This function identifies the 7-bit Slave mode address mask that is currently being used to determine which slave addresses the module will respond.

Remarks

The 7-bit address mask will be right-aligned in the 8-bit return value.

This function is not supported on microcontrollers with I2C modules that do not support the slave address mask feature. Refer to the specific device data sheet to determine whether this feature is supported for your device.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveMask in your application to determine whether this feature is available.

Preconditions

The address mask provided may not be valid if it has not been previously been set.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t slaveAddr;
uint8_t slaveAddressMsk;

if ( !PLIB_I2C_SlaveAddressModeIs10Bits ( MY_I2C_ID ) )
{
    slaveAddr     = PLIB_I2C_SlaveAddress7BitGet ( MY_I2C_ID );
    slaveAddressMsk = PLIB_I2C_SlaveMask7BitGet ( MY_I2C_ID );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

uint8_t PLIB_I2C_SlaveMask7BitGet (I2C_MODULE_ID index)

PLIB_I2C_SlaveMask7BitSet Function

Sets the 7-bit mask for Slave mode addressing .

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveMask7BitSet(I2C_MODULE_ID index, uint8_t mask);
```

Returns

None.

Description

This function sets the 7-bit mask for Slave mode addressing. The address mask (if supported) is used, along with the slave address to identify to which addresses the module will respond when operating in Slave mode. It acts as an "ignore" mask, allowing the module to ignore bits within the slave address and will respond to multiple slave addresses on microcontrollers with I2C modules that support the mask feature.

Remarks

I2C modules on some microcontroller families may not support the mask feature, in which case the PLIB_I2C_SlaveMask7BitSet function will not be supported. Refer to the specific device data sheet to determine whether this feature is supported for your device.

The MY_SLAVE_ADDRESS_7_BIT and MY_SLAVE_ADDRESS_MASK_7_BIT macros in the example code are used as placeholders for the actual desired slave address and mask that must be filled in by the caller.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveMask in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID                   I2C_ID_1
#define MY_SLAVE_ADDR_7_BIT         0x23
#define MY_SLAVE_ADDR_MASK_7_BIT    0x12

PLIB_I2C_SlaveAddress7BitSet ( MY_I2C_ID, MY_SLAVE_ADDR_7_BIT );
PLIB_I2C_SlaveMask7BitSet ( MY_I2C_ID, MY_SLAVE_ADDR_MASK_7_BIT );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module
mask	This parameter identifies bits in the address that are "don't care" bits. These bits will be ignored when attempting to match the address, effectively allowing the module to recognize multiple slave addresses. (To match an address exactly, this parameter must be zero (0).)

Function

void PLIB_I2C_SlaveMask7BitSet (I2C_MODULE_ID index, uint8_t mask)

f) Slave Control Functions

PLIB_I2C_AcksequenceIsInProgress Function

Checks whether the acknowledge sequence is in progress or it is completed.

File

plib_i2c.h

C

```
bool PLIB_I2C_AcksequenceIsInProgress(I2C_MODULE_ID index);
```

Returns

- true - Acknowledge sequence is in progress.
- false - Acknowledge sequence is not started or completed.

Description

This function checks whether the acknowledge sequence is in progress or it is completed.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsAcksequenceProgress in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled.

Example

```
#define MY_I2C_ID I2C_ID_1

if ( PLIB_I2C_AcksequenceIsInProgress ( MY_I2C_ID ) )
{
  //Transmission completed
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_AcksequenceIsInProgress (I2C_MODULE_ID index)

PLIB_I2C_DataLineHoldTimeSet Function

Sets the data line hold time.

File

plib_i2c.h

C

```
void PLIB_I2C_DataLineHoldTimeSet(I2C_MODULE_ID index, I2C_SDA_MIN_HOLD_TIME sdaHoldTimeNs);
```

Returns

None.

Description

This function sets the data line hold time.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsDataLineHoldTime in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_PLIB_I2C_DataLineHoldTimeSet ( MY_I2C_ID, I2C_SDA_MIN_HOLD_TIME_300NS );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module.
sdaHoldTimeNs	SDA hold time in nanoseconds.

Function

void PLIB_I2C_DataLineHoldTimeSet (I2C_MODULE_ID index, I2C_SDA_MIN_HOLD_TIME sdaHoldTimeNs)

PLIB_I2C_SlaveBufferOverwriteDisable Function

Disables buffer overwrite.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveBufferOverwriteDisable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function disables buffer overwrite. If the buffer overwrite is disabled, on data receive, when the previous data is not read, the buffer will not be overwritten.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveBufferOverwrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveBufferOverwriteDisable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveBufferOverwriteDisable (I2C_MODULE_ID index)

PLIB_I2C_SlaveBufferOverwriteEnable Function

Enables buffer overwrite.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveBufferOverwriteEnable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function enables buffer overwrite. If the buffer overwrite is enabled, on data receive, even if the previous data is not read, the buffer will be

filled with new data and acknowledge will be generated.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveBufferOverwrite in your application to determine whether this feature is available.

This API is applicable only in I2C slave mode.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveBufferOverwriteEnable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveBufferOverwriteEnable (I2C_MODULE_ID index)

PLIB_I2C_SlaveBusCollisionDetectDisable Function

Disables bus collision detect interrupts.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveBusCollisionDetectDisable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function disables bus collision detect interrupts.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_SlaveBusCollisionDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveBusCollisionDetectDisable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_SlaveBusCollisionDetectDisable (I2C_MODULE_ID index)

PLIB_I2C_SlaveBusCollisionDetectEnable Function

Enables slave bus collision interrupts.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveBusCollisionDetectEnable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function enables bus collision interrupts.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_SlaveBusCollisionDetect in your application to determine whether this feature is available.

This API is applicable only in I2C slave mode.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveAddressHoldEnable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveBusCollisionDetectEnable (I2C_MODULE_ID index)

PLIB_I2C_SlaveClockHold Function

Holds the SCL clock line low after receiving a byte.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveClockHold(I2C_MODULE_ID index);
```

Returns

None.

Description

This function allows an I2C slave to stretch the SCL clock line, holding it low to throttle data transfer from a master transmitter.

Remarks

This function will cause the SCL line to be forced low, after the current byte has been fully received.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveClockHold in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, and a transfer must have been previously started by an external master.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveClockHold ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveClockHold (I2C_MODULE_ID index)

PLIB_I2C_SlaveClockRelease Function

Releases a previously held SCL clock line.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveClockRelease(I2C_MODULE_ID index);
```

Returns

None.

Description

This function allows a slave receiver to release a previously held SCL clock line, allowing it to go high and allowing data transfer to continue.

Remarks

Calling this function when the clock has not been held will not cause any problems.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveClockHold in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, and a transfer must have been previously started by an external master, and the SCL clock line should have been previously held (forced low) by the I2C module.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveClockRelease ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveClockRelease (I2C_MODULE_ID index)

PLIB_I2C_SlaveDataHoldDisable Function

Disables data holding.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveDataHoldDisable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function disables data holding.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_SlaveDataHoldEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveDataHoldDisable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveDataHoldDisable (I2C_MODULE_ID index)

PLIB_I2C_SlaveDataHoldEnable Function

Enables data holding.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveDataHoldEnable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function enables data holding. If a data byte is received, following the 8th falling edge of clock for a clock line will be held low.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_SlaveDataHoldEnable in your application to determine whether this feature is available.

This API is supported only for the slave mode of I2C.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveDataHoldEnable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveDataHoldEnable (I2C_MODULE_ID index)

PLIB_I2C_SlaveInterruptOnStartDisable Function

Disables the feature of generating interrupt on start condition.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveInterruptOnStartDisable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function disables the feature of generating interrupt on start condition.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveInterruptOnStart in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveInterruptOnStartDisable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveInterruptOnStartDisable (I2C_MODULE_ID index)

PLIB_I2C_SlaveInterruptOnStartEnable Function

Enables the feature of generating interrupt on start condition.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveInterruptOnStartEnable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function enables the feature of generating interrupt on start condition.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveInterruptOnStart in your application to determine whether this feature is available.

This API is applicable only in I2C slave mode.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveInterruptOnStartEnable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveInterruptOnStartEnable (I2C_MODULE_ID index)

PLIB_I2C_SlaveInterruptOnStopDisable Function

Disables the feature of generating interrupt on stop condition.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveInterruptOnStopDisable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function disables the feature of generating interrupt on stop condition.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveInterruptOnStop in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveInterruptOnStopDisable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveInterruptOnStopDisable (I2C_MODULE_ID index)

PLIB_I2C_SlaveInterruptOnStopEnable Function

Enables the feature of generating interrupt on stop condition.

File

plib_i2c.h

C

```
void PLIB_I2C_SlaveInterruptOnStopEnable(I2C_MODULE_ID index);
```

Returns

None.

Description

This function enables the feature of generating interrupt on stop condition.

Remarks

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsSlaveInterruptOnStop in your application to determine whether this feature is available.

This API is applicable only in I2C slave mode.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_SlaveInterruptOnStopEnable ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_SlaveInterruptOnStopEnable (I2C_MODULE_ID index)

g) Master Control Functions

PLIB_I2C_MasterReceiverClock1Byte Function

Drives the bus clock to receive 1 byte of data from a slave device.

File

plib_i2c.h

C

```
void PLIB_I2C_MasterReceiverClock1Byte(I2C_MODULE_ID index);
```

Returns

None.

Description

This function drives the bus clock to receive 1 byte of data from a slave device.

Remarks

The module stops driving the bus clock after the reception of a single byte of data and this function must be called again to receive another byte.

After the module has finished receiving a data byte (determined by responding to an I2C master interrupt and/or by checking the

PLIB_I2C_ReceivedByteIsAvailable function), software should check the PLIB_I2C_ReceiverOverflowHasOccurred function to ensure that no data was lost because the receiver buffer was full when the byte was completely received and ready to be placed into the receiver buffer.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsMasterReceiverClock1Byte in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, a transfer must have been previously started, and the module must be the intended receiver of the next byte of data.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_MasterReceiverClock1Byte ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_MasterReceiverClock1Byte (I2C_MODULE_ID index)

PLIB_I2C_MasterStart Function

Sends an I2C Start condition on the I2C bus in Master mode.

File

plib_i2c.h

C

```
void PLIB_I2C_MasterStart(I2C_MODULE_ID index);
```

Returns

None.

Description

This function sends the start signal (a falling edge on SDA while SCL is high) to start a transfer on the I2C bus when acting in Master mode.

Remarks

Only an I2C master can start a transfer on the bus. The bus is considered to be busy after a Start condition.

After the Start condition has completed (detected by responding to the I2C master interrupt), software should check for arbitration loss by calling the PLIB_I2C_ArbitrationLossHasOccurred function.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsMasterStart in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled and the I2C bus must currently be idle.

Example

```
#define MY_I2C_ID I2C_ID_1

if ( PLIB_I2C_BusIsIdle ( MY_I2C_ID ) )
{
    PLIB_I2C_MasterStart ( MY_I2C_ID );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_MasterStart (I2C_MODULE_ID index)

PLIB_I2C_MasterStartRepeat Function

Sends a repeated Start condition during an ongoing transfer in Master mode.

File

plib_i2c.h

C

```
void PLIB_I2C_MasterStartRepeat(I2C_MODULE_ID index);
```

Returns

None.

Description

This function supports sending a repeated Start condition to change slave targets or transfer direction to support certain I2C transfer formats in Master mode.

Remarks

Only an I2C master that has already started a transfer can send a repeated Start condition.

After the repeated-start condition has completed (detected by responding to the I2C master interrupt), software should check for arbitration loss by the PLIB_I2C_ArbitrationLossHasOccurred function.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsMasterStartRepeat in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, and a transfer must have been previously started.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_MasterStartRepeat ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_MasterStartRepeat (I2C_MODULE_ID index)

PLIB_I2C_MasterStop Function

Sends an I2C Stop condition to terminate a transfer in Master mode.

File

plib_i2c.h

C

```
void PLIB_I2C_MasterStop(I2C_MODULE_ID index);
```

Returns

None.

Description

This function sends the stop signal (a rising edge on SDA while SCL is high) on the I2C bus, to end a transfer on the I2C bus when in Master mode.

Remarks

Only an I2C master that has already started a transfer can send a Stop condition.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsMasterStop in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately, enabled, and a previously started transfer must be completed.

Example

```
#define MY_I2C_ID I2C_ID_1

PLIB_I2C_MasterStop ( MY_I2C_ID );
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_MasterStop (I2C_MODULE_ID index)

h) Transmitter Control Functions

PLIB_I2C_TransmitterByteHasCompleted Function

Detects whether the module has finished transmitting the most recent byte.

File

plib_i2c.h

C

```
bool PLIB_I2C_TransmitterByteHasCompleted(I2C_MODULE_ID index);
```

Returns

- true - If the transmitter has completed sending the data byte
- false - If the transmitter is still busy sending the data byte

Description

This function determines if the transmitter has finished sending the most recently sent byte on the I2C bus.

Remarks

This function should be used by both master and slave transmitters.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsTransmitterByteComplete in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, a transfer must have been previously started, and a data or address byte must have been sent.

