary of the domain along *x*-axis.
For ?_Helmholtz_2D, the size of the array is *ny*+1. In case of the Dirichlet boundary condition (value of *BCtype*[1] is 'D'), it contains values of the function $G(bx, y_j)$, j=0, ..., *ny*. In case of the Neumann boundary condition (value of *BCtype*[1] is 'N'), it contains values of the function $g(bx, y_j)$, j=0, ..., *ny*. The value corresponding to the index j is placed in *bd_bx*[j].
For ?_Helmholtz_3D, the size of the array is (*ny*+1)*(*nz*+1). In case of the Dirichlet boundary condition (value of *BCtype*[1] is 'D'), it contains values of the function $G(bx, y_j, z_k)$, j=0, ..., *ny*, k=0, ..., *nz*. In case of the Neumann boundary condition (value of *BCtype*[1] is 'N'), it contains the values of the function $g(bx, y_j, z_k)$, j=0, ..., *ny*, k=0, ..., *nz*. The values are packed in the array so that the value corresponding to indices *(j, k)* is placed in *bd_bx*[$j+k$*(*ny*+1)].

bd_ay

double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.
Contains values of the boundary condition on the leftmost boundary of the domain along *y*-axis.
For ?_Helmholtz_2D, the size of the array is *nx*+1. In case of the Dirichlet boundary condition (value of *BCtype*[2] is 'D'), it contains values of the function $G(x_i, ay)$, i=0, ..., *nx*. In case of the Neumann boundary condition (value of *BCtype*[2] is 'N'), it contains values of the function $g(x_i, ay)$, i=0, ..., *nx*. The value corresponding to the index i is placed in *bd_ay*[i].
For ?_Helmholtz_3D, the size of the array is (*nx*+1)*(*nz*+1). In case of the Dirichlet boundary condition (value of *BCtype*[2] is 'D'), it contains values of the function $G(x_i,ay, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. In case of the Neumann boundary condition (value of *BCtype*[2] is 'N'), it contains the values of the function $g(x_i,ay, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. The values are packed in the array so that the value corresponding to indices *(i, k)* is placed in *bd_ay*[$i+k$*(*nx*+1)].

bd_by

double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.
Contains values of the boundary condition on the rightmost boundary of the domain along *y*-axis.
For ?_Helmholtz_2D, the size of the array is *nx*+1. In case of the Dirichlet boundary condition (value of *BCtype*[3] is 'D'), it contains values of the function $G(x_i, by)$, i=0, ..., *nx*. In case of the Neumann boundary condition (value of *BCtype*[3] is 'N'), it contains values of the function $g(x_i, by)$, i=0, ..., *nx*. The value corresponding to the index i is placed in *bd_by*[i].
For ?_Helmholtz_3D, the size of the array is (*nx*+1)*(*nz*+1). In case of the Dirichlet boundary condition (value of *BCtype*[3] is 'D'), it contains values of the function $G(x_i,by, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. In case of the Neumann boundary condition (value of *BCtype*[3] is 'N'), it contains the values of the function $g(x_i,by, z_k)$, i=0, ..., *nx*, k=0, ..., *nz*. The values are packed in the array so that the value corresponding to indices *(i, k)* is placed in *bd_by*[$i+k$*(*nx*+1)].

bd_az

double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.
This parameter is needed only for ?_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along *z*-axis.

The size of the array is (*nx*+1)*(*ny*+1). In case of the Dirichlet boundary condition (value of *BCtype*[4] is 'D'), it contains values of the function *G*(x_i, y_j,*az*), *i*=0, ..., *nx*, *j*=0, ..., *ny*. In case of the Neumann boundary condition (value of *BCtype*[4] is 'N'), it contains the values of the function *g*(x_i, y_j,*az*), *i*=0, ..., *nx*, *j*=0, ..., *ny*. The values are packed in the array so that the value corresponding to indices *(i, j)* is placed in *bd_az*[*i* +*j**(*nx*+1)].

bd_bz — `double*` for `d_Helmholtz_2D/d_Helmholtz_3D`, `float*` for `s_Helmholtz_2D/s_Helmholtz_3D`.
This parameter is needed only for `?_Helmholtz_3D`. Contains values of the boundary condition on the rightmost boundary of the domain along *z*-axis. The size of the array is (*nx*+1)*(*ny*+1). In case of the Dirichlet boundary condition (value of *BCtype*[5] is 'D'), it contains values of the function *G*(x_i, y_j,*bz*), *i*=0, ..., *nx*, *j*=0, ..., *ny*. In case of the Neumann boundary condition (value of *BCtype*[5] is 'N'), it contains the values of the function *g*(x_i, y_j,*bz*), *i*=0, ..., *nx*, *j*=0, ..., *ny*. The values are packed in the array so that the value corresponding to indices *(i, j)* is placed in *bd_bz*[*i* +*j**(*nx*+1)].

NOTE To avoid wrong computation results, do not change arrays *bd_ax*, *bd_bx*, *bd_ay*, *bd_by*, *bd_az*, *bd_bz* between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

Output Parameters

f — On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.

xhandle, yhandle — Data structures used by the Intel MKL FFT interface.

ipar — Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters.

dpar — Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters

spar — Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in Common Parameters.

stat — `int*`. Routine completion status, which is also written to *ipar[0]*. The status should be 0 to proceed to other PL routines.

Description

The `Helmholtz_2D-Helmholtz_3D` routines compute the approximate solution of Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the Poisson Library Implemented section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *ax*, *bx*, *ay*, *by*, *az*, *bz*, *nx*, *ny*, *nz*, and *BCtype* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine.

Return Values

stat= 1 — The routine completed without errors and produced some warnings.

stat= 0 — The routine successfully completed the task.

stat= -2	The routine stopped because division by zero occurred. It usually happens if the data in the *dpar* or *spar* array was altered by mistake.
stat= -3	The routine stopped because the memory was insufficient to complete the computations.
stat= -100	The routine stopped because an error in the user's data was found or the data in the *dpar*, *spar* or *ipar* array was altered by mistake.
stat= -1000	The routine stopped because of the Intel MKL FFT or TT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.
stat= -99999	The routine failed to complete the task because of a fatal error.

free_Helmholtz_2D/free_Helmholtz_3D

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE* xhandle, int* ipar, int* stat);
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE*
yhandle, int* ipar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl_poisson.h`

Input Parameters

xhandle, yhandle	`DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). The structure *yhandle* is used only by `free_Helmholtz_3D`.
ipar	`int` array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to Common Parameters).

Output Parameters

xhandle, yhandle	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
ipar	Contains integer data to be used by Fast Helmholtz Solver. Status of the routine call is written to *ipar[0]*.
stat	`int*`. Routine completion status, which is also written to *ipar[0]*.

Description

The `free_Helmholtz_2D-free_Helmholtz_3D` routine cleans the memory used by the *xhandle* and *yhandle* structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

stat= 0	The routine successfully completed the task.
stat= -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
stat= -99999	The routine failed to complete the task because of a fatal error.

PL Routines for the Spherical Solver

The section gives detailed description of spherical PL routines, their syntax, parameters and values they return. All flavors of the same routine, namely, double-precision and single-precision, periodic (having names ending in "p") and non-periodic (having names ending in "np"), are described together.

These PL routines also call the Intel MKL FFT interface (described in section "FFT Functions" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_sph_p/?_init_sph_np

Initializes basic data structures of the Fast periodic and non-periodic Helmholtz Solver on a sphere.

Syntax

```
void d_init_sph_p(double* ap, double* at, double* bp, double* bt, int* np, int* nt, double* q, int* ipar, double* dpar, int* stat);
void s_init_sph_p(float* ap, float* at, float* bp, float* bt, int* np, int* nt, float* q, int* ipar, float* spar, int* stat);
void d_init_sph_np(double* ap, double* at, double* bp, double* bt, int* np, int* nt, double* q, int* ipar, double* dpar, int* stat);
void s_init_sph_np(float* ap, float* at, float* bp, float* bt, int* np, int* nt, float* q, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl_poisson.h`

Input Parameters

ap	`double*` for `d_init_sph_p/d_init_sph_np`, `float*` for `s_init_sph_p/s_init_sph_np`. The coordinate (angle) of the leftmost boundary of the domain along φ-axis.
bp	`double*` for `d_init_sph_p/d_init_sph_np`, `float*` for `s_init_sph_p/s_init_sph_np`. The coordinate (angle) of the rightmost boundary of the domain along φ-axis.
at	`double*` for `d_init_sph_p/d_init_sph_np`, `float*` for `s_init_sph_p/s_init_sph_np`. The coordinate (angle) of the leftmost boundary of the domain along θ-axis.
bt	`double*` for `d_init_sph_p/d_init_sph_np`, `float*` for `s_init_sph_p/s_init_sph_np`. The coordinate (angle) of the rightmost boundary of the domain along θ-axis.

np	int*. The number of mesh intervals along φ-axis. Must be even in the periodic case.
nt	int*. The number of mesh intervals along θ-axis.
q	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The constant Helmholtz coefficient. Note that to solve Poisson problem, you should set the value of *q* to 0.

Output Parameters

ipar	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
dpar	double array of size 5**np*/2+*nt*+10. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
spar	float array of size 5**np*/2+*nt*+10. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
stat	int*. Routine completion status, which is also written to *ipar[0]*. The status should be 0 to proceed to other PL routines.

Description

The ?_init_sph_p/?_init_sph_np routines initialize basic data structures for Poisson Library computations of the appropriate precision. All routines invoked after a call to a ?_init_Helmholtz_2D/?_init_Helmholtz_3D routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in Common Parameters.

WARNING Data structures initialized and created by periodic/non-periodic flavors of the routine cannot be used by non-periodic/periodic flavors of any PL routines for Helmholtz Solver on a sphere, respectively.

You can skip calling this routine in your code. However, see Caveat on Parameter Modifications before doing so.

Return Values

stat= 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this *stat* value.
stat= -99999	The routine failed to complete the task because of fatal error.

?_commit_sph_p/?_commit_sph_np

Checks consistency and correctness of user's data as well as initializes certain data structures required to solve periodic/non-periodic Helmholtz problem on a sphere.

Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s,
DFTI_DESCRIPTOR_HANDLE* handle_c, int* ipar, double* dpar, int* stat);
```

```
void s_commit_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE*
handle_c, int* ipar, float* spar, int* stat);
```

```
void d_commit_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, double* dpar, int* stat);
```

```
void s_commit_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl_poisson.h`

Input Parameters

f	`double*` for `d_commit_sph_p/d_commit_sph_np`, `float*` for `s_commit_sph_p/s_commit_sph_np`. Contains the right-hand side of the problem packed in a single vector. The size of the vector is (*np*+1)*(*nt*+1) and value of the right-hand side in the mesh point (*i, j*) is stored in *f*[*i*+*j**(*np*+1)] . Note that the array *f* may be altered by the routine. Please save this vector in another memory location if you want to preserve it.
ipar	`int` array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
dpar	`double` array of size 5**np*/2+*nt*+10. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
spar	`float` array of size 5**np*/2+*nt*+10. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

f	Vector of the right-hand side of the problem. Possibly, altered on output.
ipar	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters.
dpar	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters.
spar	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters.
handle_s, handle_c, handle	`DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). *handle_s* and *handle_c* are used only in `?_commit_sph_p` and *handle* is used only in `?_commit_sph_np`.
stat	`int*`. Routine completion status, which is also written to *ipar[0]*. The status should be 0 to proceed to other PL routines.

Description

The `?_commit_sph_p/?_commit_sph_np` routines check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures *handle_s* and *handle_c*, and `?_commit_sph_np` initializes *handle*. The routines also initialize arrays *ipar* and *dpar/spar*, depending upon the routine precision. Refer to Common Parameters to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and what values are written there.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of PL routines, see the Caveat on Parameter Modifications section. Unlike ?_init_sph_p/?_init_sph_np, the routines ?_commit_sph_p/?_commit_sph_np are mandatory, and you cannot skip calling them in your code. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in a previous call to the appropriate ?_init_sph_p/?_init_sph_np routine.

Return Values

stat= 1	The routine completed without errors and produced some warnings.
stat= 0	The routine successfully completed the task.
stat= -100	The routine stopped because an error in the user's data was found or the data in the *dpar*, *spar* or *ipar* array was altered by mistake.
stat= -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.
stat= -99999	The routine failed to complete the task because of a fatal error.

?_sph_p/?_sph_np

Computes the solution of a spherical Helmholtz problem specified by the parameters.

Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, int* ipar, double* dpar, int* stat);
```

```
void s_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, int* ipar, float* spar, int* stat);
```

```
void d_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, double* dpar, int* stat);
```

```
void s_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, float* spar, int* stat);
```

Include Files

- FORTRAN 90: mkl_poisson.f90
- C: mkl_poisson.h

Input Parameters

f	double* for d_sph_p/d_sph_np, float* for s_sph_p/s_sph_np. Contains the right-hand side of the problem packed in a single vector and modified by the appropriate ?_commit_sph_p/?_commit_sph_np routine. Note that an attempt to substitute the original right-hand side vector at this point will result in a wrong solution. The size of the vector is (*np*+1)*(*nt*+1) and value of the right-hand side in the mesh point (*i, j*) is stored in *f*[*i*+*j**(*np*+1)] .

handle_s, handle_c, handle	DFTI_DESCRIPTOR_HANDLE*. Data structures used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). *handle_s* and *handle_c* are used only in ?_sph_p and *handle* is used only in ?_sph_np.
ipar	int array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
dpar	double array of size 5**np*/2+*nt*+10. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).
spar	float array of size 5**np*/2+*nt*+10. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

f	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
handle_s, handle_c, handle	Data structures used by the Intel MKL FFT interface.
ipar	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters.
dpar	Contains double-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters.
spar	Contains single-precision data to be used by Fast Helmholtz Solver on a sphere. Modified on output as explained in Common Parameters.
stat	int*. Routine completion status, which is also written to *ipar[0]*. The status should be 0 to proceed to other PL routines.

Description

The sph_p-sph_np routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the Poisson Library Implemented section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *np* and *nt* are passed to each of the routines with the *ipar* array and defined in the previous call to the appropriate ?_init_sph_p/?_init_sph_np routine.

Return Values

stat= 1	The routine completed without errors and produced some warnings.
stat= 0	The routine successfully completed the task.
stat= -2	The routine stopped because division by zero occurred. It usually happens if the data in the *dpar* or *spar* array was altered by mistake.
stat= -3	The routine stopped because the memory was insufficient to complete the computations.
stat= -100	The routine stopped because an error in the user's data was found or the data in the *dpar*, *spar* or *ipar* array was altered by mistake.
stat= -1000	The routine stopped because of an Intel MKL FFT or TT interface error.

stat= -10000	The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.
stat= -99999	The routine failed to complete the task because of a fatal error.

free_sph_p/free_sph_np

Cleans the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_sph_p(DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c,
int* ipar, int* stat);
```

```
void free_sph_np(DFTI_DESCRIPTOR_HANDLE* handle, int* ipar, int* stat);
```

Include Files

- FORTRAN 90: `mkl_poisson.f90`
- C: `mkl_poisson.h`

Input Parameters

handle_s, *handle_c*, *handle*	`DFTI_DESCRIPTOR_HANDLE*`. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). The structures *handle_s* and *handle_c* are used only in `free_sph_p`, and *handle* is used only in `free_sph_np`.
ipar	`int` array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to Common Parameters).

Output Parameters

handle_s, *handle_c*, *handle*	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
ipar	Contains integer data to be used by Fast Helmholtz Solver on a sphere. Status of the routine call is written to *ipar[0]*.
stat	`int*`. Routine completion status, which is also written to *ipar[0]*.

Description

The `free_sph_p-free_sph_np` routine cleans the memory used by the *handle_s*, *handle_c* or *handle* structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

stat= 0	The routine successfully completed the task.
stat= -1000	The routine stopped because of the Intel MKL FFT or TT interface error.
stat= -99999	The routine failed to complete the task because of a fatal error.

Common Parameters

This section provides description of array parameters *ipar*, *dpar* and *spar*, which hold PL routine options in both Cartesian and spherical cases.

NOTE Initial values are assigned to the array parameters by the appropriate ?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np and ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np routines.

ipar — `int` array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in Table "Elements of the ipar Array":

Elements of the ipar Array

Index	Description
0	Contains status value of the last called PL routine. In general, it should be 0 to proceed with Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np routines of how the Commit step of the computation should be carried out (see Figure "Typical Order of Invoking PL Routines"). A non-zero value of *ipar[0]* with decimal representation $\overline{abc} = 100a + 10b + c$ where each of *a*, *b*, and *c* is equal to 0 or 9, indicates that some parts of the Commit step should be omitted. • If *c*=9, the routine omits checking of parameters and initialization of the data structures. • If *b*=9, then in the Cartesian case, the routine omits the adjustment of the right-hand side vector *f* to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function *g*) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function *G*). In this case, the routine also omits the adjustment of the right-hand side vector *f* to the particular boundary functions. For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the *dpar*/*spar* array. • If *a*=9, then the routine omits the normalization of the right-hand side vector *f*. In the 2D Cartesian case, it is the multiplication by hy^2, where *hy* is the mesh size in the *y* direction (for details, see Poisson Library Implemented). In the 3D (Cartesian) case, it is the multiplication by hz^2, where *hz* is the mesh size in the *z* direction. For the Helmholtz solver on a sphere, it is the multiplication by h_θ^2, where h_θ is the mesh size in the θ direction (for details, see Poisson Library Implemented). Using *ipar[0]* you can adjust the routine to your needs and gain efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious using this opportunity, because misunderstanding of the commit process may cause wrong results or program failure (see also Caveat on Parameter Modifications).
1	Contains error messaging options: • *ipar[1]*=-1 indicates that all error messages will be printed to the file MKL_Poisson_Library_log.txt in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • *ipar[1]*=0 indicates that no error messages will be printed. • *ipar[1]*=1 is the default value. It indicates that all error messages will be printed to the preconnected default output device (usually, screen).

Index	Description
	In case of errors, the *stat* parameter will acquire a non-zero value regardless of the *ipar[1]* setting.
2	Contains warning messaging options: • *ipar[2]*=-1 indicates that all warning messages will be printed to the file MKL_Poisson_Library_log.txt in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • *ipar[2]*=0 indicates that no warning messages will be printed. • *ipar[2]*=1 is the default value. It indicates that all warning messages will be printed to the preconnected default output device (usually, screen). In case of warnings, the *stat* parameter will acquire a non-zero value regardless of the *ipar[2]* setting.
3	Contains the number of the combination of boundary conditions. In the Cartesian case, it corresponds to the value that the *BCtype* parameter holds: • In the 2D case, 0 corresponds to 'DDDD' 1 corresponds to 'DDDN' … 15 corresponds to 'NNNN' • In the 3D case, 0 corresponds to 'DDDDDD' 1 corresponds to 'DDDDDN' ... 63 corresponds to 'NNNNNN'. The Helmholtz solver on a sphere uses this parameter only in a periodic case. The *bp* and *bt* parameters of the ?_init_sph_p/?_init_sph_np routine, which initializes *ipar[3]*, determine its value: • 0 corresponds to the problem without poles. • 1 corresponds to the problem on the entire sphere.
Parameters 4 through 9 are used only in Cartesian case.	
4	Takes the value of 1 if *BCtype[0]*='N', 0 if *BCtype[0]*='D', and -1 otherwise.
5	Takes the value of 1 if *BCtype[1]*='N', 0 if *BCtype[1]*='D', and -1 otherwise.
6	Takes the value of 1 if *BCtype[2]*='N', 0 if *BCtype[2]*='D', and -1 otherwise.
7	Takes the value of 1 if *BCtype[3]*='N', 0 if *BCtype[3]*='D', and -1 otherwise.
8	Takes the value of 1 if *BCtype[4]*='N', 0 if *BCtype[4]*='D', and -1 otherwise. This parameter is used only in the 3D case.
9	Takes the value of 1 if *BCtype[5]*='N', 0 if *BCtype[5]*='D', and -1 otherwise. This parameter is used only in the 3D case.
10	Takes the value of • *nx*, that is, the number of intervals along x-axis, in the Cartesian case. • *np*, that is, the number of intervals along φ-axis, in the spherical case.
11	Takes the value of

Index	Description
	• *ny*, that is, the number of intervals along *y*-axis, in the Cartesian case • *nt*, that is, the number of intervals along θ-axis, in the spherical case.
12	Takes the value of *nz*, the number of intervals along *z*-axis. This parameter is used only in the 3D case (Cartesian).
13	Takes the value of 6, which specifies the internal partitioning of the *dpar/spar* array.
14	Takes the value of *ipar[13]*+*ipar[10]*+1, which specifies the internal partitioning of the *dpar/spar* array.

Subsequent values of *ipar* depend upon the dimension of the problem or upon whether the solver on a sphere is periodic.

Index	2D case	3D case	Periodic case	Non-periodic case
15	Unused	Takes the value of *ipar[14]*+1, which specifies the internal partitioning of the *dpar/spar* array.		
16	Unused	Takes the value of *ipar[14]*+ *ipar[11]*+1, which specifies the internal partitioning of the *dpar/spar* array.		
17	Takes the value of *ipar[14]*+1, which specifies the internal partitioning of the *dpar/spar* array.	Takes the value of *ipar[16]*+1, which specifies the internal partitioning of the *dpar/spar* array.		
18	Takes the value of *ipar[14]*+3**ipar[10]* /2+1, which specifies the internal partitioning of the *dpar/spar* array.	Takes the value of *ipar[16]*+3* *ipar[10]*/2+1, which specifies the internal partitioning of the *dpar/spar* array.	Takes the value of *ipar[16]*+3 **ipar[10]*/4+1, which specifies the internal partitioning of the *dpar/spar* array.	Takes the value of *ipar[16]* +3**ipar[10]* / 2+1, which specifies the internal partitioning of the *dpar/spar* array.
19	Unused	Takes the value of *ipar[18]*+1, which specifies the internal partitioning of the *dpar/spar* array.		Unused
20	Unused	Takes the value of *ipar[18]*+ 3**ipar[11]*/2+1, which specifies the internal partitioning of the dpar/spar array.	Takes the value of *ipar[18]*+3**ipar[10]* /4+1, which specifies the internal partitioning of the dpar/spar array.	Unused

Subsequent values of *ipar* are assigned regardless.

21	Contains message style options: • *ipar[21]*=0 indicates that PL routines print all error and warning messages in Fortran-style notations. • *ipar[21]*=1 (default) indicates that PL routines print the messages in C-style notations.
22	Contains the number of threads to be used for computations in a multithreaded environment. The default value is 1 in the serial mode, and the result returned by the mkl_get_max_threads function otherwise.

Index	Description
23 through 39	Unused in the current implementation of the Poisson Library.
40 through 59	Contain the first twenty elements of the *ipar* array of the first Trigonometric Transform that the Solver uses. (For details, see Common Parameters in the "Trigonometric Transform Routines" chapter.)
60 through 79	Contain the first twenty elements of the *ipar* array of the second Trigonometric Transform that the 3D and periodic solvers use. (For details, see Common Parameters in the "Trigonometric Transform Routines" chapter.)

NOTE You may declare the *ipar* array in your code as `int ipar[80]`. However, for compatibility with later versions of Intel MKL Poisson Library, which may require more *ipar* values, it is highly recommended to declare *ipar* as `int ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

dpar Holds data needed for double-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, `double` array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case; initialized in the `d_init_Helmholtz_2D/d_init_Helmholtz_3D` and `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` routines.
- For the spherical solver, `double` array of size 5*np/2+nt+10; initialized in the `d_init_sph_p/d_init_sph_np` and `d_commit_sph_p/d_commit_sph_np` routines.

spar Holds data needed for single-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, `float` array of size 5*nx/2+7 in the 2D case or 5*(nx+ny)/2+9 in the 3D case; initialized in the `s_init_Helmholtz_2D/s_init_Helmholtz_3D` and `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` routines.
- For the spherical solver, `float` array of size 5*np/2+nt+10; initialized in the `s_init_sph_p/s_init_sph_np` and `s_commit_sph_p/s_commit_sph_np` routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table "Elements of the dpar and spar Arrays":

Elements of the dpar and spar Arrays

Index	Description
0	In the Cartesian case, contains the length of the interval along x-axis right after a call to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine or the mesh size h_x in the x direction (for details, see Poisson Library Implemented) after a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine. In the spherical case, contains the length of the interval along φ-axis right after a call to the `?_init_sph_p/?_init_sph_np` routine or the mesh size h_φ in the φ direction (for details, see Poisson Library Implemented) after a call to the `?_commit_sph_p/?_commit_sph_np` routine.
1	In the Cartesian case, contains the length of the interval along y-axis right after a call to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine or the mesh size h_y in the y direction (for details, see Poisson Library Implemented) after a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine.

Index	Description
	In the spherical case, contains the length of the interval along θ-axis right after a call to the ?_init_sph_p/?_init_sph_np routine or the mesh size h_θ in the θ direction (for details, see Poisson Library Implemented) after a call to the ?_commit_sph_p/?_commit_sph_np routine.
2	In the Cartesian case, contains the length of the interval along z-axis right after a call to the ?_init_Helmholtz_2D/?_init_Helmholtz_3D routine or the mesh size h_z in the z direction (for details, see Poisson Library Implemented) after a call to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine. In the Cartesian solver, this parameter is used only in the 3D case. In the spherical solver, contains the coordinate of the leftmost boundary along θ-axis after a call to the ?_init_sph_p/?_init_sph_np routine.
3	Contains the value of the coefficient q after a call to the ?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np routine.
4	Contains the tolerance parameter after a call to the ?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np routine. • In the Cartesian case, this value is used only for the pure Neumann boundary conditions (*BCtype*="NNNN" in the 2D case; *BCtype*="NNNNNN" in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient q is zero. Poisson Library verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, Poisson Library computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the ?_Helmholtz_2D/?_Helmholtz_3D routine informs the user that the solution may not exist in a classical sense (up to rounding errors). • In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the above described Cartesian case with pure Neumann boundary conditions. So, here Poisson Library computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors. The default value for this parameter is 1.0E-10 in case of double-precision computations or 1.0E-4 in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.
ipar[13]-1 through *ipar[14]*-1	In the Cartesian case, contain the spectrum of the 1D problem along x-axis after a call to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine. In the spherical case, contains the spectrum of the 1D problem along φ-axis after a call to the ?_commit_sph_p/?_commit_sph_np routine.
ipar[15]-1 through *ipar[16]*-1	In the Cartesian case, contain the spectrum of the 1D problem along y-axis after a call to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine. These elements are used only in the 3D case. In the spherical case, contains the spherical weights after a call to the ?_commit_sph_p/?_commit_sph_np routine.
ipar[17]-1 through *ipar[18]*-1	Take the values of the (staggered) sine/cosine in the mesh points: • along x-axis after a call to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine for a Cartesian solver • along φ-axis after a call to the ?_commit_sph_p/?_commit_sph_np routine for a spherical solver.

Index	Description
ipar[19]-1 through *ipar[20]*-1	Take the values of the (staggered) sine/cosine in the mesh points: • along *y*-axis after a call to the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine for a Cartesian 3D solver • along φ-axis after a call to the ?_commit_sph_p routine for a spherical periodic solver. These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.

NOTE You may define the array size depending upon the type of the problem to solve.

Caveat on Parameter Modifications

Flexibility of the PL interface enables you to skip calling the ?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the ?_commit_Helmholtz_2D/?_commit_Helmholtz_3D routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

NOTE To supply correct and consistent parameters to PL routines, you should have considerable experience in using the PL interface and good understanding of the solution process as well as elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail in tuning parameters for the Fast Helmholtz Solver. In cases like these, refer for technical support at http://www.intel.com/software/products/support/ .

WARNING The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Implementation Details

Several aspects of the Intel MKL PL interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, users are provided with the PL language-specific header files to include in their code. Currently, the following header files are available:

- mkl_poisson.h, to be used together with mkl_dfti.h, for C programs.
- mkl_poisson.f90, to be used together with mkl_dfti.f90, for Fortran 90 programs.

Use of the Intel MKL PL software without including one of the above header files is not supported.

The include files define function prototypes for appropriate languages.

C-specific Header File

The C-specific header file defines the following function prototypes for the Cartesian solver:

```
void d_init_Helmholtz_2D(double*, double*, double*, double*, int*, int*, char*, double*, int*, double*,
int*);

void d_commit_Helmholtz_2D(double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, int*,
double*, int*);

void d_Helmholtz_2D(double*, double*, double*, double*, double*, DFTI_DESCRIPTOR_HANDLE*, int*,
double*, int*);

void s_init_Helmholtz_2D(float*, float*, float*, float*, int*, int*, char*, float*, int*, float*, int*);

void s_commit_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, int*,
float*, int*);

void s_Helmholtz_2D(float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*,
int*);

void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE*, int*, int*);

void d_init_Helmholtz_3D(double*, double*, double*, double*, double*, double*, int*, int*, int*, char*,
double*, int*, double*, int*);

void d_commit_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void d_Helmholtz_3D(double*, double*, double*, double*, double*, double*, double*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_init_Helmholtz_3D(float*, float*, float*, float*, float*, float*, int*, int*, int*, char*,
float*, int*, float*, int*);

void s_commit_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*,
DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void s_Helmholtz_3D(float*, float*, float*, float*, float*, float*, float*, DFTI_DESCRIPTOR_HANDLE*,
DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);
```

The C-specific header file defines the following function prototypes for the spherical solver:

```
void d_init_sph_p(double*, double*, double*, double*, int*, int*, double*, int*, double*, int*);

void d_commit_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void d_sph_p(double*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_init_sph_p(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);

void s_commit_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void s_sph_p(float*, DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void free_sph_p(DFTI_DESCRIPTOR_HANDLE*, DFTI_DESCRIPTOR_HANDLE*, int*, int*);

void d_init_sph_np(double*, double*, double*, double*, int*, int*, double*, int*, double*, int*);

void d_commit_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void d_sph_np(double*, DFTI_DESCRIPTOR_HANDLE*, int*, double*, int*);

void s_init_sph_np(float*, float*, float*, float*, int*, int*, float*, int*, float*, int*);

void s_commit_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void s_sph_np(float*, DFTI_DESCRIPTOR_HANDLE*, int*, float*, int*);

void free_sph_np(DFTI_DESCRIPTOR_HANDLE*, int*, int*);
```

Fortran-Specific Header File

The Fortran90-specific header file defines the following function prototypes for the Cartesian solver:

```
SUBROUTINE D_INIT_HELMHOLTZ_2D (AX, BX, AY, BY, NX, NY, BCTYPE, Q, IPAR, DPAR, STAT)

```

Fortran 90 specifics of the PL routines usage are similar for all Intel MKL PDE support tools and described in the Calling PDE Support Routines from Fortran 90 section.

Calling PDE Support Routines from Fortran 90

The calling interface for all the Intel MKL TT and PL routines is designed to be easily used in C. However, you can invoke each TT or PL routine directly from Fortran 90 if you are familiar with the inter-language calling conventions of your platform.

The TT or PL interface cannot be invoked from Fortran 77 due to restrictions imposed by the use of the Intel MKL FFT interface.

The inter-language calling conventions include, but are not limited to, the argument passing mechanisms for the language, the data type mappings from C to Fortran 90 and how C external names are decorated on the platform.

To promote portability and relieve a user of dealing with the calling conventions specifics, Fortran 90 header file `mkl_trig_transforms.f90` for TT routines and `mkl_poisson.f90` for PL routines, used together with `mkl_dfti.f90`, declare a set of macros and introduce type definitions intended to hide the inter-language calling conventions and provide an interface to the routines that looks natural in Fortran 90.

For example, consider a hypothetical library routine, `foo`, which takes a double-precision vector of length `n`. C users access such a function as follows:

```
int n;
double *x;
…
foo(x, &n);
```

As noted above, to invoke `foo`, Fortran 90 users would need to know what Fortran 90 data types correspond to C types `int` and `double` (or `float` in case of single-precision), what argument-passing mechanism the C compiler uses and what, if any, name decoration is performed by the C compiler when generating the external symbol `foo`. However, with the Fortran 90 header files `mkl_trig_transforms.f90` / `mkl_poisson.f90` and `mkl_dfti.f90` included, the invocation of `foo` within a Fortran 90 program will look as follows:

- For TT interface,

```
use mkl_dfti
use mkl_trig_transforms
INTEGER n
DOUBLE PRECISION, ALLOCATABLE :: x
…
CALL FOO(x,n)
```

- For PL interface,

```
use mkl_dfti
use mkl_poisson
INTEGER n
DOUBLE PRECISION, ALLOCATABLE :: x
…
CALL FOO(x,n)
```

Note that in the above example, the header files `mkl_trig_transforms.f90 / mkl_poisson.f90` and `mkl_dfti.f90` provide a definition for the subroutine `FOO`. To ease the use of PL or TT routines in Fortran 90, the general approach of providing Fortran 90 definitions of names is used throughout the libraries. Specifically, if a name from a PL or TT interface is documented as having the C-specific name `foo`, then the Fortran 90 header files provide an appropriate Fortran 90 language type definition `FOO`.

One of the key differences between Fortran 90 and C is the language argument-passing mechanism: C programs use pass-by-value semantics and Fortran 90 programs use pass-by-reference semantics. The Fortran 90 headers ensure proper treatment of this difference. In particular, in the above example, the header files `mkl_trig_transforms.f90 / mkl_poisson.f90` and `mkl_dfti.f90` hide the difference by defining a macro `FOO` that takes the address of the appropriate arguments.

Nonlinear Optimization Problem Solvers

14

Intel® Math Kernel Library (Intel® MKL) provides tools for solving nonlinear least squares problems using the Trust-Region (TR) algorithms. The solver routines are grouped according to their purpose as follows:

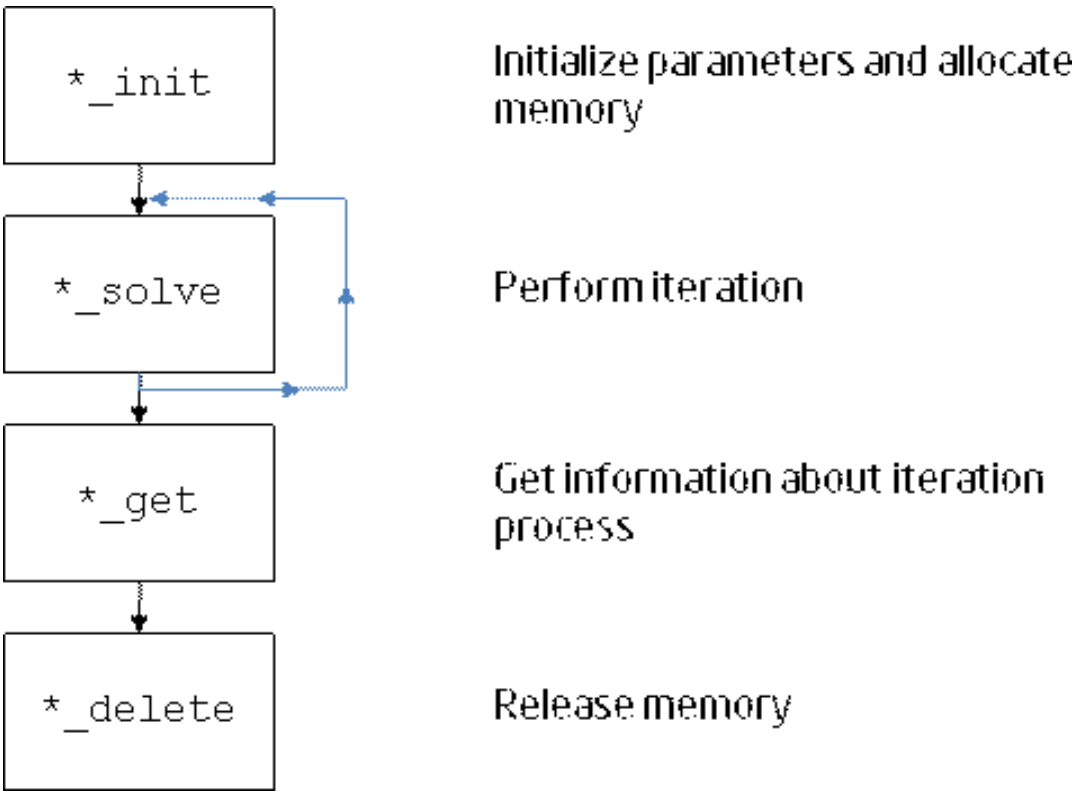
- Nonlinear Least Squares Problem without Constraints
- Nonlinear Least Squares Problem with Linear (Boundary) Constraints
- Jacobian Matrix Calculation Routines

For more information on the key concepts required to understand the use of the Intel MKL nonlinear least squares problem solver routines, see [Conn00].

Organization and Implementation

The Intel MKL solver routines for nonlinear least squares problems use reverse communication interfaces (RCI). That means you need to provide the solver with information required for the iteration process, for example, the corresponding Jacobian matrix, or values of the objective function. RCI removes the dependency of the solver on specific implementation of the operations. However, it does require that you organize a computational loop.

Typical order for invoking RCI solver routines



The nonlinear least squares problem solver routines, or Trust-Region (TR) solvers, are implemented with the OpenMP* support. You can manage the threads using threading control functions.

Memory Allocation and Handles

To make the TR solver routines easy to use, you are not required to allocate temporary working storage. The solver allocates any required memory. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a *handle*. Each TR solver routine creates, uses, or deletes a handle. To declare a handle, include `mkl_rci.h` or `mkl_rci.fi`.

For a C and C++ program, declare a handle as one of the following:

```
#include "mkl_rci.h"
_TRNSP_HANDLE_t handle;
```

or

```
_TRNSPBC_HANDLE_t handle;
```

The first declaration is used for nonlinear least squares problems without boundary constraints, and the second is used for nonlinear least squares problems with boundary constraints.

For a Fortran program using compilers that support eight byte integers, declare a handle as:

```
INCLUDE "mkl_rci.fi"
INTEGER*8 handle
```

Routine Naming Conventions

The TR routine names have the following structure:

```
      <character><name>_<action>( )
```

where

- <*character*> indicates the data type:

`s`	real, single precision
`d`	real, double precision

- <*name*> indicates the task type:

`trnlsp`	nonlinear least squares problem without constraints
`trnlspbc`	nonlinear least squares problem with boundary constraints
`jacobi`	computation of the Jacobian matrix using central differences

- <*action*> indicates an action on the task:

`init`	initializes the solver
`check`	checks correctness of the input parameters
`solve`	solves the problem
`get`	retrieves the number of iterations, the stop criterion, the initial residual, and the final residual
`delete`	releases the allocated data

Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in R^n} \|F(x)\|_2^2 = \min_{x \in R^n} \|y - f(x)\|_2^2, \; y \in R^m, \; x \in R^n, \; f : R^n \to R^m, \; m \geq n,$$

where

$F(x) : R^n \to R^m$ is a twice differentiable function in R^n.

Solving a nonlinear least squares problem means searching for the best approximation to the vector y with the model function $f_i(x)$ and nonlinear variables x. The best approximation means that the sum of squares of residuals $y_i - f_i(x)$ is the minimum.

See usage examples in FORTRAN and C in the `examples\solver\source` folder of your Intel MKL directory (`ex_nlsqp_f.f` and `ex_nlsqp_c.c`, respectively).

RCI TR Routines

Routine Name	Operation
`?trnlsp_init`	Initializes the solver.
`?trnlsp_check`	Checks correctness of the input parameters.
`?trnlsp_solve`	Solves a nonlinear least squares problem using the Trust-Region algorithm.
`?trnlsp_get`	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
`?trnlsp_delete`	Releases allocated data.

?trnlsp_init

Initializes the solver of a nonlinear least squares problem.

Syntax

Fortran:

```
res = strnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
res = dtrnlsp_init(handle, n, m, x, eps, iter1, iter2, rs)
```

C:

```
res = strnlsp_init(&handle, &n, &m, x, eps, &iter1, &iter2, &rs);
res = dtrnlsp_init(&handle, &n, &m, x, eps, &iter1, &iter2, &rs);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?trnlsp_init` routine initializes the solver.

After initialization, all subsequent invocations of the `?trnlsp_solve` routine should use the values of the handle returned by `?trnlsp_init`.

The *eps* array contains the stopping criteria:

eps Value	Description
1	$\Delta < eps(1)$
2	$\|\|F(x)\|\|_2 < eps(2)$
3	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$

eps Value	Description
4	$\|\|s\|\|_2 < eps(4)$
5	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$
6	The trial step precision. If $eps(6) = 0$, then the trial step meets the required precision ($\leq$ 1.0D-10).