Example

```
#define MY_I2C_ID I2C_ID_1

if ( PLIB_I2C_TransmitterByteHasCompleted ( MY_I2C_ID ) )
{
  //Transmission completed
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_TransmitterByteHasCompleted (I2C_MODULE_ID index)

PLIB_I2C_TransmitterByteSend Function

Sends a byte of data on the I2C bus.

File

plib_i2c.h

C

```
void PLIB_I2C_TransmitterByteSend(I2C_MODULE_ID index, uint8_t data);
```

Returns

None.

Description

This function allows the caller to send a byte of data on the I2C bus.

Remarks

This function should be used by both master and slave transmitters.

The caller must either first call the PLIB_I2C_TransmitterIsReady function before calling this function to ensure that the transmitter is ready to receive a new byte to transmit or call the PLIB_I2C_TransmitterOverflowHasOccurred function immediately after calling this function to ensure that a transmitter write collision did not occur.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsTransmitterByteSend in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, a transfer must have been previously started, and the I2C module's transmitter must be ready to accept a byte of data to send.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t transmitData;

//set 'transmitData' variable

if ( PLIB_I2C_TransmitterIsReady ( MY_I2C_ID ) )
{
    PLIB_I2C_TransmitterByteSend ( MY_I2C_ID, transmitData );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module
data	Data byte to send on the I2C bus

Function

void PLIB_I2C_TransmitterByteSend (I2C_MODULE_ID index, uint8_t data)

PLIB_I2C_TransmitterByteWasAcknowledged Function

Determines whether the most recently sent byte was acknowledged.

File

plib_i2c.h

C

```
bool PLIB_I2C_TransmitterByteWasAcknowledged(I2C_MODULE_ID index);
```

Returns

- true - If the receiver ACKed the byte
- false - If the receiver NAKed the byte

Description

This function allows a transmitter to determine if the byte just sent was positively acknowledged (ACKed) or negatively acknowledged (NAKed) by the receiver.

Remarks

This function can be used by both master or slave transmitters.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsTransmitterByteAcknowledge in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, a transfer must have been previously started, a byte of data must have been sent on the I2C bus, and the transmission must have completed.

Example

```
#define MY_I2C_ID I2C_ID_1

if ( PLIB_I2C_TransmitterByteHasCompleted ( MY_I2C_ID ) )
{
    if ( PLIB_I2C_TransmitterByteWasAcknowledged ( MY_I2C_ID ) )
    {
        // transmission successful
    }
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_TransmitterByteWasAcknowledged (I2C_MODULE_ID index)

PLIB_I2C_TransmitterIsBusy Function

Identifies if the transmitter of the specified I2C module is currently busy (unable to accept more data).

File

plib_i2c.h

C

```
bool PLIB_I2C_TransmitterIsBusy(I2C_MODULE_ID index);
```

Returns

- true - The transmitter is busy (unable to accept new data)
- false - The transmitter is ready (able to accept new data)

Description

This function identifies if the transmitter of the specified I2C module is currently busy (unable to accept more data).

Remarks

This function returns the inverse of the PLIB_I2C_TransmitterIsReady function.

This flag is cleared automatically by the hardware when the transmitter is ready. It cannot be cleared by software.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsTransmitterIsBusy in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t transData;

//set 'transData' variable

if ( !PLIB_I2C_TransmitterIsBusy( MY_I2C_ID ) )
{
    PLIB_I2C_TransmitterByteSend( MY_I2C_ID, transData );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_TransmitterIsBusy (I2C_MODULE_ID index)

PLIB_I2C_TransmitterIsReady Function

Detects if the transmitter is ready to accept data to transmit.

File

plib_i2c.h

C

```
bool PLIB_I2C_TransmitterIsReady(I2C_MODULE_ID index);
```

Returns

- true - If the transmitter is ready to accept more data
- false - If the transmitter is not ready to accept more data

Description

This function determines if the transmitter is ready to accept more data to be transmitted on the I2C bus.

Remarks

This function should be used by both master and slave transmitters.

This function returns the inverse of the PLIB_I2C_TransmitterIsBusy function.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsTransmitterIsBusy in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately, enabled, and a transfer must have been previously started.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t sendData;

//set 'sendData' variable

if ( PLIB_I2C_TransmitterIsReady ( MY_I2C_ID ) )
{
```

```
    PLIB_I2C_TransmitterByteSend ( MY_I2C_ID, sendData );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_TransmitterIsReady (I2C_MODULE_ID index)

PLIB_I2C_TransmitterOverflowClear Function

Clears the transmitter overflow status flag.

File

plib_i2c.h

C

```
void PLIB_I2C_TransmitterOverflowClear(I2C_MODULE_ID index);
```

Returns

None.

Description

This function clears the transmitter overflow status flag.

Remarks

This flag is set by hardware when an overflow error occurs. Its status can be tested using the PLIB_I2C_TransmitterOverflowHasOccurred function. This flag must be cleared be cleared by software after the overflow error has been handled. To handle the error, software must retry the write later after the PLIB_I2C_TransmitterByteSend function returns TRUE.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsTransmitterOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t my_data;

//set 'my_data' variable
PLIB_I2C_TransmitterByteSend ( MY_I2C_ID, my_data );
if ( PLIB_I2C_TransmitterOverflowHasOccurred ( MY_I2C_ID ) )
{
    // Handle overflow error

    PLIB_I2C_TransmitterOverflowClear ( MY_I2C_ID );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_TransmitterOverflowClear (I2C_MODULE_ID index)

PLIB_I2C_TransmitterOverflowHasOccurred Function

Identifies if a transmitter overflow error has occurred.

File

plib_i2c.h

C

```
bool PLIB_I2C_TransmitterOverflowHasOccurred(I2C_MODULE_ID index);
```

Returns

- true - If software attempted to write a byte to the transmitter buffer while the transmitter was busy and unable to accept a new byte (i.e., the write will not occur)
- false - If no transmitter overflow occurred when software attempted to write a byte to the transmitter buffer (i.e., the write occurred successfully)

Description

This function identifies if a transmitter overflow error has occurred.

Remarks

This flag must be cleared be cleared by software using the PLIB_I2C_TransmitterOverflowClear function.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsTransmitterOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t txData;

//set 'txData' variable

PLIB_I2C_TransmitterByteSend ( MY_I2C_ID, txData );
if ( PLIB_I2C_TransmitterOverflowHasOccurred ( MY_I2C_ID ) )
{
    // Handle overflow error

    PLIB_I2C_TransmitterOverflowClear ( MY_I2C_ID );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_TransmitterOverflowHasOccurred (I2C_MODULE_ID index)

i) Receiver Control Functions

PLIB_I2C_ReceivedByteAcknowledge Function

Allows a receiver to acknowledge a that a byte of data has been received.

File

plib_i2c.h

C

```
void PLIB_I2C_ReceivedByteAcknowledge(I2C_MODULE_ID index, bool ack);
```

Returns

None.

Description

This function allows a receiver to positively acknowledge (ACK) or negatively acknowledge (NAK) a byte of data that has been received from the I2C bus.

Remarks

This function can only be used by master receivers. Slave receivers automatically ACK or NAK bytes.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsReceivedByteAcknowledge in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, a transfer must have been previously started, and a byte of data must have been received from the I2C bus.

Example

```
#define MY_I2C_ID I2C_ID_1

if ( PLIB_I2C_ReceivedByteIsAvailable ( MY_I2C_ID ) )
{
    if ( PLIB_I2C_MasterReceiverReadyToAcknowledge ( MY_I2C_ID ) )
    {
        PLIB_I2C_ReceivedByteAcknowledge ( MY_I2C_ID, true );
        data = PLIB_I2C_ReceivedByteGet ( MY_I2C_ID );
    }
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module
ack	Determines how the byte should be acknowledged: • If true, positively acknowledges (ACK) the byte of data received • If false, negatively acknowledges (NAK) the byte of data received

Function

void PLIB_I2C_ReceivedByteAcknowledge (I2C_MODULE_ID index, bool ack)

PLIB_I2C_ReceivedByteGet Function

Gets a byte of data received from the I2C bus interface.

File

plib_i2c.h

C

```
uint8_t PLIB_I2C_ReceivedByteGet(I2C_MODULE_ID index);
```

Returns

A byte of data received from the I2C bus.

Description

This function allows the caller to read a byte of data received from the I2C bus.

Remarks

This function should be used by both master and slave receivers.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsReceivedByteGet in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, a transfer must have been previously started, and a byte of data must have

been received from the I2C bus.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t receivedData;

if ( PLIB_I2C_ReceivedByteIsAvailable ( MY_I2C_ID ) )
{
    PLIB_I2C_ReceivedByteAcknowledge ( MY_I2C_ID, true );
    receivedData = PLIB_I2C_ReceivedByteGet ( MY_I2C_ID );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

uint8_t PLIB_I2C_ReceivedByteGet (I2C_MODULE_ID index)

PLIB_I2C_ReceivedByteIsAvailable Function

Detects whether the receiver has data available.

File

plib_i2c.h

C

```
bool PLIB_I2C_ReceivedByteIsAvailable(I2C_MODULE_ID index);
```

Returns

- true - If the receiver has data available
- false - If the receiver does not have data available

Description

This function determines if the receiver has data available to be read by software.

Remarks

This function should be used by both master and slave receivers.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsReceivedByteAvailable in your application to determine whether this feature is available.

Preconditions

The I2C module must have been configured appropriately and enabled, and a transfer must have been previously started.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t readData;

if ( PLIB_I2C_ReceivedByteIsAvailable ( MY_I2C_ID ) )
{
    readData = PLIB_I2C_ReceivedByteGet ( MY_I2C_ID );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_ReceivedByteIsAvailable (I2C_MODULE_ID index)

PLIB_I2C_ReceiverByteAcknowledgeHasCompleted Function

Determines if the previous acknowledge has completed.

File

plib_i2c.h

C

```
bool PLIB_I2C_ReceiverByteAcknowledgeHasCompleted(I2C_MODULE_ID index);
```

Returns

- true - If the acknowledgment has completed
- false - If the acknowledgment has not completed

Description

This function allows the receiver to determine if the acknowledgment signal has completed.

Remarks

This function can only be used by master receivers. Slave receivers automatically ACK or NAK bytes.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsReceivedByteAcknowledge in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, a transfer must have been previously started, a byte of data must have been received on the I2C bus, and the acknowledgment must have been started (by calling the PLIB_I2C_ReceivedByteAcknowledge function).

Example

```
PLIB_I2C_ReceivedByteAcknowledge ( MY_I2C_ID, true );

if ( PLIB_I2C_ReceiverByteAcknowledgeHasCompleted ( MY_I2C_ID ) )
{
    // acknowledgment completed
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_ReceiverByteAcknowledgeHasCompleted (I2C_MODULE_ID index)

PLIB_I2C_ReceiverOverflowClear Function

Clears the receiver overflow status flag.

File

plib_i2c.h

C

```
void PLIB_I2C_ReceiverOverflowClear(I2C_MODULE_ID index);
```

Returns

None.

Description

This function clears the receiver overflow status flag.

Remarks

This flag is set by hardware when an overflow error occurs. Its status can be tested using the PLIB_I2C_ReceiverOverflowHasOccurred function.

This flag should be cleared be cleared by software after the overflow error has been handled by reading the byte in the receiver buffer.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsReceiverOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

if ( PLIB_I2C_ReceiverOverflowHasOccurred ( MY_I2C_ID ) )
{
    // Handle overflow error

    PLIB_I2C_ReceiverOverflowClear ( MY_I2C_ID );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

void PLIB_I2C_ReceiverOverflowClear (I2C_MODULE_ID index)

PLIB_I2C_ReceiverOverflowHasOccurred Function

Identifies if a receiver overflow error has occurred.

File

plib_i2c.h

C

```
bool PLIB_I2C_ReceiverOverflowHasOccurred(I2C_MODULE_ID index);
```

Returns

- true - If a byte was received while the receiver buffer still held a previously received byte (The new byte will be lost)
- false - If no receiver overflow occurred when a byte has been received

Description

This function identifies if a receiver overflow error has occurred.

Remarks

This flag should be cleared be cleared by software using the PLIB_I2C_ReceiverOverflowClear function.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsReceiverOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_I2C_ID I2C_ID_1

if ( PLIB_I2C_ReceiverOverflowHasOccurred ( MY_I2C_ID ) )
{
    // Handle overflow error

    PLIB_I2C_ReceiverOverflowClear ( MY_I2C_ID );
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_ReceiverOverflowHasOccurred (I2C_MODULE_ID index)

PLIB_I2C_MasterReceiverReadyToAcknowledge Function

Checks whether the hardware is ready to acknowledge.

File

plib_i2c.h

C

```
bool PLIB_I2C_MasterReceiverReadyToAcknowledge(I2C_MODULE_ID index);
```

Returns

- true - If the hardware status is ready to acknowledge
- false - If the hardware is not ready to acknowledge

Description

This function checks for preconditions before acknowledging a slave.

Remarks

This function can only be used by master receivers.

The MY_I2C_ID macro in the example above is used as a placeholder for the actual I2C bus ID (as defined by the processor-specific I2C_MODULE_ID enum).

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_I2C_ExistsReceivedByteAcknowledge in your application to determine whether this feature is available.

Preconditions

The module must have been configured appropriately and enabled, a transfer must have been previously started and a byte of data must have been received from the I2C bus.

Example

```
#define MY_I2C_ID I2C_ID_1
uint8_t data;

if ( PLIB_I2C_ReceivedByteIsAvailable ( MY_I2C_ID ) )
{
    if ( PLIB_I2C_MasterReceiverReadyToAcknowledge ( MY_I2C_ID ) )
    {
        PLIB_I2C_ReceivedByteAcknowledge ( MY_I2C_ID, true );
        data = PLIB_I2C_ReceivedByteGet ( MY_I2C_ID );
    }
}
```

Parameters

Parameters	Description
index	Identifies the desired I2C module

Function

bool PLIB_I2C_MasterReceiverReadyToAcknowledge (I2C_MODULE_ID index)

j) Feature Existence Functions

PLIB_I2C_ExistsAcksequenceProgress Function

Identifies whether the AcksequenceIsInProgress feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsAcksequenceProgress(I2C_MODULE_ID index);
```

Returns

- true - If the AcksequenceIsInProgress feature is supported on the device
- false - If the AcksequenceIsInProgress feature is not supported on the device

Description

This function identifies whether the AcksequenceIsInProgress feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_AcksequenceIsInProgress

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsAcksequenceProgress(I2C_MODULE_ID index)

PLIB_I2C_ExistsArbitrationLoss Function

Identifies whether the ArbitrationLoss feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsArbitrationLoss(I2C_MODULE_ID index);
```

Returns

- true - If the ArbitrationLoss feature is supported on the device
- false - If the ArbitrationLoss feature is not supported on the device

Description

This function identifies whether the ArbitrationLoss feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_ArbitrationLossHasOccurred
- PLIB_I2C_ArbitrationLossClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsArbitrationLoss(I2C_MODULE_ID index)

PLIB_I2C_ExistsBaudRate Function

Identifies whether the BaudRate feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsBaudRate(I2C_MODULE_ID index);
```

Returns

- true - If the BaudRate feature is supported on the device
- false - If the BaudRate feature is not supported on the device

Description

This function identifies whether the BaudRate feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_BaudRateSet
- PLIB_I2C_BaudRateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsBaudRate(I2C_MODULE_ID index)

PLIB_I2C_ExistsBusIsIdle Function

Identifies whether the BusIdle feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsBusIsIdle(I2C_MODULE_ID index);
```

Returns

- true - If the BusIdle feature is supported on the device
- false - If the BusIdle feature is not supported on the device

Description

This function identifies whether the BusIdle feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_BusIsIdle

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsBusIsIdle(I2C_MODULE_ID index)

PLIB_I2C_ExistsClockStretching Function

Identifies whether the ClockStretching feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsClockStretching(I2C_MODULE_ID index);
```

Returns

- true - If the ClockStretching feature is supported on the device
- false - If the ClockStretching feature is not supported on the device

Description

This function identifies whether the ClockStretching feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveClockStretchingEnable
- PLIB_I2C_SlaveClockStretchingDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsClockStretching(I2C_MODULE_ID index)

PLIB_I2C_ExistsDataLineHoldTime Function

Identifies whether the DataLineHoldTime feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsDataLineHoldTime(I2C_MODULE_ID index);
```

Returns

- true - If the DataLineHoldTime feature is supported on the device
- false - If the DataLineHoldTime feature is not supported on the device

Description

This function identifies whether the DataLineHoldTime feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_DataLineHoldTimeSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsDataLineHoldTime(I2C_MODULE_ID index)

PLIB_I2C_ExistsGeneralCall Function

Identifies whether the GeneralCall feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsGeneralCall(I2C_MODULE_ID index);
```

Returns

- true - If the GeneralCall feature is supported on the device
- false - If the GeneralCall feature is not supported on the device

Description

This function identifies whether the GeneralCall feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_GeneralCallEnable
- PLIB_I2C_GeneralCallDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsGeneralCall(I2C_MODULE_ID index)

PLIB_I2C_ExistsGeneralCallAddressDetect Function

Identifies whether the GeneralCallAddressDetect feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsGeneralCallAddressDetect(I2C_MODULE_ID index);
```

Returns

- true - If the GeneralCallAddressDetect feature is supported on the device
- false - If the GeneralCallAddressDetect feature is not supported on the device

Description

This function identifies whether the GeneralCallAddressDetect feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_SlaveAddressIsGeneralCall

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsGeneralCallAddressDetect(I2C_MODULE_ID index)

PLIB_I2C_ExistsHighFrequency Function

Identifies whether the HighFrequency feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsHighFrequency(I2C_MODULE_ID index);
```

Returns

- true - If the HighFrequency feature is supported on the device
- false - If the HighFrequency feature is not supported on the device

Description

This function identifies whether the HighFrequency feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_HighFrequencyEnable
- PLIB_I2C_HighFrequencyDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsHighFrequency(I2C_MODULE_ID index)

PLIB_I2C_ExistsIPMI Function

Identifies whether the IPMI feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsIPMI(I2C_MODULE_ID index);
```

Returns

- true - If the IPMI feature is supported on the device
- false - If the IPMI feature is not supported on the device

Description

This function identifies whether the IPMI feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_IPMIEnable
- PLIB_I2C_IPMIDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsIPMI(I2C_MODULE_ID index)

PLIB_I2C_ExistsMasterReceiverClock1Byte Function

Identifies whether the MasterReceiverClock1Byte feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsMasterReceiverClock1Byte(I2C_MODULE_ID index);
```

Returns

- true - If the MasterReceiverClock1Byte feature is supported on the device
- false - If the MasterReceiverClock1Byte feature is not supported on the device

Description

This function identifies whether the MasterReceiverClock1Byte feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_MasterReceiverClock1Byte

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsMasterReceiverClock1Byte(I2C_MODULE_ID index)

PLIB_I2C_ExistsMasterStart Function

Identifies whether the MasterStart feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsMasterStart(I2C_MODULE_ID index);
```

Returns

- true - If the MasterStart feature is supported on the device
- false - If the MasterStart feature is not supported on the device

Description

This function identifies whether the MasterStart feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_MasterStart

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsMasterStart(I2C_MODULE_ID index)

PLIB_I2C_ExistsMasterStartRepeat Function

Identifies whether the MasterStartRepeat feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsMasterStartRepeat(I2C_MODULE_ID index);
```

Returns

- true - If the MasterStartRepeat feature is supported on the device
- false - If the MasterStartRepeat feature is not supported on the device

Description

This function identifies whether the MasterStartRepeat feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_MasterStartRepeat

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsMasterStartRepeat(I2C_MODULE_ID index)

PLIB_I2C_ExistsMasterStop Function

Identifies whether the MasterStop feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsMasterStop(I2C_MODULE_ID index);
```

Returns

- true - If the MasterStop feature is supported on the device
- false - If the MasterStop feature is not supported on the device

Description

This function identifies whether the MasterStop feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_MasterStop

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsMasterStop(I2C_MODULE_ID index)

PLIB_I2C_ExistsModuleEnable Function

Identifies whether the ModuleEnable feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsModuleEnable(I2C_MODULE_ID index);
```

Returns

- true - If the ModuleEnable feature is supported on the device
- false - If the ModuleEnable feature is not supported on the device

Description

This function identifies whether the ModuleEnable feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_Enable
- PLIB_I2C_Disable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsModuleEnable(I2C_MODULE_ID index)

PLIB_I2C_ExistsReceivedByteAcknowledge Function

Identifies whether the ReceivedByteAcknowledge feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsReceivedByteAcknowledge(I2C_MODULE_ID index);
```

Returns

- true - If the ReceivedByteAcknowledge feature is supported on the device
- false - If the ReceivedByteAcknowledge feature is not supported on the device

Description

This function identifies whether the ReceivedByteAcknowledge feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_ReceivedByteAcknowledge
- PLIB_I2C_ReceiverByteAcknowledgeHasCompleted
- PLIB_I2C_MasterReceiverReadyToAcknowledge

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsReceivedByteAcknowledge(I2C_MODULE_ID index)

PLIB_I2C_ExistsReceivedByteAvailable Function

Identifies whether the ReceivedByteAvailable feature exists on the I2C module

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsReceivedByteAvailable(I2C_MODULE_ID index);
```

Returns

- true - If the ReceivedByteAvailable feature is supported on the device
- false - If the ReceivedByteAvailable feature is not supported on the device

Description

This function identifies whether the ReceivedByteAvailable feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_ReceivedByteIsAvailable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsReceivedByteAvailable(I2C_MODULE_ID index)

PLIB_I2C_ExistsReceivedByteGet Function

Identifies whether the ReceivedByteGet feature exists on the I2C module

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsReceivedByteGet(I2C_MODULE_ID index);
```

Returns

- true - If the ReceivedByteGet feature is supported on the device
- false - If the ReceivedByteGet feature is not supported on the device

Description

This function identifies whether the ReceivedByteGet feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_ReceivedByteGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsReceivedByteGet(I2C_MODULE_ID index)

PLIB_I2C_ExistsReceiverOverflow Function

Identifies whether the ReceiverOverflow feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsReceiverOverflow(I2C_MODULE_ID index);
```

Returns

- true - If the ReceiverOverflow feature is supported on the device
- false - If the ReceiverOverflow feature is not supported on the device

Description

This function identifies whether the ReceiverOverflow feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_ReceiverOverflowHasOccurred
- PLIB_I2C_ReceiverOverflowClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsReceiverOverflow(I2C_MODULE_ID index)

PLIB_I2C_ExistsReservedAddressProtect Function

Identifies whether the ReservedAddressProtect feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsReservedAddressProtect(I2C_MODULE_ID index);
```

Returns

- true - If the ReservedAddressProtect feature is supported on the device
- false - If the ReservedAddressProtect feature is not supported on the device

Description

This function identifies whether the ReservedAddressProtect feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_ReservedAddressProtectEnable
- PLIB_I2C_ReservedAddressProtectDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsReservedAddressProtect(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveAddress10Bit Function

Identifies whether the SlaveAddress10Bit feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveAddress10Bit(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveAddress10Bit feature is supported on the device
- false - If the SlaveAddress10Bit feature is not supported on the device

Description

This function identifies whether the SlaveAddress10Bit feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveAddress10BitSet
- PLIB_I2C_SlaveAddress10BitGet
- PLIB_I2C_SlaveAddressModeIs10Bits

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveAddress10Bit(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveAddress7Bit Function

Identifies whether the SlaveAddress7Bit feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveAddress7Bit(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveAddress7Bit feature is supported on the device
- false - If the SlaveAddress7Bit feature is not supported on the device

Description

This function identifies whether the SlaveAddress7Bit feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveAddress7BitSet
- PLIB_I2C_SlaveAddress7BitGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveAddress7Bit(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveAddressDetect Function

Identifies whether the SlaveAddressDetect feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveAddressDetect(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveAddressDetect feature is supported on the device
- false - If the SlaveAddressDetect feature is not supported on the device

Description

This function identifies whether the SlaveAddressDetect feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_SlaveAddress10BitWasDetected

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveAddressDetect(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveAddressHoldEnable Function

Identifies whether the SlaveAddressHoldEnable feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveAddressHoldEnable(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveAddressHoldEnable feature is supported on the device
- false - If the SlaveAddressHoldEnable feature is not supported on the device

Description

This function identifies whether the SlaveAddressHoldEnable feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveAddressHoldEnable
- PLIB_I2C_SlaveAddressHoldDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveAddressHoldEnable(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveBufferOverwrite Function

Identifies whether the SlaveBufferOverwrite feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveBufferOverwrite(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveBufferOverwrite feature is supported on the device
- false - If the SlaveBufferOverwrite feature is not supported on the device

Description

This function identifies whether the SlaveBufferOverwrite feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveBufferOverwriteEnable
- PLIB_I2C_SlaveBufferOverwriteDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveBufferOverwrite(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveBusCollisionDetect Function

Identifies whether the SlaveBusCollisionDetect feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveBusCollisionDetect(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveBusCollisionDetect feature is supported on the device
- false - If the SlaveBusCollisionDetect feature is not supported on the device

Description

This function identifies whether the SlaveBusCollisionDetect feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveBusCollisionDetectEnable
- PLIB_I2C_SlaveBusCollisionDetectDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveBusCollisionDetect(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveClockHold Function

Identifies whether the SlaveClockHold feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveClockHold(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveClockHold feature is supported on the device
- false - If the SlaveClockHold feature is not supported on the device

Description

This function identifies whether the SlaveClockHold feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveClockHold
- PLIB_I2C_SlaveClockRelease

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveClockHold(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveDataDetect Function

Identifies whether the SlaveDataDetect feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveDataDetect(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveDataDetect feature is supported on the device
- false - If the SlaveDataDetect feature is not supported on the device

Description

This function identifies whether the SlaveDataDetect feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveDataIsDetected
- PLIB_I2C_SlaveAddressIsDetected

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveDataDetect(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveInterruptOnStart Function

Identifies whether the SlaveInterruptOnStart feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveInterruptOnStart(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveInterruptOnStart feature is supported on the device
- false - If the SlaveInterruptOnStart feature is not supported on the device

Description

This function identifies whether the SlaveInterruptOnStart feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveInterruptOnStartEnable
- PLIB_I2C_SlaveInterruptOnStartDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveInterruptOnStart(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveInterruptOnStop Function

Identifies whether the SlaveInterruptOnStop feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveInterruptOnStop(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveInterruptOnStop feature is supported on the device
- false - If the SlaveInterruptOnStop feature is not supported on the device

Description

This function identifies whether the SlaveInterruptOnStop feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveInterruptOnStopEnable
- PLIB_I2C_SlaveInterruptOnStopDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveInterruptOnStop(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveMask Function

Identifies whether the SlaveMask feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveMask(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveMask feature is supported on the device
- false - If the SlaveMask feature is not supported on the device

Description

This function identifies whether the SlaveMask feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveMask7BitSet
- PLIB_I2C_SlaveMask7BitGet
- PLIB_I2C_SlaveMask10BitSet
- PLIB_I2C_SlaveMask10BitGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveMask(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveReadRequest Function

Identifies whether the SlaveReadRequest feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveReadRequest(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveReadRequest feature is supported on the device
- false - If the SlaveReadRequest feature is not supported on the device

Description

This function identifies whether the SlaveReadRequest feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_SlaveReadIsRequested

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveReadRequest(I2C_MODULE_ID index)

PLIB_I2C_ExistsSMBus Function

Identifies whether the SMBus feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSMBus(I2C_MODULE_ID index);
```

Returns

- true - If the SMBus feature is supported on the device
- false - If the SMBus feature is not supported on the device

Description

This function identifies whether the SMBus feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SMBEnable
- PLIB_I2C_SMBDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSMBus(I2C_MODULE_ID index)

PLIB_I2C_ExistsStartDetect Function

Identifies whether the StartDetect feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsStartDetect(I2C_MODULE_ID index);
```

Returns

- true - If the StartDetect feature is supported on the device
- false - If the StartDetect feature is not supported on the device

Description

This function identifies whether the StartDetect feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_StartWasDetected
- PLIB_I2C_StartClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsStartDetect(I2C_MODULE_ID index)

PLIB_I2C_ExistsStopDetect Function

Identifies whether the StopDetect feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsStopDetect(I2C_MODULE_ID index);
```

Returns

- true - If the StopDetect feature is supported on the device
- false - If the StopDetect feature is not supported on the device

Description

This function identifies whether the StopDetect feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_StopWasDetected
- PLIB_I2C_StopClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsStopDetect(I2C_MODULE_ID index)

PLIB_I2C_ExistsStopInIdle Function

Identifies whether the StopInIdle feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsStopInIdle(I2C_MODULE_ID index);
```