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

n — INTEGER. Length of x.

m — INTEGER. Length of $F(x)$.

x — REAL for strnlsp_init
DOUBLE PRECISION for dtrnlsp_init
Array of size n. Initial guess.

eps — REAL for strnlsp_init
DOUBLE PRECISION for dtrnlsp_init
Array of size 6; contains stopping criteria. See the values in the Description section.

iter1 — INTEGER. Specifies the maximum number of iterations.

iter2 — INTEGER. Specifies the maximum number of iterations of trial step calculation.

rs — REAL for strnlsp_init
DOUBLE PRECISION for dtrnlsp_init
Definition of initial size of the trust region (boundary of the trial step). The minimum value is 0.1, and the maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. The default value is 100.0.

Output Parameters

handle — Type _TRNSP_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

res — INTEGER. Indicates task completion status.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

See Also

?trnlsp_solve

?trnlsp_check

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, and stopping criteria.

Syntax

Fortran:

```
res = strnlsp_check(handle, n, m, fjac, fvec, eps, info)
res = dtrnlsp_check(handle, n, m, fjac, fvec, eps, info)
```

C:

```
res = strnlsp_check(&handle, &n, &m, fjac, fvec, eps, info);
res = dtrnlsp_check(&handle, &n, &m, fjac, fvec, eps, info);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?trnlsp_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `NaN` values, the routine sets the flag in output array *info* (see the description of the values returned in the Output Parameters section for the *info* array).

Input Parameters

handle	Type `_TRNSPBC_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.
n	`INTEGER`. Length of x.
m	`INTEGER`. Length of $F(x)$.
fjac	`REAL` for `strnlsp_check` `DOUBLE PRECISION` for `dtrnlsp_check` Array of size m by n. Contains the Jacobian matrix of the function.
fvec	`REAL` for `strnlsp_check` `DOUBLE PRECISION` for `dtrnlsp_check` Array of size m. Contains the function values at `X`, where $fvec(i) = (y_i - f_i(x))$.
eps	`REAL` for `strnlsp_check` `DOUBLE PRECISION` for `dtrnlsp_check` Array of size 6; contains stopping criteria. See the values in the Description section of the `?trnlsp_init`.

Output Parameters

info	`INTEGER` Array of size 6. Results of input parameter checking:

Parameter		Used for	Value	Description
C Language	Fortran Language			
info(0)	*info*(1)	Flags for *handle*	0	The handle is valid.
			1	The handle is not allocated.
info(1)	*info*(2)	Flags for *fjac*	0	The *fjac* array is valid.
			1	The *fjac* array is not allocated
			2	The *fjac* array contains NaN.
			3	The *fjac* array contains Inf.
info(2)	*info*(3)	Flags for *fvec*	0	The *fvec* array is valid.
			1	The *fvec* array is not allocated
			2	The *fvec* array contains NaN.
			3	The *fvec* array contains Inf.
info(3)	*info*(4)	Flags for *eps*	0	The *eps* array is valid.
			1	The *eps* array is not allocated
			2	The *eps* array contains NaN.
			3	The *eps* array contains Inf.
			4	The *eps* array contains a value less than or equal to zero.

res INTEGER. Information about completion of the task.
res = TR_SUCCESS - the routine completed the task normally.
TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

?trnlsp_solve

Solves a nonlinear least squares problem using the TR algorithm.

Syntax

Fortran:

```
res = strnlsp_solve(handle, fvec, fjac, RCI_Request)
res = dtrnlsp_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = strnlsp_solve(&handle, fvec, fjac, &RCI_Request);
res = dtrnlsp_solve(&handle, fvec, fjac, &RCI_Request);
```

Include Files

- Fortran: mkl_rci.fi

- C: `mkl_rci.h`

Description

The `?trnlsp_solve` routine uses the TR algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in R^n} \|F(x)\|_2^2 = \min_{x \in R^n} \|y - f(x)\|_2^2, \; y \in R^m, \; x \in R^n, \; f : R^n \to R^m, \; m \geq n,$$

where

- $F(x) : R^n \to R^m$
- $m \geq n$

From a current point $x_{current}$, the algorithm uses the trust-region approach:

$$\min_{x \in R^n} \|F(x_{current}) + J(x_{current})(x_{new} - x_{current})\|_2^2 \quad \text{subject to} \quad \|x_{new} - x_{current}\| \leq \Delta_{current}$$

to get $x_{new} = x_{current} + s$ that satisfies

$$\min_{x \in R^n} \|J^T(x)J(x)s + J^T F(x)\|_2^2$$

where

- $J(x)$ is the Jacobian matrix
- s is the trial step
- $||s||_2 \leq \Delta_{current}$

The *RCI_Request* parameter provides additional information:

RCI_Request **Value**	**Description**
2	Request to calculate the Jacobian matrix and put the result into *fjac*
1	Request to recalculate the function at vector `X` and put the result into *fvec*
0	One successful iteration step on the current trust-region radius (that does not mean that the value of x has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < eps(1)$
-3	$\|\|F(x)\|\|_2 < eps(2)$
-4	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3), \; j = 1, \ldots, n$
-5	$\|\|s\|\|_2 < eps(4)$
-6	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle	Type _TRNSP_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.
fvec	REAL for strnlsp_solve DOUBLE PRECISION for dtrnlsp_solve Array of size m. Contains the function values at X, where $fvec(i) = (y_i - f_i(x))$.
fjac	REAL for strnlsp_solve DOUBLE PRECISION for dtrnlsp_solve Array of size (m,n). Contains the Jacobian matrix of the function.

Output Parameters

fvec	REAL for strnlsp_solve DOUBLE PRECISION for dtrnlsp_solve Array of size m. Updated function evaluated at x.
RCI_Request	INTEGER. Informs about the task stage. See the Description section for the parameter values and their meaning.
res	INTEGER. Indicates the task completion. *res* = TR_SUCCESS - the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

?trnlsp_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = strnlsp_get(handle, iter, st_cr, r1, r2)
res = dtrnlsp_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = strnlsp_get(&handle, &iter, &st_cr, &r1, &r2);
res = dtrnlsp_get(&handle, &iter, &st_cr, &r1, &r2);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The initial residual is the value of the functional $(||y - f(x)||)$ of the initial x values provided by the user.

The final residual is the value of the functional $(||y - f(x)||)$ of the final x resulting from the algorithm operation.

The *st_cr* parameter contains the stop criterion:

st_cr **Value**	**Description**
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < eps(1)$
3	$\|\|F(x)\|\|_2 < eps(2)$
4	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$
5	$\|\|s\|\|_2 < eps(4)$
6	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle	Type `_TRNSP_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

iter	`INTEGER`. Contains the current number of iterations.
st_cr	`INTEGER`. Contains the stop criterion. See the Description section for the parameter values and their meanings.
r1	`REAL` for `strnlsp_get` `DOUBLE PRECISION` for `dtrnlsp_get` Contains the residual, $(||y - f(x)||)$ given the initial x.
r2	`REAL` for `strnlsp_get` `DOUBLE PRECISION` for `dtrnlsp_get` Contains the final residual, that is, the value of the functional $(||y - f(x)||)$ of the final x resulting from the algorithm operation.
res	`INTEGER`. Indicates the task completion. *res* = `TR_SUCCESS` - the routine completed the task normally. `TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

?trnlsp_delete

Releases allocated data.

Syntax

Fortran:

```
res = strnlsp_delete(handle)
res = dtrnlsp_delete(handle)
```

C:

```
res = strnlsp_delete(&handle);
res = dtrnlsp_delete(&handle);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?trnlsp_delete routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function mkl_free_buffers.

Input Parameters

handle	Type _TRNSP_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

Output Parameters

res	INTEGER. Indicates the task completion. *res* = TR_SUCCESS means the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints is very similar to the nonlinear least squares problem without constraints but it has the following constraints:

$$l_i \le x_i \le u_i, i = 1,\ldots,n, \quad l,u \in R^n.$$

See usage examples in FORTRAN and C in the examples\solver\source folder of your Intel MKL directory (ex_nlsqp_bc_f.f and ex_nlsqp_bc_c.c, respectively).

RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
?trnlspbc_init	Initializes the solver.
?trnlspbc_check	Checks correctness of the input parameters.
?trnlspbc_solve	Solves a nonlinear least squares problem using RCI and the Trust-Region algorithm.
?trnlspbc_get	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
?trnlspbc_delete	Releases allocated data.

?trnlspbc_init

Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.

Syntax

Fortran:

```
res = strnlspbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
res = dtrnlspbc_init(handle, n, m, x, LW, UP, eps, iter1, iter2, rs)
```

C:

```
res = strnlspbc_init(&handle, &n, &m, x, LW, UP, eps, &iter1, &iter2, &rs);
res = dtrnlspbc_init(&handle, &n, &m, x, LW, UP, eps, &iter1, &iter2, &rs);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?trnlspbc_init` routine initializes the solver.

After initialization all subsequent invocations of the `?trnlspbc_solve` routine should use the values of the handle returned by `?trnlspbc_init`.

The *eps* array contains the stopping criteria:

eps **Value**	**Description**
1	$\Delta < eps(1)$
2	$\|\|F(x)\|\|_2 < eps(2)$
3	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$
4	$\|\|s\|\|_2 < eps(4)$
5	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$
6	The trial step precision. If $eps(6) = 0$, then the trial step meets the required precision ($\leq$ 1.0D-10).

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

n	INTEGER. Length of x.
m	INTEGER. Length of $F(x)$.
x	REAL for `strnlspbc_init`

DOUBLE PRECISION for dtrnlspbc_init
Array of size n. Initial guess.

LW
REAL for strnlspbc_init
DOUBLE PRECISION for dtrnlspbc_init
Array of size n.
Contains low bounds for x ($lw_i < x_i$).

UP
REAL for strnlspbc_init
DOUBLE PRECISION for dtrnlspbc_init
Array of size n.
Contains upper bounds for x ($up_i > x_i$).

eps
REAL for strnlspbc_init
DOUBLE PRECISION for dtrnlspbc_init
Array of size 6; contains stopping criteria. See the values in the Description section.

iter1
INTEGER. Specifies the maximum number of iterations.

iter2
INTEGER. Specifies the maximum number of iterations of trial step calculation.

rs
REAL for strnlspbc_init
DOUBLE PRECISION for dtrnlspbc_init
Definition of initial size of the trust region (boundary of the trial step). The minimum value is 0.1, and the maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. The default value is 100.0.

Output Parameters

handle
Type _TRNSPBC_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

res
INTEGER. Informs about the task completion.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

?trnlspbc_check

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, lower and upper bounds, and stopping criteria.

Syntax

Fortran:

```
res = strnlspbc_check(handle, n, m, fjac, fvec, LW, UP, eps, info)
res = dtrnlspbc_check(handle, n, m, fjac, fvec, LW, UP, eps, info)
```

C:

```
res = strnlspbc_check(&handle, &n, &m, fjac, fvec, LW, UP, eps, info);
res = dtrnlspbc_check(&handle, &n, &m, fjac, fvec, LW, UP, eps, info);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?trnlspbc_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `NaN` values, the routine sets the flag in output array *info* (see the description of the values returned in the Output Parameters section for the *info* array).

Input Parameters

handle Type `_TRNSPBC_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

n `INTEGER`. Length of x.

m `INTEGER`. Length of $F(x)$.

fjac
`REAL` for `strnlspbc_check`
`DOUBLE PRECISION` for `dtrnlspbc_check`
Array of size m by n. Contains the Jacobian matrix of the function.

fvec
`REAL` for `strnlspbc_check`
`DOUBLE PRECISION` for `dtrnlspbc_check`
Array of size m. Contains the function values at `X`, where $fvec(i) = (y_i - f_i(x))$.

LW
`REAL` for `strnlspbc_check`
`DOUBLE PRECISION` for `dtrnlspbc_check`
Array of size n.
Contains low bounds for x ($lw_i < x_i$).

UP
`REAL` for `strnlspbc_check`
`DOUBLE PRECISION` for `dtrnlspbc_check`
Array of size n.
Contains upper bounds for x ($up_i > x_i$).

eps
`REAL` for `strnlspbc_check`
`DOUBLE PRECISION` for `dtrnlspbc_check`
Array of size 6; contains stopping criteria. See the values in the Description section of the `?trnlspbc_init`.

Output Parameters

info `INTEGER`
Array of size 6.
Results of input parameter checking:

Parameter		Used for	Value	Description
C Language	Fortran Language			
info(0)	*info*(1)	Flags for *handle*	0	The handle is valid.
			1	The handle is not allocated.
info(1)	*info*(2)	Flags for *fjac*	0	The *fjac* array is valid.
			1	The *fjac* array is not allocated
			2	The *fjac* array contains `NaN`.

Parameter		Used for	Value	Description
C Language	Fortran Language			
			3	The *fjac* array contains Inf.
info(2)	*info*(3)	Flags for *fvec*	0	The *fvec* array is valid.
			1	The *fvec* array is not allocated
			2	The *fvec* array contains NaN.
			3	The *fvec* array contains Inf.
info(3)	*info*(4)	Flags for *LW*	0	The *LW* array is valid.
			1	The *LW* array is not allocated
			2	The *LW* array contains NaN.
			3	The *LW* array contains Inf.
			4	The lower bound is greater than the upper bound.
info(4)	*info*(5)	Flags for *up*	0	The *up* array is valid.
			1	The *up* array is not allocated
			2	The *up* array contains NaN.
			3	The *up* array contains Inf.
			4	The upper bound is less than the lower bound.
info(5)	*info*(6)	Flags for *eps*	0	The *eps* array is valid.
			1	The *eps* array is not allocated
			2	The *eps* array contains NaN.
			3	The *eps* array contains Inf.
			4	The *eps* array contains a value less than or equal to zero.

res INTEGER. Information about completion of the task.
res = TR_SUCCESS - the routine completed the task normally.
TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

?trnlspbc_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

Syntax

Fortran:

```
res = strnlspbc_solve(handle, fvec, fjac, RCI_Request)
res = dtrnlspbc_solve(handle, fvec, fjac, RCI_Request)
```

C:

```
res = strnlspbc_solve(&handle, fvec, fjac, &RCI_Request);
res = dtrnlspbc_solve(&handle, fvec, fjac, &RCI_Request);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?trnlspbc_solve` routine, based on RCI, uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in R^n} \left\| F(x) \right\|_2^2 = \min_{x \in R^n} \left\| y - f(x) \right\|_2^2, y \in R^m, x \in R^n, f : R^n \to R^m, m \geq n$$

where

$l_i \leq x_i \leq u_i$

$i = 1, \ldots, n$.

The *RCI_Request* parameter provides additional information:

RCI_Request **Value**	**Description**
2	Request to calculate the Jacobian matrix and put the result into *fjac*
1	Request to recalculate the function at vector `X` and put the result into *fvec*
0	One successful iteration step on the current trust-region radius (that does not mean that the value of x has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < eps(1)$
-3	$\|\|F(x)\|\|_2 < eps(2)$
-4	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3), j = 1, \ldots, n$
-5	$\|\|s\|\|_2 < eps(4)$
-6	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.

- s is the trial step.

Input Parameters

handle	Type _TRNSPBC_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.
fvec	REAL for strnlspbc_solve DOUBLE PRECISION for dtrnlspbc_solve Array of size *m*. Contains the function values at X, where *fvec(i)* = (y_i – $f_i(x)$).
fjac	REAL for strnlspbc_solve DOUBLE PRECISION for dtrnlspbc_solve Array of size *m* by *n*. Contains the Jacobian matrix of the function.

Output Parameters

fvec	REAL for strnlspbc_solve DOUBLE PRECISION for dtrnlspbc_solve Array of size *m*. Updated function evaluated at x.
RCI_Request	INTEGER. Informs about the task stage. See the Description section for the parameter values and their meaning.
res	INTEGER. Informs about the task completion. *res* = TR_SUCCESS means the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

?trnlspbc_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

Fortran:

```
res = strnlspbc_get(handle, iter, st_cr, r1, r2)
res = dtrnlspbc_get(handle, iter, st_cr, r1, r2)
```

C:

```
res = strnlspbc_get(&handle, &iter, &st_cr, &r1, &r2);
res = dtrnlspbc_get(&handle, &iter, &st_cr, &r1, &r2);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The *st_cr* parameter contains the stop criterion:

st_cr Value	Description
1	The algorithm has exceeded the maximum number of iterations

st_cr Value	Description
2	$\Delta < eps(1)$
3	$\|\|F(x)\|\|_2 < eps(2)$
4	The Jacobian matrix is singular. $\|\|J(x)_{(1:m,j)}\|\|_2 < eps(3),\ j = 1, \ldots, n$
5	$\|\|s\|\|_2 < eps(4)$
6	$\|\|F(x)\|\|_2 - \|\|F(x) - J(x)s\|\|_2 < eps(5)$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle	Type _TRNSPBC_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

Output Parameters

iter	INTEGER. Contains the current number of iterations.
st_cr	INTEGER. Contains the stop criterion. See the Description section for the parameter values and their meanings.
r1	REAL for strnlspbc_get DOUBLE PRECISION for dtrnlspbc_get Contains the residual, $(\|\|y - f(x)\|\|)$ given the initial x.
r2	REAL for strnlspbc_get DOUBLE PRECISION for dtrnlspbc_get Contains the final residual, that is, the value of the function $(\|\|y - f(x)\|\|)$ of the final x resulting from the algorithm operation.
res	INTEGER. Informs about the task completion. *res* = TR_SUCCESS - the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

?trnlspbc_delete

Releases allocated data.

Syntax

Fortran:

```
res = strnlspbc_delete(handle)
res = dtrnlspbc_delete(handle)
```

C:

```
res = strnlspbc_delete(&handle);
res = dtrnlspbc_delete(&handle);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?trnlspbc_delete routine releases all memory allocated for the handle.

NOTE This routine flags memory as not used, but to actually release all memory you must call the support function mkl_free_buffers.

Input Parameters

handle	Type _TRNSPBC_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

Output Parameters

res	INTEGER. Informs about the task completion. *res* = TR_SUCCESS means the routine completed the task normally. TR_SUCCESS is defined in the mkl_rci.h and mkl_rci.fi include files.

Jacobian Matrix Calculation Routines

This section describes routines that compute the Jacobian matrix using the central difference algorithm. Jacobian matrix calculation is required to solve a nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobian matrix have the "Black-Box" interfaces, where you pass the objective function via parameters. Your objective function must have a fixed interface.

Jacobian Matrix Calculation Routines

Routine Name	Operation
?jacobi_init	Initializes the solver.
?jacobi_solve	Computes the Jacobian matrix of the function on the basis of RCI using the central difference algorithm.
?jacobi_delete	Removes data.
?jacobi	Computes the Jacobian matrix of the fcn function using the central difference algorithm.
?jacobix	Presents an alternative interface for the ?jacobi function enabling you to pass additional data into the objective function.

?jacobi_init

Initializes the solver for Jacobian calculations.

Syntax

Fortran:

```
res = sjacobi_init(handle, n, m, x, fjac, esp)
res = djacobi_init(handle, n, m, x, fjac, esp)
```

C:

```
res = sjacobi_init(&handle, &n, &m, x, fjac, &eps);
res = djacobi_init(&handle, &n, &m, x, fjac, &eps);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The routine initializes the solver.

Input Parameters

n	INTEGER. Length of *x*.
m	INTEGER. Length of *F*.
x	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Array of size *n*. Vector, at which the function is evaluated.
eps	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Precision of the Jacobian matrix calculation.
fjac	REAL for sjacobi_init DOUBLE PRECISION for djacobi_init Array of size (*m*,*n*). Contains the Jacobian matrix of the function.

Output Parameters

handle	Data object of the _JACOBIMATRIX_HANDLE_t type in C/C++ and INTEGER*8 in FORTRAN.
res	INTEGER. Indicates task completion status. • *res* = TR_SUCCESS - the routine completed the task normally. • *res* = TR_INVALID_OPTION - there was an error in the input parameters. • *res* = TR_OUT_OF_MEMORY - there was a memory error. TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

?jacobi_solve

Computes the Jacobian matrix of the function using RCI and the central difference algorithm.

Syntax

Fortran:

```
res = sjacobi_solve(handle, f1, f2, RCI_Request)
res = djacobi_solve(handle, f1, f2, RCI_Request)
```

C:

```
res = sjacobi_solve(&handle, f1, f2, &RCI_Request);
res = djacobi_solve(&handle, f1, f2, &RCI_Request);
```

Include Files

- Fortran: mkl_rci.fi
- C: mkl_rci.h

Description

The ?jacobi_solve routine computes the Jacobian matrix of the function using RCI and the central difference algorothm.

See usage examples in FORTRAN and C in the examples\solver\source folder of your Intel MKL directory (sjacobi_rci_f.f, djacobi_rci_f.f and sjacobi_rci_c.c, djacobi_rci_c.c, respectively).

Input Parameters

handle	Type _JACOBIMATRIX_HANDLE_t in C/C++ and INTEGER*8 in FORTRAN.

Output Parameters

f1	REAL for sjacobi_solve DOUBLE PRECISION for djacobi_solve Contains the updated function values at *x* + *eps*.
f2	REAL for sjacobi_solve DOUBLE PRECISION for djacobi_solve Array of size *m*. Contains the updated function values at *x* - *eps*.
RCI_Request	INTEGER. Informs about the task completion. When equal to 0, the task has completed successfully. *RCI_Request*= 1 indicates that you should compute the function values at the current *x* point and put the results into *f1*. *RCI_Request*= 2 indicates that you should compute the function values at the current *x* point and put the results into *f2*.
res	INTEGER. Indicates the task completion status. • *res* = TR_SUCCESS - the routine completed the task normally. • *res* = TR_INVALID_OPTION - there was an error in the input parameters. TR_SUCCESS and TR_INVALID_OPTION are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

See Also

?jacobi_init

?jacobi_delete

Releases allocated data.

Syntax

Fortran:

```
res = sjacobi_delete(handle)
res = djacobi_delete(handle)
```

C:

```
res = sjacobi_delete(&handle);
```

```
res = djacobi_delete(&handle);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?jacobi_delete` routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function mkl_free_buffers.

Input Parameters

handle	Type `_JACOBIMATRIX_HANDLE_t` in C/C++ and `INTEGER*8` in FORTRAN.

Output Parameters

res	`INTEGER`. Informs about the task completion. *res* = `TR_SUCCESS` means the routine completed the task normally. `TR_SUCCESS` is defined in the `mkl_rci.h` and `mkl_rci.fi` include files.

?jacobi

Computes the Jacobian matrix of the objective function using the central difference algorithm.

Syntax

Fortran:

```
res = sjacobi(fcn, n, m, fjac, x, jac_eps)
res = djacobi(fcn, n, m, fjac, x, jac_eps)
```

C:

```
res = sjacobi(fcn, &n, &m, fjac, x, &jac_eps);
res = djacobi(fcn, &n, &m, fjac, x, &jac_eps);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?jacobi` routine computes the Jacobian matrix for function *fcn* using the central difference algorithm. This routine has a "Black-Box" interface, where you input the objective function via parameters. Your objective function must have a fixed interface.

See calling and usage examples in FORTRAN and C in the `examples\solver\source` folder of your Intel MKL directory (`ex_nlsqp_f.f`, `ex_nlsqp_bc_f.f` and `ex_nlsqp_c.c`, `ex_nlsqp_bc_c.c`, respectively).

Input Parameters

fcn	User-supplied subroutine to evaluate the function that defines the least squares problem. Call `fcn` (*m*, *n*, *x*, *f*) with the following parameters:

Parameter	Type	Description
Input Parameters		
m	INTEGER	Length of *f*
n	INTEGER	Length of *x*
x	REAL for sjacobi DOUBLE PRECISION for djacobi	Array of size *n*. Vector, at which the function is evaluated. The fcn function should not change this parameter.
Output Parameters		
f	REAL for sjacobix DOUBLE PRECISION for djacobix	Array of size *m*; contains the function values at *x*.

You need to declare fcn as EXTERNAL in the calling program.

n INTEGER. Length of *X*.

m INTEGER. Length of *F*.

x REAL for sjacobi
DOUBLE PRECISION for djacobi
Array of size *n*. Vector at which the function is evaluated.

eps REAL for sjacobi
DOUBLE PRECISION for djacobi
Precision of the Jacobian matrix calculation.

Output Parameters

fjac REAL for sjacobi
DOUBLE PRECISION for djacobi
Array of size (*m*,*n*). Contains the Jacobian matrix of the function.

res INTEGER. Indicates task completion status.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

See Also

?jacobix

?jacobix

Alternative interface for ?jacobi function for passing additional data into the objective function.

Syntax

Fortran:

```
res = sjacobix(fcn, n, m, fjac, x, jac_eps, user_data)
res = djacobix(fcn, n, m, fjac, x, jac_eps, user_data)
```

C:

```
res = sjacobix(fcn, &n, &m, fjac, x, &jac_eps, user_data);
res = djacobix(fcn, &n, &m, fjac, x, &jac_eps, user_data);
```

Include Files

- Fortran: `mkl_rci.fi`
- C: `mkl_rci.h`

Description

The `?jacobix` routine presents an alternative interface for the `?jacobi` function that enables you to pass additional data into the objective function *fcn*.

See calling and usage examples in FORTRAN and C in the `examples\solver\source` folder of your Intel MKL directory (`ex_nlsqp_f_x.f`, `ex_nlsqp_bc_f_x.f` and `ex_nlsqp_c_x.c`, `ex_nlsqp_bc_c_x.c`, respectively).

Input Parameters

fcn

User-supplied subroutine to evaluate the function that defines the least squares problem. Call `fcn` (*m*, *n*, *x*, *f*, *user_data*) with the following parameters:

Parameter	Type	Description
Input Parameters		
m	`INTEGER`	Length of *f*
n	`INTEGER`	Length of *x*
x	`REAL` for `sjacobix` `DOUBLE PRECISION` for `djacobix`	Array of size *n*. Vector, at which the function is evaluated. The `fcn` function should not change this parameter.
user_data	`INTEGER*8`, for Fortran	(Fortran) Your additional data, if any. Otherwise, a dummy argument.
	`void*`, for C	(C) Pointer to your additional data, if any. Otherwise, a dummy argument.
Output Parameters		
f	`REAL` for `sjacobix` `DOUBLE PRECISION` for `djacobix`	Array of size *m*; contains the function values at *x*.

You need to declare `fcn` as `EXTERNAL` in the calling program.

n

`INTEGER`. Length of *X*.

m

`INTEGER`. Length of *F*.

x

`REAL` for `sjacobix`
`DOUBLE PRECISION` for `djacobix`
Array of size *n*. Vector at which the function is evaluated.

eps

`REAL` for `sjacobix`
`DOUBLE PRECISION` for `djacobix`
Precision of the Jacobian matrix calculation.

user_data (Fortran) INTEGER*8. Contains your additional data. If there is no additional data, this is a dummy argument.
(C) void*. Pointer to your additional data. If there is no additional data, this is a dummy argument.

Output Parameters

fjac REAL for sjacobix
DOUBLE PRECISION for djacobix
Array of size (*m*,*n*). Contains the Jacobian matrix of the function.

res INTEGER. Indicates task completion status.

- *res* = TR_SUCCESS - the routine completed the task normally.
- *res* = TR_INVALID_OPTION - there was an error in the input parameters.
- *res* = TR_OUT_OF_MEMORY - there was a memory error.

TR_SUCCESS, TR_INVALID_OPTION, and TR_OUT_OF_MEMORY are defined in mkl_rci.fi (Fortran) and mkl_rci.h (C) include files.

15 Support Functions

Intel® Math Kernel Library (Intel® MKL) support functions are used to:

- retrieve information about the current Intel MKL version
- additionally control the number of threads
- handle errors
- test characters and character strings for equality
- measure user time for a process and elapsed CPU time
- measure CPU frequency
- free memory allocated by Intel MKL memory management software
- facilitate easy linking

Functions described below are subdivided according to their purpose into the following groups:

Version Information Functions

Threading Control Functions

Error Handling Functions

Equality Test Functions

Timing Functions

Memory Functions

Miscellaneous Utility Functions

Functions Supporting the Single Dynamic Library

Table "Intel MKL Support Functions" contains the list of support functions common for Intel MKL.

Intel MKL Support Functions

Function Name	Operation
Version Information Functions	
mkl_get_version	Returns information about the active library version.
mkl_get_version_string	Returns information about the library version string.
Threading Control Functions	
mkl_set_num_threads	Suggests the number of threads to use.
mkl_domain_set_num_threads	Suggests the number of threads for a particular function domain.
mkl_set_dynamic	Enables Intel MKL to dynamically change the number of threads.
mkl_get_max_threads	Inquires about the number of threads targeted for parallelism.
mkl_domain_get_max_threads	Inquires about the number of threads targeted for parallelism in different domains.
mkl_get_dynamic	Returns the current value of the MKL_DYNAMIC variable.
Error Handling Functions	

Function Name	Operation
xerbla	Handles error conditions for the BLAS, LAPACK, VSL, VML routines.
pxerbla	Handles error conditions for the ScaLAPACK routines.
Equality Test Functions	
lsame	Tests two characters for equality regardless of the case.
lsamen	Tests two character strings for equality regardless of the case.
Timing Functions	
second/dsecnd	Returns user time for a process.
mkl_get_cpu_clocks	Returns full precision elapsed CPU clocks.
mkl_get_cpu_frequency	Returns CPU frequency value in GHz.
mkl_get_max_cpu_frequency	Returns the maximum CPU frequency value in GHz.
mkl_get_clocks_frequency	Returns the frequency value in GHz based on constant-rate Time Stamp Counter.
Memory Functions	
mkl_free_buffers	Frees memory buffers.
mkl_thread_free_buffers	Frees memory buffers allocated only in the current thread.
mkl_mem_stat	Reports an amount of memory utilized by Intel MKL memory management software.
mkl_disable_fast_mm	Enables Intel MKL to dynamically turn off memory management.
mkl_malloc	Allocates the aligned memory buffer.
mkl_free	Frees the aligned memory buffer allocated by MKL_malloc.
Miscellaneous Utility Functions	
mkl_progress	Tracks computational progress of selective MKL routines.
mkl_enable_instructions	Allows Intel MKL to dispatch Intel® Advanced Vector Extensions (Intel® AVX) if run on the respective hardware (or simulation).
Functions Supporting the Single Dynamic Library (SDL)	
mkl_set_interface_layer	Sets the interface layer for Intel MKL at run time.
mkl_set_threading_layer	Sets the threading layer for Intel MKL at run time.
mkl_set_xerbla	Replaces the error handling routine. Use with SDL on Windows* OS.
mkl_set_progress	Replaces the progress information routine. Use with SDL on Windows* OS.

Version Information Functions

Intel® MKL provides two methods for extracting information about the library version number:

- extracting a version string using the `mkl_get_version_string` function
- using the `mkl_get_version` function to obtain an `MKLVersion` structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

mkl_get_version

Returns information about the active library C version.

Syntax

```
void mkl_get_version( MKLVersion* pVersion );
```

Include Files

- C: `mkl_service.h`

Output Parameters

pVersion	Pointer to the `MKLVersion` structure.

Description

The `mkl_get_version` function collects information about the active C version of the Intel MKL software and returns this information in a structure of `MKLVersion` type by the *pVersion* address. The `MKLVersion` structure type is defined in the `mkl_types.h` file. The following fields of the `MKLVersion` structure are available:

`MajorVersion`	is the major number of the current library version.
`MinorVersion`	is the minor number of the current library version.
`UpdateVersion`	is the update number of the current library version.
`ProductStatus`	is the status of the current library version. Possible variants could be “Beta”, “Product”.
`Build`	is the string that contains the build date and the internal build number.
`Processor`	is the processor optimization that is targeted for the specific processor. It is not the definition of the processor installed in the system, rather the MKL library detection that is optimal for the processor installed in the system.

NOTE `MKLGetVersion` is an obsolete name for the `mkl_get_version` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

Optimization Notice
use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

mkl_get_version Usage

```
--------------------------------------------------------------------------------
#include <stdio.h>
#include <stdlib.h>
#include "mkl_service.h"

int main(void)
  {
    MKLVersion Version;

    mkl_get_version(&Version);

  //  MKL_Get_Version(&Version);

    printf("Major version:           %d\n",Version.MajorVersion);
    printf("Minor version:           %d\n",Version.MinorVersion);
    printf("Update version:          %d\n",Version.UpdateVersion);
    printf("Product status:          %s\n",Version.ProductStatus);
    printf("Build:                   %s\n",Version.Build);
    printf("Processor optimization:  %s\n",Version.Processor);
    printf("================================================================\n");
    printf("\n");

    return 0;
  }
```

Output:

Major Version	9
Minor Version	0
Update Version	0
Product status	Product
Build	061909.09
Processor optimization	Intel® Xeon® Processor with Intel® 64 architecture

mkl_get_version_string

Gets the library version string.

Syntax

Fortran:

```
call mkl_get_version_string( buf )
```

C:

```
mkl_get_version_string( buf, len );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Output Parameters

Name	Type	Description
buf	**FORTRAN:** `CHARACTER*198` **C:** `char*`	Source string
len	**FORTRAN:** `INTEGER` **C:** `int`	Length of the source string

Description

The function returns a string that contains the library version information.

NOTE `MKLGetVersionString` is an obsolete name for the `mkl_get_version_string` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

See example below:

Examples

Fortran Example

```
program mkl_get_version_string

character*198  buf

call mkl_get_version_string(buf)
write(*,'(a)') buf

end
```

C Example

```
#include <stdio.h>
#include "mkl_service.h"

int main(void)
{
  int len=198;
  char buf[198];
  mkl_get_version_string(buf, len);
  printf("%s\n",buf);
```

```
  printf("\n");
  return 0;
}
```

Threading Control Functions

Intel® MKL provides optional threading control functions that take precedence over OpenMP* environment variable settings with the same purpose (see *Intel® MKL User's Guide* for details).

These functions enable you to specify the number of threads for Intel MKL independently of the OpenMP* settings and takes precedence over them. Although Intel MKL may actually use a different number of threads from the number suggested, the controls also enable you to instruct the library to try using the suggested number when the number used in the calling application is unavailable.

See the following examples of Fortran and C usage:

Fortran Usage

```
call mkl_set_num_threads( foo )
ierr = mkl_domain_set_num_threads( num, MKL_DOMAIN_BLAS )
call mkl_set_dynamic ( 1 )
num = mkl_get_max_threads()
num = mkl_domain_get_max_threads( MKL_DOMAIN_BLAS );
ret = mkl_get_dynamic()
```

C Usage

```
#include "mkl.h"  // Mandatory to make these definitions work!
mkl_set_num_threads(num);
return_code = mkl_domain_set_num_threads( num, MKL_DOMAIN_FFT );
mkl_set_dynamic( 1 );
num = mkl_get_max_threads();
num = mkl_domain_get_max_threads( MKL_DOMAIN_FFT );
return_code = mkl_get_dynamic();
```

NOTE Always remember to add `#include "mkl.h"` to use the C usage syntax.

mkl_set_num_threads

Suggests the number of threads to use.

Syntax

Fortran:

```
call mkl_set_num_threads( number )
```

C:

```
void mkl_set_num_threads( number );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

Name	Type	Description
number	**FORTRAN:** INTEGER **C:** int	Number of threads suggested by user

Description

This function allows you to specify how many threads Intel MKL should use. The number is a hint, and there is no guarantee that exactly this number of threads will be used. Enter a positive integer. This routine takes precedence over the MKL_NUM_THREADS environment variable.

NOTE Always remember to add #include "mkl.h" to use the C usage syntax.

See *Intel MKL User's Guide* for implementation details.

mkl_domain_set_num_threads

Suggests the number of threads for a particular function domain.

Syntax

Fortran:

```
ierr = mkl_domain_set_num_threads( num, mask )
```

C:

```
ierr = mkl_domain_set_num_threads( num, mask );
```

Include Files

- FORTRAN 77: mkl_service.fi
- C: mkl_service.h

Input Parameters

Name	Type	Description
num	**FORTRAN:** INTEGER **C:** int	Number of threads suggested by user
mask	**FORTRAN:** INTEGER **C:** int	Name of the targeted domain

Description

This function allows you to request different domains of Intel MKL to use different numbers of threads. The currently supported domains are:

- MKL_DOMAIN_BLAS - BLAS
- MKL_DOMAIN_FFT - FFT (excluding cluster FFT)
- MKL_DOMAIN_VML - Vector Math Library
- MKL_DOMAIN_PARDISO - PARDISO
- MKL_DOMAIN_ALL - another way to do what mkl_set_num_threads does

This is only a hint, and use of this number of threads is not guaranteed. Enter a valid domain and a positive integer for the number of threads. This routine has precedence over the MKL_DOMAIN_NUM_THREADS environment variable.

See *Intel MKL User's Guide* for implementation details.

Return Values

1(true)	Indicates no error, execution is successful.
0(false)	Indicates failure, possibly because the inputs were invalid.

mkl_set_dynamic

Enables Intel MKL to dynamically change the number of threads.

Syntax

Fortran:

```
call mkl_set_dynamic( boolean_var )
```

C:

```
void mkl_set_dynamic( boolean_var );
```

Include Files

- FORTRAN 77: mkl_service.fi
- C: mkl_service.h

Input Parameters

Name	Type	Description
boolean_var	**FORTRAN:** INTEGER **C:** int	The parameter that determines whether dynamic adjustment of the number of threads is enabled or disabled.

Description

This function indicates whether or not Intel MKL can dynamically change the number of threads. The default for this is true, regardless of how the OMP_DYNAMIC variable is set. This will also hold precedent over the OMP_DYNAMIC variable.

A value of false does not guarantee that the user's requested number of threads will be used. But it means that Intel MKL will attempt to use that value. This routine takes precedence over the environment variable MKL_DYNAMIC.

Note that if Intel MKL is called from within a parallel region, Intel MKL may not thread unless MKL_DYNAMIC is set to false, either with the environment variable or by this routine call.

See *Intel MKL User's Guide* for implementation details.

mkl_get_max_threads

Inquires about the number of threads targeted for parallelism.

Syntax

Fortran:

```
num = mkl_get_max_threads()
```

C:

```
num = mkl_get_max_threads();
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Description

This function allows you to inquire independently of OpenMP* how many threads Intel MKL is targeting for parallelism. The number is a hint, and there is no guarantee that exactly this number of threads will be used.

See *Intel MKL User's Guide* for implementation details.

Return Values

The output is `INTEGER` equal to the number of threads.

mkl_domain_get_max_threads

Inquires about the number of threads targeted for parallelism in different domains.

Syntax

Fortran:

```
ierr = mkl_domain_get_max_threads( mask )
```

C:

```
ierr = mkl_domain_get_max_threads( mask );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

Name	Type	Description
mask	**FORTRAN:** `INTEGER` **C:** `int`	The name of the targeted domain

Description

This function allows the user of different domains of Intel MKL to inquire what number of threads is being used as a hint. The inquiry does not imply that this is the actual number of threads used. The number may vary depending on the value of the `MKL_DYNAMIC` variable and/or problem size, system resources, etc. But the function returns the value that MKL is targeting for a given domain.

The currently supported domains are:

- `MKL_DOMAIN_BLAS` - BLAS

- MKL_DOMAIN_FFT - FFT (excluding cluster FFT)
- MKL_DOMAIN_VML - Vector Math Library
- MKL_DOMAIN_PARDISO - PARDISO
- MKL_DOMAIN_ALL - another way to do what mkl_get_max_threads does.

You are supposed to enter a valid domain.

See *Intel MKL User's Guide* for implementation details.

Return Values

Returns the hint about the number of threads for a given domain.

mkl_get_dynamic

Returns current value of MKL_DYNAMIC *variable.*

Syntax

Fortran:

```
ret = mkl_get_dynamic()
```

C:

```
ret = mkl_get_dynamic();
```

Include Files

- FORTRAN 77: mkl_service.fi
- C: mkl_service.h

Description

This function returns the current value of the MKL_DYNAMIC variable. This variable can be changed by manipulating the MKL_DYNAMIC environment variable before the Intel MKL run is launched or by calling mkl_set_dynamic(). Doing the latter has precedence over the former.

The function returns a value of 0 or 1: 1 indicates that MKL_DYNAMIC is true, 0 indicates that MKL_DYNAMIC is false. This variable indicates whether or not Intel MKL can dynamically change the number of threads. A value of false does not guarantee that the number of threads you requested will be used. But it means that Intel MKL will attempt to use that value.

Note that if Intel MKL is called from within a parallel region, Intel MKL may not thread unless MKL_DYNAMIC is set to false, either with the environment variable or by this routine call.

See *Intel MKL User's Guide* for implementation details.