Returns

- true - If the StopInIdle feature is supported on the device
- false - If the StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_StopInIdleEnable
- PLIB_I2C_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsStopInIdle(I2C_MODULE_ID index)

PLIB_I2C_ExistsTransmitterByteAcknowledge Function

Identifies whether the TransmitterByteAcknowledge feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsTransmitterByteAcknowledge(I2C_MODULE_ID index);
```

Returns

- true - If the TransmitterByteAcknowledge feature is supported on the device
- false - If the TransmitterByteAcknowledge feature is not supported on the device

Description

This function identifies whether the TransmitterByteAcknowledge feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_TransmitterByteWasAcknowledged

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsTransmitterByteAcknowledge(I2C_MODULE_ID index)

PLIB_I2C_ExistsTransmitterByteComplete Function

Identifies whether the TransmitterByteComplete feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsTransmitterByteComplete(I2C_MODULE_ID index);
```

Returns

- true - If the TransmitterByteComplete feature is supported on the device
- false - If the TransmitterByteComplete feature is not supported on the device

Description

This function identifies whether the TransmitterByteComplete feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_TransmitterByteHasCompleted

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsTransmitterByteComplete(I2C_MODULE_ID index)

PLIB_I2C_ExistsTransmitterByteSend Function

Identifies whether the TransmitterByteSend feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsTransmitterByteSend(I2C_MODULE_ID index);
```

Returns

- true - If the TransmitterByteSend feature is supported on the device
- false - If the TransmitterByteSend feature is not supported on the device

Description

This function identifies whether the TransmitterByteSend feature is available on the I2C module. When this function returns true, this function is supported on the device:

- PLIB_I2C_TransmitterByteSend

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsTransmitterByteSend(I2C_MODULE_ID index)

PLIB_I2C_ExistsTransmitterIsBusy Function

Identifies whether the TransmitterBusy feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsTransmitterIsBusy(I2C_MODULE_ID index);
```

Returns

- true - If the TransmitterBusy feature is supported on the device
- false - If the TransmitterBusy feature is not supported on the device

Description

This function identifies whether the TransmitterBusy feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_TransmitterIsBusy
- PLIB_I2C_TransmitterIsReady

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsTransmitterIsBusy(I2C_MODULE_ID index)

PLIB_I2C_ExistsTransmitterOverflow Function

Identifies whether the TransmitterOverflow feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsTransmitterOverflow(I2C_MODULE_ID index);
```

Returns

- true - If the TransmitterOverflow feature is supported on the device
- false - If the TransmitterOverflow feature is not supported on the device

Description

This function identifies whether the TransmitterOverflow feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_TransmitterOverflowHasOccurred
- PLIB_I2C_TransmitterOverflowClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsTransmitterOverflow(I2C_MODULE_ID index)

PLIB_I2C_ExistsSlaveDataHoldEnable Function

Identifies whether the SlaveDataHoldEnable feature exists on the I2C module.

File

plib_i2c.h

C

```
bool PLIB_I2C_ExistsSlaveDataHoldEnable(I2C_MODULE_ID index);
```

Returns

- true - If the SlaveDataHoldEnable feature is supported on the device
- false - If the SlaveDataHoldEnable feature is not supported on the device

Description

This function identifies whether the SlaveDataHoldEnable feature is available on the I2C module. When this function returns true, these functions are supported on the device:

- PLIB_I2C_SlaveDataHoldEnable
- PLIB_I2C_SlaveDataHoldDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_I2C_ExistsSlaveDataHoldEnable(I2C_MODULE_ID index)

k) Data Types and Constants

I2C_MODULE_ID Enumeration

File

plib_i2c_help.h

C