Return Values

1	Indicates MKL_DYNAMIC is true.
0	Indicates MKL_DYNAMIC is false.

Error Handling Functions

xerbla

Error handling routine called by BLAS, LAPACK, VML, VSL routines.

Syntax

Fortran:

```
call xerbla( srname, info )
```

C:

```
xerbla( srname, info, len );
```

Include Files

- FORTRAN 77: `mkl_blas.fi`
- C: `mkl_blas.h`

Input Parameters

Name	Type	Description
srname	**FORTRAN:** `CHARACTER*(*)` **C:** `char*`	The name of the routine that called `xerbla`
info	**FORTRAN:** `INTEGER` **C:** `int*`	The position of the invalid parameter in the parameter list of the calling routine
len	**C:** `int`	Length of the source string

Description

The routine `xerbla` is an error handler for the BLAS, LAPACK, VSL, and VML routines. It is called by a BLAS, LAPACK, VSL or VML routine if an input parameter has an invalid value. If an issue is found with an input parameter, `xerbla` prints a message similar to the following:

```
MKL ERROR: Parameter 6 was incorrect on entry to DGEMM
```

and then returns to your application. Comments in the LAPACK reference code (http://www.netlib.org/lapack/explore-html/xerbla.f.html) suggest this behavior though the LAPACK User's Guide recommends that the execution should stop when an error is found.

Note that `xerbla` is an internal function. You can change or disable printing of an error message by providing your own `xerbla` function. See the FORTRAN and C examples below.

Examples

```
subroutine xerbla (srname, info)

character*(*) srname  !Name of subprogram that called xerbla

integer*4     info    !Position of the invalid parameter in the
parameter list

return                !Return to the calling subprogram

end
```

```
void xerbla(char* srname, int* info, int len){
// srname - name of the function that called xerbla
// info - position of the invalid parameter in the parameter list
// len - length of the name in bytes
printf("\nXERBLA is called :%s: %d\n",srname,*info);
}
```

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

`call pxerbla(`*`ictxt`*`, `*`srname`*`, `*`info`*`)`

Include Files

- C: `mkl_scalapack.h`

Input Parameters

`ictxt`	(global) `INTEGER` The BLACS context handle, indicating the global context of the operation. The context itself is global.
`srname`	(global) `CHARACTER*6` The name of the routine which called `pxerbla`.
`info`	(global) `INTEGER`. The position of the invalid parameter in the parameter list of the calling routine.

Description

This routine is an error handler for the *ScaLAPACK* routines. It is called if an input parameter has an invalid value. A message is printed and program execution continues. For ScaLAPACK driver and computational routines, a `RETURN` statement is issued following the call to `pxerbla`.

Control returns to the higher-level calling routine, and you can determine how the program should proceed. However, in the specialized low-level ScaLAPACK routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `pxerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a nonzero value of *`info`* on return from a ScaLAPACK routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Equality Test Functions

lsame

Tests two characters for equality regardless of the case.

Syntax

Fortran:

```
val = lsame( ca, cb )
```

C:

```
val = lsame( ca, cb );
```

Include Files

- FORTRAN 77: `mkl_blas.fi`
- C: `mkl_blas.h`

Input Parameters

Name	Type	Description
ca, *cb*	**FORTRAN:** `CHARACTER*1`	**FORTRAN:** The single characters to be compared
	C: `const char*`	**C:** Pointers to the single characters to be compared

Output Parameters

Name	Type	Description
val	**FORTRAN:** `LOGICAL`	Result of the comparison
	C: `int`	

Description

This logical function returns `.TRUE.` if *ca* is the same letter as *cb* regardless of the case, and `.FALSE.` otherwise.

lsamen

Tests two character strings for equality regardless of the case.

Syntax

Fortran:

```
val = lsamen( n, ca, cb )
```

C:

```
val = lsamen( n, ca, cb );
```

Include Files

- FORTRAN 77: `mkl_lapack.fi`
- C: `mkl_lapack.h`

Input Parameters

Name	Type	Description
n	**FORTRAN:** `INTEGER`	**FORTRAN:** The number of characters in *ca* and *cb* to be compared.

Name	Type	Description
	C: `const int*`	**C:** Pointer to the number of characters in *ca* and *cb* to be compared.
ca, *cb*	**FORTRAN:** `CHARACTER*(*)` **C:** `const char*`	Specify two character strings of length at least *n* to be compared. Only the first *n* characters of each string will be accessed.

Output Parameters

Name	Type	Description
val	**FORTRAN:** `LOGICAL` **C:** `int`	**FORTRAN:** Result of the comparison. `.TRUE.` if *ca* and *cb* are equivalent except for the case, and `.FALSE.` otherwise. The function also returns `.FALSE.` if `len`(*ca*) or `len`(*cb*) is less than *n*. **C:** Result of the comparison. Non-zero if *ca* and *cb* are equivalent except for the case, and zero otherwise.

Description

This logical function tests if the first *n* letters of one string are the same as the first *n* letters of another string, regardless of the case.

Timing Functions

second/dsecnd

Returns elapsed CPU time in seconds.

Syntax

Fortran:

```
val = second()
val = dsecnd()
```

C:

```
val = second();
val = dsecnd();
```

Include Files

- FORTRAN 77: `mkl_lapack.fi`
- C: `mkl_lapack.h`

Output Parameters

Name	Type	Description
val	**FORTRAN:** `REAL` for `second` `DOUBLE PRECISION` for `dsecnd`	Elapsed CPU time in seconds

Name	Type	Description
	C: `float` for `second` `double` for `dsecnd`	

Description

The `second`/`dsecnd` functions return the elapsed CPU time in seconds. The difference between these functions is that `dsecnd` returns the result with double precision.

Apply each function in pairs: the first time, directly before a call to the routine to be measured, and the second time - after the measurement. The difference between the returned values is the time spent in the routine.

The `second`/`dsecnd` functions get the time from the elapsed CPU clocks divided by frequency. Obtaining the frequency may take some time when the `second`/`dsecnd` function runs for the first time. To eliminate the effect of this extra time on your measurements, make the first call to `second`/`dsecnd` in advance.

Do not use `second` for measuring short time intervals because the single-precision format is not capable of holding sufficient timer precision.

mkl_get_cpu_clocks

Returns full precision elapsed CPU clocks.

Syntax

Fortran:

```
call mkl_get_cpu_clocks( clocks )
```

C:

```
mkl_get_cpu_clocks( &clocks );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Output Parameters

Name	Type	Description
clocks	**FORTRAN:** `INTEGER*8`	Elapsed CPU clocks
	C: `unsigned MKL_INT64`	

Description

The `mkl_get_cpu_clocks` function returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `mkl_get_cpu_clocks` function is also applied in pairs like `second/dsecnd`. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

NOTE `getcpuclocks` is an obsolete name for the `mkl_get_cpu_clocks` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_get_cpu_frequency

Returns the current CPU frequency value in GHz.

Syntax

Fortran:

```
freq = mkl_get_cpu_frequency()
```

C:

```
freq = mkl_get_cpu_frequency();
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Output Parameters

Name	Type	Description
freq	**FORTRAN:** `DOUBLE PRECISION` **C:** `double`	Current CPU frequency value in GHz

Description

The function `mkl_get_cpu_frequency` returns the current CPU frequency in GHz.

NOTE `getcpufrequency` is an obsolete name for the `mkl_get_cpu_frequency` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_get_max_cpu_frequency

Returns the maximum CPU frequency value in GHz.

Syntax

Fortran:

```
freq = mkl_get_max_cpu_frequency()
```

C:

```
freq = mkl_get_max_cpu_frequency();
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Output Parameters

Name	Type	Description
freq	**FORTRAN:** `DOUBLE PRECISION`	Maximum CPU frequency value in GHz
	C: `double`	

Description

The function `mkl_get_max_cpu_frequency` returns the maximum CPU frequency in GHz.

mkl_get_clocks_frequency

Returns the frequency value in GHz based on constant-rate Time Stamp Counter.

Syntax

Fortran:

```
freq = mkl_get_clocks_frequency()
```

C:

```
freq = mkl_get_clocks_frequency();
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Output Parameters

Name	Type	Description
freq	**FORTRAN:** `DOUBLE PRECISION`	Frequency value in GHz
	C: `double`	

Description

The function `mkl_get_clocks_frequency` returns the CPU frequency value (in GHz) based on constant-rate Time Stamp Counter (TSC). Use of the constant-rate TSC ensures that each clock tick is constant even if the CPU frequency changes. Therefore, the returned frequency is constant.

NOTE Obtaining the frequency may take some time when `mkl_get_clocks_frequency` is called for the first time. The same holds for functions `second/dsecnd`, which call `mkl_get_clocks_frequency`.

See Also

second/dsecnd

Memory Functions

This section describes the Intel MKL memory support functions. See the *Intel© MKL User's Guide* for details of the Intel MKL memory management.

mkl_free_buffers

Frees memory buffers.

Syntax

Fortran:

```
call mkl_free_buffers
```

C:

```
mkl_free_buffers();
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Description

The `mkl_free_buffers` function frees the memory allocated by the Intel MKL memory management software. The memory management software allocates new buffers if no free buffers are currently available. Call `mkl_free_buffers()` to free all memory buffers and to avoid memory leaking on completion of work with the Intel MKL functions, that is, after the last call of an Intel MKL function from your application.

See *Intel© MKL User's Guide* for details.

NOTE `MKL_FreeBuffers` is an obsolete name for the `mkl_free_buffers` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_free_buffers Usage with FFT Functions

```
-------------------------------------------------------------------------------------------
DFTI_DESCRIPTOR_HANDLE hand1;
DFTI_DESCRIPTOR_HANDLE hand2;
void mkl_free_buffers(void);
. . . . . .
/* Using MKL FFT */
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
. . . . . .
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
. . . . . .
Status = DftiFreeDescriptor(&hand1);
/* Do not call mkl_free_buffers() here as the hand2 descriptor will be corrupted!  */
. . . . . .
Status = DftiComputeBackward(hand2, s_array2));
Status = DftiFreeDescriptor(&hand2);

/* Here user finishes the MKL FFT usage */
/* Memory leak will be triggered by any memory control tool */

/* Use mkl_free_buffers() to avoid memory leaking */
mkl_free_buffers();

-------------------------------------------------------------------------------------------
```

If the memory space is sufficient, use `mkl_free_buffers` after the last call of the MKL functions. Otherwise, a drop in performance can occur due to reallocation of buffers for the subsequent MKL functions.

WARNING For FFT calls, do not use `mkl_free_buffers` between `DftiCreateDescriptor(hand)` and `DftiFreeDescriptor(&hand)`.

mkl_thread_free_buffers

Frees memory buffers allocated in the current thread.

Syntax

Fortran:

```
call mkl_thread_free_buffers
```

C:

```
mkl_thread_free_buffers();
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Description

The `mkl_thread_free_buffers` function frees the memory allocated by the Intel MKL memory management in the current thread only. Memory buffers allocated in other threads are not affected. Call `mkl_thread_free_buffers()` to avoid memory leaking if you are unable to call the `mkl_free_buffers` function in the multi-threaded application when you are not sure if all the other running Intel MKL functions completed operation.

mkl_disable_fast_mm

Enables Intel MKL to dynamically turn off memory management.

Syntax

Fortran:

```
mm = mkl_disable_fast_mm
```

C:

```
mm = mkl_disable_fast_mm();
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Description

The Intel MKL memory management software is turned on by default. To turn it off dynamically before any Intel MKL function call, you can use the `mkl_disable_fast_mm` function similarly to the `MKL_DISABLE_FAST_MM` environment variable (See *Intel© MKL User's Guide* for details.) Run `mkl_disable_fast_mm` function to allocate and free memory from call to call. Note that disabling the Intel MKL memory management software negatively impacts performance of some Intel MKL routines, especially for small problem sizes.

The function return value 1 indicates that the Intel MKL memory management was turned off successfully. The function return value 0 indicates a failure.

mkl_mem_stat

Reports amount of memory utilized by Intel MKL memory management software.

Syntax

Fortran:

```
AllocatedBytes = mkl_mem_stat( AllocatedBuffers )
```

C:

```
AllocatedBytes = mkl_mem_stat( &AllocatedBuffers );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Output Parameters

Name	Type	Description
AllocatedBytes	**FORTRAN:** `INTEGER*8` **C:** `MKL_INT64`	Amount of allocated bytes
AllocatedBuffers	**FORTRAN:** `INTEGER*4`, **C:** `int`	Number of allocated buffers

Description

The function returns the amount of the allocated memory in the *AllocatedBuffers* buffers. If there are no allocated buffers at the moment, the function returns 0. Call the `mkl_mem_stat()` function to check the Intel MKL memory status.

Note that after calling `mkl_free_buffers` there should not be any allocated buffers.

See Example "mkl_malloc(), mkl_free(), mkl_mem_stat() Usage".

NOTE `MKL_MemStat` is an obsolete name for the `MKL_Mem_Stat` function that is referenced in the library for back compatibility purposes but is deprecated and subject to removal in subsequent releases.

mkl_malloc

Allocates the aligned memory buffer.

Syntax

Fortran:

```
a_ptr = mkl_malloc( alloc_size, alignment )
```

C:

```
a_ptr = mkl_malloc( alloc_size, alignment );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

Name	Type	Description
alloc_size	**FORTRAN:** `INTEGER*4` **C:** `size_t`	Size of the buffer to be allocated Note that Fortran type `INTEGER*4` is given for the 32-bit systems. Otherwise, it is `INTEGER*8`.
alignment	**FORTRAN:** `INTEGER*4`	Alignment of the allocated buffer

Name	Type	Description
	C: `int`	

Output Parameters

Name	Type	Description
a_ptr	**FORTRAN:** `POINTER`	Pointer to the allocated buffer
	C: `void*`	

Description

The function allocates a *size*-bytes buffer, aligned on the *alignment* boundary, and returns a pointer to this buffer.

The function returns `NULL` if *size* < 1. If alignment is not power of 2, the alignment 32 is used.

See Example "mkl_malloc(), mkl_free(), mkl_mem_stat() Usage".

mkl_free

Frees the aligned memory buffer allocated by `mkl_malloc`.

Syntax

Fortran:

```
call mkl_free( a_ptr )
```

C:

```
mkl_free( a_ptr );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

Name	Type	Description
a_ptr	**FORTRAN:** `POINTER`	Pointer to the buffer to be freed
	C: `void*`	

Description

The function frees the buffer pointed by *ptr* and allocated by `mkl_malloc()`.

See Example "mkl_malloc(), mkl_free(), mkl_mem_stat() Usage".

Examples of mkl_malloc(), mkl_free(), mkl_mem_stat() Usage

Usage Example in Fortran

```
 PROGRAM FOO

 REAL*8     A,B,C
```

```
  POINTER    (A_PTR,A(1)), (B_PTR,B(1)), (C_PTR,C(1)
  INTEGER    N, I
  REAL*8     ALPHA, BETA
  INTEGER*8  ALLOCATED_BYTES
  INTEGER*4  ALLOCATED_BUFFERS

  #ifdef _SYSTEM_BITS32
        INTEGER*4 MKL_MALLOC
        INTEGER*4 ALLOC_SIZE
  #else
        INTEGER*8 MKL_MALLOC
        INTEGER*8 ALLOC_SIZE
  #endif

  INTEGER    MKL_MEM_STAT
  EXTERNAL   MKL_MALLOC, MKL_FREE, MKL_MEM_STAT

  ALPHA = 1.1; BETA = -1.2
  N = 1000
  ALLOC_SIZE = 8*N*N
  A_PTR = MKL_MALLOC(ALLOC_SIZE,64)
  B_PTR = MKL_MALLOC(ALLOC_SIZE,64)
  C_PTR = MKL_MALLOC(ALLOC_SIZE,64)
  DO I=1,N*N
    A(I) = I
    B(I) = -I
    C(I) = 0.0
  END DO

  CALL DGEMM('N','N',N,N,N,ALPHA,A,N,B,N,BETA,C,N);

  ALLOCATED_BYTES = MKL_MEM_STAT(ALLOCATED_BUFFERS)
  PRINT *,'DGEMM uses ',ALLOCATED_BYTES,' bytes in ',
 $  ALLOCATED_BUFFERS,' buffers '

  CALL MKL_FREE_BUFFERS

  ALLOCATED_BYTES = MKL_MEM_STAT(ALLOCATED_BUFFERS)
  IF (ALLOCATED_BYTES > 0) THEN
    PRINT *,'MKL MEMORY LEAK!'
    PRINT *,'AFTER MKL_FREE_BUFFERS there are ',
 $    ALLOCATED_BYTES,' bytes in ',
 $    ALLOCATED_BUFFERS,' buffers'
  END IF

  CALL MKL_FREE(A_PTR)
  CALL MKL_FREE(B_PTR)
  CALL MKL_FREE(C_PTR)

  STOP
  END
```

Usage Example in C

```
#include <stdio.h>
#include <mkl.h>
int main(void) {
  double *a, *b, *c;
  int n, i;
  double alpha, beta;
  MKL_INT64 AllocatedBytes;
  int N_AllocatedBuffers;

  alpha = 1.1; beta = -1.2;
  n = 1000;
  a = (double*)mkl_malloc(n*n*sizeof(double),64);
  b = (double*)mkl_malloc(n*n*sizeof(double),64);
  c = (double*)mkl_malloc(n*n*sizeof(double),64);
  for (i=0;i<(n*n);i++) {
     a[i] = (double)(i+1);
     b[i] = (double)(-i-1);
```

```
    c[i] = 0.0;
  }

  dgemm("N","N",&n,&n,&n,&alpha,a,&n,b,&n,&beta,c,&n);

  AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
  printf("\nDGEMM uses %ld bytes in %d buffers",(long)AllocatedBytes,N_AllocatedBuffers);

  mkl_free_buffers();

  AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
  if (AllocatedBytes > 0) {
      printf("\nMKL memory leak!");
      printf("\nAfter mkl_free_buffers there are %ld bytes in %d buffers",
         (long)AllocatedBytes,N_AllocatedBuffers);
  }

  mkl_free(a);
  mkl_free(b);
  mkl_free(c);

  return 0;
}
```

Miscellaneous Utility Functions

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

mkl_progress

Provides progress information.

Syntax

Fortran:

```
stopflag = mkl_progress( thread, step, stage )
```

C:

```
stopflag = mkl_progress( thread, step, stage, lstage );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_lapack.h` and `mkl_service.h`

Input Parameters

Name	Type	Description
thread	**FORTRAN:** `INTEGER*4` **C:** `const int*`	**FORTRAN:** The number of the thread the progress routine is called from. 0 is passed for sequential code.

Name	Type	Description
		C: Pointer to the number of the thread the progress routine is called from. 0 is passed for sequential code.
step	**FORTRAN:** INTEGER*4 **C:** const int*	**FORTRAN:** The linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation. **C:** Pointer to the linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.
stage	**FORTRAN:** CHARACTER*(*) **C:** const char*	Message indicating the name of the routine or the name of the computation stage the progress routine is called from.
lstage	**C:** int	The length of a stage string excluding the trailing NULL character.

Output Parameters

Name	Type	Description
stopflag	**FORTRAN:** INTEGER **C:** int	The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value.

Description

The mkl_progress function is intended to track progress of a lengthy computation and/or interrupt the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. You can set it to perform certain operations during the routine computation, for instance, to print a progress indicator. A non-zero return value may be supplied by the redefined function to break the computation.

The progress function mkl_progress is regularly called from some LAPACK and DSS/PARDISO functions during the computation. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not.

Application Notes

Note that mkl_progress is a Fortran routine, that is, to redefine the progress routine from C, the name should be spelt differently, parameters should be passed by reference, and an extra parameter meaning the length of the stage string should be considered. The stage string is not terminated with the NULL character. The C interface of the progress routine is as follows:

```
int mkl_progress_( int* thread, int* step, char* stage, int lstage ); // Linux, Mac
int MKL_PROGRESS( int* thread, int* step, char* stage, int lstage ); // Windows
```

See further the examples of printing a progress information on the standard output in Fortran and C languages:

Examples

Fortran example:

```
integer function mkl_progress( thread, step, stage )
integer*4 thread, step
character*(*) stage
print*,'Thread:',thread,',stage:',stage,',step:',step
mkl_progress = 0
return
end
```

C example:

```
#include <stdio.h>
#include <string.h>
#define BUFLEN 16
int mkl_progress_( int* ithr, int* step, char* stage, int lstage )
{
  char buf[BUFLEN];
  if( lstage >= BUFLEN ) lstage = BUFLEN-1;
  strncpy( buf, stage, lstage );
  buf[lstage] = '\0';
  printf( "In thread %i, at stage %s, steps passed %i\n", *ithr, buf, *step );
  return 0;
}
```

mkl_enable_instructions

Allows dispatching Intel® Advanced Vector Extensions.

Syntax

Fortran:

```
irc = mkl_enable_instructions(MKL_AVX_ENABLE)
```

C:

```
irc = mkl_enable_instructions(MKL_AVX_ENABLE);
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

MKL_AVX_ENABLE	Parameter indicating which new instructions the user needs to enable.

Output Parameters

Name	Type	Description	
irc	**FORTRAN:** `INTEGER*4` **C:** `int`	Value reflecting AVX usage status:	
		=1	MKL uses the AVX code, if the hardware supports Intel® AVX.
		=0	The request is rejected. Most likely, `mkl_enable_instructions` has been called after another Intel MKL function.

Description

This function is currently void and deprecated but can be used in future Intel MKL releases.

NOTE Always remember to add `#include "mkl.h"` to use the C usage syntax.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on

Functions Supporting the Single Dynamic Library

Intel® MKL provides the Single Dynamic Library (SDL), which enables setting the interface and threading layer for Intel MKL at run time. See *Intel® MKL User's Guide* for details of SDL and layered model concept. This section describes the functions supporting SDL.

mkl_set_interface_layer

Sets the interface layer for Intel MKL at run time. Use with the Single Dynamic Library.

Syntax

Fortran:

```
interface = mkl_set_interface_layer( required_interface )
```

C:

```
interface = mkl_set_interface_layer( required_interface );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

Name	Type	Description
required_interface	**FORTRAN:** `INTEGER` **C:** `int`	Determines the interface layer. Possible values: `MKL_INTERFACE_LP64` for the LP64 interface. `MKL_INTERFACE_ILP64` for the ILP64 interface.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_interface_layer` function sets LP64 or ILP64 interface for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_threading_layer`. You can call `mkl_set_interface_layer` and `mkl_set_threading_layer` in any order.

The `mkl_set_interface_layer` function takes precedence over the `MKL_INTERFACE_LAYER` environment variable.

See *Intel MKL User's Guide* for the layered model concept and usage details of SDL.

mkl_set_threading_layer

Sets the threading layer for Intel MKL at run time. Use with the Single Dynamic Library (SDL).

Syntax

Fortran:

```
threading = mkl_set_threading_layer( required_threading )
```

C:

```
threading = mkl_set_threading_layer( required_threading );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

Name	Type	Description
required_threading	**FORTRAN:** `INTEGER` **C:** `int`	Determines the threading layer. Possible values: `MKL_THREADING_INTEL` for Intel threading. `MKL_THREADING_SEQUENTIAL` for the sequential mode of Intel MKL. `MKL_THREADING_PGI` for PGI threading on Windows* or Linux* operating system only. `MKL_THREADING_GNU` for GNU threading on Linux* operating system only.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_threading_layer` function sets the specified threading layer for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_interface_layer`.

You can call `mkl_set_threading_layer` and `mkl_set_interface_layer` in any order.

The `mkl_set_threading_layer` function takes precedence over the `MKL_THREADING_LAYER` environment variable.

See *Intel MKL User's Guide* for the layered model concept and usage details of SDL.

mkl_set_xerbla

Replaces the error handling routine. Use with the Single Dynamic Library on Windows OS.*

Syntax

Fortran:

```
old_xerbla_ptr = mkl_set_xerbla( new_xerbla_ptr )
```

C:

```
old_xerbla_ptr = mkl_set_xerbla( new_xerbla_ptr );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

Name	Type	Description
new_xerbla_ptr	XerblaEntry	Pointer to the error handling routine to be used.

Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows* OS, the `mkl_set_xerbla` function replaces the error handling routine that is called by Intel MKL functions with the routine specified by the parameter.

See *Intel MKL User's Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced error handling routine.

See Also

xerbla

mkl_set_progress

Replaces the progress information routine. Use with the Single Dynamic Library (SDL) on Windows OS.*

Syntax

Fortran:

```
old_progress_ptr mkl_set_progress( new_progress_ptr )
```

C:

```
old_progress_ptr mkl_set_progress( new_progress_ptr );
```

Include Files

- FORTRAN 77: `mkl_service.fi`
- C: `mkl_service.h`

Input Parameters

Name	Type	Description
new_progress_ptr	ProgressEntry	Pointer to the progress information routine to be used.

Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows* OS, the `mkl_set_progress` function replaces the currently used progress information routine with the routine specified by the parameter.

See *Intel MKL User's Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced progress information routine.

mkl_progress

BLACS Routines 16

This chapter describes the Intel® Math Kernel Library implementation of FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel MKL intended for the Linux* and Windows* OSs as the communication layer of ScaLAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic matrix shapes in a special section.

The BLACS routines implemented in Intel MKL are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The Combines take data distributed over processes and combine the data to produce a result. The Point to Point routines are intended for point-to-point communication and Broadcast routines send data possessed by one process to all processes within a scope.

The Support routines perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of *m* rows and *n* columns, with a leading dimension, *lda*, that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

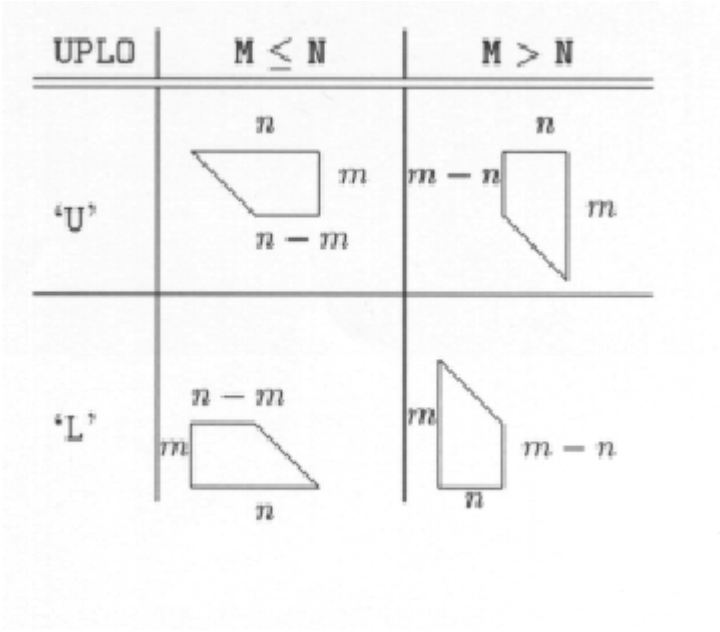
m	(input) INTEGER. The number of matrix rows to be operated on.
n	(input) INTEGER. The number of matrix columns to be operated on.
a	(input/output) TYPE (depends on routine), array of dimension (*lda*,*n*). A pointer to the beginning of the (sub)array to be sent.
lda	(input) INTEGER. The distance between two elements in matrix row.

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by *m*, *n*, and *lda*, as above, but they have two additional parameters as well. These parameters are:

uplo	(input) CHARACTER*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.
diag	(input) CHARACTER*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

Trapezoidal Arrays Shapes



The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

BLACS Combine Operations

This section describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (`max`/`min`/`sum`) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4 x 2 array of inputs produces a 4 x 2 answer array.

When the `max`/`min` comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol `?` in the routine names below masks the data type:

`i`	integer
`s`	single precision real

d	double precision real
c	single precision complex
z	double precision complex.

BLACS Combines

Routine name	Results of operation
gamx2d	Entries of result matrix will have the value of the greatest absolute value found in that position.
gamn2d	Entries of result matrix will have the value of the smallest absolute value found in that position.
gsum2d	Entries of result matrix will have the summation of that position.

?gamx2d

Performs element-wise absolute value maximization.

Syntax

```
call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
top	CHARACTER*1. Communication pattern to use during the combine operation.
m	INTEGER. The number of matrix rows to be combined.
n	INTEGER. The number of matrix columns to be combined.
a	TYPE array (*lda*, *n*). Matrix to be compared with to produce the maximum.
lda	INTEGER. The leading dimension of the matrix *A*, that is, the distance between two successive elements in a matrix row.
rcflag	INTEGER. If *rcflag* = -1, the arrays *ra* and *ca* are not referenced and need not exist. Otherwise, *rcflag* indicates the leading dimension of these arrays, and so must be $\geq m$.
rdest	INTEGER. The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.
cdest	INTEGER. The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a	TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
ra	INTEGER array (*rcflag*, *n*). If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* x *n*) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
ca	INTEGER array (*rcflag*, *n*). If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* x *n*) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

See Also

BLACS Routines Usage Example

?gamn2d

Performs element-wise absolute value minimization.

Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
top	CHARACTER*1. Communication pattern to use during the combine operation.
m	INTEGER. The number of matrix rows to be combined.
n	INTEGER. The number of matrix columns to be combined.
a	TYPE array (*lda*, *n*). Matrix to be compared with to produce the minimum.

lda INTEGER. The leading dimension of the matrix *A*, that is, the distance between two successive elements in a matrix row.

rcflag INTEGER.
If *rcflag* = -1, the arrays *ra* and *ca* are not referenced and need not exist. Otherwise, *rcflag* indicates the leading dimension of these arrays, and so must be ≥ *m*.

rdest INTEGER.
The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

cdest INTEGER.
The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

ra INTEGER array (*rcflag*, *n*).
If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* x *n*) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

ca INTEGER array (*rcflag*, *n*).
If *rcflag* = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least *rcflag* x *n*) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value minimization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Routines Usage Example

?gsum2d

Performs element-wise summation.

Syntax

```
call igsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call sgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call dgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call cgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

```
call zgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
top	CHARACTER*1. Communication pattern to use during the combine operation.
m	INTEGER. The number of matrix rows to be combined.
n	INTEGER. The number of matrix columns to be combined.
a	TYPE array (*lda*, *n*). Matrix to be added to produce the sum.
lda	INTEGER. The leading dimension of the matrix *A*, that is, the distance between two successive elements in a matrix row.
rdest	INTEGER. The process row coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.
cdest	INTEGER. The process column coordinate of the process that should receive the result. If *rdest* or *cdest* = -1, all processes within the indicated scope receive the answer.

Output Parameters

a	TYPE array (*lda*, *n*). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

Description

This routine performs element-wise summation, that is, each element of matrix *A* is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Routines Usage Example

BLACS Point To Point Communication

This section describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
 IF (IAM .EQ. 0) THEN
   SEND TO PROCESS 1
   RECV FROM PROCESS 1
ELSE IF (IAM .EQ. 1) THEN
   SEND TO PROCESS 0
   RECV FROM PROCESS 0
END IF
```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them A, B, and C) to process 1, process 1 must receive A before it can receive B, and message C can be received only after both A and B. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . ., 3 send messages A, . . ., D to process 4, process 4 may receive these messages in any order that is convenient.

Convention

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

`i`	integer
`s`	single precision real
`d`	double precision real
`c`	single precision complex
`z`	double precision complex
`ge`	The data to be communicated is stored in a general rectangular matrix.
`tr`	The data to be communicated is stored in a trapezoidal matrix.
`sd`	Send. One process sends to another.
`rv`	Receive. One process receives from another.

BLACS Point To Point Communication

Routine name	Operation performed
gesd2d trsd2d	Take the indicated matrix and send it to the destination process.
gerv2d trrv2d	Receive a message from the process into the matrix.

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specifed that the data being exchanged is the double precision vector *X*, which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)

IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
   CALL DGESD2D(5, 1, X, 5, 1, 0)
   CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
   CALL DGESD2D(5, 1, X, 5, 0, 0)
   CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

?gesd2d

Takes a general rectangular matrix and sends it to the destination process.

Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
m, *n*, *a*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.

rdest	INTEGER. The process row coordinate of the process to send the message to.
cdest	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

See Also

BLACS Routines Usage Example

?trsd2d

Takes a trapezoidal matrix and sends it to the destination process.

Syntax

```
call itrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call dtrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
uplo, *diag*, *m*, *n*, *a*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rdest	INTEGER. The process row coordinate of the process to send the message to.
cdest	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix *A*) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?gerv2d

Receives a message from the process into the general rectangular matrix.

Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

```
call zgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
m, *n*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rsrc	INTEGER. The process row coordinate of the source of the message.
csrc	INTEGER. The process column coordinate of the source of the message.

Output Parameters

a	An array of dimension (*lda*,*n*) to receive the incoming message into.

Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

See Also

BLACS Routines Usage Example

?trrv2d

Receives a message from the process into the trapezoidal matrix.

Syntax

```
call itrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call strrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
uplo, *diag*, *m*, *n*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rsrc	INTEGER. The process row coordinate of the source of the message.
csrc	INTEGER. The process column coordinate of the source of the message.

Output Parameters

a	An array of dimension (*lda*,*n*) to receive the incoming message into.

Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix *A*. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into *A*.

BLACS Broadcast Routines

This section describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast*/*send*. All processes within the same scope must then issue the complementary *broadcast*/*receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with `SCOPE = 'ALL'` must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

`i`	integer
`s`	single precision real
`d`	double precision real
`c`	single precision complex
`z`	double precision complex
`ge`	The data to be communicated is stored in a general rectangular matrix.
`tr`	The data to be communicated is stored in a trapezoidal matrix.
`bs`	Broadcast/send. A process begins the broadcast of data within a scope.
`br`	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

BLACS Broadcast Routines

Routine name	Operation performed
gebs2d trbs2d	Start a broadcast along a scope.
gebr2d trbr2d	Receive and participate in a broadcast along a scope.

?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebs2d( icontxt, scope, top, m, n, a, lda )
call sgebs2d( icontxt, scope, top, m, n, a, lda )
call dgebs2d( icontxt, scope, top, m, n, a, lda )
call cgebs2d( icontxt, scope, top, m, n, a, lda )
call zgebs2d( icontxt, scope, top, m, n, a, lda )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
top	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
m, *n*, *a*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

BLACS Routines Usage Example

?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call strbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ztrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
top	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
uplo, *diag*, *m*, *n*, *a*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?gebr2d

Receives and participates in a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
top	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
m, *n*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rsrc	INTEGER. The process row coordinate of the process that called broadcast/send.
csrc	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

a	An array of dimension (*lda*,*n*) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also
BLACS Routines Usage Example

?trbr2d
Receives and participates in a broadcast along a scope for a trapezoidal matrix.

Syntax
```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
top	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
uplo, *diag*, *m*, *n*, *lda*	Describe the matrix to be sent. See Matrix Shapes for details.
rsrc	INTEGER. The process row coordinate of the process that called broadcast/send.
csrc	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

a	An array of dimension (*lda*,*n*) to receive the incoming message into.

Description
This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

BLACS Support Routines
The support routines perform distinct tasks that can be used for:

Initialization

Destruction

Information Purposes

Miscellaneous Tasks.

Initialization Routines
This section describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

BLACS Initialization Routines

Routine name	Operation performed
blacs_pinfo	Returns the number of processes available for use.
blacs_setup	Allocates virtual machine and spawns processes.
blacs_get	Gets values that BLACS use for internal defaults.
blacs_set	Sets values that BLACS use for internal defaults.
blacs_gridinit	Assigns available processes into BLACS process grid.
blacs_gridmap	Maps available processes into BLACS process grid.

blacs_pinfo

Returns the number of processes available for use.

Syntax

```
call blacs_pinfo( mypnum, nprocs )
```

Output Parameters

mypnum	INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.
nprocs	INTEGER.The number of processes available for BLACS use.

Description

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is, *nprows * npcols <= nprocs*. In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the keyboard, it receives *mypnum* of 0, and all other processes get *mypnum* of -1. As a result, the user can distinguish between processes. Only after the virtual machine has been set up via a call to BLACS_SETUP, this routine returns the correct values for *mypnum* and *nprocs*.

See Also

BLACS Routines Usage Example

blacs_setup

Allocates virtual machine and spawns processes.

Syntax

```
call blacs_setup( mypnum, nprocs )
```

Input Parameters

nprocs	INTEGER. On the process spawned from the keyboard rather than from pvmspawn, this parameter indicates the number of processes to create when building the virtual machine.

Output Parameters

mypnum	INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.

nprocs	INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.

Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to blacs_pinfo. The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

blacs_setup is used to allocate the virtual machine and spawn off processes. It reads in a file called blacs_setup.dat, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (PvmTaskDefault), 4 (PvmTaskDebug), 8 (PvmTaskTrace), and 12 (PvmTaskDebug + PvmTaskTrace). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

nprocs is input on the process which has no PVM parent (that is, *mypnum*=0), and both parameters are output for all processes. So, on PVM systems, the call to blacs_pinfo informs you that the virtual machine has not been set up, and a call to blacs_setup then sets up the machine and returns the real values for *mypnum* and *nprocs*.

Note that if the file blacs_setup.dat does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

See Also

BLACS Routines Usage Example

blacs_get

Gets values that BLACS use for internal defaults.

Syntax

```
call blacs_get( icontxt, what, val )
```

Input Parameters

icontxt	INTEGER. On values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
what	INTEGER. Indicates what BLACS internal(s) should be returned in *val*. Present options are: • *what* = 0 : Handle indicating default system context • *what* = 1 : The BLACS message ID range • *what* = 2 : The BLACS debug level the library was compiled with • *what* = 10 : Handle indicating the system context used to define the BLACS context whose handle is *icontxt* • *what* = 11 : Number of rings multiring topology is presently using • *what* = 12 : Number of branches general tree topology is presently using.

Output Parameters

val	INTEGER. The value of the BLACS internal.

Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into `blacs_gridinit` or `blacs_gridmap`.

Some systems, such as MPI*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use `blacs_get` to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter *icontxt* is unused.

`blacs_get` returns information on three quantities that are tied to an individual BLACS context, which is passed in as *icontxt*. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for `TOP = 'M'` (multiring broadcast)
- The number of branches for `TOP = 'T'` (general tree broadcast/general tree gather).

See Also

BLACS Routines Usage Example

blacs_set

Sets values that BLACS use for internal defaults.

Syntax

```
call blacs_set( icontxt, what, val )
```

Input Parameters

icontxt	`INTEGER`. For values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
what	`INTEGER`. Indicates what BLACS internal(s) should be set. Present values are: • 1 = The BLACS message ID range • 11 = Number of rings for multiring topology to use • 12 = Number of branches for general tree topology to use.
val	`INTEGER`. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on *what* values, as discussed in Description below.

Description

This routine sets the BLACS internal defaults depending on *what* values:

what = 1	Setting the BLACS message ID range. If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to `blacs_gridinit` or `blacs_gridmap`. Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter *icontxt* is ignored, and *val* is defined as: `VAL (input) INTEGER` array of dimension (2) `VAL(1)` : The smallest message ID (also called message type or message tag) the BLACS should use.

	VAL(2) : The largest message ID (also called message type or message tag) the BLACS should use.
what = 11	Set number of rings for TOP = 'M' (multiring broadcast).This quantity is tied to a context, so *icontxt* is used, and *val* is defined as: VAL (input) INTEGER array of dimension (1) VAL(1) : The number of rings for multiring topology to use.
what = 12	Set number of rings for TOP = 'T' (general tree broadcast/general tree gather). This quantity is tied to a context, so *icontxt* is used, and *val* is defined as: VAL (input) INTEGER array of dimension (1) VAL(1) : The number of branches for general tree topology to use.

blacs_gridinit

Assigns available processes into BLACS process grid.

Syntax

```
call blacs_gridinit( icontxt, order, nprow, npcol )
```

Input Parameters

icontxt	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call blacs_get to obtain a default system context.
order	CHARACTER*1. Indicates how to map processes to BLACS grid. Options are: • 'R' : Use row-major natural ordering • 'C' : Use column-major natural ordering • ELSE : Use row-major natural ordering
nprow	INTEGER. Indicates how many process rows the process grid should contain.
npcol	INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt	INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine blacs_gridmap. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine blacs_setup should be used to create the virtual machine.

This routine creates a simple nprow x npcol process grid. This process grid uses the first nprow * npcol processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call blacs_gridmap.

blacs_gridmap
blacs_setup

blacs_gridmap

Maps available processes into BLACS process grid.

Syntax

```
call blacs_gridmap( icontxt, usermap, ldumap, nprow, npcol )
```

Input Parameters

icontxt	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call blacs_get to obtain a default system context.
usermap	INTEGER. Array, dimension (*ldumap*, *npcol*), indicating the process-to-grid mapping.
ldumap	INTEGER. Leading dimension of the 2D array *usermap*. *ldumap* ≥ *nprow*.
nprow	INTEGER. Indicates how many process rows the process grid should contain.
npcol	INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt	INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine blacs_gridinit. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine blacs_setup should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. usermap(i,j) holds the process number of the process to be placed in {i, j} of the process grid. On most distributed systems, this process number is a machine defined number between 0 ... *nprow*-1. For PVM, these node numbers are the PVM TIDS (Task IDs). The blacs_gridmap routine is intended for an experienced user. The blacs_gridinit routine is much simpler. blacs_gridinit simply performs a gridmap where the first

nprow * npcol processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, blacs_gridmap allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The blacs_gridmap routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. blacs_gridmap also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

Destruction Routines

This section describes BLACS routines that destroy grids, abort processes, and free resources.

BLACS Destruction Routines

Routine name	Operation performed
blacs_freebuff	Frees BLACS buffer.
blacs_gridexit	Frees a BLACS context.
blacs_abort	Aborts all processes.
blacs_exit	Frees all BLACS contexts and releases all allocated memory.

blacs_freebuff

Frees BLACS buffer.

Syntax

```
call blacs_freebuff( icontxt, wait )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the BLACS context.
wait	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call freebuff to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The *wait* parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If *wait* = 0, the BLACS free any buffers that can be freed without waiting. If *wait* is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

blacs_gridexit

Frees a BLACS context.

Syntax

```
call blacs_gridexit( icontxt )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the BLACS context to be freed.

Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

blacs_abort

Aborts all processes.

Syntax

```
call blacs_abort( icontxt, errornum )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the BLACS context to be aborted.
errornum	INTEGER. User-defined integer error number.

Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

blacs_exit

Frees all BLACS contexts and releases all allocated memory.

Syntax

```
call blacs_exit( continue )
```

Input Parameters

continue	INTEGER. Flag indicating whether message passing continues after the BLACS are done. If *continue* is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.

Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called;

otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM send/recvs will be called after the BLACS routines are used. Make sure your code calls pvm_exit. PVM users should either call blacs_exit or explicitly call pvm_exit to avoid PVM problems.

BLACS Routines Usage Example

Informational Routines

This section describes BLACS routines that return information involving the process grid.

BLACS Informational Routines

Routine name	Operation performed
blacs_gridinfo	Returns information on the current grid.
blacs_pnum	Returns the system process number of the process in the process grid.
blacs_pcoord	Returns the row and column coordinates in the process grid.

blacs_gridinfo
Returns information on the current grid.

Syntax
```
call blacs_gridinfo( icontxt, nprow, npcol, myprow, mypcol )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.

Output Parameters

nprow	INTEGER. Number of process rows in the current process grid.
npcol	INTEGER. Number of process columns in the current process grid.
myprow	INTEGER. Row coordinate of the calling process in the process grid.
mypcol	INTEGER. Column coordinate of the calling process in the process grid.

Description
This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

See Also
BLACS Routines Usage Example

blacs_pnum
Returns the system process number of the process in the process grid.

Syntax
```
call blacs_pnum( icontxt, prow, pcol )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.

prow	INTEGER. Row coordinate of the process the system process number of which is to be determined.
pcol	INTEGER. Column coordinate of the process the system process number of which is to be determined.

Description

This function returns the system process number of the process at {PROW, PCOL} in the process grid.

See Also

BLACS Routines Usage Example

blacs_pcoord

Returns the row and column coordinates in the process grid.

Syntax

```
call blacs_pcoord( icontxt, pnum, prow, pcol )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
pnum	INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a tid for PVM.

Output Parameters

prow	INTEGER. Row coordinates of the *pnum* process in the BLACS grid.
pcol	INTEGER. Column coordinates of the *pnum* process in the BLACS grid.

Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

BLACS Routines Usage Example

Miscellaneous Routines

This section describes blacs_barrier routine.

BLACS Informational Routines

Routine name	Operation performed
blacs_barrier	Holds up execution of all processes within the indicated scope until they have all called the routine.

blacs_barrier

Holds up execution of all processes within the indicated scope.

Syntax

```
call blacs_barrier( icontxt, scope )
```

Input Parameters

icontxt	INTEGER. Integer handle that indicates the context.
scope	CHARACTER*1. Parameter that indicates whether a process row (*scope*='R'), column ('C'), or entire grid ('A') will participate in the barrier.

Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

Examples of BLACS Routines Usage

Example. BLACS Usage. Hello World

The following routine takes the available processes, forms them into a process grid, and then has each process check in with the process at {0,0} in the process grid.

```
      PROGRAM HELLO
*     -- BLACS example code --
*     Written by Clint Whaley 7/26/94
*     Performs a simple check-in type hello world
*     ..
*     .. External Functions ..

3000  FORMAT('Process {',i2,',',i2,'} (node number =',I,
     $       ') has checked in.')

      STOP
      END
```

Example. BLACS Usage. PROCMAP

This routine maps processes to a grid using `blacs_gridmap`.

```
      SUBROUTINE PROCMAP(CONTEXT, MAPPING, BEGPROC, NPROW, NPCOL, IMAP)
*
*     -- BLACS example code --

*     Written by Clint Whaley 7/26/94
*     ..
*     .. Scalar Arguments ..
      INTEGER CONTEXT, MAPPING, BEGPROC, NPROW, NPCOL
```

```
*     ..
*     .. Array Arguments ..
      INTEGER IMAP(NPROW, *)
*     ..
*
*  Purpose
*  =======
*  PROCMAP maps NPROW*NPCOL processes starting from process BEGPROC to
*  the grid in a variety of ways depending on the parameter MAPPING.

*
*  Arguments

*  =========
*
*  CONTEXT      (output) INTEGER
*               This integer is used by the BLACS to indicate a context.
*               A context is a universe where messages exist and do not
*               interact with other context's messages.  The context
*               includes the definition of a grid, and each process's
*               coordinates in it.
*
*  MAPPING      (input) INTEGER
*               Way to map processes to grid.  Choices are:
*               1 : row-major natural ordering
*               2 : column-major natural ordering
*
*  BEGPROC      (input) INTEGER
*               The process number (between 0 and NPROCS-1) to use as

*               {0,0}. From this process, processes will be assigned
*               to the grid as indicated by MAPPING.
*
*  NPROW        (input) INTEGER
*               The number of process rows the created grid

*               should have.
*
*  NPCOL        (input) INTEGER
*               The number of process columns the created grid

*               should have.
*
*  IMAP         (workspace) INTEGER array of dimension (NPROW, NPCOL)
*               Workspace, where the array which maps the

*               processes to the grid will be stored for the
*               call to GRIDMAP.

17 Data Fitting Functions

Data Fitting functions in Intel® MKL provide spline-based interpolation capabilities that you can use to approximate functions, function derivatives or integrals, and perform cell search operations.

The Data Fitting component is task based. The task is a data structure or descriptor that holds the parameters related to a specific Data Fitting operation. You can modify the task parameters using the task editing functionality of the library.

For definition of the implemented operations, see Mathematical Conventions.

Data Fitting routines use the following workflow to process a task:

1. Create a task or multiple tasks.
2. Modify the task parameters.
3. Perform a Data Fitting computation.
4. Destroy the task or tasks.

All Data Fitting functions fall into the following categories:

Task Creation and Initialization Routines - routines that create a new Data Fitting task descriptor and initialize the most common parameters, such as partition of the interpolation interval, values of the vector-valued function, and the parameters describing their structure.

Task Editors - routines that set or modify parameters in an existing Data Fitting task.

Computational Routines - routines that perform Data Fitting computations, such as construction of a spline, interpolation, computation of derivatives and integrals, and search.

Task Destructors - routines that delete Data Fitting task descriptors and deallocate resources.

You can access the Data Fitting routines through the Fortran and C89/C99 language interfaces. You can also use the C89 interface with more recent versions of C/C++, or the Fortran 90 interface with programs written in Fortran 95

The `${MKL}/include` directory of the Intel® MKL contains the following Data Fitting header files:

- C/C++: `mkl_df.h`
- Fortran: `mkl_df.f90` and `mkl_df.f77`

You can find examples that demonstrate C/C++ and Fortran usage of Data Fitting routines in the `${MKL}/examples/datafittingc` and `${MKL}/examples/datafittingf` directories, respectively.

Naming Conventions

The Fortran interfaces of the Data Fitting functions are in lowercase, while the names of the types and constants are in uppercase.

The C/C++ interface of the Data Fitting functions, types, and constants are case-sensitive and can be in lowercase, uppercase, and mixed case.

The names of all routines have the following structure:

`df[`*`datatype`*`]<`*`base_name`*`>`

where

- `df` is a prefix indicating that the routine belongs to the Data Fitting component of Intel MKL.
- `[`*`datatype`*`]` field specifies the type of the input and/or output data and can be `s` (for the single precision real type), `d` (for the double precision real type), or `i` (for the integer type). This field is omitted in the names of the routines that are not data type dependent.
- `<`*`base_name`*`>` field specifies the functionality the routine performs. For example, this field can be `NewTask1D`, `Interpolate1D`, or `DeleteTask`.

Data Types

The Data Fitting component provides routines for processing single and double precision real data types. The results of cell search operations are returned as a generic integer data type.

All Data Fitting routines use the following data type:

Type	Data Object
Fortran: `TYPE(DF_TASK)`	Pointer to a task
C: `DFTaskPtr`	

NOTE The actual size of the generic integer type is platform-dependent. Before compiling your application, you need to set an appropriate byte size for integers. For details, see section *Using the ILP64 Interface vs. LP64 Interface* of the Intel® MKL User's Guide.

Mathematical Conventions

This section explains the notation used for Data Fitting function descriptions. Spline notations are based on the terminology and definitions of [deBoor2001]. The definition of Subbotin quadratic splines follows the conventions of [StechSub76].

Mathematical Notation in the Data Fitting Component

Concept	Mathematical Notation
Partition of interpolation interval $[a, b]$, where • x_i denotes breakpoints. • $[x_i, x_{i+1})$ denotes a sub-interval (cell) of size Δx_{i+1}-x_i .	$\{x_i\}_{i=1,\ldots,n}$, where $a = x_1 < x_2 < \ldots < x_n = b$
Vector-valued function of dimension p being fit	$f(x) = (f_1(x),\ldots, f_p(x))$
Piecewise polynomial (PP) function f of order k+1	$f(x) := P_i(x)$, if $x \in [x_i, x_{i+1})$, $i = 1,\ldots, n$-1 where • $\{x_i\}_{i= 1,\ldots, n}$ is a strictly increasing sequence of breakpoints. • $P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \ldots + c_{i,k}(x - x_i)^k$ is a polynomial of degree k (order k+1) over the interval $x \in [x_i, x_{i+1})$.
Function p agrees with function g at the points $\{x_i\}_{i=1,\ldots,n}$.	For every point ζ in sequence $\{x_i\}_{i=1,\ldots,n}$ that occurs m times, the equality $p^{(i-1)}(\zeta) = g^{(i-1)}(\zeta)$ holds for all $i = 1,\ldots,m$, where $p^{(i)}(t)$ is the derivative of the i-th order.
The k-th divided difference of function g at points $x_i,\ldots, x_{i+k}$. This difference is the leading coefficient of the polynomial of order k+1 that agrees with g at $x_i,\ldots, x_{i+k}$.	$[x_i,\ldots, x_{i+k}]\, g$ In particular, • $[x_1]g = g(x_1)$ • $[x_1, x_2]\, g = (g(x_1) - g(x_2)) / (x_1 - x_2)$
A k-order derivative of interpolant $f(x)$ at interpolation site τ .	$f^{(k)}(\tau)$

Interpolants to the Function g at $x_i, \ldots, x_n$ and Boundary Conditions

Concept	Mathematical Notation
Linear interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i)$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = g(x_i)$ • $c_{2,i} = [x_i, x_{i+1}]g$ • $i = 1,\ldots, n\text{-}1$
Piecewise parabolic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2$, $x \in [x_i, x_{i+1})$ Coefficients $c_{1,i}$, $c_{2,i}$, and $c_{3,i}$ depend on the conditions: • $P_i(x_i) = g(x_i)$ • $P_i(x_{i+1}) = g(x_{i+1})$ • $P_i((x_{i+1} + x_i) / 2) = v_{i+1}$ where parameter v_{i+1} depends on the interpolant being continuously differentiable: $P_{i\text{-}1}^{(1)}(x_i) = P_i^{(1)}(x_i)$
Piecewise parabolic Subbotin interpolant	$P(x) = P_i(x) = c_{1,i}+c_{2,i}(x-x_i)+c_{3,i}(x-x_i)^2+d_{3,i}((x-t_i)_+)^2$, where • $x \in [t_i, t_{i+1})$ • $\{t_i\}_{i=1,\ldots,n+1}$ is a sequence of knots such that • $t_1 = x_1$, $t_{n+1} = x_n$ • $t_i \in (x_{i\text{-}1}, x_i)$, $i = 2,\ldots, n$ • $x_+ = f(x) = \begin{cases} 0, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$ Coefficients $c_{1,i}$, $c_{2,i}$, $c_{3,i}$, and $d_{3,i}$ depend on the following conditions: • $P_i(x_i) = g(x_i)$, $P_i(x_{i+1}) = g(x_{i+1})$ • $P(x)$ is a continuously differentiable polynomial of the second degree on $[t_i, t_{i+1})$, $i = 1,\ldots, n$.
Piecewise cubic Hermite interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = g(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]g - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]g) / (\Delta x_i)^2$ • $i = 1,\ldots, n\text{-}1$ • $s_i = g^{(1)}(x_i)$
Piecewise cubic Bessel interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = g(x_i)$

Concept	Mathematical Notation
	• $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]g - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]g) / (\Delta x_i)^2$ • $i = 1,..., n-1$ • $s_i = (\Delta x_i[x_{i-1}, x_i]g + \Delta x_{i-1}[x_i, x_{i+1}]g) / (\Delta x_i + \Delta x_{i+1})$
Piecewise cubic Akima interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = g(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]g - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]g) / (\Delta x_i)^2$ • $i = 1,..., n-1$ • $s_i = (w_{i+1}[x_{i-1}, x_i]g + w_{i-1}[x_i, x_{i+1}]g) / (w_{i+1} + w_{i-1})$, where $w_i = \lvert[x_i, x_{i+1}]g - [x_{i-1}, x_i]g\rvert$
Piecewise natural cubic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where • $x \in [x_i, x_{i+1})$ • $c_{1,i} = g(x_i)$ • $c_{2,i} = s_i$ • $c_{3,i} = ([x_i, x_{i+1}]g - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ • $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]g) / (\Delta x_i)^2$ • $i = 1,..., n-1$ • Parameter s_i depends on the condition that the interpolant is twice continuously differentiable: $P_{i-1}^{(2)}(x_i) = P_i^{(2)}(x_i)$.
Not-a-knot boundary condition.	Parameters s_1 and s_n provide $P_1 = P_2$ and $P_{n-1} = P_n$, so that the first and the last interior breakpoints are inactive.
Free-end boundary condition.	$f''(x_1) = f''(x_n) = 0$
Look-up interpolator for discrete set of points $(x_1, y_1),..., (x_n, y_n)$.	$$y(x) = \begin{cases} y_1, & if\ x = x_1 \\ y_2, & if\ x = x_2 \\ \quad\dots & \\ y_n, & if\ x = x_n \\ error, & otherwise \end{cases}$$
Step-wise constant continuous right interpolator.	$$y(x) = \begin{cases} y_1, & \text{if } x_1 \le x < x_2 \\ y_2, & \text{if } x_2 \le x < x_3 \\ \quad\dots & \\ y_{n-1}, & \text{if } x_{n-1} \le x < x_n \\ y_n, & if\ x = x_n \end{cases}$$

Concept	Mathematical Notation
Step-wise constant continuous left interpolator.	$y(x)=\begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x_1 < x \le x_2 \\ y_3, & \text{if } x_2 < x \le x_3 \\ \dots & \\ y_n, & \text{if } x_{n-1} < x \le x_n \end{cases}$

Data Fitting Usage Model

Consider an algorithm that uses the Data Fitting functions. Typically, such algorithms consist of four steps or stages:

1. Create a task. You can call the Data Fitting function several times to create multiple tasks.

```
status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );
```

2. Modify the task parameters.

```
status = dfdEditPPSpline1D( task, s_order, c_type, bc_type, bc, ic_type, ic, scoeff,
scoeffhint );
```

3. Perform Data Fitting spline-based computations. You may reiterate steps 2-3 as needed.

```
status = dfdInterpolate1D(task, estimate, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell );
```

4. Destroy the task or tasks.

```
status = dfDeleteTask( &task );
```

Data Fitting Usage Examples

Data Fitting Usage Examples

The examples below illustrate several operations that you can perform with Data Fitting routines. If you want to run or reuse similar examples, you can get both C and Fortran source code in the `.\examples\datafittingc` and `.\examples\datafittingf` subdirectories of the Intel MKL installation directory.

The following C example demonstrates the construction of a linear spline using Data Fitting routines. The spline approximates a scalar function defined on non-uniform partition. The coefficients of the spline are returned as a one-dimensional array:

C Example of Linear Spline Construction

```
#include "mkl.h"
#define N 500                    /* Size of partition, number of breakpoints */
#define SPLINE_ORDER DF_PP_LINEAR /* Linear spline to construct */

int main()
{
    int status;          /* Status of a Data Fitting operation */
    DFTaskPtr task;      /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx;          /* The size of partition x */
    double x[N];         /* Partition x */
    MKL_INT xhint;       /* Additional information about the structure of breakpoints */

    /* Parameters describing the function */
    MKL_INT ny;          /* Function dimension */
    double y[N];         /* Function values at the breakpoints */
```

```
    MKL_INT yhint;       /* Additional information about the function */

    /* Parameters describing the spline */
    MKL_INT  s_order;    /* Spline order */
    MKL_INT  s_type;     /* Spline type */
    MKL_INT  ic_type;    /* Type of internal conditions */
    MKL_INT* ic;         /* Array of internal conditions */
    MKL_INT  bc_type;    /* Type of boundary conditions */
    MKL_INT* bc;         /* Array of boundary conditions */

    double scoeff[(N-1)* ORDER];   /* Array of spline coefficients */
    MKL_INT scoeffhint;            /* Additional information about the coefficients */

    /* Initialize the partition */
    nx = N;
    /* Set values of partition x */
    ...
    xhint = DF_NO_HINT;    /* No additional information about the function is provided.
                              By default, the partition is non-uniform. */
    /* Initialize the function */
     ny = 1;               /* The function is scalar. */

    /* Set function values */
    ...
    yhint = DF_NO_HINT;    /* No additional information about the function is provided. */

    /* Create a Data Fitting task */
    status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );

    /* Check the Data Fitting operation status */
    ...

    /* Initialize spline parameters */
    s_order = DF_PP_LINEAR;    /* Spline is of the second order. */
    s_type = DF_PP_DEFAULT;    /* Spline is of the default type. */

    /* Define internal conditions for linear spline construction (none in this example) */
    ic_type = DF_NO_IC;
    ic = NULL;

    /* Define boundary conditions for linear spline construction (none in this example) */
    bc_type = DF_NO_BC;
    bc = NULL;
    scoeffhint = DF_NO_HINT;    /* No additional information about the spline. */

    /* Set spline parameters  in the Data Fitting task */
    status = dfdEditPPSpline1D( task, s_order, s_type, bc_type, bc, ic_type,
                                ic, scoeff, scoeffhint );

    /* Check the Data Fitting operation status */
    ...

    /* Use a standard computation method to construct a linear spline: */
    /* P_i(x) = c_1,i+c_2,i(x-x_i), i=0,..., N-2 */
    /* The library packs spline coefficients to array scoeff. */
    /* scoeff[2*i+0]=c_1,i and scoeff[2*i+1]=c_2,i, i=0,..., N-2 */
    status = dfdConstruct1D( task, DF_PP_SPLINE, DF_METHOD_STD );

    /* Check the Data Fitting operation status */
    ...

    /* Process spline coefficients */
    ...

    /* Deallocate Data Fitting task resources */
    status = dfDeleteTask( &task ) ;

    /* Check the Data Fitting operation status */
    ...
    return 0 ;
}
```

The following C example demonstrates cubic spline-based interpolation using Data Fitting routines. In this example, a scalar function defined on non-uniform partition is approximated by Bessel cubic spline using not-a-knot boundary conditions. Once the spline is constructed, you can use the spline to compute spline values at the given sites. Computation results are packed by the Data Fitting routine in row-major format.

C Example of Cubic Spline-Based Interpolation

```
#include "mkl.h"

#define NX 100                      /* Size of partition, number of breakpoints */
#define NSITE 1000                  /* Number of interpolation sites */
#define SPLINE_ORDER DF_PP_CUBIC    /* A cubic spline to construct */

int main()
{
    int status;          /* Status of a Data Fitting operation */
    DFTaskPtr task;      /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx;          /* The size of partition x */
    double x[N];         /* Partition x */
    MKL_INT xhint;       /* Additional information about the structure of breakpoints */

    /* Parameters describing the function */
    MKL_INT ny;          /* Function dimension */
    double y[N];         /* Function values at the breakpoints */
    MKL_INT yhint;       /* Additional information about the function */

    /* Parameters describing the spline */

    dorder = 1;
    datahint = DF_NO_APRIORI_INFO;  /* No additional information about breakpoints or
                                       sites is provided. */
    rhint = DF_MATRIX_STORAGE_ROWS; /* The library packs interpolation results
                                       in row-major format. */
    cell = NULL;                   /* Cell indices are not required. */

    /* Solve interpolation problem using the default method: compute the sline values
       at the points site(i), i=0,..., nsite-1 and place the results to array r */
    status = dfdInterpolate1D( task, DF_INTERP, DF_METHOD_STD, nsite, site,
    sitehint, ndorder, &dorder, datahint, r, rhint, cell );

    /* Check Data Fitting operation status */
     ...

    /* De-allocate Data Fitting task resources */
     status = dfDeleteTask( &task );
    /* Check Data Fitting operation status */
     ...
    return 0;
}
```

The following C example demonstrates how to compute indices of cells containing given sites. This example uses uniform partition presented with two boundary points. The sites are in the ascending order.

C Example of Cell Search

```
#include "mkl.h"

#define NX 100                    /* Size of partition, number of breakpoints */
#define NSITE 1000                /* Number of interpolation sites */

int main()
{
    int status;          /* Status of a Data Fitting operation */
    DFTaskPtr task;      /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx;          /* The size of partition x */
    double x[2];         /* Partition x is uniform and holds endpoints
                            of interpolation interval [a, b] */
    MKL_INT xhint;       /* Additional information about the structure of breakpoints */

    /* Parameters describing the function */
    MKL_INT ny;          /* Function dimension */
    float   *y;          /* Function values at the breakpoints */
    MKL_INT yhint;       /* Additional information about the function */

    /* Parameters describing cell search */
    MKL_INT nsite;       /* Number of interpolation sites */
    double  site[NSITE]; /* Array of interpolation sites  */
    MKL_INT sitehint;    /* Additional information about the structure of sites */

    float* datahint;     /* Additional information on partition and interpolation sites */

    MKL_INT cell[NSITE]; /* Array for cell indices */

    /* Initialize a uniform partition */
    nx = N;
    /* Set values of partition x: for uniform partition,           */
    /* provide end-points of the interpolation interval [-1.0,1.0] */
    x[0] = -1.0f; x[1] = 1.0f;
    xhint = DF_UNIFORM_PARTITION; /* Partition is uniform */

    /* Initialize function parameters */
    /* In cell search, function values are not necessary and are set to zero/NULL values */
    ny    = 0;
    y     = NULL;
    yhint = DF_NO_HINT;

    /* Create a Data Fitting task */
    status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );

    /* Check Data Fitting operation status */
    ...

    /* Initialize interpolation (cell search) parameters */
    nsite = NSITE;

   /* Set sites in the ascending order */
    ...
    sitehint = DF_SORTED_DATA;      /* Sites are provided in the ascending order. */
    datahint = DF_NO_APRIORI_INFO;  /* No additional information
                                       about breakpoints/sites is provided.*/

    /* Use a standard method to compute indices of the cells that contain
       interpolation sites. The library places the index of the cell containing
       site(i) to the cell(i), i=0,...,nsite-1 */
    status = dfsSearchCells1D( task, DF_METHOD_STD, nsite, site, sitehint,
                               datahint, cell );
    /* Check Data Fitting operation status */
     ...

    /* Process cell indices */
     ...
```

```
    /* Deallocate Data Fitting task resources */
    status = dfDeleteTask( &task );

    /* Check Data Fitting operation status */
     ...
    return 0;
}
```

Task Status and Error Reporting

The Data Fitting routines report a task status through integer values. Negative status values indicate errors, while positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names predefined in the respective header files. For the C/C++ interface, these names are defined as macros via the `#define` statements. For the Fortran interface, the names are defined as integer constants via the `PARAMETER` operators.

If no error occurred, the function returns the `DF_STATUS_OK` code defined as zero:

```
C/C++:          #define DF_STATUS_OK 0
F90/F95:        INTEGER, PARAMETER::DF_STATUS_OK = 0
```

In case of an error, the function returns a non-zero error code that specifies the origin of the failure. Header files for both C/C++ and Fortran languages define the following status codes:

Status Codes in the Data Fitting Component

Status Code	Description
Common Status Codes	
DF_STATUS_OK	Operation completed successfully.
DF_ERROR_NULL_TASK	Data Fitting task is a NULL pointer.
DF_ERROR_MEM_FAILURE	Memory allocation failure.
DF_ERROR_METHOD_NOT_SUPPORTED	Requested method is not supported.
DF_ERROR_COMP_TYPE_NOT_SUPPORTED	Requested computation type is not supported.
Data Fitting Task Creation and Initialization, and Generic Editing Operations	
DF_ERROR_BAD_NX	Invalid number of breakpoints.
DF_ERROR_BAD_X	Array of breakpoints is invalid.
DF_ERROR_BAD_X_HINT	Invalid hint describing the platform structure.
DF_ERROR_BAD_NY	Invalid dimension of vector-valued function *y*.
DF_ERROR_BAD_Y	Array of function values is invalid.
DF_ERROR_BAD_Y_HINT	Invalid flag describing the structure of function *y*
Data Fitting Task-Specific Editing Operations	
DF_ERROR_BAD_SPLINE_ORDER	Invalid spline order.
DF_ERROR_BAD_SPLINE_TYPE	Invalid spline type.
DF_ERROR_BAD_IC_TYPE	Type of internal conditions used for spline construction is invalid.

Status Code	Description
DF_ERROR_BAD_IC	Array of internal conditions for spline construction is not defined.
DF_ERROR_BAD_BC_TYPE	Type of boundary conditions used in spline construction is invalid.
DF_ERROR_BAD_BC	Array of boundary conditions for spline construction is not defined.
DF_ERROR_BAD_PP_COEFF	Array of piecewise polynomial spline coefficients is not defined.
DF_ERROR_BAD_PP_COEFF_HINT	Invalid flag describing the structure of the piecewise polynomial spline coefficients.
DF_ERROR_BAD_PERIODIC_VAL	Function values at the endpoints of the interpolation interval are not equal as required in periodic boundary conditions.
DF_ERROR_BAD_DATA_ATTR	Invalid attribute of the pointer to be set or modified in Data Fitting task descriptor with the `df?editidxptr` task editor.
DF_ERROR_BAD_DATA_IDX	Index of the pointer to be set or modified in the Data Fitting task descriptor with the `df?editidxptr` task editor is out of the pre-defined range.
Data Fitting Computation Operations	
DF_ERROR_BAD_NSITE	Invalid number of interpolation sites.
DF_ERROR_BAD_SITE	Array of interpolation sites is not defined.
DF_ERROR_BAD_SITE_HINT	Invalid flag describing the structure of interpolation sites.
DF_ERROR_BAD_NDORDER	Invalid size of the array defining derivative orders to be computed at interpolation sites.
DF_ERROR_BAD_DORDER	Array defining derivative orders to be computed at interpolation sites is not defined.
DF_ERROR_BAD_DATA_HINT	Invalid flag providing additional information about partition or interpolation sites.
DF_ERROR_BAD_INTERP	Array of spline-based interpolation results is not defined.
DF_ERROR_BAD_INTERP_HINT	Invalid flag defining the structure of spline-based interpolation results.
DF_ERROR_BAD_CELL_IDX	Array of indices of partition cells containing interpolation sites is not defined.
DF_ERROR_BAD_NLIM	Invalid size of arrays containing integration limits.
DF_ERROR_BAD_LLIM	Array of the left-side integration limits is not defined.
DF_ERROR_BAD_RLIM	Array of the right-side integration limits is not defined.

Status Code	Description
DF_ERROR_BAD_INTEGR	Array of spline-based integration results is not defined.
DF_ERROR_BAD_INTEGR_HINT	Invalid flag providing the structure of the array of spline-based integration results.
DF_ERROR_BAD_LOOKUP_INTERP_SITE	Bad site provided for interpolation with look-up interpolator.

NOTE The routine that estimates piecewise polynomial cubic spline coefficients can return internal error codes related to the specifics of the implementation. Such error codes indicate invalid input data or other issues unrelated to Data Fitting routines.

Task Creation and Initialization Routines

Task creation and initialization routines are functions used to create a new task descriptor and initialize its parameters. The Data Fitting component provides the df?newtask1d routine that creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

df?newtask1d

Creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

Syntax

Fortran:

```
status = dfsnewtask1d(task, nx, x, xhint, ny, y, yhint)
status = dfdnewtask1d(task, nx, x, xhint, ny, y, yhint)
```

C:

```
status = dfsNewTask1D(&task, nx, x, xhint, ny, y, yhint)
status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

Include Files

- Fortran: mkl_df.f90 and mkl_df.f77
- C: mkl_df.h

Input Parameters

Name	Type	Description
nx	**Fortran:** INTEGER **C:** MKL_INT*	Number of breakpoints representing partition of interpolation interval [a, b].
x	**Fortran:** REAL(KIND=4) DIMENSION(*) for dfsnewtask1d REAL(KIND=8) DIMENSION(*) for dfdnewtask1d	One-dimensional array containing the sorted breakpoints from interpolation interval [a, b]. The structure of the array is defined by parameter *xhint*: • If partition is non-uniform or quasi-uniform, the array should contain *nx* ordered values.

Name	Type	Description
	C: `float*` for `dfsNewTask1D` `double*` for `dfdNewTask1D`	• If partition is uniform, the array should contain two entries that represent endpoints of interpolation interval [`a`, `b`].
xhint	**Fortran:** `INTEGER` **C:** `MKL_INT`	A flag describing the structure of partition *x*. For the list of possible values of *xhint*, see table "Hint Values for Partition *x*". If you set the flag to the `DF_NO_HINT` value, the library interprets the partition as non-uniform.
ny	**Fortran:** `INTEGER` **C:** `MKL_INT`	Dimension of vector-valued function *y*.
y	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsnewtask1d` `REAL(KIND=8) DIMENSION(*)` for `dfdnewtask1d` **C:** `float*` for `dfsNewTask` `double*` for `dfdNewTask`	Vector-valued function *y*, array of size *nx***ny*. The storage format of function values in the array is defined by the value of flag *yhint*.
yhint	**Fortran:** `INTEGER` **C:** `MKL_INT`	A flag describing the structure of array *y*. Valid hint values are listed in table "Hint Values for Vector-Valued Function *y*". If you set the flag to the `DF_NO_HINT` value, the library assumes that all *ny* coordinates of the vector-valued function *y* are provided and stored in row-major format.

Output Parameters

Name	Type	Description
task	**Fortran:** `TYPE(DF_TASK)` **C:** `DFTaskPtr`	Descriptor of the task.
status	**Fortran:** `INTEGER` **C:** `int`	Status of the routine: • `DF_STATUS_OK` if the task is created successfully. • Non-zero error code if the task creation failed. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?newtask1d` routine creates and initializes a new Data Fitting task descriptor with user-specified parameters for a one-dimensional Data Fitting task. The *x* and *nx* parameters representing the partition of interpolation interval [*a*, *b*] are mandatory. If you provide invalid values for these parameters, such as a `NULL` pointer *x* or the number of breakpoints smaller than two, the routine does not create the Data Fitting task and returns an error code.

If you provide a vector-valued function *y*, make sure that the function dimension *ny* and the array of function values *y* are both valid. If any of these parameters are invalid, the routine does not create the Data Fitting task and returns an error code.

If you store coordinates of the vector-valued function *y* in non-contiguous memory locations, you can set the *yhint* flag to DF_1ST_COORDINATE, and pass only the first coordinate of the function into the task creation routine. After successful creation of the Data Fitting task, you can pass the remaining coordinates using the df?editidxptr task editor.

If the routine fails to create the task descriptor, it returns a NULL task pointer.

The routine supports the following hint values for partition *x*:

Hint Values for Partition *x*

Value	Description
DF_NON_UNIFORM_PARTITION	Partition is non-uniform.
DF_QUASI_UNIFORM_PARTITION	Partition is quasi-uniform.
DF_UNIFORM_PARTITION	Partition is uniform.
DF_NO_HINT	No hint is provided. By default, partition is interpreted as non-uniform.

The routine supports the following hint values for the vector-valued function:

Hint Values for Vector-Valued Function *y*

Value	Description
DF_MATRIX_STORAGE_ROWS	Data is stored in row-major format according to C conventions.
DF_MATRIX_STORAGE_COLS	Data is stored in column-major format according to Fortran conventions.
DF_1ST_COORDINATE	The first coordinate of vector-valued data is provided.
DF_NO_HINT	No hint is provided. By default, the coordinates of vector-valued function *y* are provided and stored in row-major format.

Task Editors

Task editors initialize or change the predefined Data Fitting task parameters. You can use task editors to initialize or modify pointers to arrays or parameter values.

Task editors can be task-specific and generic. Task-specific editors can modify more than one parameter related to a specific task. Generic editors modify a single parameter at a time.

The Data Fitting component of the Intel MKL provides the following task editors:

Data Fitting Task Editors

Editor	Description	Type
df? editppspline1d	Changes parameters of the piecewise polynomial spline.	Task-specific
df?editptr	Changes a pointer in the task descriptor.	Generic
dfieditval	Changes a value in the task descriptor.	Generic
df?editidxptr	Changes a coordinate of data represented in matrix format. For example, a vector-valued function or spline coefficients.	Generic

df?editppspline1d

Modifies parameters representing a spline in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfseditppspline1d(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
status = dfdeditppspline1d(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

C:

```
status = dfsEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
status = dfdEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff, scoeffhint)
```

Include Files

- Fortran: `mkl_df.f90` and `mkl_df.f77`
- C: `mkl_df.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(DF_TASK)` **C:** `DFTaskPtr`	Descriptor of the task.
s_order	**Fortran:** `INTEGER` **C:** `MKL_INT`	Spline order. The parameter takes one of the values described in table "Spline Orders Supported by Data Fitting Functions".
s_type	**Fortran:** `INTEGER` **C:** `MKL_INT`	Spline type. The parameter takes one of the values described in table "Spline Types Supported by Data Fitting Functions".
bc_type	**Fortran:** `INTEGER` **C:** `MKL_INT`	Type of boundary conditions. The parameter takes one of the values described in table "Boundary Conditions Supported by Data Fitting Functions".
bc	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfseditppspline1d` `REAL(KIND=8) DIMENSION(*)` for `dfdeditppspline1d` **C:** `float*` for `dfsEditPPSpline1D` `double*` for `dfdEditPPSpline1D`	Pointer to boundary conditions. The size of the array is defined by the value of parameter *bc_type*: • If you set free-end or not-a-knot boundary conditions, pass the `NULL` pointer to this parameter. • If you combine boundary conditions at the endpoints of the interpolation interval, pass an array of two elements. • If you set a boundary condition for the default quadratic spline or a periodic condition for Hermite or the default cubic spline, pass an array of one element.

Name	Type	Description
ic_type	**Fortran:** INTEGER **C:** MKL_INT	Type of internal conditions. The parameter takes one of the values described in table "Internal Conditions Supported by Data Fitting Functions".
ic	**Fortran:** REAL(KIND=4) DIMENSION(*) for dfseditppspline1d REAL(KIND=8) DIMENSION(*) for dfdeditppspline1d **C:** float* for dfsEditPPSpline1D double* for dfdEditPPSpline1D	A non-NULL pointer to the array of internal conditions. The size of the array is defined by the value of parameter *ic_type*: • If you set first derivatives or second derivatives internal conditions (*ic_type*=DF_IC_1ST_DER or *ic_type*=DF_IC_2ND_DER), pass an array of n-1 derivative values at the internal points of the interpolation interval. • If you set the knot values internal condition for Subbotin spline (*ic_type*=DF_IC_Q_KNOT) and the knot partition is non-uniform, pass an array of n+1 elements. • If you set the knot values internal condition for Subbotin spline (*ic_type*=DF_IC_Q_KNOT) and the knot partition is uniform, pass an array of four elements.
scoeff	**Fortran:** REAL(KIND=4) DIMENSION(*) for dfseditppspline1d REAL(KIND=8) DIMENSION(*) for dfdeditppspline1d **C:** float* for dfsEditPPSpline1D double* for dfdEditPPSpline1D	Spline coefficients. An array of size *s_order**(*nx*-1). The storage format of the coefficients in the array is defined by the value of flag *scoeffhint*.
scoeffhint	**Fortran:** INTEGER **C:** MKL_INT	A flag describing the structure of the array of spline coefficients. For valid hint values, see table "Hint Values for Spline Coefficients". The library stores the coefficients in row-major format. The default value is DF_NO_HINT.

Output Parameters

Name	Type	Description
status	**Fortran:** INTEGER **C:** int	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The editor modifies parameters that describe the order, type, boundary conditions, internal conditions, and coefficients of a spline. The spline order definition is provided in the "Mathematical Conventions" section. You can set the spline order to any value supported by Data Fitting functions. The table below lists the available values:

Spline Orders Supported by the Data Fitting Functions

Order	Description
DF_PP_STD	Artificial value. Use this value for look-up and step-wise constant interpolants only.
DF_PP_LINEAR	Piecewise polynomial spline of the second order (linear spline).
DF_PP_QUADRATIC	Piecewise polynomial spline of the third order (quadratic spline).
DF_PP_CUBIC	Piecewise polynomial spline of the fourth order (cubic spline).

To perform computations with a spline not supported by Data Fitting routines, set the parameter defining the spline order and pass the spline coefficients to the library in one of the supported formats. For formats description, see table "Storage Formats for Spline Coefficients".

The table below lists the supported spline types:

Spline Types Supported by Data Fitting Functions

Type	Description
DF_PP_DEFAULT	The default spline type. You can use this type with linear, quadratic, or user-defined splines.
DF_PP_SUBBOTIN	Quadratic splines based on Subbotin algorithm, [StechSub76].
DF_PP_NATURAL	Natural cubic spline.
DF_PP_HERMITE	Hermite cubic spline.
DF_PP_BESSEL	Bessel cubic spline.
DF_PP_AKIMA	Akima cubic spline.
DF_LOOKUP_INTERPOLANT	Look-up interpolant.
DF_CR_STEPWISE_CONST_INTERPOLANT	Continuous right step-wise constant interpolant.
DF_CL_STEPWISE_CONST_INTERPOLANT	Continuous left step-wise constant interpolant.

If you perform computations with look-up or step-wise constant interpolants, set the spline order to the DF_PP_STD value.

Construction of specific splines may require boundary or internal conditions. To compute coefficients of such splines, you should pass boundary or internal conditions to the library by specifying the type of the conditions and providing the necessary values. For splines that do not require additional conditions, such as linear splines, set condition types to DF_NO_BC and DF_NO_IC, and pass NULL pointers to the conditions. The table below defines the supported boundary conditions:

Boundary Conditions Supported by Data Fitting Functions

Boundary Condition	Description	Spline
DF_BC_NOT_A_KNOT	Not-a-knot boundary conditions.	Akima, Bessel, Hermite, natural cubic
DF_BC_FREE_END	Free-end boundary conditions.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_LEFT_DER	The first derivative at the left endpoint is zero.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_RIGHT_DER	The first derivative at the right endpoint is zero.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ST_LEFT_DER	The second derivative at the left endpoint is zero.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ND_RIGHT_DER	The second derivative at the right endpoint is zero.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_PERIODIC	Periodic boundary conditions.	Linear, all cubic splines
DF_BC_Q_VAL	Function value at point $(x_0 + x_1)/2$	Default quadratic

You can combine the values of boundary conditions with a bitwise OR operation. This permits you to pass combinations of first and second derivatives at the endpoints of the interpolation interval into the library. To pass a first derivative at the left endpoint and a second derivative at the right endpoint, set the boundary conditions to DF_BC_1ST_LEFT_DER OR DF_BC_2ND_RIGHT_DER.

You should pass the combined boundary conditions as an array of two elements. The first entry of the array contains the value of the boundary condition for the left endpoint of the interpolation interval, and the second entry - for the right endpoint. Pass other boundary conditions as arrays of one element.

For the conditions defined as a combination of valid values, the library applies the following rules to identify the boundary condition type:

- If not required for spline construction, the value of boundary conditions is ignored.
- Not-a-knot condition has the highest priority. If set, other boundary conditions are ignored.
- Free-end condition has the second priority after the not-a-knot condition. If set, other boundary conditions are ignored.
- Periodic boundary condition has the next priority after the free-end condition.
- The first derivative has higher priority than the second derivative at the right and left endpoints.

If you set the periodic boundary condition, make sure that function values at the endpoints of the interpolation interval are identical. Otherwise, the library returns an error code. The table below specifies the values to be provided for each type of spline if the periodic boundary condition is set.

Boundary Requirements for Periodic Conditions

Spline Type	Periodic Boundary Condition Support	Boundary Value
Linear	Yes	Not required
Default quadratic	No	
Subbotin quadratic	No	
Natural cubic	Yes	Not required

Spline Type	Periodic Boundary Condition Support	Boundary Value
Bessel	Yes	Not required
Akima	Yes	Not required
Hermite cubic	Yes	First derivative
Default cubic	Yes	Second derivative

Internal conditions supported in the Data Fitting domain that you can use for the *ic_type* parameter are the following:

Internal Conditions Supported by Data Fitting Functions

Internal Condition	Description	Spline
DF_IC_1ST_DER	Array of first derivatives of size n-2, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Hermite cubic
DF_IC_2ND_DER	Array of second derivatives of size n-2, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Default cubic
DF_IC_Q_KNOT	Knot array of size n+1, where n is the number of breakpoints.	Subbotin quadratic

To construct a Subbotin quadratic spline, you have three options to get the array of knots in the library:

- If you do not provide the knots, the library uses the default values of knots $t = \{t_i\}$, $i = 0, \ldots, n$ according to the rule:

  $t_0 = x_0$, $t_n = x_{n-1}$, $t_i = (x_i + x_{i-1})/2$, $i = 1, \ldots, n - 1$.
- If you provide the knots in an array of size $n + 1$, the knots form a non-uniform partition. Make sure that the knot values you provide meet the following conditions:

  $t_0 = x_0$, $t_n = x_{n-1}$, $t_i \in (x_{i-1}, x_i)$, $i = 1,\ldots, n - 1$.
- If you provide the knots in an array of size 4, the knots form a uniform partition

  $t_0 = x_0$, $t_1 = l$, $t_2 = r$, $t_3 = x_{n-1}$, where $l \in (x_0, x_1)$ and $r \in (x_{n-2}, x_{n-1})$.

  In this case, you need to set the value of the *ic_type* parameter holding the type of internal conditions to DF_IC_Q_KNOT OR DF_UNIFORM_PARTITION.

NOTE Since the partition is uniform, perform an OR operation with the DF_UNIFORM_PARTITION partition hint value described in Table Hint Values for Partition x.

For computations based on look-up and step-wise constant interpolants, you can avoid calling the df?editppspline1d editor and directly call one of the routines for spline-based computation of spline values, derivatives, or integrals. For example, you can call the df?construct1d routine to construct the required spline with the given attributes, such as order or type.

The memory location of the spline coefficients is defined by the *scoeff* parameter. Make sure that the size of the array is sufficient to hold *s_order* * (*nx*-1) values.

The df?editppspline1d routine supports the following hint values for spline coefficients:

Hint Values for Spline Coefficients

Order	Description
DF_1ST_COORDINATE	The first coordinate of vector-valued data is provided.
DF_NO_HINT	No hint is provided. By default, all sets of spline coefficients are stored in row-major format.

The coefficients for all coordinates of the vector-valued function are packed in memory one by one in successive order, from function y_1 to function y_{ny}.

Within each coordinate, the library stores the coefficients as an array, in row-major format:

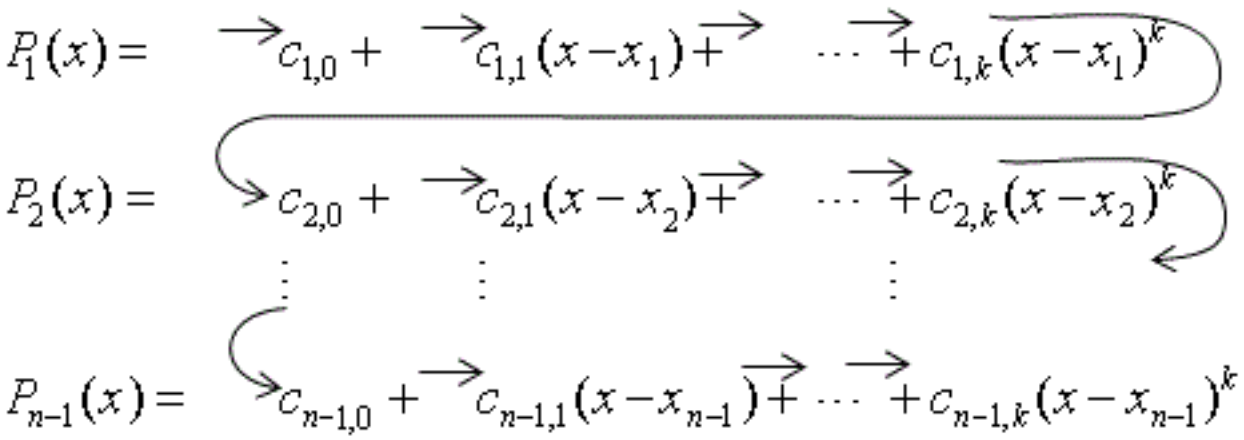
$c_{1,0}, c_{1,1}, \ldots, c_{1,k}, c_{2,0}, c_{2,1}, \ldots, c_{2,k}, \ldots, c_{n-1,0}, c_{n-1,1}, \ldots, c_{n-1,k}$

Mapping of the coefficients to storage in the *scoeff* array is described below, where $c_{i,j}$ is the jth coefficient of the function

$$P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \ldots + c_{i,k}(x - x_i)^k.$$

See Mathematical Conventions for more details on nomenclature and interpolants.

Row-major Coefficient Storage Format



If you store splines corresponding to different coordinates of the vector-valued function at non-contiguous memory locations, do the following:

1. Set the *scoeffhint* flag to DF_1ST_COORDINATE and provide the spline for the first coordinate.
2. Pass the spline coefficients for the remaining coordinates into the Data Fitting task using the df?editidxptr task editor.

Using the df?editppspline1d task editor, you can provide to the Data Fitting task an already constructed spline that you want to use in computations. To ensure correct interpretation of the memory content, you should set the following parameters:

- Spline order and type, if appropriate. If the spline is not supported by the library, set the *s_type* parameter to DF_PP_DEFAULT.
- Pointer to the array of spline coefficients in row-major format.
- The *scoeffhint* parameter describing the structure of the array:

- Set the *scoeffhint* flag to the DF_1ST_COORDINATE value to pass spline coefficients stored at different memory locations. In this case, you can set the parameters that describe boundary and internal conditions to zero.
- Use the default value DF_NO_HINT for all other cases.

After you provide the spline to the Data Fitting task, you can run computations that use this spline.

df?editptr

Modifies a pointer to an array held in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfseditptr(task, ptr_type, ptr)
status = dfdeditptr(task, ptr_type, ptr)
status = dfieditptr(task, ptr_type, ptr)
```

C:

```
status = dfsEditPtr(task, ptr_type, ptr)
status = dfdEditPtr(task, ptr_type, ptr)
status = dfiEditPtr(task, ptr_type, ptr)
```

Include Files

- Fortran: mkl_df.f90 and mkl_df.f77
- C: mkl_df.h

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(DF_TASK) **C:** DFTaskPtr	Descriptor of the task.
ptr_type	**Fortran:** INTEGER **C:** MKL_INT	The parameter to change. For details, see the *Pointer Type* column in table "Pointers Supported by the df?editptr Task Editor".
ptr	**Fortran:** REAL(KIND=4) DIMENSION(*) for dfseditptr REAL(KIND=8) DIMENSION(*) for dfdeditptr INTEGER DIMENSION(*) for dfieditptr **C:** float* for dfsEditPtr double* for dfdEditPtr MKL_INT* for dfiEditPtr	New pointer. For details, see the *Purpose* column in table "Pointers Supported by the df?editptr Task Editor".

Output Parameters

Name	Type	Description
status	**Fortran:** INTEGER **C:** int	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The df?editptr editor replaces the pointer of type *ptr_type* stored in a Data Fitting task descriptor with a new pointer *ptr*. The table below describes types of pointers supported by the editor:

Pointers Supported by the df?editptr Task Editor

Pointer Type	Purpose
DF_X	Partition *x* of the interpolation interval
DF_Y	Vector-valued function *y*
DF_IC	Internal conditions for spline construction. For details, see table "Internal Conditions Supported by Data Fitting Functions".
DF_BC	Boundary conditions for spline construction. For details, see table "Boundary Conditions Supported by Data Fitting Functions".
DF_PP_SCOEFF	Spline coefficients

You can use df?editptr to modify different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory. Use the df?editidxptr editor if you need to modify pointers to coordinates of the vector-valued function or spline coefficients stored at non-contiguous memory locations.

If you pass a NULL pointer to the df?editptr task editor, the task remains unchanged and the routine returns an error code. For the predefined error codes, please see "Task Status and Error Reporting".

dfieditval

Modifies a parameter value in a Data Fitting task descriptor.

Syntax

Fortran:

```
status = dfieditval(task, val_type, val)
```

C:

```
status = dfiEditVal(task, val_type, val)
```

Include Files

- Fortran: mkl_df.f90 and mkl_df.f77
- C: mkl_df.h

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(DF_TASK) **C:** DFTaskPtr	Descriptor of the task.
val_type	**Fortran:** INTEGER **C:** MKL_INT	The parameter to change. See table "Parameters Supported by the dfieditval Task Editor".
val	**Fortran:** INTEGER **C:** MKL_INT	A new parameter value. See table "Parameters Supported by the dfieditval Task Editor".

Output Parameters

Name	Type	Description
status	**Fortran:** INTEGER **C:** int	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The dfieditval task editor replaces the parameter of type *val_type* stored in a Data Fitting task descriptor with a new value *val*. The table below describes valid types of parameter *val_type* supported by the editor:

Parameters Supported by the dfieditval Task Editor

Parameter	Purpose
DF_NX	Number of breakpoints
DF_XHINT	A flag describing the structure of partition. See table "Hint Values for Partition *x*" for the list of available values.
DF_NY	Dimension of the vector-valued function
DF_YHINT	A flag describing the structure of the vector-valued function. See table "Hint Values for Vector Function *y*" for the list of available values.
DF_SPLINE_ORDER	Spline order. See table "Spline Orders Supported by Data Fitting Functions" for the list of available values.
DF_SPLINE_TYPE	Spline type. See table "Spline Types Supported by Data Fitting Functions" for the list of available values.
DF_BC_TYPE	Type of boundary conditions used in spline construction. See table "Boundary Conditions Supported by Data Fitting Functions" for the list of available values.
DF_IC_TYPE	Type of internal conditions used in spline construction. See table "Internal Conditions Supported by Data Fitting Functions" for the list of available values.

Parameter	Purpose
DF_PP_COEFF_HINT	A flag describing the structure of spline coefficients. See table "Hint Values for Spline Coefficients" for the list of available values.

If you pass a zero value for the parameter describing the size of the arrays that hold coefficients for a partition, a vector-valued function, or a spline, the parameter held in the Data fitting task remains unchanged and the routine returns an error code. For the predefined error codes, see "Task Status and Error Reporting".

If you modify the parameter describing dimensions of the arrays that hold the vector-valued function or spline coefficients in contiguous memory, you should call the df?editptr task editor with the corresponding pointers to the vector-valued function or spline coefficients even when this pointer remains unchanged. Call the df?editidxptr editor if those arrays are stored in non-contiguous memory locations.

df?editidxptr

Modifies a pointer to the memory representing a coordinate of the data stored in matrix format.

Syntax

Fortran:

```
status = dfseditidxptr(task, type, idx, ptr)
status = dfdeditidxptr(task, type, idx, ptr)
```

C:

```
status = dfsEditIdxPtr(task, type, idx, ptr)
status = dfdEditIdxPtr(task, type, idx, ptr)
```

Include Files

- Fortran: mkl_df.f90 and mkl_df.f77
- C: mkl_df.h

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(DF_TASK) **C:** DFTaskPtr	Descriptor of the task.
type	**Fortran:** INTEGER **C:** MKL_INT	Type of the data to be modified. The parameter takes one of the values described in "Data Attributes Supported by the df?editidxptr Task Editor".
idx	**Fortran:** INTEGER **C:** MKL_INT	Index of the coordinate whose pointer is to be modified.
ptr	**Fortran:** REAL(KIND=4) DIMENSION(*) for dfseditidxptr REAL(KIND=8) DIMENSION(*) for dfdeditidxptr	Pointer to the data that holds values of coordinate *idx*. For details, see table "Data Attributes Supported by the df?editidxptr Task Editor".

Name	Type	Description
	C: `float*` for `dfsEditIdxPtr` `double*` for `dfdEditIdxPtr`	

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Status of the routine: • `DF_STATUS_OK` if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The routine modifies a pointer to the array that holds the *idx* coordinate of vector-valued function *y* or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the editor if you need to pass into a Data Fitting task or modify the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations.

Before calling this editor, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?editppspline1d` editor.

Data Attributes Supported by the df?editidxptr Task Editor

Data Attribute	Description
`DF_Y`	Vector-valued function *y*
`DF_PP_SCOEFF`	Piecewise polynomial spline coefficients

When using `df?editidxptr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension *ny* of the vector-valued function.
- You pass a `NULL` pointer to the editor. In this case, the task remains unchanged.

The code example below demonstrates how to use the editor for providing values of a vector-valued function stored in two non-contiguous arrays:

```
#define NX 1000  /* number of break points       */
#define NY 2     /* dimension of vector-valued function */
int main()
{
    DFTaskPtr task;
    double x[NX];
    double y1[NX], y2[NX]; /* vector-valued function is stored as two arrays */
    /* Provide first coordinate of two-dimensional function y into creation routine */
    status = dfdNewTask1D( &task, NX, x, DF_NON_UNIFORM_PARTITION, NY, y1,
                           DF_1ST_COORDINATE );
    /* Provide second coordiante of two-dimensional function */
    status = dfdEditIdxPtr(task, DF_Y, 1, y2 );
    ...
}
```

Computational Routines

Data Fitting computational routines are functions used to perform spline-based computations, such as:

- spline construction
- computation of values, derivatives, and integrals of the predefined order
- cell search

Once you create a Data Fitting task and initialize the required parameters, you can call computational routines as many times as necessary.

The table below lists the available computational routines:

Data Fitting Computational Routines

Routine	Description
df?construct1d	Constructs a spline for a one-dimensional Data Fitting task.
df?interpolate1d	Computes spline values and derivatives.
df?interpolateex1d	Computes spline values and derivatives by calling user-provided interpolants.
df?integrate1d	Computes spline-based integrals.
df?integrateex1d	Computes spline-based integrals by calling user-provided integrators.
df?searchcells1d	Finds indices of cells containing interpolation sites.
df?searchcellsex1d	Finds indices of cells containing interpolation sites by calling user-provided cell searchers.

If a Data Fitting computation completes successfully, the computational routines return the `DF_STATUS_OK` code. If an error occurs, the routines return an error code specifying the origin of the failure. Some possible errors are the following:

- The task pointer is `NULL`.
- Memory allocation failed.
- The computation failed for another reason.

For the list of available status codes, see "Task Status and Error Reporting".

NOTE Data Fitting computational routines do not control errors for floating-point conditions, such as overflow, gradual underflow, or operations with Not a Number (NaN) values.

df?construct1d

Constructs a spline of the given type.

Syntax

Fortran:

```
status = dfsconstruct1d(task, s_format, method)
status = dfdconstruct1d(task, s_format, method)
```

C:

```
status = dfsConstruct1D(task, s_format, method)
status = dfdConstruct1D(task, s_format, method)
```

Include Files

- Fortran: `mkl_df.f90` and `mkl_df.f77`
- C: `mkl_df.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(DF_TASK)` **C:** `DFTaskPtr`	Descriptor of the task.
s_format	**Fortran:** `INTEGER` **C:** `MKL_INT`	Spline format. The supported value is `DF_PP_SPLINE`.
method	**Fortran:** `INTEGER` **C:** `MKL_INT`	Construction method. The supported value is `DF_METHOD_STD`.

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Status of the routine: • `DF_STATUS_OK` if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

Before calling `df?construct1d`, you need to create and initialize the task, and set the parameters representing the spline. Then you can call the `df?construct1d` routine to construct the spline. The format of the spline is defined by parameter *s_format*. The method for spline construction is defined by parameter *method*. Upon successful construction, the spline coefficients are available in the user-provided memory location in the format you set through the Data Fitting editor. For the available storage formats, see table "Hint Values for Spline Coefficients".

df?interpolate1d/df?interpolateex1d

Runs data fitting computations.

Syntax

Fortran:

status = dfsinterpolate1d(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*)

status = dfdinterpolate1d(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*)

status = dfsinterpolateex1d(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

status = dfdinterpolateex1d(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

C:

status = dfsInterpolate1D(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*)

status = dfdInterpolate1D(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*)

status = dfsInterpolateEx1D(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

status = dfdInterpolateEx1D(*task*, *type*, *method*, *nsite*, *site*, *sitehint*, *ndorder*, *dorder*, *datahint*, *r*, *rhint*, *cell*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

Include Files

- Fortran: `mkl_df.f90` and `mkl_df.f77`
- C: `mkl_df.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(DF_TASK)` **C:** `DFTaskPtr`	Descriptor of the task.
type	**Fortran:** `INTEGER` **C:** `MKL_INT`	Type of spline-based computations. The parameter takes one or more values combined with an `OR` operation. For the list of possible values, see table "Computation Types Supported by the `df?interpolate1d`/ `df?interpolate1d` Routines".
method	**Fortran:** `INTEGER` **C:** `MKL_INT`	Computation method. The supported value is `DF_METHOD_PP`.
nsite	**Fortran:** `INTEGER` **C:** `MKL_INT`	Number of interpolation sites.
site	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsinterpolate1d`/ `dfsinterpolateex1d` `REAL(KIND=8) DIMENSION(*)` for `dfdinterpolate1d`/ `dfdinterpolateex1d` **C:** `float*` for `dfsInterpolate1D`/ `dfsInterpolateEx1D`	Array of interpolation sites of size *nsite*. The structure of the array is defined by the *sitehint* parameter: • If sites form a non-uniform partition, the array should contain *nsite* values. • If sites form a uniform partition, the array should contain two entries that represent the left and the right interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.

Name	Type	Description
	`double*` for `dfdInterpolate1D`/ `dfdInterpolateEx1D`	
sitehint	**Fortran:** `INTEGER` **C:** `MKL_INT`	A flag describing the structure of the interpolation sites. For the list of possible values of *sitehint*, see table "Hint Values for Interpolation Sites". If you set the flag to `DF_NO_HINT`, the library interprets the site-defined partition as non-uniform.
ndorder	**Fortran:** `INTEGER` **C:** `MKL_INT`	Maximal derivative order increased by one to be computed at interpolation sites.
dorder	**Fortran:** `INTEGER DIMENSION(*)` **C:** `MKL_INT*`	Array of size *ndorder* that defines the order of the derivatives to be computed at the interpolation sites. If all the elements in *dorder* are zero, the library computes the spline values only. If you do not need interpolation computations, set *ndorder* to zero and pass a `NULL` pointer to *dorder*.
datahint	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsinterpolate1d`/ `dfsinterpolateex1d` `REAL(KIND=8) DIMENSION(*)` for `dfdinterpolate1d`/ `dfdinterpolateex1d` **C:** `float*` for `dfsInterpolate1D`/ `dfsInterpolateEx1D` `double*` for `dfdInterpolate1D`/ `dfdInterpolateEx1D`	Array that contains additional information about the structure of partition *x* and interpolation sites. This data helps to speed up the computation. If you provide a `NULL` pointer, the routine uses the default settings for computations. For details on the *datahint* array, see table "Structure of the *datahint* Array".
r	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsinterpolate1d`/ `dfsinterpolateex1d` `REAL(KIND=8) DIMENSION(*)` for `dfdinterpolate1d`/ `dfdinterpolateex1d` **C:** `float*` for `dfsInterpolate1D`/ `dfsInterpolateEx1D` `double*` for `dfdInterpolate1D`/ `dfdInterpolateEx1D`	Array that contains results of computations at the interpolation sites. If you do not need spline-based interpolation or integration, set this pointer to `NULL`.

Name	Type	Description
rhint	**Fortran:** INTEGER **C:** MKL_INT	A flag describing the structure of the results. For the list of possible values of *rhint*, see table "Hint Values for the *rhint* Parameter". If you set the flag to DF_NO_HINT, the library stores the result in row-major format.
cell	**Fortran:** INTEGER DIMENSION(*) **C:** MKL_INT*	Array of cell indices in partition *x* that contain the interpolation sites. If you do not need cell indices, set this parameter to NULL.
le_cb	**Fortran:** INTEGER **C:** dfsInterpCallBack for dfsInterpolateEx1D dfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for extrapolation at the sites to the left of the interpolation interval.
le_params	**Fortran:** INTEGER DIMENSION(*) **C:** void*	Pointer to additional user-defined parameters passed by the library to the *le_cb* function.
re_cb	**Fortran:** INTEGER **C:** dfsInterpCallBack for dfsInterpolateEx1D dfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for extrapolation at the sites to the right of the interpolation interval.
re_params	**Fortran:** INTEGER DIMENSION(*) **C:** void*	Pointer to additional user-defined parameters passed by the library to the *re_cb* function.
i_cb	**Fortran:** INTEGER **C:** dfsInterpCallBack for dfsInterpolateEx1D dfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for interpolation within the interpolation interval.
i_params	**Fortran:** INTEGER DIMENSION(*) **C:** void*	Pointer to additional user-defined parameters passed by the library to the *i_cb* function.
search_cb	**Fortran:** INTEGER **C:** dfsSearchCellsCallBack for dfsInterpolateEx1D dfdSearchCellsCallBack for dfdInterpolateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites.
search_params	**Fortran:** INTEGER DIMENSION(*)	Pointer to additional user-defined parameters passed by the library to the *search_cb* function.

Name	Type	Description
	C: `void*`	

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Status of the routine: • `DF_STATUS_OK` if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?interpolate1d`/`df?interpolateex1d` routine performs spline-based computations with user-defined settings. The routine supports two types of computations for interpolation sites provided in array *site*:

Computation Types Supported by the df?interpolate1d/df?interpolateex1d Routines

Type	Description
`DF_INTERP`	Compute derivatives of predefined order. The derivative of the zero order is the spline value.
`DF_CELL`	Compute indices of cells in partition x that contain the sites.

If the sites do not belong to interpolation interval $[a, b]$, the library uses:

- polynomial P_0 of the spline constructed on interval $[x_0, x_1]$ for computations at the sites to the left of a.
- polynomial P_{n-2} of the spline constructed on interval $[x_{n-2}, x_{n-1}]$ for computations at the sites to the right of b.

Interpolation sites support the following hints:

Hint Values for Interpolation Sites

Value	Description
`DF_NON_UNIFORM_PARTITION`	Partition is non-uniform.
`DF_UNIFORM_PARTITION`	Partition is uniform.
`DF_SORTED_DATA`	Interpolation sites are sorted in the ascending order and define a non-uniform partition.
`DF_NO_HINT`	No hint is provided. By default, the partition defined by interpolation sites is interpreted as non-uniform.

NOTE If you pass a sorted array of interpolation sites to the Intel MKL, set the *sitehint* parameter to the `DF_SORTED_DATA` value. The library uses this information when choosing the search algorithm and ignores any other data hints about the structure of the interpolation sites.

Data Fitting computation routines can use the following hints to speed up the computation:

- `DF_UNIFORM_PARTITION` describes the structure of breakpoints and the interpolation sites.

- DF_QUASI_UNIFORM_PARTITION describes the structure of breakpoints.

Pass the above hints to the library when appropriate.

The *r* pointer defines the memory location for the sets of interpolation and integration results for all coordinates of function *y*. The sets are stored one by one, in the successive order of the function coordinates from y_1 to y_{ny}.

You can define the following settings for packing the results within each set:

- Computation type: interpolation, integration, or both.
- Computation parameters: derivative orders.
- Storage format for the results. You can specify the format using the *rhint* parameter values described in the table below:

Hint Values for the *rhint* Parameter

Value	Description
DF_MATRIX_STORAGE_ROWS	Data is stored in row-major format according to C conventions.
DF_MATRIX_STORAGE_COLS	Data is stored in column-major format according to Fortran conventions.
DF_NO_HINT	No hint is provided. By default, the results are stored in row-major format.

For spline-based interpolation, you should set the derivatives whose values are required for the computation. You can provide the derivatives by setting the *dorder* array of size *ndorder* as follows:

$$dorder[i] = \begin{cases} 1, \text{if derivative of the } i-\text{th order is required} \\ 0, \text{otherwise} \end{cases} \qquad i = 0, \ldots, ndorder-1$$

See below a common structure of the storage formats of the interpolation results within each set *r* for computing derivatives of order $i_1, i_2, \ldots, i_m$ at *nsite* interpolation sites. In this description, *j* is the coordinate of the vector-valued function:

- Row-major format

$r_j(i_1, 0)$	$r_j(i_2, 0)$	...	$r_j(i_m, 0)$
$r_j(i_1, 1)$	$r_j(i_2, 1)$	...	$r_j(i_m, 1)$
...	...	...	...
$r_j(i_1, nsite - 1)$	$r_j(i_2, nsite - 1)$	...	$r_j(i_m, nsite - 1)$

- Column-major format

$r_j(i_1, 0)$	$r_j(i_1, 1)$	...	$r_j(i_1, nsite - 1)$
$r_j(i_2, 0)$	$r_j(i_2, 1)$	...	$r_j(i_2, nsite - 1)$
...	...	...	...
$r_j(i_m, 0)$	$r_j(i_m, 1)$	...	$r_j(i_m, nsite - 1)$

To speed up Data Fitting computations, use the *datahint* parameter that provides additional information about the structure of the partition and interpolation sites. This data represents a floating-point or a double array with the following structure:

Structure of the *datahint* Array

Element Number	Description
0	Task dimension
1	Type of additional information
2	Reserved field
3	The total number *q* of elements containing additional information.
4	Element (1)
...	...
q+3	Element (*q*)

Data Fitting computation functions support the following types of additional information for *datahint*[1]:

Types of Additional Information

Type	Element Number	Parameter
DF_NO_APRIORI_INFO	0	No parameters are provided. Information about the data structure is absent.
DF_APRIORI_MOST_LIKELY_CELL	1	Index of the cell that is likely to contain interpolation sites.

To compute indices of the cells that contain interpolation sites, provide the pointer to the array of size *nsite* for the results. The library supports the following scheme of cell indexing for the given partition$\{x_i\}$, $i=1,...,nx$:

$cell[j] = i$, if $site[j] \in [x_i, x_{i+1})$, $i = 0,..., nx$,

where

- $x_0 = -\infty$
- $x_{nx+1} = +\infty$
- $j = 0,..., nsite-1$

To perform interpolation computations with spline types unsupported in the Data Fitting component, use the extended version of the routine `df?interpolateex1d`. With this routine, you can provide user-defined callback functions for computations within, to the left of, or to the right of interpolaton interval [*a*, *b*]. The callback functions compute indices of the cells that contain the specified interpolation sites or can serve as an approximation for computing the exact indices of such cells.

If you do not pass any function for computations at the sites outside the interval [*a*, *b*], the routine uses the default settings.

See Also

df?interpcallback
df?searchcellscallback

df?integrate1d/df?integrateex1d

Computes a spline-based integral.

Syntax

Fortran:

status = dfsintegrate1d(*task*, *method*, *nlim*, *llim*, *llimhint*, *rlim*, *rlimhint*, *ldatahint*, *rdatahint*, *r*, *rhint*)

status = dfdintegrate1d(*task*, *method*, *nlim*, *llim*, *llimhint*, *rlim*, *rlimhint*, *ldatahint*, *rdatahint*, *r*, *rhint*)

status = dfsintegrateex1d(*task*, *method*, *nlim*, *llim*, *llimhint*, *rlim*, *rlimhint*, *ldatahint*, *rdatahint*, *r*, *rhint*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

status = dfdintegrateex1d(*task*, *method*, *nlim*, *llim*, *llimhint*, *rlim*, *rlimhint*, *ldatahint*, *rdatahint*, *r*, *rhint*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

C:

status = dfsIntegrate1D(*task*, *method*, *nlim*, *llim*, *llimhint*, *rlim*, *rlimhint*, *ldatahint*, *rdatahint*, *r*, *rhint*)

status = dfdIntegrate1D(*task*, *method*, *nlim*, *llim*, *llimhint*, *rlim*, *rlimhint*, *ldatahint*, *rdatahint*, *r*, *rhint*)

status = dfsIntegrateEx1D(*task*, *method*, *nlim*, *llim*, *llimhint*, *rlim*, *rlimhint*, *ldatahint*, *rdatahint*, *r*, *rhint*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

status = dfdIntegrateEx1D(*task*, *method*, *nlim*, *llim*, *llimhint*, *rlim*, *rlimhint*, *ldatahint*, *rdatahint*, *r*, *rhint*, *le_cb*, *le_params*, *re_cb*, *re_params*, *i_cb*, *i_params*, *search_cb*, *search_params*)

Include Files

- Fortran: `mkl_df.f90` and `mkl_df.f77`
- C: `mkl_df.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(DF_TASK)` **C:** `DFTaskPtr`	Descriptor of the task.
method	**Fortran:** `INTEGER` **C:** `MKL_INT`	Integration method. The supported value is `DF_METHOD_PP`.
nlim	**Fortran:** `INTEGER` **C:** `MKL_INT`	Number of pairs of integraion limits.
llim	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrate1d`/ `dfsintegrateex1d`	Array of size *nlim* that defines the left-side integration limits.

Name	Type	Description
	`REAL(KIND=8) DIMENSION(*)` for `dfdintegrate1d`/ `dfdintegrateex1d` **C:** `float*` for `dfsIntegrate1D`/ `dfsIntegrateEx1D` `double*` for `dfdIntegrate1D`/ `dfdIntegrateEx1D`	
llimhint	**Fortran:** `INTEGER` **C:** `MKL_INT`	A flag describing the structure of the left-side integration limits *llim*. For the list of possible values of *llimhint*, see table "Hint Values for Integration Limits". If you set the flag to the `DF_NO_HINT` value, the library assumes that the left-side integration limits define a non-uniform partition.
rlim	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrate1d`/ `dfsintegrateex1d` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrate1d`/ `dfdintegrateex1d` **C:** `float*` for `dfsIntegrate1D`/ `dfsIntegrateEx1D` `double*` for `dfdIntegrate1D`/ `dfdIntegrateEx1D`	Array of size *nlim* that defines the right-side integration limits.
rlimhint	**Fortran:** `INTEGER` **C:** `MKL_INT`	A flag describing the structure of the right-side integration limits *rlim*. For the list of possible values of *rlimhint*, see table "Hint Values for Integration Limits". If you set the flag to the `DF_NO_HINT` value, the library assumes that the right-side integration limits define a non-uniform partition.
ldatahint	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrate1d`/ `dfsintegrateex1d` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrate1d`/ `dfdintegrateex1d` **C:** `float*` for `dfsIntegrate1D`/ `dfsIntegrateEx1D`	Array that contains additional information about the structure of partition *x* and left-side integration limits. For details on the *ldatahint* array, see table "Structure of the *datahint* Array" in the description of the `df?Intepolate1D` function.

Name	Type	Description
	`double*` for `dfdIntegrate1D`/ `dfdIntegrateEx1D`	
rdatahint	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrate1d`/ `dfsintegrateex1d` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrate1d`/ `dfdintegrateex1d` **C:** `float*` for `dfsIntegrate1D`/ `dfsIntegrateEx1D` `double*` for `dfdIntegrate1D`/ `dfdIntegrateEx1D`	Array that contains additional information about the structure of partition *x* and right-side integration limits. For details on the *rdatahint* array, see table "Structure of the *datahint* Array" in the description of the `df? Intepolate1D` function.
r	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrate1d`/ `dfsintegrateex1d` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrate1d`/ `dfdintegrateex1d` **C:** `float*` for `dfsIntegrate1D`/ `dfsIntegrateEx1D` `double*` for `dfdIntegrate1D`/ `dfdIntegrateEx1D`	Array of `integration` results. The size of the array should be sufficient to hold *nlim***ny* values, where *ny* is the dimension of the vector-valued function. The integration results are packed according to the settings in *rhint*.
rhint	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrate1d`/ `dfsintegrateex1d` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrate1d`/ `dfdintegrateex1d` **C:** `float*` for `dfsIntegrate1D`/ `dfsIntegrateEx1D`	A flag describing the structure of the results. For the list of possible values of *rhint*, see table "Hint Values for Integration Results". If you set the flag to the `DF_NO_HINT` value, the library stores the results in row-major format.

Name	Type	Description
	`double*` for `dfdIntegrate1D`/ `dfdIntegrateEx1D`	
le_cb	**Fortran:** `INTEGER` **C:** `dfsIntegrCallBack` for `dfsIntegrateEx1D` `dfdIntegrCallBack` for `dfdIntegrateEx1D`	User-defined callback function for integration on interval [*llim*[*i*], `min`(*rlim*[*i*], *a*)) for *llim*[*i*] < *a* .
le_params	**Fortran:** `INTEGER DIMENSION(*)` **C:** `void*`	Pointer to additional user-defined parameters passed by the library to the *le_cb* function.
re_cb	**Fortran:** `INTEGER` **C:** `dfsInterpCallBack` for `dfsIntegrateEx1D` `dfdInterpCallBack` for `dfdIntegrateEx1D`	User-defined callback function for integration on interval [`max`(*llim*[*i*], *b*), *rlim*[*i*]) for *rlim*[*i*] ≥ *b*.
re_params	**Fortran:** `INTEGER DIMENSION(*)` **C:** `void*`	Pointer to additional user-defined parameters passed by the library to the *re_cb* function.
i_cb	**Fortran:** `INTEGER` **C:** `dfsIntegrCallBack` for `dfsIntegrateEx1D` `dfdIntegrCallBack` for `dfdIntegrateEx1D`	User-defined callback function for integration on interval [`max`(*a*, *llim*[*i*],), `min`(*rlim*[*i*], *b*)).
i_params	**Fortran:** `INTEGER DIMENSION(*)` **C:** `void*`	Pointer to additional user-defined parameters passed by the library to the *i_cb* function.
search_cb	**Fortran:** `INTEGER` **C:** `dfsSearchCellsCallBack` for `dfsIntegrateEx1D` `dfdSearchCellsCallBack` for `dfdIntegrateEx1D`	User-defined callback function for computing indices of cells that can contain interpolation sites.
search_params	**Fortran:** `INTEGER DIMENSION(*)` **C:** `void*`	Pointer to additional user-defined parameters passed by the library to the *search_cb* function.

Output Parameters

Name	Type	Description
status	**Fortran:** INTEGER **C:** int	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The df?integrate1d/df?integrateex1d routine computes spline-based integral on user-defined intervals

$$I(i,j) = \int_{llim[i]}^{rlim[i]} f_j(x)dx,\ i = 0,\ldots,nlim-1,\ j = 0,\ldots,ny-1$$

If *rlim*[*i*] < *llim*[*i*], the routine returns

$$I(i,j) = -\int_{rlim[i]}^{llim[i]} f_j(x)dx$$

The routine supports the following hint values for integration results:

Hint Values for Integration Results

Value	Description
DF_MATRIX_STORAGE_ROWS	Data is stored in row-major format according to C conventions.
DF_MATRIX_STORAGE_COLS	Data is stored in column-major format according to Fortran conventions.
DF_NO_HINT	No hint is provided. By default, the coordinates of vector-valued function *y* are provided and stored in row-major format.

A common structure of the storage formats for the integration results is as follows:

- Row-major format

I (0, 0)	...	*I* (0, *nlim* - 1])
...	...	...
I (*ny* – 1, 0)	...	*I* (*ny* - 1, *nlim* - 1])

- Column-major format

I (0, 0)	...	*I* (*ny* – 1, 0)
...	...	...
I (0, *nlim* - 1])	...	*I* (*ny* - 1, *nlim* - 1])

Using the *llimhint* and *rlimhint* parameters, you can provide the following hint values for integration limits:

Hint Values for Integration Limits

Value	Description
DF_SORTED_DATA	Integration limits are sorted in the ascending order and define a non-uniform partition.
DF_NON_UNIFORM_PARTITION	Partition defined by integration limits is non-uniform.
DF_UNIFORM_PARTITION	Partition defined by integration limits is uniform.
DF_NO_HINT	No hint is provided. By default, partition defined by integration limits is interpreted as non-uniform.

To compute integration with splines unsupported in the Data Fitting component, use the extended version of the routine df?integrateex1d. With this routine, you can provide user-defined callback functions that compute:

- integrals within, to the left of, or to the right of the interpolation interval [*a*, *b*]
- indices of cells that contain the provided integration limits or can serve as an approximation for computing the exact indices of such cells

If you do not pass a callback function, the routine uses the default settings.

status = dfdSearchCellsEx1D(*task*, *method*, *nsite*, *site*, *sitehint*, *datahint*, *cell*, *search_cb*, *search_params*)

Include Files

- Fortran: mkl_df.f90 and mkl_df.f77
- C: mkl_df.h

Input Parameters

Name	Type	Description
task	**Fortran:** TYPE(DF_TASK) **C:** DFTaskPtr	Descriptor of the task.
method	**Fortran:** INTEGER **C:** MKL_INT	Search method. The supported value is DF_METHOD_STD.
nsite	**Fortran:** INTEGER **C:** MKL_INT*	Number of interpolation sites.
site	**Fortran:** REAL(KIND=4) DIMENSION(*) for dfssearchcells1d/ dfssearchcellsex1d REAL(KIND=8) DIMENSION(*) for dfdsearchcells1d/ dfdsearchcellsex1d **C:** float* for dfsSearchCells1D/ dfsSearchCellsEx1D double* for dfdSearchCells1D/ dfdSearchCellsEx1D	Array of interpolation sites of size *nsite*. The structure of the array is defined by the *sitehint* parameter: • If the sites form a non-uniform partition, the array should contain *nsite* values. • If the sites form a uniform partition, the array should contain two entries that represent the left-most and the right-most interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.
sitehint	**Fortran:** INTEGER **C:** MKL_INT	A flag describing the structure of the interpolation sites. For the list of possible values of *sitehint*, see table "Hint Values for Interpolation Sites". If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.
datahint	**Fortran:** REAL(KIND=4) DIMENSION(*) for dfssearchcells1d/ dfssearchcellsex1d REAL(KIND=8) DIMENSION(*) for dfdsearchcells1d/ dfdsearchcellsex1d **C:** float* for dfsSearchCells1D/ dfsSearchCellsEx1D double* for dfdSearchCells1D/ dfdSearchCellsEx1D	Array that contains additional information about the structure of partition *x* and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the *datahint* array, see table "Structure of the *datahint* Array".
cell	**Fortran:** INTEGER DIMENSION(*) **C:** MKL_INT*	Array of cell indices in partition *x* that contain the interpolation sites.

Name	Type	Description
search_cb	**Fortran:** INTEGER **C:** dfsSearchCellsCallBack for dfsSearchCellsEx1D dfdSearchCellsCallBack for dfdSearchCellsEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites.
search_params	**Fortran:** INTEGER DIMENSION(*) **C:** void*	Pointer to additional user-defined parameters passed by the library to the *search_cb* function.

Output Parameters

Name	Type	Description
status	**Fortran:** INTEGER **C:** int	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The df?searchcells1d/df?searchcellsex1d routines return array *cell* of indices of sub-intervals (cells) in partition *x* that contain interpolation sites available in array *site*. For details on the cell indexing scheme, see the description of the df?interpolate1d/df?interpolateex1d computation routines.