```
typedef enum {
  I2C_ID_1,
  I2C_ID_2,
  I2C_ID_3,
  I2C_ID_4,
  I2C_ID_5,
  I2C_NUMBER_OF_MODULES
} I2C_MODULE_ID;
```

Members

Members	Description
I2C_ID_1	I2C Module 1 ID
I2C_ID_2	I2C Module 2 ID
I2C_ID_3	I2C Module 3 ID
I2C_ID_4	I2C Module 4 ID
I2C_ID_5	I2C Module 5 ID
I2C_NUMBER_OF_MODULES	Number of available I2C modules.

Description

This is type I2C_MODULE_ID.

Files

Files

Name	Description
plib_i2c.h	This file contains the interface definition for the I2C Peripheral Library.
plib_i2c_help.h	Identifies the supported I2C modules.

Description

This section lists the source and header files used by the library.

plib_i2c.h

This file contains the interface definition for the I2C Peripheral Library.

Functions

	Name	Description
	PLIB_I2C_AcksequenceIsInProgress	Checks whether the acknowledge sequence is in progress or it is completed.
	PLIB_I2C_ArbitrationLossClear	Clears the arbitration loss status flag
	PLIB_I2C_ArbitrationLossHasOccurred	Identifies if bus arbitration has been lost.
	PLIB_I2C_BaudRateGet	Calculates the I2C module's current SCL clock frequency.
	PLIB_I2C_BaudRateSet	Sets the desired baud rate.
	PLIB_I2C_BusIsIdle	Determines whether the I2C bus is idle or busy.
	PLIB_I2C_DataLineHoldTimeSet	Sets the data line hold time.
	PLIB_I2C_Disable	Disables the specified I2C module.
	PLIB_I2C_Enable	Enables the specified I2C module.
	PLIB_I2C_ExistsAcksequenceProgress	Identifies whether the AcksequenceIsInProgress feature exists on the I2C module.

	PLIB_I2C_ExistsArbitrationLoss	Identifies whether the ArbitrationLoss feature exists on the I2C module.
	PLIB_I2C_ExistsBaudRate	Identifies whether the BaudRate feature exists on the I2C module.
	PLIB_I2C_ExistsBusIsIdle	Identifies whether the BusIdle feature exists on the I2C module.
	PLIB_I2C_ExistsClockStretching	Identifies whether the ClockStretching feature exists on the I2C module.
	PLIB_I2C_ExistsDataLineHoldTime	Identifies whether the DataLineHoldTime feature exists on the I2C module.
	PLIB_I2C_ExistsGeneralCall	Identifies whether the GeneralCall feature exists on the I2C module.
	PLIB_I2C_ExistsGeneralCallAddressDetect	Identifies whether the GeneralCallAddressDetect feature exists on the I2C module.
	PLIB_I2C_ExistsHighFrequency	Identifies whether the HighFrequency feature exists on the I2C module.
	PLIB_I2C_ExistsIPMI	Identifies whether the IPMI feature exists on the I2C module.
	PLIB_I2C_ExistsMasterReceiverClock1Byte	Identifies whether the MasterReceiverClock1Byte feature exists on the I2C module.
	PLIB_I2C_ExistsMasterStart	Identifies whether the MasterStart feature exists on the I2C module.
	PLIB_I2C_ExistsMasterStartRepeat	Identifies whether the MasterStartRepeat feature exists on the I2C module.
	PLIB_I2C_ExistsMasterStop	Identifies whether the MasterStop feature exists on the I2C module.
	PLIB_I2C_ExistsModuleEnable	Identifies whether the ModuleEnable feature exists on the I2C module.
	PLIB_I2C_ExistsReceivedByteAcknowledge	Identifies whether the ReceivedByteAcknowledge feature exists on the I2C module.
	PLIB_I2C_ExistsReceivedByteAvailable	Identifies whether the ReceivedByteAvailable feature exists on the I2C module
	PLIB_I2C_ExistsReceivedByteGet	Identifies whether the ReceivedByteGet feature exists on the I2C module
	PLIB_I2C_ExistsReceiverOverflow	Identifies whether the ReceiverOverflow feature exists on the I2C module.
	PLIB_I2C_ExistsReservedAddressProtect	Identifies whether the ReservedAddressProtect feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveAddress10Bit	Identifies whether the SlaveAddress10Bit feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveAddress7Bit	Identifies whether the SlaveAddress7Bit feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveAddressDetect	Identifies whether the SlaveAddressDetect feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveAddressHoldEnable	Identifies whether the SlaveAddressHoldEnable feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveBufferOverwrite	Identifies whether the SlaveBufferOverwrite feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveBusCollisionDetect	Identifies whether the SlaveBusCollisionDetect feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveClockHold	Identifies whether the SlaveClockHold feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveDataDetect	Identifies whether the SlaveDataDetect feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveDataHoldEnable	Identifies whether the SlaveDataHoldEnable feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveInterruptOnStart	Identifies whether the SlaveInterruptOnStart feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveInterruptOnStop	Identifies whether the SlaveInterruptOnStop feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveMask	Identifies whether the SlaveMask feature exists on the I2C module.
	PLIB_I2C_ExistsSlaveReadRequest	Identifies whether the SlaveReadRequest feature exists on the I2C module.
	PLIB_I2C_ExistsSMBus	Identifies whether the SMBus feature exists on the I2C module.
	PLIB_I2C_ExistsStartDetect	Identifies whether the StartDetect feature exists on the I2C module.
	PLIB_I2C_ExistsStopDetect	Identifies whether the StopDetect feature exists on the I2C module.
	PLIB_I2C_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the I2C module.
	PLIB_I2C_ExistsTransmitterByteAcknowledge	Identifies whether the TransmitterByteAcknowledge feature exists on the I2C module.
	PLIB_I2C_ExistsTransmitterByteComplete	Identifies whether the TransmitterByteComplete feature exists on the I2C module.
	PLIB_I2C_ExistsTransmitterByteSend	Identifies whether the TransmitterByteSend feature exists on the I2C module.
	PLIB_I2C_ExistsTransmitterIsBusy	Identifies whether the TransmitterBusy feature exists on the I2C module.
	PLIB_I2C_ExistsTransmitterOverflow	Identifies whether the TransmitterOverflow feature exists on the I2C module.
	PLIB_I2C_GeneralCallDisable	Disables the I2C module from recognizing the general call address.
	PLIB_I2C_GeneralCallEnable	Enables the I2C module to recognize the general call address.
	PLIB_I2C_HighFrequencyDisable	Disables the I2C module from using high frequency (400 kHz or 1 MHz) signaling.
	PLIB_I2C_HighFrequencyEnable	Enables the I2C module to use high frequency (400 kHz or 1 MHz) signaling.
	PLIB_I2C_IPMIDisable	Disables the I2C module's support for the IPMI specification

	PLIB_I2C_IPMIEnable	Enables the I2C module to support the Intelligent Platform Management Interface (IPMI) specification (see Remarks).
	PLIB_I2C_MasterReceiverClock1Byte	Drives the bus clock to receive 1 byte of data from a slave device.
	PLIB_I2C_MasterReceiverReadyToAcknowledge	Checks whether the hardware is ready to acknowledge.
	PLIB_I2C_MasterStart	Sends an I2C Start condition on the I2C bus in Master mode.
	PLIB_I2C_MasterStartRepeat	Sends a repeated Start condition during an ongoing transfer in Master mode.
	PLIB_I2C_MasterStop	Sends an I2C Stop condition to terminate a transfer in Master mode.
	PLIB_I2C_ReceivedByteAcknowledge	Allows a receiver to acknowledge a that a byte of data has been received.
	PLIB_I2C_ReceivedByteGet	Gets a byte of data received from the I2C bus interface.
	PLIB_I2C_ReceivedByteIsAvailable	Detects whether the receiver has data available.
	PLIB_I2C_ReceiverByteAcknowledgeHasCompleted	Determines if the previous acknowledge has completed.
	PLIB_I2C_ReceiverOverflowClear	Clears the receiver overflow status flag.
	PLIB_I2C_ReceiverOverflowHasOccurred	Identifies if a receiver overflow error has occurred.
	PLIB_I2C_ReservedAddressProtectDisable	Disables the I2C module from protecting reserved addresses, allowing it to respond to them.
	PLIB_I2C_ReservedAddressProtectEnable	Enables the I2C module to protect (not respond to) reserved addresses.
	PLIB_I2C_SlaveAddress10BitGet	Identifies the current 10-bit Slave mode address.
	PLIB_I2C_SlaveAddress10BitSet	Selects 10-bit Slave mode addressing and sets the address value.
	PLIB_I2C_SlaveAddress10BitWasDetected	Detects reception of the second byte of a 10-bit slave address.
	PLIB_I2C_SlaveAddress7BitGet	Identifies the current 7-bit Slave mode address.
	PLIB_I2C_SlaveAddress7BitSet	Selects 7-bit Slave mode addressing and sets the slave address value.
	PLIB_I2C_SlaveAddressHoldDisable	Disables Address holding.
	PLIB_I2C_SlaveAddressHoldEnable	Enables address holding.
	PLIB_I2C_SlaveAddressIsDetected	Detects if the most recent byte received is a data or an address byte.
	PLIB_I2C_SlaveAddressIsGeneralCall	Identifies if the current slave address received is the general call address.
	PLIB_I2C_SlaveAddressModeIs10Bits	Identifies if the current slave address mode is 7-bits or 10-bits.
	PLIB_I2C_SlaveBufferOverwriteDisable	Disables buffer overwrite.
	PLIB_I2C_SlaveBufferOverwriteEnable	Enables buffer overwrite.
	PLIB_I2C_SlaveBusCollisionDetectDisable	Disables bus collision detect interrupts.
	PLIB_I2C_SlaveBusCollisionDetectEnable	Enables slave bus collision interrupts.
	PLIB_I2C_SlaveClockHold	Holds the SCL clock line low after receiving a byte.
	PLIB_I2C_SlaveClockRelease	Releases a previously held SCL clock line.
	PLIB_I2C_SlaveClockStretchingDisable	Disables the I2C module from stretching the slave clock.
	PLIB_I2C_SlaveClockStretchingEnable	Enables the I2C module to stretch the slave clock.
	PLIB_I2C_SlaveDataHoldDisable	Disables data holding.
	PLIB_I2C_SlaveDataHoldEnable	Enables data holding.
	PLIB_I2C_SlaveDataIsDetected	Detects if the most recent byte received is a data or an address byte.
	PLIB_I2C_SlaveInterruptOnStartDisable	Disables the feature of generating interrupt on start condition.
	PLIB_I2C_SlaveInterruptOnStartEnable	Enables the feature of generating interrupt on start condition.
	PLIB_I2C_SlaveInterruptOnStopDisable	Disables the feature of generating interrupt on stop condition.
	PLIB_I2C_SlaveInterruptOnStopEnable	Enables the feature of generating interrupt on stop condition.
	PLIB_I2C_SlaveMask10BitGet	Identifies the current 10-bit Slave mode address mask.
	PLIB_I2C_SlaveMask10BitSet	Sets the 10-bit mask for Slave mode addressing.
	PLIB_I2C_SlaveMask7BitGet	Identifies the current 7-bit Slave mode address mask.
	PLIB_I2C_SlaveMask7BitSet	Sets the 7-bit mask for Slave mode addressing .
	PLIB_I2C_SlaveReadIsRequested	Detects if the request from the master was a read or write.
	PLIB_I2C_SMBDisable	Disable the I2C module support for SMBus electrical signaling levels.
	PLIB_I2C_SMBEnable	Enables the I2C module to support System Management Bus (SMBus) electrical signaling levels.
	PLIB_I2C_StartClear	Clears the start status flag
	PLIB_I2C_StartWasDetected	Identifies when a Start condition has been detected.
	PLIB_I2C_StopClear	Clears the stop status flag
	PLIB_I2C_StopInIdleDisable	Disables the Stop-in-Idle feature.
	PLIB_I2C_StopInIdleEnable	Enables the I2C module to stop when the processor enters Idle mode
	PLIB_I2C_StopWasDetected	Identifies when a Stop condition has been detected
	PLIB_I2C_TransmitterByteHasCompleted	Detects whether the module has finished transmitting the most recent byte.

	PLIB_I2C_TransmitterByteSend	Sends a byte of data on the I2C bus.
	PLIB_I2C_TransmitterByteWasAcknowledged	Determines whether the most recently sent byte was acknowledged.
	PLIB_I2C_TransmitterIsBusy	Identifies if the transmitter of the specified I2C module is currently busy (unable to accept more data).
	PLIB_I2C_TransmitterIsReady	Detects if the transmitter is ready to accept data to transmit.
	PLIB_I2C_TransmitterOverflowClear	Clears the transmitter overflow status flag.
	PLIB_I2C_TransmitterOverflowHasOccurred	Identifies if a transmitter overflow error has occurred.

Description

I2C Peripheral Library Interface Header

This library provides a low-level abstraction of the Inter-Integrated Circuit (I2C) module on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences between one microcontroller variant and another.

File Name

plib_i2c.h

Company

Microchip Technology Inc.

plib_i2c_help.h

Identifies the supported I2C modules.

Enumerations

	Name	Description
	I2C_MODULE_ID	This is type I2C_MODULE_ID.

Description

I2C Module ID

This enumeration identifies the available I2C modules.

Remarks

The caller should not rely on the specific numbers assigned to any of these values as they may change from one processor to the next.

Not all modules will be available on all microcontrollers. Refer to the data sheet for the specific controller in use to determine which modules are supported. The numbers used in the enumeration values will match the numbers specified in the data sheet.

Input Capture Peripheral Library

This section describes the Input Capture Peripheral Library.

Introduction

This library provides a low-level abstraction of the Input Capture (IC) Peripheral Library that is available on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, there by hiding differences from one microcontroller variant to another.

Description

The Input Capture (IC) module is used to capture a timer value on the occurrence of an event on an input pin. The IC module plays a major role in applications requiring frequency measurement.

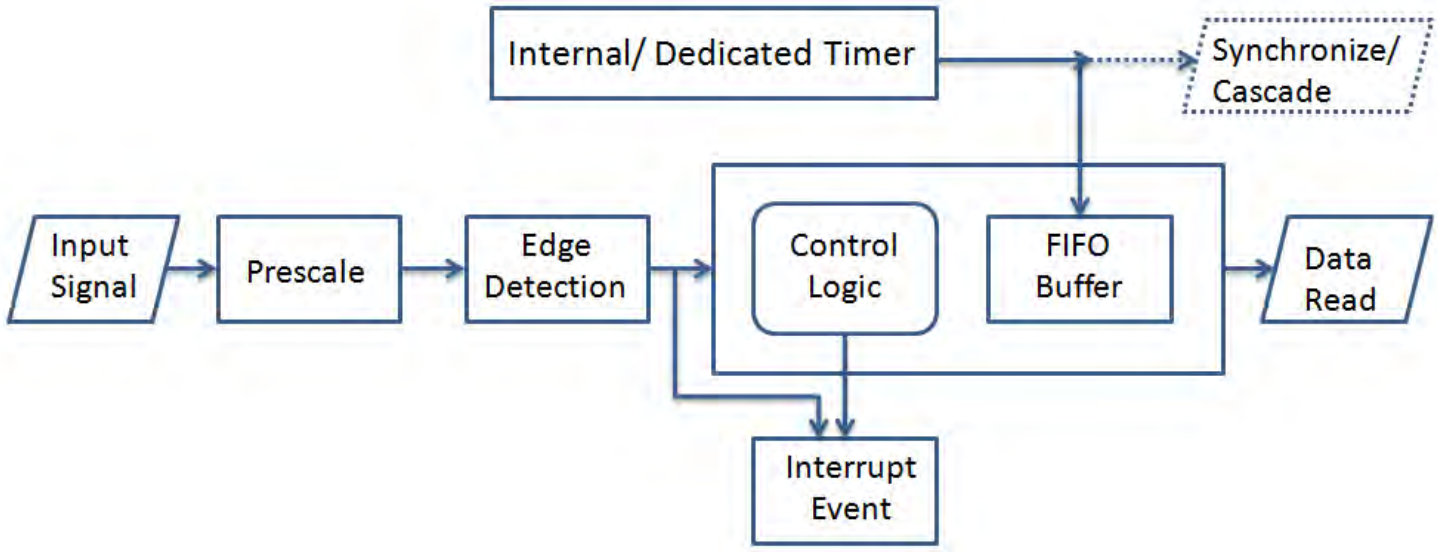

Figure 1: Input Capture Module

Figure 1 shows the functionality of an Input Capture module. An input signal is provided to the input of this module. The input may be prescaled. An edge detection block detects if the input is undergoing a rising or falling transition. Control logic undertakes the capture of the timer value depending upon the operating mode selected.

Some devices have Input Capture modules with dedicated timers that can be used to synchronize multiple IC modules together or cascade 16-bit timers to obtain a 32-bit timer. The timer may be triggered by an external, asynchronous input to start counting as well.

The IC module has multiple modes of operation which can be used for different applications. Operating modes include the following:

- Timer value capture at falling edge of input signal
- Timer value capture at rising edge of input signal
- Timer value capture at both edges of input signal
- Timer value capture on a specified edge of the input signal and every edge thereafter
- Timer value capture on every fourth or sixteenth rising edge of the input signal
- Interrupt-only mode in which Input Capture module acts as a source of external interrupt. This mode is functional only in device Sleep and Idle modes.

The IC module also incorporates a First In First Out (FIFO) buffer, which temporarily holds the captured value until it is read by the user application. The IC module is capable of generating interrupts when a set number of captures have taken place.

Using the Library

This topic describes the basic architecture of the Input Capture Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_ic.h`

The interface to the Input Capture Peripheral library is defined in the `plib_ic.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Input Capture Peripheral library must include `peripheral.h`.

Library File: The IC Peripheral library archive (`.a`) file is installed with MPLAB Harmony.

Please refer to the What is MPLAB Harmony? section for how the Peripheral interacts with the framework.

Hardware Abstraction Model

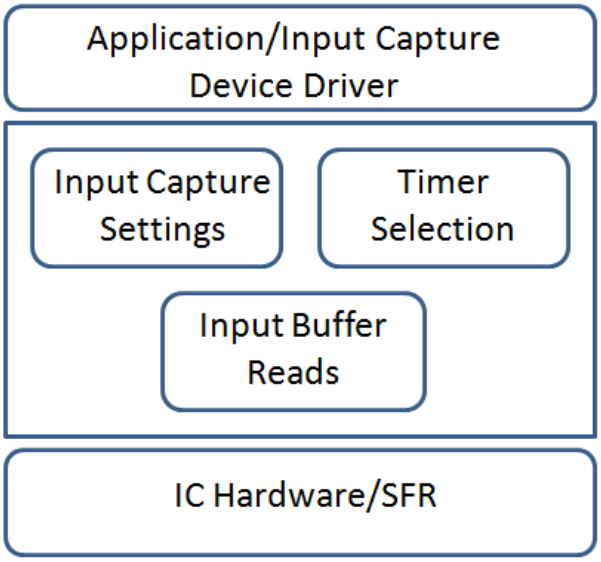
This library provides the low-level abstraction of the Input Capture (IC) module on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in the software and introduces the library interface.

Note: The interface provided is a superset of all of the functionality of the available IC module on the device. Refer to the **"Input Capture"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine the set of functions that are supported for each IC module on your device.

Description

The IC Peripheral Library is used to simplify low-level access to the IC module without having the need to directly interact with the module registers. The names of the functions are generic and lead to easier access to the IC module on different device variants.

Input Capture module Software Abstraction Block Diagram



The IC module can be described from a software standpoint as having functions to configure the module itself and select an intended mode of operation. Separate functions exist to select the timer whose value is captured by the IC module. When an external input event occurs, the IC module captures the timer value and stores it in a First In First Out (FIFO) buffer. The captured value can be read from the FIFO buffer by performing an input buffer read by calling the respective function.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Input Capture module.

Library Interface Section	Description
General Setup Functions	Provides setup, configuration, and status interface routines for the overall operation of the Input Capture module.
Timer Functions	Provides timer interface routines.
Input Capture Buffer Functions	Provides buffer interface routines.
Operation Modes Functions	Provides operation mode routines.
Power-Saving Modes Functions	Provides Power-Saving Modes routines.
Feature Existence Functions	Determine whether particular features exist on a device.

How the Library Works

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine the supported modes.

All of the interface functions in this library are classified according to:

- General setup functions: These functions deal with general setup of the IC module
- Timer functions: These routines are used to select the timer, input for the timer, and configure synchronous or triggered operation for the timer
- Operation Modes routine: The PLIB_IC_ModeSelect function is used to select an operation mode of IC module
- Input capture buffer routines: These routines deal with reading the capture value stored in the IC buffer and performing status checks on the IC buffer
- Power-Saving modes:
  - In Sleep mode, the IC module can function only as an external interrupt source. A rising edge input wakes the device from sleep. An interrupt will be generated if it is enabled for that module.
  - In Idle mode, the IC module can be configured to either stop its operation or continue its operation
- Exists functions: These functions determine whether or not a particular feature is present on a device

Subsequent sections provide examples that depict the use of interface routines to perform general tasks such as IC module setup and reading captured values.

Input Capture Module Setup

This section shows the steps required to initialize and configure the IC module. The IC module is configured such that a capture event occurs at the first falling edge of the input signal, and then at every subsequent edge of the input signal.

Example:

```
/* This example shows how to initialize and configure IC module */
/* Disable IC module */
PLIB_IC_Disable(MY_IC_ID);

/* Disable any peripherals multiplexed with Input Capture pin */

/* Configure I/O pin as input pin. Refer PORTS Peripheral Library */

/* Stop in Idle mode is disabled for IC module. IC mode functions even in Idle mode */
PLIB_IC_StopInIdleDisable(MY_IC_ID);

/* Every Edge Capture mode of operation is selected for IC module */
PLIB_IC_ModeSelect(MY_IC_ID, IC_INPUT_CAPTURE_EVERY_EDGE_MODE);

/* Timer2 is selected as a clock source for the IC module  */
PLIB_IC_TimerSelect(MY_IC_ID, IC_TIMER_TMR2);

/* 32-bit timer is selected*/
PLIB_IC_BufferSizeSelect(MY_IC_ID, IC_BUFFER_SIZE_32BIT);

/* IC module is enabled */
PLIB_IC_Enable(MY_IC_ID);
```

Reading a Capture Value

This section shows how to read a capture value from the input capture buffer.

Example:

```
/* This example shows how to read a Capture value */
uint32_t bufferVal;

/* Reading a value from an empty Capture Buffer leads to indeterminate data*/
/* Read value from a non-empty buffer */
if(!PLIB_IC_BufferIsEmpty(MY_IC_ID))
{
     /* Read the buffer value */
     bufferVal = PLIB_IC_Buffer32BitGet(MY_IC_ID);
}

/* Buffer Overflow condition */
while(PLIB_IC_BufferOverflowHasOccurred)
```

```
{
    /*Read buffer values until buffer is empty and overflow condition ceases*/
    bufferVal = PLIB_IC_Buffer32BitGet(MY_IC_ID);

}
```

Configuring the Library

The library is configured for the supported Input Capture module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Setup Functions

	Name	Description
	PLIB_IC_Disable	Disables the IC module.
	PLIB_IC_Enable	Enables the IC module.
	PLIB_IC_EventsPerInterruptSelect	Selects the number of capture events before an interrupt is issued.
	PLIB_IC_FirstCaptureEdgeSelect	Captures the timer count value at the first selected edge of input signal.

b) Timer Functions

	Name	Description
	PLIB_IC_TimerSelect	Selects the clock source for the IC module.
	PLIB_IC_AlternateClockDisable	Selects Timer2 and Timer3, instead of the alternate clock source.
	PLIB_IC_AlternateClockEnable	Selects the alternate clock source.
	PLIB_IC_AlternateTimerSelect	Selects an alternate timer as a clock source for the IC module.
	PLIB_IC_ExistsAlternateTimerSelect	Identifies whether the AlternateTimerSelect feature exists on the IC module.

c) Input Capture Buffer Functions

	Name	Description
	PLIB_IC_Buffer16BitGet	Obtains the 16-bit input capture buffer value.
	PLIB_IC_Buffer32BitGet	Obtains the 32-bit input capture buffer value.
	PLIB_IC_BufferIsEmpty	Checks whether the input capture buffer is empty.
	PLIB_IC_BufferOverflowHasOccurred	Checks whether an input capture buffer overflow has occurred.
	PLIB_IC_BufferSizeSelect	Sets the input capture buffer size.

d) Operation Modes Functions

	Name	Description
	PLIB_IC_ModeSelect	Selects the input capture mode for IC module.

e) Power-Saving Modes Functions

	Name	Description
	PLIB_IC_StopInIdleDisable	Continues module operation when the device enters Idle mode
	PLIB_IC_StopInIdleEnable	Discontinues IC module operation when the device enters Idle mode.

f) Feature Existence Functions

	Name	Description
	PLIB_IC_ExistsAlternateClock	Identifies whether the AlternateClock feature exists on the IC module.
	PLIB_IC_ExistsBufferIsEmptyStatus	Identifies whether the BufferIsEmptyStatus feature exists on the IC module
	PLIB_IC_ExistsBufferOverflowStatus	Identifies whether the BufferOverflowStatus feature exists on the IC module.
	PLIB_IC_ExistsBufferSize	Identifies whether the BufferSize feature exists on the IC module.
	PLIB_IC_ExistsBufferValue	Identifies whether the BufferValue feature exists on the IC module.
	PLIB_IC_ExistsCaptureMode	Identifies whether the CaptureMode feature exists on the IC module.
	PLIB_IC_ExistsEdgeCapture	Identifies whether the EdgeCapture feature exists on the IC module.
	PLIB_IC_ExistsEnable	Identifies whether the EnableControl feature exists on the IC module
	PLIB_IC_ExistsEventsPerInterruptSelect	Identifies whether the EventsPerInterruptSelect feature exists on the IC module.
	PLIB_IC_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the IC module.

	PLIB_IC_ExistsTimerSelect	Identifies whether the TimerSelect feature exists on the IC module.

g) Data Types and Constants

	Name	Description
	IC_BUFFER_SIZE	Selects the IC Buffer size.
	IC_EDGE_TYPES	Lists the options to select a rising or falling edge for input capture.
	IC_EVENTS_PER_INTERRUPT	Lists the number of input capture events for an interrupt to occur.
	IC_INPUT_CAPTURE_MODES	Lists all of the input capture modes for the IC module.
	IC_MODULE_ID	IC_MODULE_ID This enumeration defines the number of modules that are available on the microcontroller. This is the superset of all of the possible instances that might be available on a Microchip microcontroller. Refer to the specific device data sheet to determine the correct number of modules defined for the device.
	IC_TIMERS	Lists the different 16-bit timers for the IC module.
	IC_ALT_TIMERS	Lists the different 16-bit alternate timers for the IC module.

Description

This section describes the Application Programming Interface (API) functions of the Input Capture Peripheral Library.

Refer to each section for a detailed description.

a) General Setup Functions

PLIB_IC_Disable Function

Disables the IC module.

File

plib_ic.h

C

```
void PLIB_IC_Disable(IC_MODULE_ID index);
```

Returns

None.

Description

This function disables the IC module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_IC_ID IC_ID_1

PLIB_IC_Disable(MY_IC_ID);
```

Parameters

Parameters	Description
index	Identifies the IC module

Function

void PLIB_IC_Disable(IC_MODULE_ID index)

PLIB_IC_Enable Function

Enables the IC module.

File

plib_ic.h

C

```
void PLIB_IC_Enable(IC_MODULE_ID index);
```

Returns

None.

Description

This function enables the IC module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsEnable in your application to determine whether this feature is available.

Preconditions

The module should be appropriately configured before being enabled.

Example

```
#define MY_IC_ID IC_ID_1

//Do all the other configurations before enabling.

PLIB_IC_Enable(MY_IC_ID);
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

void PLIB_IC_Enable(IC_MODULE_ID index)

PLIB_IC_EventsPerInterruptSelect Function

Selects the number of capture events before an interrupt is issued.

File

plib_ic.h

C

```
void PLIB_IC_EventsPerInterruptSelect(IC_MODULE_ID index, IC_EVENTS_PER_INTERRUPT event);
```

Returns

None.

Description

The IC module can be configured to generate interrupts depending upon the occurrence of a certain number of capture events. The number of capture events before an interrupt is generated is set by this function.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsEventsPerInterruptSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_IC_ID IC_ID_1
// IC module is configured to generate interrupt on every capture event
PLIB_IC_EventsPerInterruptSelect(MY_IC_ID, IC_INTERRUPT_ON_EVERY_CAPTURE_EVENT );
```

Parameters

Parameters	Description
index	Identifies the desired IC module
event	Identifies the interrupt control mode

Function

void PLIB_IC_EventsPerInterruptSelect(IC_MODULE_ID index,IC_EVENTS_PER_INTERRUPT event)

PLIB_IC_FirstCaptureEdgeSelect Function

Captures the timer count value at the first selected edge of input signal.

File

plib_ic.h

C

```
void PLIB_IC_FirstCaptureEdgeSelect(IC_MODULE_ID index, IC_EDGE_TYPES edgeType);
```

Returns

None.

Description

This function captures the timer count value at the first selected edge of the input signal.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsEdgeCapture in your application to determine whether this feature is available.

Preconditions

This setting applies only when the Every Edge Capture mode is set. The capture mode is set by the PLIB_IC_ModeSelect function.

Example

```
#define MY_IC_ID IC_ID_1

PLIB_IC_FirstCaptureEdgeSelect(MY_IC_ID,IC_EDGE_FALLING);
```

Parameters

Parameters	Description
index	Identifies the desired IC module
edgeType	Identifies the edge type (i.e., whether rising or falling edge)

Function

void PLIB_IC_FirstCaptureEdgeSelect(IC_MODULE_ID index, IC_EDGE_TYPES edgeType)

b) Timer Functions

PLIB_IC_TimerSelect Function

Selects the clock source for the IC module.

File

plib_ic.h

C

```
void PLIB_IC_TimerSelect(IC_MODULE_ID index, IC_TIMERS tmr);
```

Returns

None.

Description

This function selects the 16-bit timer source for the IC module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsTimerSelect in your application to determine whether this feature is available.

Preconditions

The 16-bit time base needs to be set.

Example

```
#define MY_IC_ID IC_ID_1
// 16-bit Timer-2 is selected
PLIB_IC_TimerSelect(MY_IC_ID, IC_TIMER_TMR2);
```

Parameters

Parameters	Description
index	Identifies the desired IC module
tmr	Identifies the 16-bit timer

Function

void PLIB_IC_TimerSelect(IC_MODULE_ID index, IC_TIMERS tmr)

PLIB_IC_AlternateClockDisable Function

Selects Timer2 and Timer3, instead of the alternate clock source.

File

plib_ic.h

C

```
void PLIB_IC_AlternateClockDisable(IC_MODULE_ID index);
```

Returns

None.

Description

Selects Timer2 and Timer3, instead of the alternate clock source.

Remarks

The feature is not supported on all devices. Please refer to the specific device data sheet to determine availability. A system unlock must be performed before this function can be executed. This function applies to all input capture modules, regardless of the IC_MODULE_ID passed in the call.

Preconditions

A system unlock PLIB_DEVCON_SystemUnlock must be performed before this function can be executed.

Example

```
// Call system service to unlock oscillator
#define MY_IC_ID IC_ID_1
PLIB_IC_AlternateClockDisable( MY_IC_ID );
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

void PLIB_IC_AlternateClockDisable(IC_MODULE_ID index)

PLIB_IC_AlternateClockEnable Function

Selects the alternate clock source.

File

plib_ic.h

C

```
void PLIB_IC_AlternateClockEnable(IC_MODULE_ID index);
```

Returns

None.

Description

Selects the alternate clock source instead of Timer2/3.

Remarks

The feature is not supported on all devices. Please refer to the specific device data sheet to determine availability. A system unlock must be performed before this function can be executed. This function applies to all input capture modules, regardless of the IC_MODULE_ID passed in the call.

Preconditions

A system unlock PLIB_DEVCON_SystemUnlock must be performed before this function can be executed.

Example

```
// Call system service to unlock oscillator
#define MY_IC_ID IC_ID_1
PLIB_IC_AlternateClockEnable( MY_IC_ID );
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

void PLIB_IC_AlternateClockEnable(IC_MODULE_ID index)

PLIB_IC_AlternateTimerSelect Function

Selects an alternate timer as a clock source for the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_AlternateTimerSelect(IC_MODULE_ID index, IC_ALT_TIMERS tmr);
```

Returns

Boolean

- true - Alternate timer selected successfully.
- false - Alternate timer selection failure, select appropriate alternate timer for the IC module index.

Description

This function selects an alternate timer as a clock source for the IC module. IC_ID_1,IC_ID_2,IC_ID_3 : Can use Timer4 or Timer5 as alternate timers. IC_ID_4,IC_ID_5,IC_ID_6 : Can use Timer2 or Timer3 as alternate timers. IC_ID_7,IC_ID_8,IC_ID_9 : Can use Timer6 or Timer7 as alternate timers.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use

PLIB_IC_ExistsAlternateTimerSelect in your application to determine whether this feature is available.

Preconditions

The 16-bit time base needs to be set. PLIB_IC_AlternateClockEnable API should be called for the IC module to enable the alternate clock selection.

Example

```
#define MY_IC_ID   IC_ID_1
bool result;

//Enabling alternate timer selection
// Call system service to unlock oscillator
PLIB_IC_AlternateClockEnable( MY_IC_ID );

// 16-bit Timer4 is selected as the clock source for IC module 1
result = PLIB_IC_AlternateTimerSelect(MY_IC_ID, IC_ALT_TIMER_TMR4);

if(false == result)
{
    //Selected alternate timer does not available for the desired IC module.
    //Select appropriate alternate timer.
}
```

Parameters

Parameters	Description
index	Identifies the desired IC module
tmr	Identifies the alternate timer

Function

bool PLIB_IC_AlternateTimerSelect(IC_MODULE_ID index, IC_ALT_TIMERS tmr)

PLIB_IC_ExistsAlternateTimerSelect Function

Identifies whether the AlternateTimerSelect feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsAlternateTimerSelect(IC_MODULE_ID index);
```

Returns

- true - If the AlternateTimerSelect feature is supported on the device
- false - If the AlternateTimerSelect feature is not supported on the device

Description

This function identifies whether the AlternateTimerSelect feature is available on the IC module. When this function returns true, this function is supported on the device:

- PLIB_IC_AlternateTimerSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_IC_ExistsAlternateTimerSelect(IC_MODULE_ID index)

c) Input Capture Buffer Functions

PLIB_IC_Buffer16BitGet Function

Obtains the 16-bit input capture buffer value.

File

plib_ic.h

C

```
uint16_t PLIB_IC_Buffer16BitGet(IC_MODULE_ID index);
```

Returns

None.

Description

This function reads the 16-bit value of the IC buffer to obtain the captured timer value. This function is used when the buffer size is set to 16-bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsBufferValue in your application to determine whether this feature is available.

Preconditions

The buffer size should be set to 16 bits (i.e., PLIB_IC_BufferSizeSet(MY_IC_ID, IC_BUFFER_SIZE_16BIT).

Example

```
#define MY_IC_ID IC_ID_1
uint16_t bufferVal;
// Read input capture buffer value and store it in 'bufferVal'
bufferVal = PLIB_IC_Buffer16BitGet(MY_IC_ID);
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

uint16_t PLIB_IC_Buffer16BitGet(IC_MODULE_ID index)

PLIB_IC_Buffer32BitGet Function

Obtains the 32-bit input capture buffer value.

File

plib_ic.h

C

```
uint32_t PLIB_IC_Buffer32BitGet(IC_MODULE_ID index);
```

Returns

None.

Description

This function reads the 32-bit value of the IC buffer to obtain the captured timer value. This function is used when the buffer size is set to 32 bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsBufferValue in your application to determine whether this feature is available.

Preconditions

The buffer size should be set to 32 bits (i.e., PLIB_IC_BufferSizeSet(MY_IC_ID, IC_BUFFER_SIZE_32BIT).

Example

```
#define MY_IC_ID IC_ID_1
uint32_t bufferVal;
// Read input capture buffer value and store it in 'bufferVal'
bufferVal = PLIB_IC_Buffer32BitGet(MY_IC_ID);
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

uint32_t PLIB_IC_Buffer32BitGet(IC_MODULE_ID index)

PLIB_IC_BufferIsEmpty Function

Checks whether the input capture buffer is empty.

File

plib_ic.h

C

```
bool PLIB_IC_BufferIsEmpty(IC_MODULE_ID index);
```

Returns

Boolean

- true - The input capture buffer is empty
- false - The input capture buffer is not empty

Description

This function returns 'true' if the input capture buffer is empty and 'false' if the buffer is not empty.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsBufferIsEmptyStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_IC_ID IC_ID_1
if(!PLIB_IC_BufferIsEmpty(MY_IC_ID))
{
    // Do some operation
};
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

bool PLIB_IC_BufferIsEmpty(IC_MODULE_ID index)

PLIB_IC_BufferOverflowHasOccurred Function

Checks whether an input capture buffer overflow has occurred.

File

plib_ic.h

C

```
bool PLIB_IC_BufferOverflowHasOccurred(IC_MODULE_ID index);
```

Returns

Boolean

- true - An overflow of the input capture buffer has occurred
- false - An overflow of the input capture buffer has not occurred

Description

This function returns 'true' if an input capture buffer has overflowed and 'false' if the buffer has not overflowed.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsBufferOverflowStatus in your application to determine whether this feature is available.

Preconditions

This function only applies when not in Edge Detect mode.