Use the *datahint* parameter to provide additional information about the structure of the partition and/or interpolation sites. The definition of the *datahint* parameter is availalbe in the description of the df?interpolate1d/df?interpolateex1d computation routines.

For description of the user-defined callback for computation of cell indices, see df?searchcellscallback.

df?interpcallback

A callback function for user-defined interpolation to be passed into df?interpolateex1d.

Syntax

Fortran:

```
status = dfsinterpcallback(n, cell, site, r, params)
status = dfdinterpcallback(n, cell, site, r, params)
```

C:

```
status = dfsInterpCallBack(n, cell, site, r, params)
status = dfdInterpCallBack(n, cell, site, r, params)
```

Include Files

- Fortran: `mkl_df.f90` and `mkl_df.f77`
- C: `mkl_df.h`

Input Parameters

Name	Type	Description
n	**Fortran:** `INTEGER(KIND=8)` **C:** `long long*`	Number of interpolation sites.
cell	**Fortran:** `INTEGER(KIND=8) DIMENSION(*)` **C:** `long long*`	Array of size *n* containing indices of the cells to which the interpolation sites in array *site* belong.
site	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsinterpcallback` `REAL(KIND=8) DIMENSION(*)` for `dfdinterpcallback` **C:** `float*` for `dfsInterpCallBack` `double*` for `dfdInterpCallBack`	Array of interpolation sites of size *n*.
r	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsinterpcallback` `REAL(KIND=8) DIMENSION(*)` for `dfdinterpcallback` **C:** `float*` for `dfsInterpCallBack` `double*` for `dfdInterpCallBack`	Array of the computed interpolation results packed in row-major format.
params	**Fortran:** `INTEGER DIMENSION(*)` **C:** `void*`	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	The status returned by the callback function: • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • A positive value indicates a warning.

Name	Type	Description
		See "Task Status and Error Reporting" for error code definitions.

Description

When passed into the `df?interpolateex1d` routine, this function performs user-defined interpolation operation.

df?integrcallback

A callback function that you can pass into `df?integrateex1d` *to define integration computations.*

Syntax

Fortran:

```
status = dfsintegrcallback(n, lcell, llim, rcell, rlim, r, params)
status = dfdintegrcallback(n, lcell, llim, rcell, rlim, r, params)
```

C:

```
status = dfsIntegrCallBack(n, lcell, llim, rcell, rlim, r, params)
status = dfdIntegrCallBack(n, lcell, llim, rcell, rlim, r, params)
```

Include Files

- Fortran: `mkl_df.f90` and `mkl_df.f77`
- C: `mkl_df.h`

Input Parameters

Name	Type	Description
n	**Fortran:** `INTEGER(KIND=8)` **C:** `long long*`	Number of pairs of integration limits.
lcell	**Fortran:** `INTEGER(KIND=8) DIMENSION(*)` **C:** `long long*`	Array of size *n* with indices of the cells that contain the left-side integration limits in array *llim*.
llim	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrcallback` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrcallback` **C:** `float*` for `dfsIntegrCallBack`	Array of size *n* that holds the left-side integration limits.

Name	Type	Description
	`double*` for `dfdIntegrCallBack`	
rcell	**Fortran:** `INTEGER(KIND=8) DIMENSION(*)` **C:** `long long*`	Array of size *n* with indices of the cells that contain the right-side integration limits in array *rlim*.
rlim	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrcallback` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrcallback` **C:** `float*` for `dfsIntegrCallBack` `double*` for `dfdIntegrCallBack`	Array of size *n* that holds the right-side integration limits.
r	**Fortran:** `REAL(KIND=4) DIMENSION(*)` for `dfsintegrcallback` `REAL(KIND=8) DIMENSION(*)` for `dfdintegrcallback` **C:** `float*` for `dfsIntegrCallBack` `double*` for `dfdIntegrCallBack`	Array of integration results. For packing the results in row-major format, follow the instructions described in `df?interpolate1d/df?interpolateex1d`.
params	**Fortran:** `INTEGER DIMENSION(*)` **C:** `void*`	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	The status returned by the callback function: • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • A positive value indicates a warning. See "Task Status and Error Reporting" for error code definitions.

Description

When passed into the df?integrateex1d routine, this function defines integration computations. If at least one of the integration limits is outside the interpolation interval [*a*, *b*], the library decomposes the integration into sub-intervals that belong to the extrapolation range to the left of *a*, the extrapolation range to the right of *b*, and the interpolation interval [*a*, *b*], as follows:

- If the left integration limit is to the left of the interpolation interval (*llim*< *a*), the df?integrateex1d routine passes *llim* as the left integration limit and min(*rlim*, *a*) as the right integration limit to the user-defined callback function.
- If the right integration limit is to the right of the interpolation interval (*rlim*> *b*), the df?integrateex1d routine passes max(*llim*, *b*) as the left integration limit and *rlim* as the right integration limit to the user-defined callback function.
- If the left and the right integration limits belong to the interpolation interval, the df?integrateex1d routine passes them to the user-defined callback function unchanged.

The value of the integral is the sum of integral values obtained on the sub-intervals.

df?integrcallback
df?searchcellscallback

df?searchcellscallback

A callback function for user-defined search to be passed into df?interpolateex1d *or* df?searchcellsex1d*.*

Syntax

Fortran:

status = dfssearchcellscallback(*n*, *site*, *cell*, *flag*, *params*)

status = dfdsearchcellscallback(*n*, *site*, *cell*, *flag*, *params*)

C:

status = dfsSearchCellsCallBack(*n*, *site*, *cell*, *flag*, *params*)

status = dfdSearchCellsCallBack(*n*, *site*, *cell*, *flag*, *params*)

Include Files

- Fortran: mkl_df.f90 and mkl_df.f77
- C: mkl_df.h

Input Parameters

Name	Type	Description
n	**Fortran:** INTEGER(KIND=8) **C:** long long*	Number of interpolation sites.
site	**Fortran:** REAL(KIND=4) DIMENSION(*) for dfssearchcellscallback	Array of interpolation sites of size *n*.

Name	Type	Description
	`REAL(KIND=8) DIMENSION(*)` for `dfdsearchcellscallback` **C:** `float*` for `dfsSearchCellsCallBack` `double*` for `dfdSearchCellsCallBack`	
cell	**Fortran:** `INTEGER(KIND=8) DIMENSION(*)` **C:** `long long*`	Array of size *n* that returns indices of the cells computed by the callback function.
flag	**Fortran:** `INTEGER(KIND=4) DIMENSION(*)` **C:** `int*`	Array of size *n*, with values set as follows: • If the cell with index *cell*[*i*] contains *site*[*i*], set *flag*[*i*] to 1. • Otherwise, set *flag*[*i*] to zero. In this case, the library interprets the index as an approximation and computes the index of the cell containing *site*[*i*] by using the provided index as a starting point for the search.
params	**Fortran:** `INTEGER DIMENSION(*)` **C:** `void*`	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	The status returned by the callback function: • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • The `DF_STATUS_EXACT_RESULT` status indicates that cell indices returned by the callback function are exact. In this case, you do not need to initialize entries of the *flag* array. • A positive value indicates a warning. See "Task Status and Error Reporting" for error code definitions.

Description

When passed into the `df?interpolateex1d` or `df?searchcellsex1d` routine, this function performs a user-defined search.

Task Destructors

Task destructors are routines used to delete task descriptors and deallocate the corresponding memory resources. The Data Fitting task destructor `dfdeletetask` destroys a Data Fitting task and frees the memory.

dfdeletetask

Destroys a Data Fitting task object and frees the memory.

Syntax

Fortran:

```
status = dfdeletetask(task)
```

C:

```
status = dfDeleteTask(&task)
```

Include Files

- Fortran: `mkl_df.f90` and `mkl_df.f77`
- C: `mkl_df.h`

Input Parameters

Name	Type	Description
task	**Fortran:** `TYPE(DF_TASK)` **C:** `DFTaskPtr`	Descriptor of the task to destroy.

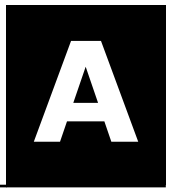
Output Parameters

Name	Type	Description
status	**Fortran:** `INTEGER` **C:** `int`	Status of the routine: • `DF_STATUS_OK` if the task is deleted successfully. • Non-zero error code if the operation failed. See "Task Status and Error Reporting" for error code definitions.

Description

Given a pointer to a task descriptor, this routine deletes the Data Fitting task descriptor and frees the memory allocated for the structure. If the task is deleted successfully, the routine sets the task pointer to `NULL`. Otherwise, the routine returns an error code.

Linear Solvers Basics



Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation, $Ax = b$, where A is an m-by-n matrix, x is the n element column vector and b is the m element column vector. The matrix A is usually referred to as the coefficient matrix, and the vectors x and b are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in section Sparse Linear Systems that follows.

Sparse Linear Systems

In many real-life applications, most of the elements in A are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation $Ax = b$ can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

Iterative Solvers start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix A. Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently for the right applications, iterative solvers can be very efficient.

Direct Solvers, on the other hand, often factor the matrix A into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array A.

Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row i and column j in matrix A is denoted by $a(i,j)$. For example, a 3 by 4 matrix A, is written as follows:

$$A = \begin{bmatrix} a(1,1) & a(1,2) & a(1,3) & a(1,4) \\ a(2,1) & a(2,2) & a(2,3) & a(2,4) \\ a(3,1) & a(3,2) & a(3,3) & a(3,4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix A with the property that $a(i,j) = a(j,i)$, is called a symmetric matrix. A complex matrix A with the property that $a(i,j) = conj(a(j,i))$, is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix A is the matrix obtained by "flipping" the elements of the array about its diagonal. That is, we exchange the elements $a(i,j)$ and $a(j,i)$. For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix A are denoted by A^T and A^H respectively.

A column vector, or simply a vector, is a $n \times 1$ matrix, and a row vector is a $1 \times n$ matrix. A real or complex matrix A is said to be positive definite if the vector-matrix product x^TAx is greater than zero for all non-zero vectors x. A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix P is called a permutation matrix if, for any matrix A, the result of the matrix product PA is identical to A except for interchanging the rows of A. For a square matrix, it can be shown that if PA is a permutation of the rows of A, then AP^T is the same permutation of the columns of A. Additionally, it can be shown that the inverse of P is P^T.

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the i-th row of a matrix to the j-th row, then the i-th element of the permutation vector is j.

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system $Ax = b$ is to first factor A into triangular matrices. That is, find a lower triangular matrix L and an upper triangular matrix U, such that $A = LU$. Having obtained such a factorization (usually referred to as an LU decomposition or LU factorization), the solution to the original problem can be rewritten as follows.

$$Ax = b$$
$$\Rightarrow \quad LUx = b$$
$$\Rightarrow \quad L(Ux) = b$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations $Ly = b$.
2. Solve the system $Ux = y$.

Solving the systems $Ly = b$ and $Ux = y$ is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix A is also positive definite, it can be shown that A can be factored as LL^T where L is a lower triangular matrix. Similarly, a Hermitian matrix, A, that is positive definite can be factored as $A = LL^H$. For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix U in an LU decomposition is either L^T or L^H. Consequently, a solver can increase its efficiency by only storing L, and one-half of A, and not computing U. Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if A is symmetric but not positive definite, then A can be factored as $A = LDL^T$, where D is a diagonal matrix and L is a lower unit triangular matrix. Similarly, if A is Hermitian, it can be factored as $A = LDL^H$. In either case, we again only need to store L, D, and half of A and we need not compute U. However, the backward solve phases must be amended to solving $L^Tx = D^{-1}y$ rather than $L^Tx = y$.

Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation $Ax = b$, where A is a symmetric positive definite sparse matrix, and A and b are defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & \frac{1}{2} & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & * & \frac{5}{8} & * \\ 3 & * & * & * & 16 \end{bmatrix}, b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (*) is used to represent zeros and to emphasize the sparsity of A. The Cholesky factorization of A is: $A = LL^T$, where L is the following:

Notice that even though the matrix A is relatively sparse, the lower triangular matrix L has no zeros below the diagonal. If we computed L and then used it for the forward and backward solve phase, we would do as much computation as if A had been dense.

The situation of L having non-zeros in places where A has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of A in such a way as to reduce the fill-in when computing L. By doing this, the solver would only need to compute the non-zero entries in L. Toward this end, consider permuting the rows and columns of A. As described in Matrix Fundamentals section , the permutations of the rows of A can be represented as a permutation matrix, P. The result of permuting the rows is the product of P and A. Suppose, in the above example, we swap the first and fifth row

of A, then swap the first and fifth columns of A, and call the resulting matrix B. Mathematically, we can express the process of permuting the rows and columns of A to get B as $B = PAP^T$. After permuting the rows and columns of A, we see that B is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since B is obtained from A by simply switching rows and columns, the numbers of non-zero entries in A and B are the same. However, when we find the Cholesky factorization, $B = LL^T$, we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{\frac{3}{5}}}{4} \end{bmatrix}$$

The fill-in associated with B is much smaller than the fill-in associated with A. Consequently, the storage and computation time needed to factor B is much smaller than to factor A. Based on this, we see that an efficient sparse solver needs to find permutation P of the matrix A, which minimizes the fill-in for factoring $B = PAP^T$, and then use the factorization of B to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general LU decomposition. Specifically, let P be a permutation matrix, $B = PAP^T$ and suppose that B can be factored as $B = LU$. Then

$Ax = b$

$\Rightarrow$ $PA(P^{-1}P)x = Pb$

$\Rightarrow$ $PA(P^TP)x = Pb$

$\Rightarrow$ $(PAP^T)(Px) = Pb$

$\Rightarrow$ $B(Px) = Pb$

$\Rightarrow$ $LU(Px) = Pb$

It follows that if we obtain an LU factorization for B, we can solve the original system of equations by a three step process:

1. Solve $Ly = Pb$.
2. Solve $Uz = y$.
3. Set $x = P^T z$.

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation $Ly = Pb$:

$$Ly = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{\frac{3}{5}}}{4} \end{bmatrix} * \begin{bmatrix} y1 \\ y2 \\ y3 \\ y4 \\ y5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

This gives: $y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{\frac{3}{5}}}{12}$.

The second step is to perform the backward solve, $Uz = y$. Or, in this case, since a Cholesky factorization is used, $L^T z = y$.

$$\begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{\frac{3}{5}}}{4} \end{bmatrix}^T * \begin{bmatrix} z1 \\ z2 \\ z3 \\ z4 \\ z5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{\frac{3}{5}}}{12} \end{bmatrix}$$

This gives $z^T = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}$.

The third and final step is to set $x = P^T z$. This gives $X^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}$.

Sparse Matrix Storage Formats

As discussed above, it is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

Storage Formats for the Direct Sparse Solvers

The storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel MKL direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel MKL sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

values	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the *values* array using the row-major upper triangular storage mapping described above.
columns	Element *i* of the integer array *columns* is the number of the column that contains the *i*-th element in the *values* array.
rowIndex	Element *j* of the integer array *rowIndex* gives the index of the element in the *values* array that is first non-zero element in a row *j*.

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the *rowIndex* array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the *i*-th row is equal to the difference of *rowIndex*(*i*) and *rowIndex*(*i*+1).

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of *rowIndex*. Its value is equal to the number of non-zero elements plus one. This makes the total length of the *rowIndex* array one larger than the number of rows in the matrix.

NOTE The Intel MKL sparse storage scheme for the direct sparse solvers supports both with one-based indexing and zero-based indexing.

Consider the symmetric matrix *A*:

$$A = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{bmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix *A* are as follows:

Storage Arrays for a Symmetric Matrix

one-based indexing									
values	=	(1	-1	-3	5	4	6	4	7	-5)
columns	=	(1	2	4	2	3	4	5	4	5)
rowIndex	=	(1	4	5	8	9	10)			
zero-based indexing									
values	=	(1	-1	-3	5	4	6	4	7	-5)
columns	=	(0	1	3	1	2	3	4	3	4)
rowIndex	=	(0	3	4	7	8	9)			

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix *B*:

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{bmatrix}$$

The matrix *B* has 13 non-zero elements, and all of them are stored as follows:

Storage Arrays for a Non-Symmetric Matrix

one-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
rowIndex	=	(1	4	6	9	12	14)							
zero-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
rowIndex	=	(0	3	5	8	11	13)							

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if *a*(*j*,*i*) is not zero if and only if *a*(*j*, *i*) is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value

is equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix *B* can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{bmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{bmatrix}$$

The matrix *B* can be considered to be symmetrically structured with 15 non-zero elements and represented as:

Storage Arrays for a Symmetrically Structured Matrix

one-based indexing															
values	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
columns	=	(1	2	4	1	2	5	3	4	5	1	3	4	2	3	5)
rowIndex	=	(1	4	7	10	13	16)									
zero-based indexing															
values	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)
columns	=	(0	1	3	0	1	4	2	3	4	0	2	3	1	2	4)
rowIndex	=	(0	3	6	9	12	15)									

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);

- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

Sparse Matrix Storage Formats for Sparse BLAS Levels 2 and Level 3

This section describes in detail the sparse matrix storage formats supported in the current version of the Intel MKL Sparse BLAS Level 2 and Level 3.

CSR Format

The Intel MKL compressed sparse row (CSR) format is specified by four arrays: the *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

values	A real or complex array that contains the non-zero elements of *A*. Values of the non-zero elements of *A* are mapped into the *values* array using the row-major storage mapping described above.
columns	Element *i* of the integer array *columns* is the number of the column in *A* that contains the *i*-th value in the *values* array.

pointerB	Element *j* of this integer array gives the index of the element in the *values* array that is first non-zero element in a row *j* of *A*. Note that this index is equal to *pointerB*(*j*) – *pointerB*(1)+1 .
pointerE	An integer array that contains row indices, such that *pointerE*(*j*)–*pointerB*(1) is the index of the element in the *values* array that is last non-zero element in a row *j* of *A*.

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*.The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

NOTE Note that the Intel MKL Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

The matrix *B*

can be represented in the CSR format as:

Storage Arrays for a Matrix in CSR Format

one-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
pointerB	=	(1	4	6	9	12)								
pointerE	=	(4	6	9	12	14)								
zero-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
pointerB	=	(0	3	5	8	11)								
pointerE	=	(3	5	8	11	13)								

This storage format is used in the NIST Sparse BLAS library [Rem05].

Note that the storage format accepted for the direct sparse solvers and described above (see Storage Formats for the Direct Sparse Solvers) is a variation of the CSR format. It also is used in the Intel MKL Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix *B* can be represented in this format (referred to as the 3-array variation of the CSR format) as:

Storage Arrays for a Matrix in CSR Format (3-Array Variation)

one-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
columns	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)
rowIndex	=	(1	4	6	9	12	14)							
zero-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)

columns	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)
rowIndex	=	(0	3	5	8	11	13)							

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row *J* goes just after the set of non-zero elements in the row *J-1* .

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

Comparing the array *rowIndex* from the Table "Storage Arrays for a Non-Symmetric Example Matrix" with the arrays *pointerB* and *pointerE* from the Table "Storage Arrays for an Example Matrix in CSR Format" it is easy to see that

```
pointerB(i) = rowIndex(i) for i=1, ..5;

pointerE(i) = rowIndex(i+1) for i=1, ..5.
```

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```
Subroutine name_routine(.... ,  values, columns, pointerB, pointerE, ...)
```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```
call name_routine(.... ,  values, columns, rowIndex, rowindex(2), ...).
```

CSC Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

values	A real or complex array that contains the non-zero elements of *A*. Values of the non-zero elements of *A* are mapped into the *values* array using the column-major storage mapping.
rows	Element *i* of the integer array *rows* is the number of the row in *A* that contains the *i*-th value in the *values* array.
pointerB	Element *j* of this integer array gives the index of the element in the *values* array that is first non-zero element in a column *j* of *A*. Note that this index is equal to *pointerB*(*j*) – *pointerB*(1)+1 .
pointerE	An integer array that contains column indices, such that *pointerE*(*j*)–*pointerB*(1) is the index of the element in the *values* array that is last non-zero element in a column *j* of *A*.

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*.The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

NOTE Note that the Intel MKL Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

The above matrix *B* can be represented in the CSC format as:

Storage Arrays for a Matrix in CSC Format

one-based indexing

values	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
rows	=	(1	2	4	1	2	5	3	4	1	3	4	2	5)
pointerB	=	(1	4	7	9	12)								
pointerE	=	(4	7	9	12	14)								
zero-based indexing														
values	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
rows	=	(0	1	3	0	1	4	2	3	0	2	3	1	4)
pointerB	=	(0	3	6	8	11)								
pointerE	=	(3	6	8	11	13)								

Coordinate Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel MKL coordinate format is specified by three arrays: *values*, *rows*, and *column*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

values	A real or complex array that contains the non-zero elements of *A* in any order.
rows	Element *i* of the integer array *rows* is the number of the row in *A* that contains the *i*-th value in the *values* array.
columns	Element *i* of the integer array *columns* is the number of the column in *A* that contains the *i*-th value in the *values* array.

NOTE Note that the Intel MKL Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *C*

$$C = \begin{bmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{bmatrix}$$

can be represented in the coordinate format as follows:

Storage Arrays for an Example Matrix in case of the coordinate format

one-based indexing													
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(1	1	1	2	2	3	3	3	4	4	4	5	5)
columns	=	(1	2	3	1	2	3	4	5	1	3	4	2	5)
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)

columns	=	(0	1	2	0	1	2	3	4	0	2	3	1	4)

Diagonal Storage Format

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel MKL diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

values	A real or complex two-dimensional array is dimensioned as *lval* by *ndiag*. Each column of it contains the non-zero elements of certain diagonal of *A*. The key point of the storage is that each element in *values* retains the row number of the original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of *distance*(*i*) is the number of elements to be padded for diagonal *i*.
distance	An integer array with dimension *ndiag*. Element *i* of the array *distance* is the distance between *i*-diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *C* can be represented in the diagonal storage format as follows:

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel MKL triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

Skyline Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel MKL can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

values	A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.
pointers	An integer array with dimension *(m+1)*, where *m* is the number of rows for lower triangle (columns for the upper triangle). *pointers(i) – pointers(1)+1* gives the index of element in *values* that is first non-zero element in row (column) *i*. The value of *pointers(m+1)* is set to *nnz+pointers(1)*, where *nnz* is the number of elements in the array *values*.

For example, the low triangle of the matrix *C* given above can be stored as follows:

```
values  = ( 1  -2   5   4  -4   0   2   7   8   0   0   -5 )

pointers = ( 1   2   4   5   9   13 )
```

and the upper triangle of this matrix *C* can be stored as follows:

```
values   = ( 1  -1   5  -3   0   4   6   7  4   0   -5 )

pointers = ( 1   2   4   7   9   12 )
```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Note that the Intel MKL Sparse BLAS routines operating with the skyline storage format does not support general matrices.

BSR Format

The Intel MKL block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

values	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
columns	Element *i* of the integer array *columns* is the number of the column in the block matrix that contains the *i*-th non-zero block.
pointerB	Element *j* of this integer array gives the index of the element in the *columns* array that is first non-zero block in a row *j* of the block matrix.
pointerE	Element *j* of this integer array gives the index of the element in the *columns* array that contains the last non-zero block in a row *j* of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

NOTE Note that the Intel MKL Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix *D*

$$D = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 1 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix D can be represented as a 3x3 block matrix E with the following structure:

$$E = \begin{bmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 1 \end{bmatrix}, P = \begin{bmatrix} 4 & 3 \\ 0 & 0 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The matrix D can be represented in the BSR format as follows:

one-based indexing

```
values  = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)

columns  = (1   2   2   2   3)

pointerB = (1   3   4)

pointerE = (3   4   6)
```

zero-based indexing

```
values  = (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)

columns  = (0   1   1   1   2)

pointerB = (0   2   3)

pointerE = (2   3   5)
```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Intel MKL supports the variation of the BSR format that is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes these arrays.

values	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
columns	Element *i* of the integer array *columns* is the number of the column in the block matrix that contains the *i*-th non-zero block.
rowIndex	Element *j* of this integer array gives the index of the element in the *columns* array that is first non-zero block in a row *j* of the block matrix.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *i*-th row is equal to the difference of *rowIndex*(*i*) and *rowIndex*(*i*+1).

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zeros blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

```
values  =  (1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0)

columns  = (1   2   2   2   3)

rowIndex = (1   3   4   6)
```

zero-based indexing

```
values  =  (1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0)

columns  = (0   1   1   1   2)

rowIndex = (0   2   3 5)
```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix *F*:

$$F = \begin{bmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{bmatrix}$$

If the size of the block equals 2, then the sparse matrix F can be represented as a 3x3 block matrix G with the following structure:

$$G = \begin{bmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{bmatrix}$$

where

$$L = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix}, M = \begin{bmatrix} 6 & 7 \\ 8 & 2 \end{bmatrix}, M' = \begin{bmatrix} 6 & 8 \\ 7 & 2 \end{bmatrix}, N = \begin{bmatrix} 1 & 4 \\ 5 & 2 \end{bmatrix}, Q = \begin{bmatrix} 7 & 2 \\ 0 & 0 \end{bmatrix}$$

The symmetric matrix F can be represented in this 3-array variation of the BSR format (storing only upper triangular) as follows:

one-based indexing

```
values  =  (1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0)

columns  = (1   2   2   3)

rowIndex = (1   3   4 5)
```

zero-based indexing

```
values  =  (1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0)

columns  = (0   1   1   2)

rowIndex = (0   2   3 4)
```

Routine and Function Arguments

B

The major arguments in the BLAS routines are vector and matrix, whereas VML functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length *n* and increment *incx* is passed in a one-dimensional array *x* whose values are defined as

```
x(1), x(1+|incx|), ..., x(1+(n-1)* |incx|)
```

If *incx* is positive, then the elements in array *x* are stored in increasing order. If *incx* is negative, the elements in array *x* are stored in decreasing order with the first element defined as *x*(1+(*n*-1)* |*incx*|). If *incx* is zero, then all elements of the vector have the same value, *x*(1). The dimension of the one-dimensional array that stores the vector must always be at least

```
idimx = 1 + (n-1)* |incx |
```

Example. One-dimensional Real Array

Let *x*(1:7) be the one-dimensional real array

```
x = (1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0).
```

If *incx* =2 and *n* = 3, then the vector argument with elements in order from first to last is (1.0, 5.0, 9.0).

If *incx* = -2 and *n* = 4, then the vector elements in order from first to last is (13.0, 9.0, 5.0, 1.0).

If *incx* = 0 and *n* = 4, then the vector elements in order from first to last is (1.0, 1.0, 1.0, 1.0).

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified. In Fortran, storing the *m*-by-*n* matrix is based on column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is *m*, and the increment between elements on the same diagonal is *m* + 1.

Example. Two-dimensional Real Matrix

Let *a* be the real 5 x 4 matrix declared as REAL A (5,4).

To scale the third column of *a* by 2.0, use the BLAS routine sscal with the following calling sequence:

```
callsscal (5, 2.0, a(1,3), 1)
```

To scale the second row, use the statement:

```
callsscal (4, 2.0, a(2,1), 5)
```

To scale the main diagonal of A by 2.0, use the statement:

```
callsscal (5, 2.0, a(1,1), 6)
```

NOTE The default vector argument is assumed to be 1.

Vector Arguments in VML

Vector arguments of VML mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length n is passed contiguously in an array a whose values are defined as `a[0], a[1], ..., a[n-1]` (for the C interface).

To accommodate for arrays with other increments, or more complicated indexing, VML contains auxiliary pack/unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array a as

```
a[m0], a[m1], ..., a[mn-1]
```

and need to be regrouped into an array y as

```
y[k0], y[k1], ..., y[kn-1],
```

VML pack/unpack functions can use one of the following indexing methods:

Positive Increment Indexing

```
kj = incy * j, mj = inca * j, j = 0 ,..., n-1
```

Constraint: `incy > 0` and `inca > 0`.

For example, setting incy = 1 specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

Index Vector Indexing

```
kj = iy[j], mj = ia[j], j = 0 ,..., n-1,
```

where ia and iy are arrays of length n that contain index vectors for the input and output arrays a and y, respectively.

Mask Vector Indexing

Indices `kj` , `mj` are such that:

```
my[kj] ≠ 0, ma[mj] ≠ 0 , j = 0,..., n-1,
```

where `ma` and `my` are arrays that contain mask vectors for the input and output arrays a and y, respectively.

Matrix Arguments

Matrix arguments of the Intel® Math Kernel Library routines can be stored in either one- or two-dimensional arrays, using the following storage schemes:

- conventional full storage (in a two-dimensional array)
- packed storage for Hermitian, symmetric, or triangular matrices (in a one-dimensional array)
- band storage for band matrices (in a two-dimensional array)
- rectangular full packed storage for symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels.

Full storage is the following obvious scheme: a matrix A is stored in a two-dimensional array a, with the matrix element a_{ij} stored in the array element $a(i,j)$.

If a matrix is triangular (upper or lower, as specified by the argument *uplo*), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if *uplo* ='U', a_{ij} is stored in *a*(*i*,*j*) for $i \le j$, other elements of *a* need not be set.

if *uplo* ='L', a_{ij} is stored in *a*(*i*,*j*) for $j \le i$, other elements of *a* need not be set.

Packed storage allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument *uplo*) is packed by columns in a one-dimensional array *ap*:

if *uplo* ='U', a_{ij} is stored in *ap*(*i*+*j*(*j*-1)/2) for $i \le j$

if *uplo* ='L', a_{ij} is stored in *ap*(*i*+(2**n*-*j*)*(*j*-1)/2) for $j \le i$.

In descriptions of LAPACK routines, arrays with packed matrices have names ending in *p*.

Band storage is as follows: an *m*-by-*n* band matrix with *kl* non-zero sub-diagonals and *ku* non-zero super-diagonals is stored compactly in a two-dimensional array *ab* with *kl*+*ku*+1 rows and *n* columns. Columns of the matrix are stored in the corresponding columns of the array, and diagonals of the matrix are stored in rows of the array. Thus,

a_{ij} is stored in *ab*(*ku*+1+*i*-*j*,*j*) for $\max(1,j-ku) \le i \le \min(n,j+kl)$.

Use the band storage scheme only when *kl* and *ku* are much less than the matrix size *n*. Although the routines work correctly for all values of *kl* and *ku*, using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

m = *n* = 6, *kl* = 2, *ku* = 1

Array elements marked * are not used by the routines:

Banded matrix A

$$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 & 0 & 0 \\ a_{31} & a_{32} & a_{33} & a_{34} & 0 & 0 \\ 0 & a_{42} & a_{43} & a_{44} & a_{45} & 0 \\ 0 & 0 & a_{53} & a_{54} & a_{55} & a_{56} \\ 0 & 0 & 0 & a_{64} & a_{65} & a_{66} \end{bmatrix}$$

Band storage of A

$$\begin{matrix} * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{matrix}$$

When a general band matrix is supplied for *LU factorization*, space must be allowed to store *kl* additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with *kl* + *ku* super-diagonals. Thus,

a_{ij} is stored in *ab*(*kl*+*ku*+1+*i*-*j*,*j*) for $\max(1,j-ku) \le i \le \min(n,j+kl)$.

The band storage scheme for LU factorization is illustrated by the following example, when*m* = *n* = 6, *kl* = 2, *ku* = 1:

Banded matrix A

$$\begin{bmatrix} a_{11} & a_{12} & 0 & 0 & 0 & 0 \\ a_{21} & a_{22} & a_{23} & 0 & 0 & 0 \\ a_{31} & a_{32} & a_{33} & a_{34} & 0 & 0 \\ 0 & a_{42} & a_{43} & a_{44} & a_{45} & 0 \\ 0 & 0 & a_{53} & a_{54} & a_{55} & a_{56} \\ 0 & 0 & 0 & a_{64} & a_{65} & a_{66} \end{bmatrix}$$

Band storage of A

$$\begin{matrix} * & * & * & + & + & + \\ * & * & + & + & + & + \\ * & a_{12} & a_{23} & a_{34} & a_{45} & a_{56} \\ a_{11} & a_{22} & a_{33} & a_{44} & a_{55} & a_{66} \\ a_{21} & a_{32} & a_{43} & a_{54} & a_{65} & * \\ a_{31} & a_{42} & a_{53} & a_{64} & * & * \end{matrix}$$

Array elements marked * are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

where u_{ij} are the elements of the upper triangular matrix U, and m_{ij} are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either $kl = 0$ if upper triangular, or $ku = 0$ if lower triangular. For symmetric or Hermitian band matrices with k sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if *uplo* ='U', a_{ij} is stored in $ab(k+1+i-j,j)$ for $\max(1,j-k) \le i \le j$

if *uplo* ='L', a_{ij} is stored in $ab(1+i-j,j)$ for $j \le i \le \min(n,j+k)$.

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in *b*.

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or *'n'*	normal (no conjugation, no transposition)
'T' or *'t'*	transpose
'C' or *'c'*	conjugate transpose.

Example. Two-Dimensional Complex Array

Suppose `A (1:5, 1:4)` is the complex two-dimensional array presented by matrix

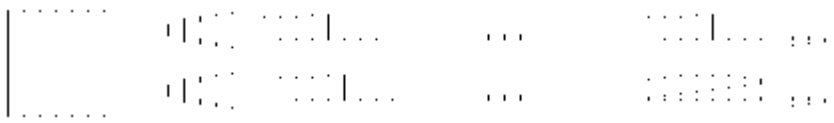
$$\begin{bmatrix} (1.1,0.11) & (1.2,0.12) & (1.3,0.13) & (1.4,0.14) \\ (2.1,0.21) & (2.2,0.22) & (2.3,0.23) & (1.4,0.24) \\ (3.1,0.31) & (3.2,0.32) & (3.3,0.33) & (1.4,0.34) \\ (4.1,0.41) & (4.2,0.42) & (4.3,0.43) & (1.4,0.44) \\ (5.1,0.51) & (5.2,0.52) & (5.3,0.53) & (1.4,0.54) \end{bmatrix}$$

Let *transa* be the transposition parameter, *m* be the number of rows, *n* be the number of columns, and *lda* be the leading dimension. Then if

transa = '*N*', *m* = 4, *n* = 2, and *lda* = 5, the matrix argument would be

$$\begin{bmatrix} (1.1,0.11) & (1.2,0.12) \\ (2.1,0.21) & (2.2,0.22) \\ (3.1,0.31) & (3.2,0.32) \\ (4.1,0.41) & (4.2,0.42) \end{bmatrix}$$

If *transa* = '*T*', *m* = 4, *n* = 2, and *lda* =5, the matrix argument would be



If *transa* = '*C*', *m* = 4, *n* = 2, and *lda* =5, the matrix argument would be

$$\begin{bmatrix} (1.1,-0.11) & (2.1,-0.21) & (3.1,-0.31) & (4.1,-0.41) \\ (1.2,-0.12) & (2.2,-0.22) & (3.2,-0.32) & (4.2,-0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array *A* above is declared as `COMPLEX A (5,4)`.

Then if *transa* = '*N*', *m* = 3, *n* = 4, and *lda* = 4, the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

Rectangular Full Packed storage allows you to store symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels. To store an n-by-n triangle (and suppose for simplicity that n is even), you partition the triangle into three parts: two $n/2$-by-$n/2$ triangles and an $n/2$-by-$n/2$ square, then pack this as an n-by-$n/2$ rectangle (or $n/2$-by-n rectangle), by transposing (or transpose-conjugating) one of the triangles and packing it next to the other triangle. Since the two triangles are stored in full storage, you can use existing efficient routines on them.

There are eight cases of RFP storage representation: when n is even or odd, the packed matrix is transposed or not, the triangular matrix is lower or upper. See below for all the eight storage schemes illustrated:

n is odd, A is lower triangular

Full format

$$\begin{matrix} a_{11} & x & x & x & x & x & x \\ a_{21} & a_{22} & x & x & x & x & x \\ a_{31} & a_{32} & a_{33} & x & x & x & x \\ a_{41} & a_{42} & a_{43} & a_{44} & x & x & x \\ \mathbf{a_{51}} & \mathbf{a_{52}} & \mathbf{a_{53}} & \mathbf{a_{54}} & a_{55} & x & x \\ \mathbf{a_{61}} & \mathbf{a_{62}} & \mathbf{a_{63}} & \mathbf{a_{64}} & a_{65} & a_{66} & x \\ \mathbf{a_{71}} & \mathbf{a_{72}} & \mathbf{a_{73}} & \mathbf{a_{74}} & a_{75} & a_{76} & a_{77} \end{matrix}$$

RFP (not transposed)

$$\begin{matrix} a_{11} & a_{55} & a_{65} & a_{75} \\ a_{21} & a_{22} & a_{66} & a_{76} \\ a_{31} & a_{32} & a_{33} & a_{77} \\ a_{41} & a_{42} & a_{43} & a_{44} \\ \mathbf{a_{51}} & \mathbf{a_{52}} & \mathbf{a_{53}} & \mathbf{a_{54}} \\ \mathbf{a_{61}} & \mathbf{a_{62}} & \mathbf{a_{63}} & \mathbf{a_{64}} \\ \mathbf{a_{71}} & \mathbf{a_{72}} & \mathbf{a_{73}} & \mathbf{a_{74}} \end{matrix}$$

RFP (transposed)

$$\begin{matrix} a_{11} & a_{21} & a_{31} & a_{41} & \mathbf{a_{51}} & \mathbf{a_{61}} & \mathbf{a_{71}} \\ a_{55} & a_{22} & a_{32} & a_{42} & \mathbf{a_{52}} & \mathbf{a_{62}} & \mathbf{a_{72}} \\ a_{65} & a_{66} & a_{33} & a_{43} & \mathbf{a_{53}} & \mathbf{a_{63}} & \mathbf{a_{73}} \\ a_{75} & a_{76} & a_{77} & a_{44} & \mathbf{a_{54}} & \mathbf{a_{64}} & \mathbf{a_{74}} \end{matrix}$$

n is even, A is lower triangular

Full format

$$\begin{matrix} a_{11} & x & x & x & x & x \\ a_{21} & a_{22} & x & x & x & x \\ a_{31} & a_{32} & a_{33} & x & x & x \\ \mathbf{a_{41}} & \mathbf{a_{42}} & \mathbf{a_{43}} & a_{44} & x & x \\ \mathbf{a_{51}} & \mathbf{a_{52}} & \mathbf{a_{53}} & a_{54} & a_{55} & x \\ \mathbf{a_{61}} & \mathbf{a_{62}} & \mathbf{a_{63}} & a_{64} & a_{65} & a_{66} \end{matrix}$$

RFP (not transposed)

$$\begin{matrix} a_{44} & a_{54} & a_{64} \\ a_{11} & a_{55} & a_{65} \\ a_{21} & a_{22} & a_{66} \\ a_{31} & a_{32} & a_{33} \\ \mathbf{a_{41}} & \mathbf{a_{42}} & \mathbf{a_{43}} \\ \mathbf{a_{51}} & \mathbf{a_{52}} & \mathbf{a_{53}} \\ \mathbf{a_{61}} & \mathbf{a_{62}} & \mathbf{a_{63}} \end{matrix}$$

RFP (transposed)

$$\begin{matrix} a_{44} & a_{11} & a_{21} & a_{31} & \mathbf{a_{41}} & \mathbf{a_{51}} & \mathbf{a_{61}} \\ a_{54} & a_{55} & a_{22} & a_{32} & \mathbf{a_{42}} & \mathbf{a_{52}} & \mathbf{a_{62}} \\ a_{64} & a_{65} & a_{66} & a_{33} & \mathbf{a_{43}} & \mathbf{a_{53}} & \mathbf{a_{63}} \end{matrix}$$

n is odd, A is upper triangular

Full format

$$\begin{matrix} a_{11} & a_{12} & a_{13} & \mathbf{a_{14}} & \mathbf{a_{15}} & \mathbf{a_{16}} & \mathbf{a_{17}} \\ x & a_{22} & a_{23} & \mathbf{a_{24}} & \mathbf{a_{25}} & \mathbf{a_{26}} & \mathbf{a_{27}} \\ x & x & a_{33} & \mathbf{a_{34}} & \mathbf{a_{35}} & \mathbf{a_{36}} & \mathbf{a_{37}} \\ x & x & x & a_{44} & a_{45} & a_{46} & a_{47} \\ x & x & x & x & a_{55} & a_{56} & a_{57} \\ x & x & x & x & x & a_{66} & a_{67} \\ x & x & x & x & x & x & a_{77} \end{matrix}$$

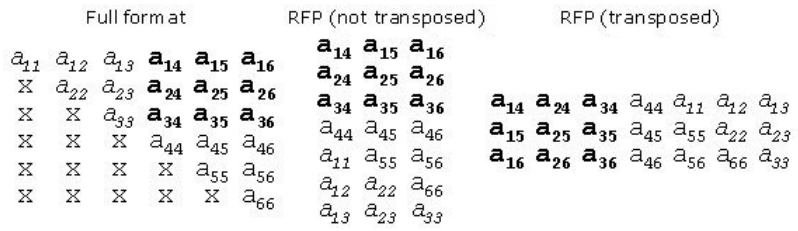
RFP (not transposed)

$$\begin{matrix} \mathbf{a_{14}} & \mathbf{a_{15}} & \mathbf{a_{16}} & \mathbf{a_{17}} \\ \mathbf{a_{24}} & \mathbf{a_{25}} & \mathbf{a_{26}} & \mathbf{a_{27}} \\ \mathbf{a_{34}} & \mathbf{a_{35}} & \mathbf{a_{36}} & \mathbf{a_{37}} \\ a_{44} & a_{45} & a_{46} & a_{47} \\ a_{11} & a_{55} & a_{56} & a_{57} \\ a_{12} & a_{22} & a_{66} & a_{67} \\ a_{13} & a_{23} & a_{33} & a_{77} \end{matrix}$$

RFP (transposed)

$$\begin{matrix} \mathbf{a_{14}} & \mathbf{a_{24}} & \mathbf{a_{34}} & a_{44} & a_{11} & a_{12} & a_{13} \\ \mathbf{a_{15}} & \mathbf{a_{25}} & \mathbf{a_{35}} & a_{45} & a_{55} & a_{22} & a_{23} \\ \mathbf{a_{16}} & \mathbf{a_{26}} & \mathbf{a_{36}} & a_{46} & a_{56} & a_{66} & a_{33} \\ \mathbf{a_{17}} & \mathbf{a_{27}} & \mathbf{a_{37}} & a_{47} & a_{57} & a_{67} & a_{77} \end{matrix}$$

n is even, A is upper triangular



Intel MKL provides a number of routines such as `?hfrk`, `?sfrk` performing BLAS operations working directly on RFP matrices, as well as some conversion routines, for instance, `?tpttf` goes from the standard packed format to RFP and `?trttf` goes from the full format to RFP.