Example

```
#define MY_IC_ID IC_ID_1
if(!PLIB_IC_BufferOverflowHasOccurred(MY_IC_ID))
{
    // Do some operation
};
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

bool PLIB_IC_BufferOverflowHasOccurred(IC_MODULE_ID index)

PLIB_IC_BufferSizeSelect Function

Sets the input capture buffer size.

File

plib_ic.h

C

```
void PLIB_IC_BufferSizeSelect(IC_MODULE_ID index, IC_BUFFER_SIZE bufSize);
```

Returns

None.

Description

This function sets the input capture buffer size for IC module. The buffer size can be set to 16 bits or 32 bits. The buffer size should be consistent with the timer selected. A 32-bit timer requires a 32-bit buffer and a 16-bit timer requires a 16-bit buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsBufferSize in your application to determine whether this feature is available.

Preconditions

The buffer size should be consistent with the timer selected.

Example

```
#define MY_IC_ID IC_ID_1
// 32-bit timer resource is selected
PLIB_IC_BufferSizeSelect(MY_IC_ID, IC_BUFFER_SIZE_32BIT);
```

Parameters

Parameters	Description
index	Identifies the desired IC module

bufSize	Sets the buffer size to 16 bits or 32 bits

Function

void PLIB_IC_BufferSizeSelect(IC_MODULE_ID index, IC_BUFFER_SIZE bufSize)

d) Operation Modes Functions

PLIB_IC_ModeSelect Function

Selects the input capture mode for IC module.

File

plib_ic.h

C

```
void PLIB_IC_ModeSelect(IC_MODULE_ID index, IC_INPUT_CAPTURE_MODES modeSel);
```

Returns

None.

Description

This function selects the input capture mode for the IC module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsCaptureMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_IC_ID IC_ID_1
// Every Edge Mode is selected
PLIB_IC_ModeSelect(MY_IC_ID, IC_INPUT_CAPTURE_EVERY_EDGE_MODE);
```

Parameters

Parameters	Description
index	Identifies the desired IC module
modeSel	Identifies the timer type required

Function

void PLIB_IC_ModeSelect(IC_MODULE_ID index, IC_INPUT_CAPTURE_MODES modeSel)

e) Power-Saving Modes Functions

PLIB_IC_StopInIdleDisable Function

Continues module operation when the device enters Idle mode

File

plib_ic.h

C

```
void PLIB_IC_StopInIdleDisable(IC_MODULE_ID index);
```

Returns

None.

Description

The function continues operation of the IC module when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_IC_ID IC_ID_1

PLIB_IC_StopInIdleDisable(MY_IC_ID);
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

void PLIB_IC_StopInIdleDisable(IC_MODULE_ID index)

PLIB_IC_StopInIdleEnable Function

Discontinues IC module operation when the device enters Idle mode.

File

plib_ic.h

C

```
void PLIB_IC_StopInIdleEnable(IC_MODULE_ID index);
```

Returns

None.

Description

This function discontinues IC module operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_IC_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_IC_ID IC_ID_1

PLIB_IC_StopInIdleEnable(MY_IC_ID);
```

Parameters

Parameters	Description
index	Identifies the desired IC module

Function

void PLIB_IC_StopInIdleEnable(IC_MODULE_ID index)

f) Feature Existence Functions

PLIB_IC_ExistsAlternateClock Function

Identifies whether the AlternateClock feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsAlternateClock(IC_MODULE_ID index);
```

Returns

- true - The AlternateClock feature is supported on the device
- false - The AlternateClock feature is not supported on the device

Description

This function identifies whether the AlternateClock feature is available on the IC module. When this function returns true, these functions are supported on the device:

- PLIB_IC_AlternateClockEnable
- PLIB_IC_AlternateClockDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsAlternateClock(IC_MODULE_ID index)

PLIB_IC_ExistsBufferIsEmptyStatus Function

Identifies whether the BufferIsEmptyStatus feature exists on the IC module

File

plib_ic.h

C

```
bool PLIB_IC_ExistsBufferIsEmptyStatus(IC_MODULE_ID index);
```

Returns

- true - The BufferIsEmptyStatus feature is supported on the device
- false - The BufferIsEmptyStatus feature is not supported on the device

Description

This function identifies whether the BufferIsEmptyStatus feature is available on the IC module. When this function returns true, this function is supported on the device:

- PLIB_IC_BufferIsEmpty

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsBufferIsEmptyStatus(IC_MODULE_ID index)

PLIB_IC_ExistsBufferOverflowStatus Function

Identifies whether the BufferOverflowStatus feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsBufferOverflowStatus(IC_MODULE_ID index);
```

Returns

- true - The BufferOverflowStatus feature is supported on the device
- false - The BufferOverflowStatus feature is not supported on the device

Description

This function identifies whether the BufferOverflowStatus feature is available on the IC module. When this function returns true, this function is supported on the device:

- PLIB_IC_BufferOverflowHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsBufferOverflowStatus(IC_MODULE_ID index)

PLIB_IC_ExistsBufferSize Function

Identifies whether the BufferSize feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsBufferSize(IC_MODULE_ID index);
```

Returns

- true - The BufferSize feature is supported on the device
- false - The BufferSize feature is not supported on the device

Description

This function identifies whether the BufferSize feature is available on the IC module. When this function returns true, this function is supported on the device:

- PLIB_IC_BufferSizeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsBufferSize(IC_MODULE_ID index)

PLIB_IC_ExistsBufferValue Function

Identifies whether the BufferValue feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsBufferValue(IC_MODULE_ID index);
```

Returns

- true - The BufferValue feature is supported on the device
- false - The BufferValue feature is not supported on the device

Description

This function identifies whether the BufferValue feature is available on the IC module. When this function returns true, these functions are supported on the device:

- PLIB_IC_Buffer32BitGet
- PLIB_IC_Buffer16BitGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsBufferValue(IC_MODULE_ID index)

PLIB_IC_ExistsCaptureMode Function

Identifies whether the CaptureMode feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsCaptureMode(IC_MODULE_ID index);
```

Returns

- true - The CaptureMode feature is supported on the device
- false - The CaptureMode feature is not supported on the device

Description

This function identifies whether the CaptureMode feature is available on the IC module. When this function returns true, this function is supported on the device:

- PLIB_IC_ModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsCaptureMode(IC_MODULE_ID index)

PLIB_IC_ExistsEdgeCapture Function

Identifies whether the EdgeCapture feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsEdgeCapture(IC_MODULE_ID index);
```

Returns

- true - The EdgeCapture feature is supported on the device
- false - The EdgeCapture feature is not supported on the device

Description

This function identifies whether the EdgeCapture feature is available on the IC module. When this function returns true, this function is supported on the device:

- PLIB_IC_FirstCaptureEdgeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsEdgeCapture(IC_MODULE_ID index)

PLIB_IC_ExistsEnable Function

Identifies whether the EnableControl feature exists on the IC module

File

plib_ic.h

C

```
bool PLIB_IC_ExistsEnable(IC_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the IC module. When this function returns true, these functions are supported on the device:

- PLIB_IC_Enable
- PLIB_IC_Disable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsEnable(IC_MODULE_ID index)

PLIB_IC_ExistsEventsPerInterruptSelect Function

Identifies whether the EventsPerInterruptSelect feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsEventsPerInterruptSelect(IC_MODULE_ID index);
```

Returns

- true - The EventsPerInterruptSelect feature is supported on the device
- false - The EventsPerInterruptSelect feature is not supported on the device

Description

This function identifies whether the EventsPerInterruptSelect feature is available on the IC module. When this function returns true, this function is supported on the device:

- PLIB_IC_EventsPerInterruptSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsEventsPerInterruptSelect(IC_MODULE_ID index)

PLIB_IC_ExistsStopInIdle Function

Identifies whether the StopInIdle feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsStopInIdle(IC_MODULE_ID index);
```

Returns

- true - The StopInIdle feature is supported on the device
- false - The StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the IC module. When this function returns true, these functions are supported on the device:

- PLIB_IC_StopInIdleEnable
- PLIB_IC_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsStopInIdle(IC_MODULE_ID index)

PLIB_IC_ExistsTimerSelect Function

Identifies whether the TimerSelect feature exists on the IC module.

File

plib_ic.h

C

```
bool PLIB_IC_ExistsTimerSelect(IC_MODULE_ID index);
```

Returns

- true - The TimerSelect feature is supported on the device
- false - The TimerSelect feature is not supported on the device

Description

This function identifies whether the TimerSelect feature is available on the IC module. When this function returns true, this function is supported on the device:

- PLIB_IC_TimerSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_IC_ExistsTimerSelect(IC_MODULE_ID index)

g) Data Types and Constants

IC_BUFFER_SIZE Enumeration

Selects the IC Buffer size.

File

plib_ic_help.h

C

```
typedef enum {
  IC_BUFFER_SIZE_32BIT,
  IC_BUFFER_SIZE_16BIT
} IC_BUFFER_SIZE;
```

Members

Members	Description
IC_BUFFER_SIZE_32BIT	32-bit timer source select
IC_BUFFER_SIZE_16BIT	16-bit timer source select

Description

IC Buffer Size

The IC buffer can be set to 16 bits or 32 bits. The buffer size is set by the PLIB_IC_BufferSizeSelect function.

IC_EDGE_TYPES Enumeration

Lists the options to select a rising or falling edge for input capture.

File

plib_ic_help.h

C

```
typedef enum {
  IC_EDGE_FALLING,
  IC_EDGE_RISING
} IC_EDGE_TYPES;
```

Members

Members	Description
IC_EDGE_FALLING	Select Falling Edge
IC_EDGE_RISING	Select Rising Edge

Description

IC Edge Types Select

This enumeration lists the options to select a rising edge input capture or a falling edge input capture. The selection is made by the PLIB_IC_FirstCaptureEdgeSelect function.

IC_EVENTS_PER_INTERRUPT Enumeration

Lists the number of input capture events for an interrupt to occur.

File

plib_ic_help.h

C

```
typedef enum {
  IC_INTERRUPT_ON_EVERY_4TH_CAPTURE_EVENT,
  IC_INTERRUPT_ON_EVERY_3RD_CAPTURE_EVENT,
  IC_INTERRUPT_ON_EVERY_2ND_CAPTURE_EVENT,
  IC_INTERRUPT_ON_EVERY_CAPTURE_EVENT
} IC_EVENTS_PER_INTERRUPT;
```

Members

Members	Description
IC_INTERRUPT_ON_EVERY_4TH_CAPTURE_EVENT	Interrupt on every 4th capture event
IC_INTERRUPT_ON_EVERY_3RD_CAPTURE_EVENT	Interrupt on every 3rd capture event
IC_INTERRUPT_ON_EVERY_2ND_CAPTURE_EVENT	Interrupt on every 2nd capture event
IC_INTERRUPT_ON_EVERY_CAPTURE_EVENT	Interrupt on every capture event

Description

IC Capture Events Per Interrupt Select

This enumeration lists the number of events that should occur before an interrupt is generated. An interrupt can occur on every capture event, and every second, third, or fourth capture event.

IC_INPUT_CAPTURE_MODES Enumeration

Lists all of the input capture modes for the IC module.

File

plib_ic_help.h

C

```
typedef enum {
  IC_INPUT_CAPTURE_INTERRUPT_MODE,
  IC_INPUT_CAPTURE_EVERY_EDGE_MODE,
  IC_INPUT_CAPTURE_EVERY_16TH_EDGE_MODE,
  IC_INPUT_CAPTURE_EVERY_4TH_EDGE_MODE,
  IC_INPUT_CAPTURE_RISING_EDGE_MODE,
  IC_INPUT_CAPTURE_FALLING_EDGE_MODE,
  IC_INPUT_CAPTURE_EDGE_DETECT_MODE,
  IC_INPUT_CAPTURE_DISABLE_MODE
} IC_INPUT_CAPTURE_MODES;
```

Members

Members	Description
IC_INPUT_CAPTURE_INTERRUPT_MODE	Interrupt only mode: Rising edge on input triggers an interrupt. This mode is used only when device is in Sleep/Idle mode
IC_INPUT_CAPTURE_EVERY_EDGE_MODE	Every Edge Capture mode: The first edge of the input signal is specified via PLIB_IC_RisingEdgeCaptureSet() or PLIB_IC_FallingEdgeCaptureSet() routines. Subsequently, timer count value is captured on every rising and falling of the input signal
IC_INPUT_CAPTURE_EVERY_16TH_EDGE_MODE	Prescaled Capture mode: Timer count value is captured every 16th rising edge of input signal
IC_INPUT_CAPTURE_EVERY_4TH_EDGE_MODE	Prescaled Capture mode: Timer count value is captured every 4th rising edge of input signal
IC_INPUT_CAPTURE_RISING_EDGE_MODE	Rising Edge mode: Timer count value is captured on every rising edge of input signal
IC_INPUT_CAPTURE_FALLING_EDGE_MODE	Falling Edge mode: Timer count value is captured on every falling edge of input signal
IC_INPUT_CAPTURE_EDGE_DETECT_MODE	Edge Detect mode: Timer count value is captured on every rising and falling of the input signal Interrupt control bits are ignored and an interrupt event is generated for every capture. Overflow status is not updated.
IC_INPUT_CAPTURE_DISABLE_MODE	Capture module is disabled.Input signal is ignored and no capture events or interrupts are generated

Description

IC Input Capture Mode Select

This enumeration lists all of the input capture modes for IC module. The capture mode is set via the PLIB_IC_ModeSelect function.

IC_MODULE_ID Enumeration

File

plib_ic_help.h

C

```
typedef enum {
```

```
  IC_ID_1,
  IC_ID_2,
  IC_ID_3,
  IC_ID_4,
  IC_ID_5,
  IC_ID_6,
  IC_ID_7,
  IC_ID_8,
  IC_ID_9,
  IC_NUMBER_OF_MODULES
} IC_MODULE_ID;
```

Members

Members	Description
IC_NUMBER_OF_MODULES	The total number of modules available.

Description

IC_MODULE_ID

This enumeration defines the number of modules that are available on the microcontroller. This is the superset of all of the possible instances that might be available on a Microchip microcontroller.

Refer to the specific device data sheet to determine the correct number of modules defined for the device.

IC_TIMERS Enumeration

Lists the different 16-bit timers for the IC module.

File

plib_ic_help.h

C

```
typedef enum {
  IC_TIMER_TMR3,
  IC_TIMER_TMR2
} IC_TIMERS;
```

Members

Members	Description
IC_TIMER_TMR3	Timer3 select
IC_TIMER_TMR2	Timer2 select

Description

IC 16-bit Timer Select

This enumeration lists the different 16-bit timers for the IC time base when the IC module is configured with a 16-bit timer resource.