Please refer to the Netlib site for more information.

Note that in the descriptions of LAPACK routines, arrays with RFP matrices have names ending in `fp`.

Code Examples

C

This appendix presents code examples of using some Intel MKL routines and functions. You can find here example code written in both Fortran and C.

Please refer to respective chapters in the manual for detailed descriptions of function parameters and operation.

BLAS Code Examples

Example. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors *x* and *y*.

Parameters

n	Specifies the number of elements in vectors *x* and *y*.
incx	Specifies the increment for the elements of *x*.
incy	Specifies the increment for the elements of *y*.

```
program dot_main
real x(10), y(10), sdot, res
integer n, incx, incy, i
external sdot
n = 5
incx = 2
incy = 1
do i = 1, 10
  x(i) = 2.0e0
  y(i) = 1.0e0
end do
res = sdot (n, x, incx, y, incy)
print*, `SDOT = `, res
end
```

As a result of this program execution, the following line is printed:

SDOT = 10.000

Example. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector *x* to a vector *y*.

Parameters

n	Specifies the number of elements in vectors *x* and *y*.
incx	Specifies the increment for the elements of *x*.
incy	Specifies the increment for the elements of *y*.

```
program copy_main
real x(10), y(10)
integer n, incx, incy, i
n = 3
```

```
incx = 3
incy = 1
do i = 1, 10
  x(i) = i
end do
call scopy (n, x, incx, y, incy)
print*, `Y = `, (y(i), i = 1, n)
end
```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

Example. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

```
a :=  alpha*x*y' + a.
```

Parameters

alpha	Specifies a scalar *alpha*.
x	*m*-element vector.
y	*n*-element vector.
a	*m*-by-*n* matrix.

```
program ger_main
real a(5,3), x(10), y(10), alpha
integer m, n, incx, incy, i, j, lda
m = 2
 n = 3
lda = 5
incx = 2
incy = 1
alpha = 0.5
do i = 1, 10
  x(i) = 1.0
  y(i) = 1.0
end do
do i = 1, m
  do j = 1, n
    a(i,j) = j
  end do
end do
call sger (m, n, alpha, x, incx, y, incy, a, lda)
print*, `Matrix A: `
do i = 1, m
  print*, (a(i,j), j = 1, n)
end do
end
```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

1.50000 2.50000 3.50000

1.50000 2.50000 3.50000

Example. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

```
c :=  alpha*a*b' + beta*c.
```

Parameters

alpha	Specifies a scalar *alpha*.
beta	Specifies a scalar *beta*.
a	Symmetric matrix
b	*m*-by-*n* matrix
c	*m*-by-*n* matrix

```
program symm_main
real a(3,3), b(3,2), c(3,3), alpha, beta
integer m, n, lda, ldb, ldc, i, j
character uplo, side
uplo = 'u'
side = 'l'
m = 3
n = 2
lda = 3
ldb = 3
ldc = 3
alpha = 0.5
beta = 2.0
do i = 1, m
  do j = 1, m
    a(i,j) = 1.0
  end do
end do
do i = 1, m
  do j = 1, n
    c(i,j) = 1.0
    b(i,j) = 2.0
  end do
end do
call ssymm (side, uplo, m, n, alpha,
a, lda, b, ldb, beta, c, ldc)
print*, `Matrix C: `
do i = 1, m
  print*, (c(i,j), j = 1, n)
end do
end
```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

5.00000 5.00000

5.00000 5.00000

5.00000 5.00000

The following example illustrates a call from a C program to the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

Example. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure *c*.

```
#include <cstdio>
#include "mkl_blas.h"
#define N 5
void main()
{
  int n, inca = 1, incb = 1, i;
  MKL_Complex16 a[N], b[N], c;
  void zdotc();
  n = N;
  for( i = 0; i < n; i++ ){
    a[i].real = (double)i; a[i].imag = (double)i * 2.0;
    b[i].real = (double)(n - i); b[i].imag = (double)i * 2.0;
  }
```

```
  zdotc( &c, &n, a, &inca, b, &incb );
  printf( "The complex dot product is: ( %6.2f, %6.2f )\n", c.real, c.imag );
}
```

NOTE Instead of calling BLAS directly from C programs, you might wish to use the CBLAS interface; this is the supported way of calling BLAS from C. For more information about CBLAS, see Appendix D , which presents CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS) implemented in Intel® MKL.

Fourier Transform Functions Code Examples

This section presents code examples of functions described in the "FFT Functions" and "Cluster FFT Functions" sections in the "Fourier Transform Functions" chapter. The examples are grouped in subsections

- Examples for FFT Functions, including Examples of Using Multi-Threading for FFT Computation
- Examples for Cluster FFT Functions
- Auxiliary data transformations.

FFT Code Examples

This section presents code examples of using the FFT interface functions described in "Fourier Transform Functions" chapter. Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in "Configuration Settings".

One-dimensional In-place FFT (Fortran Interface)

```
! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X(32)
Real :: Y(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status
!...put input data into X(1),...,X(32); Y(1),...,Y(32)

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
   DFTI_COMPLEX, 1, 32 )
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X )
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by {X(1),X(2),...,X(32)}

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,&
   DFTI_REAL, 1, 32)
Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given in CCS format.
```

One-dimensional Out-of-place FFT (Fortran Interface)

```
! Fortran example.
! 1D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex :: X_in(32)
Complex :: X_out(32)
Real :: Y_in(32)
Real :: Y_out(34)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
```

```
Integer :: Status
...put input data into X_in(1),...,X_in(32); Y_in(1),...,Y_in(32)
! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,
DFTI_COMPLEX, 1, 32 )
Status = DftiSetValue( My_Desc1_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc1_Handle )
Status = DftiComputeForward( My_Desc1_Handle, X_in, X_out )
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by {X_out(1),X_out(2),...,X_out(32)}
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor(My_Desc2_Handle, DFTI_SINGLE,
DFTI_REAL, 1, 32)
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor(My_Desc2_Handle)
Status = DftiComputeForward(My_Desc2_Handle, Y_in, Y_out)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by Y_out in CCS format.
```

One-dimensional In-place FFT (C Interface)

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x[32];
float y[34];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x[0],...,x[31]; y[0],...,y[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
          DFTI_COMPLEX, 1, 32);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x[0], ..., x[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
          DFTI_REAL, 1, 32);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given in CCS format*/
```

One-dimensional Out-of-place FFT (C Interface)

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x_in[32];
float _Complex x_out[32];
float y_in[32];
float y_out[34];

DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x_in[0],...,x_in[31]; y_in[0],...,y_in[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
          DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x_out[0], ..., x_out[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
          DFTI_REAL, 1, 32);
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc2_handle);
```

```
status = DftiComputeForward( my_desc2_handle, y_in, y_out);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given by y_out in CCS format*/
```

Two-dimensional FFT (Fortran Interface)

The following is an example of two simple two-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran example.
! 2D complex to complex, and real to conjugate-even
Use MKL_DFTI
Complex ::  X_2D(32,100)
Real :: Y_2D(34, 102)
Complex ::  X(3200)
Real :: Y(3468)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc1_Handle, My_Desc2_Handle
Integer :: Status, L(2)
!...put input data into X_2D(j,k), Y_2D(j,k), 1<=j=32,1<=k<=100
!...set L(1) = 32, L(2) = 100
!...the transform is a 32-by-100

! Perform a complex to complex transform
Status = DftiCreateDescriptor( My_Desc1_Handle, DFTI_SINGLE,&
          DFTI_COMPLEX, 2, L)
Status = DftiCommitDescriptor( My_Desc1_Handle)
Status = DftiComputeForward( My_Desc1_Handle, X)
Status = DftiFreeDescriptor(My_Desc1_Handle)
! result is given by X_2D(j,k), 1<=j<=32, 1<=k<=100

! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc2_Handle, DFTI_SINGLE,&
          DFTI_REAL, 2, L)
Status = DftiCommitDescriptor( My_Desc2_Handle)
Status = DftiComputeForward( My_Desc2_Handle, Y)
Status = DftiFreeDescriptor(My_Desc2_Handle)
! result is given by the complex value z(j,k) 1<=j<=32; 1<=k<=100
! and is stored in CCS format
```

Two-dimensional FFT (C Interface)

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x[32][100];
float y[34][102];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status, l[2];
//...put input data into x[j][k] 0<=j<=31, 0<=k<=99
//...put input data into y[j][k] 0<=j<=31, 0<=k<=99
l[0] = 32; l[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
          DFTI_COMPLEX, 2, l);
status = DftiCommitDescriptor( my_desc1_handle);
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is the complex value x[j][k], 0<=j<=31, 0<=k<=99 */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
          DFTI_REAL, 2, l);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
```

```
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex value z(j,k) 0<=j<=31; 0<=k<=99
/* and is stored in CCS format*/
```

The following examples demonstrate how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of the `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

Changing Default Settings (Fortran)

The code below illustrates how this can be done:

```
! Fortran example
! 1D complex to complex, not in place
Use MKL_DFTI
Complex :: X_in(32), X_out(32)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status
!...put input data into X_in(j), 1<=j<=32
Status = DftiCreateDescriptor( My_Desc_Handle,& DFTI_SINGLE, DFTI_COMPLEX, 1, 32)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X_in, X_out)
Status = DftiFreeDescriptor (My_Desc_Handle)
! result is X_out(1),X_out(2),...,X_out(32)
```

Changing Default Settings (C)

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status;
//...put input data into x_in[j], 0 <= j < 32
status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
   DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc_handle);
status = DftiComputeForward( my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is x_out[0], x_out[1], ..., x_out[31] */
```

Using Status Checking Functions

The example illustrates the use of status checking functions described in Chapter 11.

```
/* C */
DFTI_DESCRIPTOR_HANDLE desc;
MKL_LONG status;
// . . . descriptor creation and other code
status = DftiCommitDescriptor(desc);
if (status && !DftiErrorClass(status,DFTI_NO_ERROR))
{
   printf ('Error: %s\n', DftiErrorMessage(status));
}

! Fortran
type(DFTI_DESCRIPTOR), POINTER :: desc
integer status
! ...descriptor creation and other code
status =  DftiCommitDescriptor(desc)
```

```
if (status .ne. 0) then
  if (.not. DftiErrorClass(status,DFTI_NO_ERROR) then
     print *, 'Error: ', DftiErrorMessage(status)
  endif
endif
```

Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms. Notice that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

```
! Fortran
use mkl_dfti
Complex ::  X_2D(20,40)
Complex ::  X(800)
Equivalence (X_2D, X)
INTEGER :: STRIDE(2)
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim1
type(DFTI_DESCRIPTOR), POINTER :: Desc_Handle_Dim2
! ...
Status = DftiCreateDescriptor(Desc_Handle_Dim1, DFTI_SINGLE,&
                              DFTI_COMPLEX, 1, 20 )
Status = DftiCreateDescriptor(Desc_Handle_Dim2, DFTI_SINGLE,&
                              DFTI_COMPLEX, 1, 40 )
! perform 40 one-dimensional transforms along 1st dimension
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_INPUT_DISTANCE, 20 )
Status = DftiSetValue( Desc_Handle_Dim1, DFTI_OUTPUT_DISTANCE, 20 )
Status = DftiCommitDescriptor( Desc_Handle_Dim1 )
Status = DftiComputeForward( Desc_Handle_Dim1, X )
! perform 20 one-dimensional transforms along 2nd dimension
Stride(1) = 0; Stride(2) = 20
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_DISTANCE, 1 )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_INPUT_STRIDES, Stride )
Status = DftiSetValue( Desc_Handle_Dim2, DFTI_OUTPUT_STRIDES, Stride )
Status = DftiCommitDescriptor( Desc_Handle_Dim2 )
Status = DftiComputeForward( Desc_Handle_Dim2, X )
Status = DftiFreeDescriptor( Desc_Handle_Dim1 )
Status = DftiFreeDescriptor( Desc_Handle_Dim2 )

/* C */
#include "mkl_dfti.h"
float _Complex x[20][40];
MKL_LONG stride[2];
MKL_LONG status;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim1;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim2;
//...
status = DftiCreateDescriptor( &desc_handle_dim1, DFTI_SINGLE,
 DFTI_COMPLEX, 1, 20 );
status = DftiCreateDescriptor( &desc_handle_dim2, DFTI_SINGLE,
 DFTI_COMPLEX, 1, 40 );

/* perform 40 one-dimensional transforms along 1st dimension */
/* note that the 1st dimension data are not unit-stride */
stride[0] = 0; stride[1] = 40;
status = DftiSetValue( desc_handle_dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_STRIDES, stride );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_STRIDES, stride );
status = DftiCommitDescriptor( desc_handle_dim1 );
status = DftiComputeForward( desc_handle_dim1, x );
```

```
/* perform 20 one-dimensional transforms along 2nd dimension */
/* note that the 2nd dimension is unit stride */
status = DftiSetValue( desc_handle_dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 );
status = DftiSetValue( desc_handle_dim2,
DFTI_INPUT_DISTANCE, 40 );
status = DftiSetValue( desc_handle_dim2,
DFTI_OUTPUT_DISTANCE, 40 );
status = DftiCommitDescriptor( desc_handle_dim2 );
status = DftiComputeForward( desc_handle_dim2, x );
status = DftiFreeDescriptor( &desc_handle_dim1 );
status = DftiFreeDescriptor( &desc_handle_dim2 );
```

The following are examples of real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. Example "Two-Dimensional REAL In-place FFT (Fortran Interface)" is two-dimensional in-place transform and Example "Two-Dimensional REAL Out-of-place FFT (Fortran Interface)" is two-dimensional out-of-place transform in Fortran interface. Example "Three-Dimensional REAL FFT (C Interface)" is three-dimensional out-of-place transform in C interface. Note that the data and result parameters in computation functions are all declared as assumed-size rank-1 array `DIMENSION(0:*)`. Therefore two-dimensional array must be transformed to one-dimensional array by `EQUIVALENCE` statement or other facilities of Fortran.

Two-Dimensional REAL In-place FFT (Fortran Interface)

```
! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(34,100) ! 34  = (32/2 + 1)*2
Real :: X(3400)
Equivalence (X_2D, X)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_in(3)
Integer :: strides_out(3)
! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_in(1) = 0, strides_in(2) = 1, strides_in(3) = 34
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17
! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle, DFTI_CONJUGATE_EVEN_STORAGE,&
DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue(My_Desc_Handle, DFTI_INPUT_STRIDES, strides_in)
Status = DftiSetValue(My_Desc_Handle, DFTI_OUTPUT_STRIDES, strides_out)
Status = DftiCommitDescriptor( My_Desc_Handle)
Status = DftiComputeForward( My_Desc_Handle, X )
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in real matrix X_2D in CCE format.
```

Two-Dimensional REAL Out-of-place FFT (Fortran Interface)

```
! Fortran example.
! 2D and real to conjugate-even
Use MKL_DFTI
Real :: X_2D(32,100)
Complex :: Y_2D(17, 100) ! 17 = 32/2 + 1
Real :: X(3200)
Complex :: Y(1700)
Equivalence (X_2D, X)
Equivalence (Y_2D, Y)
type(DFTI_DESCRIPTOR), POINTER :: My_Desc_Handle
Integer :: Status, L(2)
Integer :: strides_out(3)
```

```
! ...put input data into X_2D(j,k), 1<=j=32,1<=k<=100
! ...set L(1) = 32, L(2) = 100
! ...set strides_out(1) = 0, strides_out(2) = 1, strides_out(3) = 17

! ...the transform is a 32-by-100
! Perform a real to complex conjugate-even transform
Status = DftiCreateDescriptor( My_Desc_Handle, DFTI_SINGLE,&
DFTI_REAL, 2, L )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX)
Status = DftiSetValue( My_Desc_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE )
Status = DftiSetValue(My_Desc_Handle,&
DFTI_OUTPUT_STRIDES, strides_out)

Status = DftiCommitDescriptor(My_Desc_Handle)
Status = DftiComputeForward(My_Desc_Handle, X, Y)
Status = DftiFreeDescriptor(My_Desc_Handle)
! result is given by the complex value z(j,k) 1<=j<=17; 1<=k<=100 and
! is stored in complex matrix Y_2D in CCE format.
```

Three-Dimensional REAL FFT (C Interface)

```
/* C99 example */
#include "mkl_dfti.h"
float x[32][100][19];
float _Complex y[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status, l[3];
MKL_LONG strides_out[4];

//...put input data into x[j][k][s] 0<=j<=31, 0<=k<=99, 0<=s<=18
l[0] = 32; l[1] = 100; l[2] = 19;

strides_out[0] = 0; strides_out[1] = 1000;
strides_out[2] = 10; strides_out[3] = 1;

status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
DFTI_REAL, 3, l );
status = DftiSetValue(my_desc_handle,
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE );
status = DftiSetValue(my_desc_handle,
DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x, y);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex value z(j,k,s) 0<=j<=31; 0<=k<=99, 0<=s<=9
and is stored in complex matrix y in CCE format. */
```

Examples of Using Multi-Threading for FFT Computation

The following sample program shows how to employ internal threading in Intel MKL for FFT computation (see case "a" in “Number of user threads”).

To specify the number of threads inside Intel MKL, use the following settings:

set `MKL_NUM_THREADS = 1` for one-threaded mode;

set `MKL_NUM_THREADS = 4` for multi-threaded mode.

Note that the configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must be equal to its default value 1.

Using Intel MKL Internal Threading Mode

```
#include "mkl_dfti.h"

int main ()

{
    float x[200][100];
    DFTI_DESCRIPTOR_HANDLE fft;
    MKL_LONG len[2] = {200, 100};
    // initialize x
    DftiCreateDescriptor ( &fft, DFTI_SINGLE, DFTI_REAL, 2, len );
    DftiCommitDescriptor ( fft );
    DftiComputeForward ( fft, x );
    DftiFreeDescriptor ( &fft );
    return 0;
}
```

The following Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region" and Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread" illustrate a parallel customer program with each descriptor instance used only in a single thread (see cases "b" and "c" in Number of user threads).

Specify the number of threads for Example "Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region" like this:

set `MKL_NUM_THREADS = 1` for Intel MKL to work in the single-threaded mode (recommended);

set `OMP_NUM_THREADS = 4` for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have its default value of 1.

Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel MKL (case "a"). To achieve this, you need to set the parameter `DFTI_NUMBER_OF_TRANSFORMS = 4` and to set the corresponding parameter `DFTI_INPUT_DISTANCE = 5000`.

C code for the example is as follows:

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    int th;
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(len, x)
    for (th = 0; th < nth; th++)
    {
        DFTI_DESCRIPTOR_HANDLE myFFT;

        DftiCreateDescriptor (&myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
        DftiCommitDescriptor (myFFT);
        DftiComputeForward (myFFT, x[th]);
        DftiFreeDescriptor (&myFFT);
    }
    return 0;
}
```

Fortran code for the example is as follows:

```
program fft2d_private_descr_main
  use mkl_dfti
```

```
  integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
  parameter (nth = 4, len = (/50, 100/))
  complex x(len(2)*len(1), nth)

  type(dfti_descriptor), pointer :: myFFT
  integer th, myStatus

! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x) PRIVATE(myFFT, myStatus)
  do th = 1, nth
    myStatus = DftiCreateDescriptor (myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
    myStatus = DftiCommitDescriptor (myFFT)
    myStatus = DftiComputeForward (myFFT, x(:, th))
    myStatus = DftiFreeDescriptor (myFFT)
  end do
!$OMP END PARALLEL DO
end
```

Specify the number of threads for Example "Using Parallel Mode with Multiple Descriptors Initialized in One Thread" like this:

set `MKL_NUM_THREADS` = 1 for Intel MKL to work in the single-threaded mode (obligatory);

set `OMP_NUM_THREADS` = 4 for the customer program to work in the multi-threaded mode.

The configuration parameter `DFTI_NUMBER_OF_USER_THREADS` must have the default value of 1.

Using Parallel Mode with Multiple Descriptors Initialized in One Thread

C code for the example is as follows:

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    DFTI_DESCRIPTOR_HANDLE FFT[ARRAY_LEN(x)];
    int th;

    for (th = 0; th < nth; th++)
        DftiCreateDescriptor (&FFT[th], DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    for (th = 0; th < nth; th++)
        DftiCommitDescriptor (FFT[th]);
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
    for (th = 0; th < nth; th++)
        DftiComputeForward (FFT[th], x[th]);
    for (th = 0; th < nth; th++)
        DftiFreeDescriptor (&FFT[th]);
    return 0;
}
```

Fortran code for the example is as follows:

```
program fft2d_array_descr_main
  use mkl_dfti

  integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
  parameter (nth = 4, len = (/50, 100/))
  complex x(len(2)*len(1), nth)

  type thread_data
    type(dfti_descriptor), pointer :: FFT
  end type thread_data
  type(thread_data) :: workload(nth)
```

```
  integer th, status, myStatus

  do th = 1, nth
    status = DftiCreateDescriptor (workload(th)%FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
    status = DftiCommitDescriptor (workload(th)%FFT)
  end do
! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x, workload) PRIVATE(myStatus)
  do th = 1, nth
    myStatus = DftiComputeForward (workload(th)%FFT, x(:, th))
  end do
!$OMP END PARALLEL DO
  do th = 1, nth
    status = DftiFreeDescriptor (workload(th)%FFT)
  end do
end
```

The following Example "Using Parallel Mode with a Common Descriptor" illustrates a parallel customer program with a common descriptor used in several threads (see case "d" in "Number of user threads").

In this case, the number of threads, as well as any other configuration parameter, must not be changed after FFT initialization by the `DftiCommitDescriptor()` function is done.

Using Parallel Mode with a Common Descriptor

C code for the example is as follows:

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    DFTI_DESCRIPTOR_HANDLE FFT;
    int th;

    DftiCreateDescriptor (&FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    DftiSetValue (FFT, DFTI_NUMBER_OF_USER_THREADS, nth);
    DftiCommitDescriptor (FFT);
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
    for (th = 0; th < nth; th++)
        DftiComputeForward (FFT, x[th]);
    DftiFreeDescriptor (&FFT);
    return 0;
}
```

Fortran code for the example is as follows:

```
 program fft2d_shared_descr_main
  use mkl_dfti

  integer nth, len(2)
! 4 OMP threads, each does 2D FFT 50x100 points
  parameter (nth = 4, len = (/50, 100/))
  complex x(len(2)*len(1), nth)
  type(dfti_descriptor), pointer :: FFT

  integer th, status, myStatus

  status = DftiCreateDescriptor (FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len)
  status = DftiSetValue (FFT, DFTI_NUMBER_OF_USER_THREADS, nth)
  status = DftiCommitDescriptor (FFT)
! assume x is initialized and do 2D FFTs
!$OMP PARALLEL DO SHARED(len, x, FFT) PRIVATE(myStatus)
  do th = 1, nth
    myStatus = DftiComputeForward (FFT, x(:, th))
  end do
```

```
!$OMP END PARALLEL DO
  status = DftiFreeDescriptor (FFT)
end
```

Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

2D Out-of-place Cluster FFT Computation

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len[2],v,i,j,n,s;
Complex *in,*out;

MPI_Init(...);

// Create descriptor for 2D FFT
len[0]=nx;
len[1]=ny;
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,2,len);
// Ask necessary length of in and out arrays and allocate memory
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
out=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Current process performs n rows,
// 0 row of in corresponds to s row of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Virtual global array globalIN is defined by function f as
// globalIN[i*ny+j]=f(i,j)
for(i=0;i<n;i++)
   for(j=0;j<ny;j++) in[i*ny+j]=f(i+s,j);
// Set that we want out-of-place transform (default is DFTI_INPLACE)
DftiSetValueDM(desc,DFTI_PLACEMENT,DFTI_NOT_INPLACE);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in,out);
// Virtual global array globalOUT is defined by function g as
// globalOUT[i*ny+j]=g(i,j)
// Now out contains result of FFT. out[i*ny+j]=g(i+s,j)
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();
```

1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len,v,i,n_out,s_out;
Complex *in,*work;

MPI_Init(...);
// Create descriptor for 1D FFT
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,1,len);
// Ask necessary length of array and workspace and allocate memory
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
work=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Local array has n elements,
// 0 element of in corresponds to s element of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Set work array as a workspace
DftiSetValueDM(desc,CDFT_WORKSPACE,work);
// Virtual global array globalIN is defined by function f as globalIN[i]=f(i)
for(i=0;i<n;i++) in[i]=f(i+s);
```

```
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in);
DftiGetValueDM(desc,CDFT_LOCAL_OUT_NX,&n_out);
DftiGetValueDM(desc,CDFT_LOCAL_OUT_X_START,&s_out);
// Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
// Now in contains result of FFT. Local array has n_out elements,
// 0 element of in corresponds to s_out element of virtual global array.
// in[i]==g(i+s_out)
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();
```

Auxiliary Data Transformations

This section presents code examples for conversion from the Cartesian to polar representation of complex data and vice versa.

Conversion from Cartesian to polar representation of complex data

```
// Cartesian->polar conversion of complex data
// Cartesian representation: z = re + I*im
// Polar representation: z = r * exp( I*phi )
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n,const double *re,const double *im,
                         double *r,double *phi)
{
    vdHypot(n,re,im,r);         // compute radii r[]
    vdAtan2(n,im,re,phi);       // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
                         double *temp_re,double *temp_im)
{
    vzAbs(n,z,r);               // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n,temp_im,temp_re,phi); // compute phases phi[]
}
```

Conversion from polar to Cartesian representation of complex data

```
// Polar->Cartesian conversion of complex data.
// Polar representation: z = r * exp( I*phi )
// Cartesian representation: z = re + I*im
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n,const double *r,const double *phi,
                         double *re,double *im)
{
    vdSinCos(n,phi,im,re);      // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,re,re);           // scale real part
    vdMul(n,r,im,im);           // scale imaginary part
}

void
variant2_Polar2Cartesian(int n,const double *r,const double *phi,
                         MKL_Complex16 *z,
                         double *temp_re,double *temp_im)
{
```

```
    vdSinCos(n,phi,temp_im,temp_re); // compute direction, i.e. z[]/abs(z[])
    vdMul(n,r,temp_im,temp_im); // scale imaginary part
    vdMul(n,r,temp_re,temp_re); // scale real part
    vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re
    vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im
}
```

CBLAS Interface to the BLAS

D

This appendix presents CBLAS, the C interface to the Basic Linear Algebra Subprograms (BLAS) implemented in Intel® MKL.

Similar to BLAS, the CBLAS interface includes the following levels of functions:

- "Level 1 CBLAS" (vector-vector operations)
- "Level 2 CBLAS" (matrix-vector operations)
- "Level 3 CBLAS" (matrix-matrix operations).
- "Sparse CBLAS" (operations on sparse vectors).

To obtain the C interface, the Fortran routine names are prefixed with `cblas_` (for example, `dasum` becomes `cblas_dasum`). Names of all CBLAS functions are in lowercase letters.

Complex functions `?dotc` and `?dotu` become CBLAS subroutines (void functions); they return the complex result via a void pointer, added as the last parameter. CBLAS names of these functions are suffixed with `_sub`. For example, the BLAS function `cdotc` corresponds to `cblas_cdotc_sub`.

WARNING Users of the CBLAS interface should be aware that the CBLAS are just a C interface to the BLAS, which is based on the FORTRAN standard and subject to the FORTRAN standard restrictions. In particular, the output parameters should not be referenced through more than one argument.

In the descriptions of CBLAS interfaces, links provided for each function group lead to the descriptions of the respective Fortran-interface BLAS functions.

CBLAS Arguments

The arguments of CBLAS functions comply with the following rules:

- Input arguments are declared with the `const` modifier.
- Non-complex scalar input arguments are passed by value.
- Complex scalar input arguments are passed as void pointers.
- Array arguments are passed by address.
- BLAS character arguments are replaced by the appropriate enumerated type.
- Level 2 and Level 3 routines acquire an additional parameter of type `CBLAS_ORDER` as their first argument. This parameter specifies whether two-dimensional arrays are row-major (`CblasRowMajor`) or column-major (`CblasColMajor`).

Enumerated Types

The CBLAS interface uses the following enumerated types:

```
enum CBLAS_ORDER {
   CblasRowMajor=101,  /* row-major arrays */
   CblasColMajor=102};   /* column-major arrays */
enum CBLAS_TRANSPOSE {
   CblasNoTrans=111,     /* trans='N' */
   CblasTrans=112,       /* trans='T' */
   CblasConjTrans=113};  /* trans='C' */
enum CBLAS_UPLO {
   CblasUpper=121,        /* uplo ='U' */
   CblasLower=122};       /* uplo ='L' */
enum CBLAS_DIAG {
   CblasNonUnit=131,      /* diag ='N' */
   CblasUnit=132};        /* diag ='U' */
```

```
enum CBLAS_SIDE {
   CblasLeft=141,         /* side ='L' */
   CblasRight=142};       /* side ='R' */
```

Level 1 CBLAS

This is an interface to "BLAS Level 1 Routines and Functions", which perform basic vector-vector operations.

?asum

```
float cblas_sasum(const int N, const float *X, const int incX);
double cblas_dasum(const int N, const double *X, const int incX);
float cblas_scasum(const int N, const void *X, const int incX);
double cblas_dzasum(const int N, const void *X, const int incX);
```

?axpy

```
void cblas_saxpy(const int N, const float alpha, const float *X, const int incX, float *Y, const int
incY);
void cblas_daxpy(const int N, const double alpha, const double *X, const int incX, double *Y, const int
incY);
void cblas_caxpy(const int N, const void *alpha, const void *X, const int incX, void *Y, const int
incY);
void cblas_zaxpy(const int N, const void *alpha, const void *X, const int incX, void *Y, const int
incY);
```

?copy

```
void cblas_scopy(const int N, const float *X, const int incX, float *Y, const int incY);
void cblas_dcopy(const int N, const double *X, const int incX, double *Y, const int incY);
void cblas_ccopy(const int N, const void *X, const int incX, void *Y, const int incY);
void cblas_zcopy(const int N, const void *X, const int incX, void *Y, const int incY);
```

?dot

```
float cblas_sdot(const int N, const float *X, const int incX, const float *Y, const int incY);
double cblas_ddot(const int N, const double *X, const int incX, const double *Y, const int incY);
```

?sdot

```
float cblas_sdsdot(const int N, const float SB, const float *SX, const int incX, const float *SY, const
int incY);
double cblas_dsdot(const int N, const float *SX, const int incX, const float *SY, const int incY);
```

?dotc

```
void cblas_cdotc_sub(const int N, const void *X, const int incX, const void *Y, const int incY, void
*dotc);
void cblas_zdotc_sub(const int N, const void *X, const int incX, const void *Y, const int incY, void
*dotc);
```

?dotu

```
void cblas_cdotu_sub(const int N, const void *X, const int incX, const void *Y, const int incY, void
*dotu);
void cblas_zdotu_sub(const int N, const void *X, const int incX, const void *Y, const int incY, void
*dotu);
```

?nrm2

```
float cblas_snrm2(const int N, const float *X, const int incX);
double cblas_dnrm2(const int N, const double *X, const int incX);
float cblas_scnrm2(const int N, const void *X, const int incX);
double cblas_dznrm2(const int N, const void *X, const int incX);
```

?rot

```
void cblas_srot(const int N, float *X, const int incX, float *Y, const int incY, const float c, const
float s);
void cblas_drot(const int N, double *X, const int incX, double *Y,const int incY, const double c, const
double s);
```

?rotg

```
void cblas_srotg(float *a, float *b, float *c, float *s);
void cblas_drotg(double *a, double *b, double *c, double *s);
```

?rotm

```
void cblas_srotm(const int N, float *X, const int incX, float *Y, const int incY, const float *P);
void cblas_drotm(const int N, double *X, const int incX, double *Y, const int incY, const double *P);
```

?rotmg

```
void cblas_srotmg(float *d1, float *d2, float *b1, const float b2, float *P);
void cblas_drotmg(double *d1, double *d2, double *b1, const double b2, double *P);
```

?scal

```
void cblas_sscal(const int N, const float alpha, float *X, const int incX);
void cblas_dscal(const int N, const double alpha, double *X, const int incX);
void cblas_cscal(const int N, const void *alpha, void *X, const int incX);
void cblas_zscal(const int N, const void *alpha, void *X, const int incX);
void cblas_csscal(const int N, const float alpha, void *X, const int incX);
void cblas_zdscal(const int N, const double alpha, void *X, const int incX);
```

?swap

```
void cblas_sswap(const int N, float *X, const int incX, float *Y, const int incY);
void cblas_dswap(const int N, double *X, const int incX, double *Y, const int incY);
void cblas_cswap(const int N, void *X, const int incX, void *Y, const int incY);
void cblas_zswap(const int N, void *X, const int incX, void *Y, const int incY);
```

i?amax

```
CBLAS_INDEX cblas_isamax(const int N, const float *X, const int incX);
CBLAS_INDEX cblas_idamax(const int N, const double *X, const int incX);
CBLAS_INDEX cblas_icamax(const int N, const void *X, const int incX);
CBLAS_INDEX cblas_izamax(const int N, const void *X, const int incX);
```

i?amin

```
CBLAS_INDEX cblas_isamin(const int N, const float *X, const int incX);
CBLAS_INDEX cblas_idamin(const int N, const double *X, const int incX);
CBLAS_INDEX cblas_icamin(const int N, const void *X, const int incX);
CBLAS_INDEX cblas_izamin(const int N, const void *X, const int incX);
```

?cabs1

```
double cblas_dcabs1(const void *z);
float  cblas_scabs1(const void *c);
```

Level 2 CBLAS

This is an interface to “BLAS Level 2 Routines”, which perform basic matrix-vector operations. Each C routine in this group has an additional parameter of type CBLAS_ORDER (the first argument) that determines whether the two-dimensional arrays use column-major or row-major storage.

?gbmv

```
void cblas_sgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const
int N, const int KL, const int KU, const float alpha, const float *A, const int lda, const float *X,
const int incX, const float beta, float *Y, const int incY);
void cblas_dgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const
int N, const int KL, const int KU, const double alpha, const double *A, const int lda, const double *X,
const int incX, const double beta, double *Y, const int incY);
void cblas_cgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const
int N, const int KL, const int KU, const void *alpha, const void *A, const int lda, const void *X,
const int incX, const void *beta, void *Y, const int incY);
void cblas_zgbmv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const
int N, const int KL, const int KU, const void *alpha, const void *A, const int lda, const void *X,
const int incX, const void *beta, void *Y, const int incY);
```

?gemv

```
void cblas_sgemv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const
int N, const float alpha, const float *A, const int lda, const float *X, const int incX, const float
beta, float *Y, const int incY);
void cblas_dgemv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const
int N, const double alpha, const double *A, const int lda, const double *X, const int incX, const
double beta, double *Y, const int incY);
void cblas_cgemv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const
int N, const void *alpha, const void *A, const int lda, const void *X, const int incX, const void
*beta, void *Y, const int incY);
void cblas_zgemv(const enum CBLAS_ORDER order, const enum CBLAS_TRANSPOSE TransA, const int M, const
int N, const void *alpha, const void *A, const int lda, const void *X, const int incX, const void
*beta, void *Y, const int incY);
```

?ger

```
void cblas_sger(const enum CBLAS_ORDER order, const int M, const int N, const float alpha, const float
*X, const int incX, const float *Y, const int incY, float *A, const int lda);
void cblas_dger(const enum CBLAS_ORDER order, const int M, const int N, const double alpha, const
double *X, const int incX, const double *Y, const int incY, double *A, const int lda);
```

?gerc

```
void cblas_cgerc(const enum CBLAS_ORDER order, const int M, const int N, const void *alpha, const void
*X, const int incX, const void *Y, const int incY, void *A, const int lda);

Level 3 CBLAS

This is an interface to "BLAS Level 3 Routines", which perform basic matrix-matrix operations. Each C routine in this group has an additional parameter of type `CBLAS_ORDER` (the first argument) that determines whether the two-dimensional arrays use column-major or row-major storage.

```

Sparse CBLAS

This is an interface to Sparse BLAS Level 1 Routines, which perform a number of common vector operations on sparse vectors stored in compressed form.

Note that all index parameters, *indx*, are in C-type notation and vary in the range [0..*N*–1].

?axpyi

```
void cblas_saxpyi(const int N, const float alpha, const float *X, const int *indx, float *Y);
void cblas_daxpyi(const int N, const double alpha, const double *X, const int *indx, double *Y);
void cblas_caxpyi(const int N, const void *alpha, const void *X, const int *indx, void *Y);
void cblas_zaxpyi(const int N, const void *alpha, const void *X, const int *indx, void *Y);
```

?doti

```
float cblas_sdoti(const int N, const float *X, const int *indx, const float *Y);
double cblas_ddoti(const int N, const double *X, const int *indx, const double *Y);
```

?dotci

```
void  cblas_cdotci_sub(const int N, const void *X, const int *indx, const void *Y, void *dotui);

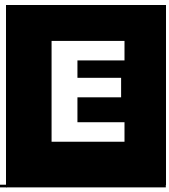
void cblas_zsctr(const int N, const void *X, const int *indx, void *Y);
```

Specific Features of Fortran 95 Interfaces for LAPACK Routines



Intel® MKL implements Fortran 95 interface for LAPACK package, further referred to as MKL LAPACK95, to provide full capacity of MKL FORTRAN 77 LAPACK routines. This is the principal difference of Intel MKL from the Netlib Fortran 95 implementation for LAPACK.

A new feature of MKL LAPACK95 by comparison with Intel MKL LAPACK77 implementation is presenting a package of source interfaces along with wrappers that make the implementation compiler-independent. As a result, the MKL LAPACK package can be used in all programming environments intended for Fortran 95.

Depending on the degree and type of difference from Netlib implementation, the MKL LAPACK95 interfaces fall into several groups that require different transformations (see "MKL Fortran 95 Interfaces for LAPACK Routines vs. Netlib Implementation"). The groups are given in full with the calling sequences of the routines and appropriate differences from Netlib analogs.

The following conventions are used:

```
<interface> ::=  <name of interface> '(' <arguments list>')'
<arguments list> ::=  <first argument> {<argument>}*
<first argument> ::=  < identifier >
<argument> ::=  <required argument>|<optional argument>
<required argument> ::=  ',' <identifier>
<optional argument> ::=  '[,' <identifier> ']'
<name of interface> ::=  <identifier>
```

where defined notions are separated from definitions by `::=`, notion names are marked by angle brackets, terminals are given in quotes, and `{…}*` denotes repetition zero, one, or more times.

<first argument> and each *<required argument>* should be present in all calls of denoted interface, *<optional argument>* may be omitted. Comments to interface definitions are provided where necessary. Comment lines begin with character `!`.

Two interfaces with one name are presented when two variants of subroutine calls (separated by types of arguments) exist.

Interfaces Identical to Netlib

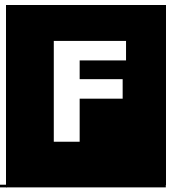
FFTW Interface to Intel® Math Kernel Library



Intel® Math Kernel Library (Intel® MKL) offers FFTW2 and FFTW3 interfaces to Intel MKL Fast Fourier Transform and Trigonometric Transform functionality. The purpose of these interfaces is to enable applications using FFTW (www.fftw.org) to gain performance with Intel MKL without changing the program source code.

Both FFTW2 and FFTW3 interfaces are provided in open source as FFTW wrappers to Intel MKL. For ease of use, FFTW3 interface is also integrated in Intel MKL.

Notational Conventions

This appendix typically employs path notations for Windows* OS.

FFTW2 Interface to Intel® Math Kernel Library

This section describes a collection of wrappers providing FFTW 2.x interface to Intel MKL. The wrappers translate calls to FFTW 2.x functions into the calls of the Intel MKL Fast Fourier Transform interface (FFT interface).

The wrappers correspond to the FFTW version 2.x and the Intel MKL versions 7.0 or higher.

Because of differences between FFTW and Intel MKL FFT functionalities, there are restrictions on using wrappers instead of the FFTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Refer to chapter 11 "Fourier Transform Functions", for better understanding the effects from the use of the wrappers.

More wrappers may be added in the future to extend FFTW functionality available with Intel MKL.

Wrappers Reference

The section provides a brief reference for the FFTW 2.x C interface. For details please refer to the original FFTW 2.x documentation available at www.fftw.org.

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed in this section, are empty and do nothing, but they are provided to avoid link errors and satisfy the function calls.

Intel MKL FFT interface operates on both float and double-precision data types.

One-dimensional Complex-to-complex FFTs

The following functions compute a one-dimensional complex-to-complex Fast Fourier transform.

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);

fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags, fftw_complex
*in, int istride, fftw_complex *out, int ostride);

void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);

void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);

void fftw_destroy_plan(fftw_plan plan);
```

Multi-dimensional Complex-to-complex FFTs

The following functions compute a multi-dimensional complex-to-complex Fast Fourier transform.

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);
fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);
fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir, int
flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir, int
flags, fftw_complex *in, int istride, fftw_complex *out, int ostride);
void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);
void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);
void fftwnd_destroy_plan(fftwnd_plan plan);
```

One-dimensional Real-to-half-complex/Half-complex-to-real FFTs

Half-complex representation of a conjugate-even symmetric vector of size N in a real array of the same size N consists of $N/2+1$ real parts of the elements of the vector followed by non-zero imaginary parts in the reverse order. Because the Intel MKL FFT interface does not currently support this representation, all wrappers of this kind are empty and do nothing.

Nevertheless, you can perform one-dimensional real-to-complex and complex-to-real transforms using `rfftwnd` functions with *rank*=1.

Multi-dimensional Real-to-complex/Complex-to-real FFTs

Multi-dimensional Real-to-complex/Complex-to-real FFTs

The following functions compute multi-dimensional real-to-complex and complex-to-real Fast Fourier transforms.

```
rfftwnd_plan rfftwnd_create_plan(int rank, const int *n, fftw_direction dir, int
flags);
rfftwnd_plan rfftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
rfftwnd_plan rfftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int
flags);
rfftwnd_plan rfftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir,
int flags, fftw_real *in, int istride, fftw_real *out, int ostride);
rfftwnd_plan rfftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int
flags, fftw_real *in, int istride, fftw_real *out, int ostride);
rfftwnd_plan rfftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir,
int flags, fftw_real *in, int istride, fftw_real *out, int ostride);
void rfftwnd_real_to_complex(rfftwnd_plan plan, int howmany, fftw_real *in, int
istride, int idist, fftw_complex *out, int ostride, int odist);
void rfftwnd_complex_to_real(rfftwnd_plan plan, int howmany, fftw_complex *in, int
istride, int idist, fftw_real *out, int ostride, int odist);
void rfftwnd_one_real_to_complex(rfftwnd_plan plan, fftw_real *in, fftw_complex *out);
```

```
void rfftwnd_one_complex_to_real(rfftwnd_plan plan, fftw_complex *in, fftw_real *out);

void rfftwnd_destroy_plan(rfftwnd_plan plan);
```

Multi-threaded FFTW

This section discusses multi-threaded FFTW wrappers only. MPI FFTW wrappers, available only with Intel MKL for the Linux* and Windows* operating systems, are described in section "MPI FFTW Wrappers".

Unlike the original FFTW interface, every computational function in the FFTW2 interface to Intel MKL provides multithreaded computation by default, with the number of threads defined by the number of processors available on the system (see section "Managing Performance and Memory" in the Intel MKL User's Guide). To limit the number of threads that use the FFTW interface, call the threaded FFTW computational functions:

```
void fftw_threads(int nthreads, fftw_plan plan, int howmany, fftw_complex *in, int
istride, int idist, fftw_complex *out, int ostride, int odist);

void fftw_threads_one(int nthreads, rfftwnd_plan plan, fftw_complex *in, fftw_complex
*out);

...

void rfftwnd_threads_real_to_complex( int nthreads, rfftwnd_plan plan, int howmany,
fftw_real *in, int istride, int idist, fftw_complex *out, int ostride, int odist);
```

Compared to its non-threaded counterpart, every threaded computational function has `threads_` as the second part of its name and additional first parameter *nthreads*. Set the *nthreads* parameter to the thread limit to ensure that the computation requires at most that number of threads.

FFTW Support Functions

The FFTW wrappers provide memory allocation functions to be used with FFTW:

```
void* fftw_malloc(size_t n);

void fftw_free(void* x);
```

The `fftw_malloc` wrapper aligns the memory on a 16-byte boundary.

If `fftw_malloc` fails to allocate memory, it aborts the application. To override this behavior, set a global variable `fftw_malloc_hook` and optionally the complementary variable `fftw_free_hook`:

```
void *(*fftw_malloc_hook) (size_t n);

void (*fftw_free_hook) (void *p);
```

The wrappers use the function `fftw_die` to abort the application in cases when a caller cannot be informed of an error otherwise (for example, in computational functions that return `void`). To override this behavior, set a global variable `fftw_die_hook`:

```
void (*fftw_die_hook)(const char *error_string);

void fftw_die(const char *s);
```

Limitations of the FFTW2 Interface to Intel MKL

The FFTW2 wrappers implement the functionality of only those FFTW functions that Intel MKL can reasonably support. Other functions are provided as no-operation functions, whose only purpose is to satisfy link-time symbol resolution. Specifically, no-operation functions include:

- Real-to-half-complex and respective backward transforms
- Print plan functions
- Functions for importing/exporting/forgetting wisdom
- Most of the FFTW functions not covered by the original FFTW2 documentation

Because the Intel MKL implementation of FFTW2 wrappers does not use plan and plan node structures declared in `fftw.h`, the behavior of an application that relies on the internals of the plan structures defined in that header file is undefined.

FFTW2 wrappers define plan as a set of attributes, such as strides, used to commit the Intel MKL FFT descriptor structure. If an FFTW2 computational function is called with attributes different from those recorded in the plan, the function attempts to adjust the attributes of the plan and recommit the descriptor. Thus, repeated calls of a computational function with the same plan but different strides, distances, and other parameters may be performance inefficient.

Plan creation functions disregard most planner flags passed through the *flags* parameter. These functions take into account only the following values of *flags*:

- FFTW_IN_PLACE

  If this value of *flags* is supplied, the plan is marked so that computational functions using that plan ignore the parameters related to output (*out*, *ostride*, and *odist*). Unlike the original FFTW interface, the wrappers never use the *out* parameter as a scratch space for in-place transforms.
- FFTW_THREADSAFE

  If this value of *flags* is supplied, the plan is marked read-only. An attempt to change attributes of a read-only plan aborts the application.

FFTW wrappers are generally not thread safe. Therefore, do not use the same plan in parallel user threads simultaneously.

Calling Wrappers from Fortran

The FFTW2 wrappers to Intel MKL provide the following subroutines for calling from Fortran:

```
call fftw_f77_create_plan(plan, n, dir, flags)
call fftw_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call fftw_f77_one(plan, in, out)
call fftw_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call fftw_f77_threads_one(nthreads, plan, in, out)
call fftw_f77_destroy_plan(plan)

call fftwnd_f77_create_plan(plan, rank, n, dir, flags)
call fftw2d_f77_create_plan(plan, nx, ny, dir, flags)
call fftw3d_f77_create_plan(plan, nx, ny, nz, dir, flags)
call fftwnd_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call fftwnd_f77_one(plan, in, out)
call fftwnd_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call fftwnd_f77_threads_one(nthreads, plan, in, out)
call fftwnd_f77_destroy_plan(plan)

call rfftw_f77_create_plan(plan, n, dir, flags)
call rfftw_f77(plan, howmany, in, istride, idist, out, ostride, odist)
call rfftw_f77_one(plan, in, out)
call rfftw_f77_threads(nthreads, plan, howmany, in, istride, idist, out, ostride,
odist)
call rfftw_f77_threads_one(nthreads, plan, in, out)
call rfftw_f77_destroy_plan(plan)

call rfftwnd_f77_create_plan(plan, rank, n, dir, flags)
```

```
call rfftw2d_f77_create_plan(plan, nx, ny, dir, flags)
call rfftw3d_f77_create_plan(plan, nx, ny, nz, dir, flags)
call rfftwnd_f77_complex_to_real(plan, howmany, in, istride, idist, out, ostride,
odist)
call rfftwnd_f77_one_complex_to_real (plan, in, out)
call rfftwnd_f77_real_to_complex(plan, howmany, in, istride, idist, out, ostride,
odist)
call rfftwnd_f77_one_real_to_complex (plan, in, out)
call rfftwnd_f77_threads_complex_to_real(nthreads, plan, howmany, in, istride, idist,
out, ostride, odist)
call rfftwnd_f77_threads_one_complex_to_real(nthreads, plan, in, out)
call rfftwnd_f77_threads_real_to_complex(nthreads, plan, howmany, in, istride, idist,
out, ostride, odist)
call rfftwnd_f77_threads_one_real_to_complex(nthreads, plan, in, out)
call rfftwnd_f77_destroy_plan(plan)
call fftw_f77_threads_init(info)
```

The FFTW Fortran functions are actually the wrappers to FFTW C functions. So, their functionality and limitations are the same as of the corresponding C wrappers.

Wrappers Reference

Limitations of the FFTW2 Interface to Intel MKL

Installation

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel MKL libraries for the FFTW library. The source code for the wrappers and makefiles with the wrapper list files are located in the `.\interfaces\fftw2xc` and `.\interfaces\fftw2xf` subdirectory in the Intel MKL directory for C and Fortran wrappers, respectively.

Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw2_mkl.h` and `fftw.h`. The `fftw2_mkl.h` file is located in the `.\interfaces\fftw2xc\wrappers` subdirectory in the Intel MKL directory.

Three header files are used to compile the Fortran wrapper library: `fftw2_mkl.h`, `fftw2_f77_mkl.h`, and `fftw.h`. The `fftw2_mkl.h` and `fftw2_f77_mkl.h` files are located in the `.\interfaces\fftw2xf\wrappers` subdirectory in the Intel MKL directory.

The file `fftw.h`, used to compile libraries for both interfaces and located in the `.\include\fftw` subdirectory in the Intel MKL directory, slightly differs from the original FFTW (www.fftw.org) header file `fftw.h`.

The source code for the wrappers, makefiles, and function list files are located in subdirectories `.\interfaces\fftw2xc` and `.\interfaces\fftw2xf` in the Intel MKL directory for C and Fortran wrappers, respectively.

A wrapper library contains C or Fortran wrappers for complex and real transforms in a serial and multi-threaded mode for one of the two data types (`double` or `float`). A makefile parameter manages the data type.

The makefile parameters specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

Because a C compiler builds the Fortran wrapper library, function names in the wrapper library and Fortran object module may be different. The file `fftw2_f77_mkl.h` in the `.\interfaces\fftw2xf\source` subdirectory in the Intel MKL directory defines function names according to the names in the Fortran module. If a required name is missing in the file, you can modify the file to add the name before building the library.

To build the library, run the `make` command on Linux* OS and Mac OS* X or the `nmake` command on Windows* OS with appropriate parameters.

For example, the command

```
make libintel64
```

builds on Linux OS a double-precision wrapper library for Intel® 64 architecture based applications using the Intel® C++ Compiler or the Intel® Fortran Compiler version 9.1 or higher (compilers and data precision are chosen by default.).

Each makefile creates the library in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/ia32` (on Linux OS and Mac OS X) or `.\lib\ia32` (on Windows* OS).

In the wrapper library names, the suffix corresponds to the used compiler, the letter `"f"` precedes the underscore for Fortran, and the letter `"c"` precedes the underscore for C.

For example,

`fftw2xf_intel.lib` (on Windows OS); `libfftw2xf_intel.a` (on Linux OS and Mac OS X);

`fftw2xc_intel.lib` (on Windows OS); `libfftw2xc_intel.a` (on Linux OS and Mac OS X);

`fftw2xc_ms.lib` (on Windows OS); `libfftw2xc_gnu.a` (on Linux OS and Mac OS X).

Application Assembling

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

Intel MKL provides examples to demonstrate how to use the MPI FFTW wrapper library. The source code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw2xc` and `.\examples\fftw2xf` subdirectories in the Intel MKL directory for C and Fortran, respectively. To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`, `rfftw.h`, `rfftw_threads.h`, and `fftw_f77.I`. These files are distributed with permission from FFTW and are available in `.\include\fftw`. The original files can also be found in FFTW 2.1.5 at http://www.fftw.org/download.html.

An example makefile uses the `function` parameter in addition to the parameters that the respective wrapper library makefile uses (see Creating a Wrapper Library). The makefile comment heading provides the exact description of these parameters.

An example makefile normally invokes examples. However, if the appropriate wrapper library is not yet created, the makefile first builds the library the same way as the wrapper library makefile does and then proceeds to examples.

If the parameter `function=<example_name>` is defined, only the specified example runs. Otherwise, all examples from the appropriate subdirectory run. The subdirectory `.\_results` is created, and the results are stored there in the `<example_name>.res` files.

MPI FFTW Wrappers

MPI FFTW wrappers for FFTW 2 are available only with Intel® MKL for the Linux* and Windows* operating systems.

MPI FFTW Wrappers Reference

The section provides a reference for MPI FFTW C interface.

Complex MPI FFTW

Complex One-dimensional MPI FFTW Transforms

```
fftw_mpi_plan fftw_mpi_create_plan(MPI_Comm comm, int n, fftw_direction dir, int flags);
```

```
void fftw_mpi(fftw_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex *work);
```

```
void fftw_mpi_local_sizes(fftw_mpi_plan p, int *local_n, int *local_start, int *local_n_after_transform, int *local_start_after_transform, int *total_local_size);
```

```
void fftw_mpi_destroy_plan(fftw_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE, FFTW_MEASURE, FFTW_SCRAMBLED_INPUT and FFTW_SCRAMBLED_OUTPUT. The same algorithm corresponds to all these values of the flags parameter. If any other *flags* value is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n_fields* is 1.

Complex Multi-dimensional MPI FFTW Transforms

```
fftwnd_mpi_plan fftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction dir, int flags);
```

```
fftwnd_mpi_plan fftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz, fftw_direction dir, int flags);
```

```
fftwnd_mpi_plan fftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction dir, int flags);
```

```
void fftwnd_mpi(fftwnd_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex *work, fftwnd_mpi_output_order output_order);
```

```
void fftwnd_mpi_local_sizes(fftwnd_mpi_plan p, int *local_nx, int *local_x_start, int *local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);
```

```
void fftwnd_mpi_destroy_plan(fftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n_fields* is 1.

Real MPI FFTW

Real-to-Complex MPI FFTW Transforms

```
rfftwnd_mpi_plan rfftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction dir, int flags);
```

```
rfftwnd_mpi_plan rfftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz, fftw_direction dir, int flags);
```

```
rfftwnd_mpi_plan rfftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction dir, int flags);
```

```
void rfftwnd_mpi(rfftwnd_mpi_plan p, int n_fields, fftw_real *local_data, fftw_real *work, fftwnd_mpi_output_order output_order);
```

```
void rfftwnd_mpi_local_sizes(rfftwnd_mpi_plan p, int *local_nx, int *local_x_start, int
*local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);

void rfftwnd_mpi_destroy_plan(rfftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n_fields* is 1.

- Function *rfftwnd_mpi_create_plan* can be used for both one-dimensional and multi-dimensional transforms.
- Both values of the *output_order* parameter are supported: FFTW_NORMAL_ORDER and FFTW_TRANSPOSED_ORDER.

Creating MPI FFTW Wrapper Library

The source code for the wrappers, makefile, and wrapper list file are located in the .\interfaces\fftw2x_cdft subdirectory in the Intel MKL directory.

A wrapper library contains C wrappers for Complex One-dimensional MPI FFTW Transforms and Complex Multi-dimensional MPI FFTW Transforms. The library also contains empty C wrappers for Real Multi-dimensional MPI FFTW Transforms. For details, see MPI FFTW Wrappers Reference.

The makefile parameters specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

To build the library, run the make command on Linux* OS and Mac OS* X or the nmake command on Windows* OS with appropriate parameters.

For example, the command

```
make libintel64
```

builds on Linux OS a double-precision wrapper library for Intel® 64 architecture based applications using Intel MPI 2.0 and the Intel® C++ Compiler version 9.1 or higher (compilers and data precision are chosen by default.).

The makefile creates the wrapper library in the directory with the Intel MKL libraries corresponding to the used platform. For example, ./lib/ia32 (on Linux OS) or .\lib\ia32 (on Windows* OS).

In the wrapper library names, the suffix corresponds to the used data precision. For example,

fftw2x_cdft_SINGLE.lib on Windows OS;

libfftw2x_cdft_DOUBLE.a on Linux OS.

Application Assembling with MPI FFTW Wrapper Library

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created MPI FFTW wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW2. The source C code for the examples, makefiles used to run them, and the example list files are located in the .\examples\fftw2x_cdft subdirectory in the Intel MKL directory. To build examples, one additional file fftw_mpi.h is needed. This file is distributed with permission from FFTW and is available in .\include\fftw. The original file can also be found in FFTW 2.1.5 at http://www.fftw.org/download.html.

Parameters for the example makefiles are described in the makefile comment headings and are similar to the wrapper library makefile parameters (see Creating MPI FFTW Wrapper Library).

The table below lists examples available in the .\examples\fftw2x_cdft\source subdirectory.

Examples of MPI FFTW Wrappers

Source file for the example	Description
`wrappers_c1d.c`	One-dimensional Complex MPI FFTW transform, using `plan = fftw_mpi_create_plan(...)`
`wrappers_c2d.c`	Two-dimensional Complex MPI FFTW transform, using `plan = fftw2d_mpi_create_plan(...)`
`wrappers_c3d.c`	Three-dimensional Complex MPI FFTW transform, using `plan = fftw3d_mpi_create_plan(...)`
`wrappers_c4d.c`	Four-dimensional Complex MPI FFTW transform, using `plan = fftwnd_mpi_create_plan(...)`
`wrappers_r1d.c`	One-dimensional Real MPI FFTW transform, using `plan = rfftw_mpi_create_plan(...)`
`wrappers_r2d.c`	Two-dimensional Real MPI FFTW transform, using `plan = rfftw2d_mpi_create_plan(...)`
`wrappers_r3d.c`	Three-dimensional Real MPI FFTW transform, using `plan = rfftw3d_mpi_create_plan(...)`
`wrappers_r4d.c`	Four-dimensional Real MPI FFTW transform, using `plan = rfftwnd_mpi_create_plan(...)`

FFTW3 Interface to Intel® Math Kernel Library

This section describes a collection of FFTW3 wrappers to Intel MKL. The wrappers translate calls of FFTW3 functions to the calls of the Intel MKL Fourier transform (FFT) or Trigonometric Transform (TT) functions. The purpose of FFTW3 wrappers is to enable developers whose programs currently use the FFTW3 library to gain performance with the Intel MKL Fourier transforms without changing the program source code.

The wrappers correspond to the FFTW release 3.2 and the Intel MKL releases starting with 10.2. **For a detailed description of FFTW interface, refer to www.fftw.org**. For a detailed description of Intel MKL FFT and TT functionality the wrappers use, see chapter 11 and section "Trigonometric Transform Routines" in chapter 13, respectively.

The FFTW3 wrappers provide a limited functionality compared to the original FFTW 3.2 library, because of differences between FFTW and Intel MKL FFT and TT functionality. This section describes limitations of the FFTW3 wrappers and hints for their usage. Nevertheless, many typical FFT tasks can be performed using the FFTW3 wrappers to Intel MKL. More functionality may be added to the wrappers and Intel MKL in the future to reduce the constraints of the FFTW3 interface to Intel MKL.

The FFTW3 wrappers are integrated in Intel MKL. The only change required to use Intel MKL through the FFTW3 wrappers is to link your application using FFTW3 against Intel MKL.

A reference implementation of the FFTW3 wrappers is also provided in open source. You can find it in the `interfaces` directory of the Intel MKL distribution. You can use the reference implementation to create your own wrapper library (see Building Your Own Wrapper Library)

Using FFTW3 Wrappers

The FFTW3 wrappers are a set of functions and data structures depending on one another. The wrappers are not designed to provide the interface on a function-per-function basis. Some FFTW3 wrapper functions are empty and do nothing, but they are present to avoid link errors and satisfy function calls.

This manual does not list the declarations of the functions that the FFTW3 wrappers provide (you can find the declarations in the `fftw3.h` header file). Instead, this section comments particular limitations of the wrappers and provides usage hints:

- The FFTW3 wrappers do not support long double precision because Intel MKL FFT functions operate only on single- and double-precision floating-point data types (`float` and `double`, respectively). Therefore the functions with prefix `fftwl_`, supporting the `long double` data type, are not provided.
- The wrappers provide equivalent implementation for double- and single-precision functions (those with prefixes `fftw_` and `fftwf_`, respectively). So, all these comments equally apply to the double- and single-precision functions and will refer to functions with prefix `fftw_`, that is, double-precision functions, for brevity.
- The FFTW3 interface that the wrappers provide is defined in header files `fftw3.h` and `fftw3.f`. These files are borrowed from the FFTW3.2 package and distributed within Intel MKL with permission. Additionally, files `fftw3_mkl.h`, `fftw3_mkl.f`, and `fftw3_mkl_f77.h` define supporting structures, supplementary constants and macros, and expose Fortran interface in C.
- Actual functionality of the plan creation wrappers is implemented in guru64 set of functions. Basic interface, advanced interface, and guru interface plan creation functions call the guru64 interface functions. Thus, all types of the FFTW3 plan creation interface in the wrappers are functional.
- Plan creation functions may return a `NULL` plan, indicating that the functionality is not supported. So, please carefully check the result returned by plan creation functions in your application. In particular, the following problems return a `NULL` plan:
  - c2r and r2c problems with a split storage of complex data.
  - r2r problems with *kind* values `FFTW_R2HC`, `FFTW_HC2R`, and `FFTW_DHT`. The only supported r2r kinds are even/odd DFTs (sine/cosine transforms).
  - Multidimensional r2r transforms.
  - Transforms of multidimensional vectors. That is, the only supported values for parameter *howmany_rank* in guru and guru64 plan creation functions are 0 and 1.
  - Multidimensional transforms with *rank* > MKL_MAXRANK.
- The `MKL_RODFT00` value of the *kind* parameter is introduced by the FFTW3 wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00`. To use this *kind* value, provide an extra first element equal to 0.0 for the input/output vectors. Consider the following example:

```
plan1 = fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
plan2 = fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

  Both plans perform the same transform, except that the *in2/out2* arrays have one extra zero element at location 0. For example, if *n*=3, *in1*={*x,y,z*} and *out1*={*u,v,w*}, then *in2*={0,*x,y,z*} and *out2*={0,*u,v,w*}.
- The *flags* parameter in plan creation functions is always ignored. The same algorithm is used regardless of the value of this parameter. In particular, *flags* values `FFTW_ESTIMATE`, `FFTW_MEASURE`, etc. have no effect.
- For multithreaded plans, use normal sequence of calls to the `fftw_init_threads()` and `fftw_plan_with_nthreads()` functions (refer to FFTW documentation).
- FFTW3 wrappers are not fully thread safe. If the new-array execute functions, such as `fftw_execute_dft()`, share the same plan from parallel user threads, set the number of the sharing threads before creation of the plan. For this purpose, the FFTW3 wrappers provide a header file `fftw3_mkl.h`, which defines a global structure `fftw3_mkl` with a field to be set to the number of sharing threads. Below is an example of setting the number of sharing threads:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.number_of_user_threads = 4;
plan = fftw_plan_dft(...);
```

- Memory allocation function `fftw_malloc` returns memory aligned at a 16-byte boundary. You must free the memory with `fftw_free`.
- The FFTW3 wrappers to Intel MKL use the 32-bit `int` type in both LP64 and ILP64 interfaces of Intel MKL. Use guru64 FFTW3 interfaces for 64-bit sizes.
- Fortran wrappers (see Calling Wrappers from Fortran) use the `INTEGER` type, which is 32-bit in LP64 interfaces and 64-bit in ILP64 interfaces.

- The wrappers typically indicate a problem by returning a NULL plan. In a few cases, the wrappers may report a descriptive message of the problem detected. By default the reporting is turned off. To turn it on, set variable fftw3_mkl.verbose to a non-zero value, for example:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.verbose = 0;
plan = fftw_plan_r2r(...);
```

- The following functions are empty:
  - For saving, loading, and printing plans
  - For saving and loading wisdom
  - For estimating arithmetic cost of the transforms.
- Do not use macro FFTW_DLL with the FFTW3 wrappers to Intel MKL.
- Do not use negative stride values. Though FFTW3 wrappers support negative strides in the part of advanced and guru FFTW interface, the underlying implementation does not.

Calling Wrappers from Fortran

Intel MKL also provides Fortran 77 interfaces of the FFTW3 wrappers. The Fortran wrappers are available for all FFTW3 interface functions and are based on C interface of the FFTW3 wrappers. Therefore they have the same functionality and restrictions as the corresponding C interface wrappers.

The Fortran wrappers use the default INTEGER type for integer arguments. The default INTEGER is 32-bit in Intel MKL LP64 interfaces and 64-bit in ILP64 interfaces. Argument *plan* in a Fortran application must have type INTEGER*8.

The wrappers that are double-precision subroutines have prefix dfftw_, single-precision subroutines have prefix sfftw_ and provide an equivalent functionality. Long double subroutines (with prefix lfftw_) are not provided.

The Fortran FFTW3 wrappers use the default Intel® Fortran compiler convention for name decoration. If your compiler uses a different convention, or if you are using compiler options affecting the name decoration (such as /Qlowercase), you may need to compile the wrappers from sources, as described in section Building Your Own Wrapper Library.

For interoperability with C, the declaration of the Fortran FFTW3 interface is provided in header file include/fftw/fftw3_mkl_f77.h.

You can call Fortran wrappers from a FORTRAN 77 or Fortran 90 application, although Intel MKL does not provide a Fortran 90 module for the wrappers. For a detailed description of the FFTW Fortran interface, refer to FFTW3 documentation (www.fftw.org).

The following example illustrates calling the FFTW3 wrappers from Fortran:

```
INTEGER*8 plan
INTEGER N
INCLUDE 'fftw3.f'
COMPLEX*16 IN(*), OUT(*)
!...initialize array IN
CALL DFFTW_PLAN_DFT_1D(PLAN, N, IN, OUT, -1, FFTW_ESTIMATE)
IF (PLAN .EQ. 0) STOP
CALL DFFTW_EXECUTE
!...result is in array OUT
```

Building Your Own Wrapper Library

The FFTW3 wrappers to Intel MKL are delivered both integrated in Intel MKL and as source code, which can be compiled to build a standalone wrapper library with exactly the same functionality. Normally you do not need to build the wrappers yourself. However, if your Fortran application is compiled with a compiler that uses a different name decoration than the Intel® Fortran compiler or if you are using compiler options altering the Fortran name decoration, you may need to build the wrappers that use the appropriate name changing convention.

The source code for the wrappers, makefiles, and function list files are located in subdirectories .\interfaces\fftw3xc and .\interfaces\fftw3xf in the Intel MKL directory for C and Fortran wrappers, respectively.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the make command on Linux* OS and Mac OS* X or the nmake command on Windows* OS with a required target and optionally several parameters.

The target, that is, one of {libia32, libintel64}, defines the platform architecture, and the other parameters facilitate selection of the compiler, size of the default INTEGER type, and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the make command is used to build the FFTW3 Fortran wrappers to MKL for use from the GNU g77 Fortran compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3xf
make libintel64 compiler=gnu fname=a_name__ install_to=/my/path
```

This command builds the wrapper library using the GNU gcc compiler, decorates the name with the second underscore, and places the result, named libfftw3xf_gcc.a, into directory /my/path. The name of the resulting library is composed of the name of the compiler used and may be changed by an optional parameter.

Building an Application

Normally, the only change needed to build your application with FFTW3 wrappers replacing original FFTW library is to add Intel MKL at the link stage (see section *"Linking Your Application with Intel® Math Kernel Library" in the Intel MKL User's Guide*).

If you recompile your application, add subdirectory include\fftw to the search path for header files to avoid FFTW3 version conflicts.

Sometimes, you may have to modify your application according to the following recommendations:

- The application requires

  `#include "fftw3.h"`,

  which it probably already includes.
- The application does not require

  `#include "mkl_dfti.h"` .
- The application does not require

  `#include "fftw3_mkl.h"` .

  It is required only in case you want to use the MKL_RODFT00 constant.
- If the application does not check whether a NULL plan is returned by plan creation functions, this check must be added, because the FFTW3 to Intel MKL wrappers do not provide 100% of FFTW3 functionality.
- If the application is threaded, take care about shared plans, because the execute functions in the wrappers are not thread safe, unlike the original FFTW3 functions. See a note about setting fftw3_mkl.number_of_user_threads in section "Using FFTW3 wrappers".

Running Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and the example list files are located in the .\examples\fftw3xc and .\examples\fftw3xf subdirectories in the Intel MKL directory. To build Fortran examples, one additional file fftw3.f is needed. This file is distributed with permission from FFTW and is available in the .\include\fftw subdirectory of the Intel MKL directory. The original file can also be found in FFTW 3.2 at http://www.fftw.org/download.html.

Example makefile parameters are similar to the wrapper library makefile parameters. Example makefiles normally build and invoke the examples. If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples will be executed. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

MPI FFTW Wrappers

This section describes a collection of MPI FFTW wrappers to Intel® MKL. The wrappers correspond to the FFTW 3.3 Alpha release and the Intel MKL releases starting with 10.3. For a detailed description of the MPI FFTW interface, refer to www.fftw.org.

MPI FFTW wrappers are available only with Intel MKL for the Linux* and Windows* operating systems.

These wrappers translate calls of MPI FFTW functions to the calls of the Intel MKL cluster Fourier transform (CFFT) functions. The purpose of the wrappers is to enable users of MPI FFTW functions improve performance of the applications without changing the program source code.

Although the MPI FFTW wrappers provide less functionality than the original FFTW 3.3 because of differences between MPI FFTW and Intel MKL CFFT, the wrappers cover many typical CFFT use cases.

The MPI FFTW wrappers are provided as source code. To use the wrappers, you need to build your own wrapper library (see Building Your Own Wrapper Library).

Cluster FFT Functions

Building Your Own Wrapper Library

The MPI FFTW wrappers for FFTW3 are delivered as source code, which can be compiled to build a wrapper library.

The source code for the wrappers, makefiles, and function list files are located in subdirectory `.\interfaces fftw3x_cdft` in the Intel MKL directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target, that is, one of {`libia32, libintel64`}, defines the platform architecture, and the other parameters specify the compiler, size of the default `INTEGER` type, as well as the name and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the MPI FFTW wrappers to Intel MKL for use from the GNU C compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3x_cdft
make libintel64 compiler=gnu mpi=openmpi INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU gcc compiler so that the final user executable can use Open MPI and places the result, named `libfftw3x_cdft_DOUBLE.a`, into directory `/my/path`.

Building an Application

Normally, the only change needed to build your application with MPI FFTW wrappers replacing original FFTW3 library is to add Intel MKL and the wrapper library at the link stage (see section "*Linking Your Application with Intel® Math Kernel Library*" in the *Intel MKL User's Guide*).

When you are recompiling your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW3. The source code for the examples, makefiles used to run them, and the example list files are located in the `.\examples\fftw3x_cdft` subdirectory in the Intel MKL directory.

Example makefile parameters are similar to the wrapper library makefile parameters. Example makefiles normally build and invoke the examples. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

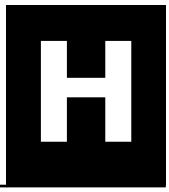
Glossary



A^H	Denotes the conjugate transpose of a general matrix A. *See also* conjugate matrix.
A^T	Denotes the transpose of a general matrix A. *See also* transpose.
band matrix	A general m-by-n matrix A such that $a_{ij} = 0$ for $\|i - j\| > l$, where $1 < l < \min(m, n)$. For example, any tridiagonal matrix is a band matrix.
band storage	A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and *diagonals* of the matrix are stored in rows of the array.
BLAS	Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.
BRNG	Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.
BRNG registration	Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.
Bunch-Kaufman factorization	Representation of a real symmetric or complex Hermitian matrix A in the form $A = PUDU^{H}P^{T}$ (or $A = PLDL^{H}P^{T}$) where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D.
c	When found as the first letter of routine names, c indicates the usage of single-precision complex data type.
CBLAS	C interface to the BLAS. *See* BLAS.
CDF	Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable X. For univariate distribution the cumulative distribution function is the function of real argument x, which for every x takes a value equal to probability of the event A: $X \le x$. For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \ldots, x_n)$, which, for every x, takes a value equal to probability of the event $A = (X_1 \le x_1 \ \& \ X_2 \le x_2, \ \& \ \ldots, \ \& \ X_n \le x_n)$.
Cholesky factorization	Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A in the form $A = U^{H}U$ or $A = LL^{H}$, where L is a lower triangular matrix and U is an upper triangular matrix.
condition number	The number $\kappa(A)$ defined for a given square matrix A as follows: $\kappa(A) = \|\|A\|\| \ \|\|A^{-1}\|\|$.
conjugate matrix	The matrix A^{H} defined for a given general matrix A as follows: $(A^{H})_{ij} = (a_{ji})^{*}$.

conjugate number	The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$.
d	When found as the first letter of routine names, d indicates the usage of double-precision real data type.
dot product	The number denoted $x \cdot y$ and defined for given vectors x and y as follows: $x \cdot y = \Sigma_i x_i y_i$. Here x_i and y_i stand for the i-th elements of x and y, respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $2.23*10^{-308} < \lvert x \rvert < 1.79*10^{308}$. For this data type, the machine precision ε is approximately 10^{-15}, which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture*.
eigenvalue	*See* eigenvalue problem.
eigenvalue problem	A problem of finding non-zero vectors x and numbers λ (for a given square matrix A) such that $Ax = \lambda x$. Here the numbers λ are called the eigenvalues of the matrix A and the vectors x are called the eigenvectors of the matrix A.
eigenvector	*See* eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$, where v is a column vector and τ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix Q in the QR factorization (the matrix Q is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. *See also* Bunch-Kaufman factorization, Cholesky factorization, LU factorization, LQ factorization, QR factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. *See* Chapter 11 of this book.
full storage	A storage scheme allowing you to store matrices of any kind. A matrix A is stored in a two-dimensional array a, with the matrix element a_{ij} stored in the array element $a(i,j)$.
Hermitian matrix	A square matrix A that is equal to its conjugate matrix A^H. The conjugate A^H is defined as follows: $(A^H)_{ij} = (a_{ji})^*$.
I	*See* identity matrix.
identity matrix	A square matrix I whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix A, $AI = A$ and $IA = A$.
i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel MKL	Abbreviation for Intel® Math Kernel Library.
inverse matrix	The matrix denoted as A^{-1} and defined for a given square matrix A as follows: $AA^{-1} = A^{-1}A = I$. A^{-1} does not exist for singular matrices A.
LQ factorization	Representation of an m-by-n matrix A as $A = LQ$ or $A = (L\ 0)Q$. Here Q is an n-by-n orthogonal (unitary) matrix. For $m \le n$, L is an m-by-m lower triangular matrix with real diagonal elements; for $m > n$, where L_1 is an n-by-n lower triangular matrix, and L_2 is a rectangular matrix.

LU factorization	Representation of a general *m*-by-*n* matrix *A* as *A = PLU*, where *P* is a permutation matrix, *L* is lower triangular with unit diagonal elements (lower trapezoidal if *m > n*) and *U* is upper triangular (upper trapezoidal if *m < n*).
machine precision	The number ε determining the precision of the machine representation of real numbers. For Intel© architecture, the machine precision is approximately 10^{-7} for single-precision data, and approximately 10^{-15} for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. *See also* double precision and single precision.
MPI	Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.
MPICH	A freely available, portable implementation of MPI standard for message-passing libraries.
orthogonal matrix	A real square matrix *A* whose transpose and inverse are equal, that is, $A^T = A^{-1}$, and therefore $AA^T = A^TA = I$. All eigenvalues of an orthogonal matrix have the absolute value 1.
packed storage	A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.
PDF	Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable *X*. The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$. For univariate distribution the relation is $$F(x) = \int_{-\infty}^{x} f(t)dt .$$ For multivariate distribution the relation is $$F(x_1,x_2, \dots ,x_n) = \int_{-\infty}^{x_1}\int_{-\infty}^{x_2}\dots\int_{-\infty}^{x_n} f(t_1,t_2, \dots ,t_n)dt_1dt_2 \dots dt_n$$
positive-definite matrix	A square matrix *A* such that $Ax \cdot x > 0$ for any non-zero vector *x*. Here · denotes the dot product.
pseudorandom number generator	A completely deterministic algorithm that imitates truly random sequences.
QR factorization	Representation of an *m*-by-*n* matrix *A* as *A = QR*, where *Q* is an *m*-by-*m* orthogonal (unitary) matrix, and *R* is *n*-by-*n* upper triangular with real diagonal elements (if $m \geq n$) or trapezoidal (if *m < n*) matrix.
random stream	An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.
RNG	Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.

Rectangular Full Packed (RFP) storage	A storage scheme combining the full and packed storage schemes for the upper or lower triangle of the matrix. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.
s	When found as the first letter of routine names, s indicates the usage of single-precision real data type.
ScaLAPACK	Stands for Scalable Linear Algebra PACKage.
Schur factorization	Representation of a square matrix A in the form $A = ZTZ^H$. Here T is an upper quasi-triangular matrix (for complex A, triangular matrix) called the Schur form of A; the matrix Z is orthogonal (for complex A, unitary). Columns of Z are called Schur vectors.
single precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $1.18*10^{-38} < \| x \| < 3.40*10^{38}$. For this data type, the machine precision (ε) is approximately 10^{-7}, which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to *Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture*.
singular matrix	A matrix whose determinant is zero. If A is a singular matrix, the inverse A^{-1} does not exist, and the system of equations $Ax = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).
singular value	The numbers defined for a given general matrix A as the eigenvalues of the matrix AA^H. *See also* SVD.
SMP	Abbreviation for Symmetric MultiProcessing. The MKL offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. *See* BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. *See* full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. *See also* Singular value decomposition section in Chapter 5.
symmetric matrix	A square matrix A such that $a_{ij} = a_{ji}$.
transpose	The transpose of a given matrix A is a matrix A^T such that $(A^T)_{ij} = a_{ji}$ (rows of A become columns of A^T, and columns of A become rows of A^T).
trapezoidal matrix	A matrix A such that $A = (A_1A_2)$, where A_1 is an upper triangular matrix, A_2 is a rectangular matrix.
triangular matrix	A matrix A is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$; for a lower triangular matrix $a_{ij} = 0$ when $i < j$.
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.
unitary matrix	A complex square matrix A whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$, and therefore $AA^H = A^HA = I$. All eigenvalues of a unitary matrix have the absolute value 1.
VML	Abbreviation for Vector Mathematical Library. *See* Chapter 9 of this book.
VSL	Abbreviation for Vector Statistical Library. *See* Chapter 10 of this book.
z	When found as the first letter of routine names, z indicates the usage of double-precision complex data type.