IC_ALT_TIMERS Enumeration

Lists the different 16-bit alternate timers for the IC module.

File

plib_ic_help.h

C

```
typedef enum {
  IC_ALT_TIMER_TMR3,
  IC_ALT_TIMER_TMR2,
  IC_ALT_TIMER_TMR5,
  IC_ALT_TIMER_TMR4,
  IC_ALT_TIMER_TMR7,
  IC_ALT_TIMER_TMR6
} IC_ALT_TIMERS;
```

Members

Members	Description
IC_ALT_TIMER_TMR3	Select Timer3 as the alternate clock source for IC module

IC_ALT_TIMER_TMR2	Select Timer2 as the alternate clock source for IC module
IC_ALT_TIMER_TMR5	Select Timer5 as the alternate clock source for IC module
IC_ALT_TIMER_TMR4	Select Timer4 as the alternate clock source for IC module
IC_ALT_TIMER_TMR7	Select Timer7 as the alternate clock source for IC module
IC_ALT_TIMER_TMR6	Select Timer6 as the alternate clock source for IC module

Description

IC 16-bit alternate Timer Select

This enumeration lists the different 16-bit timers for the IC time base when the IC module is configured with a 16-bit alternate timer resource.

Files

Files

Name	Description
plib_ic.h	This file contains the interface definition for the Input Capture (IC) peripheral library.
plib_ic_help.h	This is file plib_ic_help.h.

Description

This section lists the source and header files used by the library.

plib_ic.h

This file contains the interface definition for the Input Capture (IC) peripheral library.

Functions

	Name	Description
	PLIB_IC_AlternateClockDisable	Selects Timer2 and Timer3, instead of the alternate clock source.
	PLIB_IC_AlternateClockEnable	Selects the alternate clock source.
	PLIB_IC_AlternateTimerSelect	Selects an alternate timer as a clock source for the IC module.
	PLIB_IC_Buffer16BitGet	Obtains the 16-bit input capture buffer value.
	PLIB_IC_Buffer32BitGet	Obtains the 32-bit input capture buffer value.
	PLIB_IC_BufferIsEmpty	Checks whether the input capture buffer is empty.
	PLIB_IC_BufferOverflowHasOccurred	Checks whether an input capture buffer overflow has occurred.
	PLIB_IC_BufferSizeSelect	Sets the input capture buffer size.
	PLIB_IC_Disable	Disables the IC module.
	PLIB_IC_Enable	Enables the IC module.
	PLIB_IC_EventsPerInterruptSelect	Selects the number of capture events before an interrupt is issued.
	PLIB_IC_ExistsAlternateClock	Identifies whether the AlternateClock feature exists on the IC module.
	PLIB_IC_ExistsAlternateTimerSelect	Identifies whether the AlternateTimerSelect feature exists on the IC module.
	PLIB_IC_ExistsBufferIsEmptyStatus	Identifies whether the BufferIsEmptyStatus feature exists on the IC module
	PLIB_IC_ExistsBufferOverflowStatus	Identifies whether the BufferOverflowStatus feature exists on the IC module.
	PLIB_IC_ExistsBufferSize	Identifies whether the BufferSize feature exists on the IC module.
	PLIB_IC_ExistsBufferValue	Identifies whether the BufferValue feature exists on the IC module.
	PLIB_IC_ExistsCaptureMode	Identifies whether the CaptureMode feature exists on the IC module.
	PLIB_IC_ExistsEdgeCapture	Identifies whether the EdgeCapture feature exists on the IC module.
	PLIB_IC_ExistsEnable	Identifies whether the EnableControl feature exists on the IC module
	PLIB_IC_ExistsEventsPerInterruptSelect	Identifies whether the EventsPerInterruptSelect feature exists on the IC module.
	PLIB_IC_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the IC module.
	PLIB_IC_ExistsTimerSelect	Identifies whether the TimerSelect feature exists on the IC module.
	PLIB_IC_FirstCaptureEdgeSelect	Captures the timer count value at the first selected edge of input signal.
	PLIB_IC_ModeSelect	Selects the input capture mode for IC module.
	PLIB_IC_StopInIdleDisable	Continues module operation when the device enters Idle mode
	PLIB_IC_StopInIdleEnable	Discontinues IC module operation when the device enters Idle mode.
	PLIB_IC_TimerSelect	Selects the clock source for the IC module.

Description

IC Module Peripheral Library Interface Header

This library provides a low-level abstraction of the Input Capture (IC) module on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences between one microcontroller variant and another.

Interrupt Peripheral Library

This section describes the Interrupt Peripheral Library.

Introduction

This library provides a low-level abstraction of the Interrupt Controller module on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences from one microcontroller variant to another.

Description

The Interrupt Controller is a key component of a microcontroller. The Interrupt Controller reduces the numerous peripheral interrupt request signals to a single interrupt request signal to the microcontroller core.

The key features present on an Interrupt Controller are:

- **Interrupt source configuration**: Provides the ability to enable, disable, and prioritize a source that may interrupt the core
- **Interrupt status flags:** Identify the source of an interrupt request or exception, usually generated by a peripheral

The interrupt will be sent to the core, only if the source is enabled to generate an interrupt and interrupts have been enabled (if supported). Sources will be prioritized so that the highest priority interrupt will be sent to the core if multiple sources cause interrupts at the same time.

Many interrupt controllers also include, other optional features:

- **Global enable configuration**: Controls the generation of any interrupt to the core from the Interrupt Controller
- **Choice of edge transition**: Controls the edge transition (high-to-low or low-to-high) on which the interrupts are generated
- **Priority configuration**: Associates a programmable priority with the interrupt source

Interrupts can be handled inside the core in the following ways:

- **Vectored**: Each interrupt has an associated interrupt handler routine
- **Non-vectored**: All interrupts have a single (shared) interrupt handler routine. The software determines the interrupt source based on the interrupt status-flags register.
- **Combination of vectored and non-vectored**: Interrupts combined in groups. Each group has a single common interrupt vector or handler, but there are multiple groups (i.e., multiple vectors). Within a specific vector group, software determines which one in the group sources caused the interrupt.

A microcontroller can support one, or more than one of these modes.

Note: Please refer to the specific device data sheet to determine availability of these features for your device.

Using the Library

This topic describes the basic architecture of the Interrupt Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_int.h`

The interface to the Interrupt Peripheral Library is defined in the `plib_int.h` header file, which is included in the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Interrupt Peripheral Library must include `peripheral.h`.

Library File:

The Interrupt Peripheral Library (`.a`) file is installed with MPLAB Harmony.

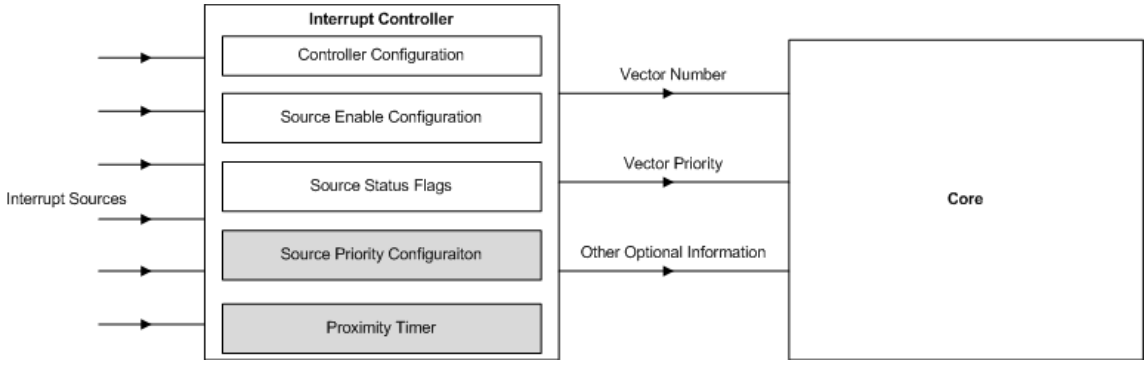
Please refer to the What is MPLAB Harmony? section for how the peripheral interacts with the framework.

Hardware Abstraction Model

This library provides a low-level abstraction of the Interrupt Controller module on Microchip microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

Hardware Abstraction Model



The **Interrupt Controller** receives requests from multiple **Interrupt Sources**. The **Interrupt Controller Configuration** controls the overall operation of the interrupt controller. Not all microcontrollers support all the following features listed:

- Interrupt nesting configuration
- Edge selection of the external interrupts
- Vector mode selection
- Priority level configuration
- Current CPU interrupt and priority status information

Source Enable Configuration enables or disables a particular source. On some microcontrollers other CPU exceptions or traps can also be controlled. **Source Status Flags** give the status of the interrupt request from a specific interrupt source.

Other optional features include the **Vector Priority Configuration**, which is available on some micro controllers and the **Proximity Timer**. Priority configuration allows a priority level to be associated with each interrupt vector. The proximity timer creates a temporal window in which a group of interrupts of the same, or lower, priority will be held off. This provides an opportunity to queue these interrupt requests and process them using tail-chaining of multiple IRQs and allows higher priority interrupts to pass through during the hold-off window.

Traps and Exceptions

Some of the things that can interrupt the normal flow of instruction execution of the CPU core are not actual interrupt sources. These are things such as a division-by-zero error or attempting to address unimplemented memory. These errors are either internal to the CPU core itself or are so catastrophic that they are non-maskable and are trapped separately. This library refers to them in general as "traps" and there are interface elements provided to allow software to handle them.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Interrupt module.

Library Interface Section	Description
General Configuration Functions	Provides setup, configuration, and status interface routines for the overall operation of the Interrupt Controller module.
Interrupt Source Control Functions	Provides setup and status routines for: • Setting up the source enable configuration • Setting up the vector priority configuration • Querying a source's interrupt status flag
Other Status and Control Functions	Provides setup and status routines for: • Global interrupt enable status • Vector number and priority of the current ISR • Proximity timer • Trap handling
Feature Existence Functions	Determine whether certain features are available.

How the Library Works

This section provides information on initialization and interrupt source setup and handling.

Description

Initialization

The steps that are required to initialize the Interrupt Controller module vary for different microcontrollers.

Note: Refer to the specific device data sheet for the correct initialization sequence for your device.

Interrupt Source Setup

An interrupt Source needs to be enabled in order for it to be able to generate a interrupt to the core. Use the function PLIB_INT_SourceEnable to enable the interrupt source. INT_SOURCE is a list of the possible interrupt sources

On some microcontrollers, each interrupt vector can be associated with a priority. Use the function PLIB_INT_VectorPrioritySet to set the interrupt vector priority. INT_VECTOR is a list of the possible interrupt vectors and INT_PRIORITY_LEVEL is the list of possible priority levels.

On some microcontrollers, each interrupt vector can be associated with a sub-priority. Use the function PLIB_INT_VectorSubPrioritySet to set the interrupt source sub-priority. INT_SUBPRIORITY_LEVEL is a list of possible sub-priority levels.

On most microcontrollers, it will be necessary to enable interrupt generation to the core by calling the PLIB_INT_Enable function.

Interrupt Handling

The status of the interrupt indicates whether or not the interrupt request was generated by the source. The status of the trap source can be obtained using the function PLIB_INT_TrapSourceFlagGet and the status of the interrupt source can be obtained using the function PLIB_INT_SourceFlagGet. The interrupt status flags can be used to indicate the interrupt status even if the interrupt is not enabled for the source. When the interrupt is not enabled for the source, no interrupt is generated to the core even though the interrupt controller still recognizes that the source requested an interrupt. INT_TRAP_SOURCE is a list of possible trap events, and INT_SOURCE is a list of possible interrupt sources.

Before the Interrupt Service Routine (ISR) ends, the status of the interrupt needs to be cleared to avoid entering the ISR repeatedly for the same interrupt event. A trap source status can be cleared using the function PLIB_INT_TrapSourceFlagClear, and an interrupt source status can be cleared using the function PLIB_INT_SourceFlagClear. INT_TRAP_SOURCE is a list of possible trap events, and INT_SOURCE is a list of possible interrupt sources.

Configuring the Library

The library is configured for the supported Interrupt module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Configuration Functions

	Name	Description
	PLIB_INT_Disable	Disables the generation of interrupts to the CPU.
	PLIB_INT_Enable	Enables the generation of interrupts to the CPU.
	PLIB_INT_ExternalFallingEdgeSelect	Selects the falling edge as the edge polarity of the external interrupt.
	PLIB_INT_ExternalRisingEdgeSelect	Selects the rising edge as the edge polarity of the external interrupt.
	PLIB_INT_IsEnabled	Identifies if interrupts are currently enabled or disabled at the top level.
	PLIB_INT_MultiVectorSelect	Configures the Interrupt Controller for Multiple Vector mode.
	PLIB_INT_PriorityGet	Returns the priority level of the latest interrupt presented to the CPU.
	PLIB_INT_ProximityTimerDisable	Disables the interrupt temporal-proximity timer.
	PLIB_INT_ProximityTimerEnable	Enables the interrupt temporal-proximity timer and selects the priority levels that start the timer.
	PLIB_INT_SingleVectorSelect	Configures the Interrupt Controller for Single Vector mode.
	PLIB_INT_SingleVectorShadowSetDisable	Disables the Shadow Register Set in Single Vector mode.
	PLIB_INT_SingleVectorShadowSetEnable	Enables the Shadow Register Set in Single Vector mode.
	PLIB_INT_SetState	Restores the status of CPU interrupts based on the value passed into the function.
	PLIB_INT_ShadowRegisterAssign	Assigns a shadow register set for an interrupt priority level.
	PLIB_INT_VariableVectorOffsetSet	Sets the offset specific to an interrupt source number.
	PLIB_INT_SoftwareNMITrigger	Triggers software NMI.

b) Interrupt Source Control Functions

	Name	Description
	PLIB_INT_SourceDisable	Disables the interrupt source
	PLIB_INT_SourceEnable	Enables the interrupt source.
	PLIB_INT_SourceFlagClear	Clears the status of the interrupt flag for the selected source.
	PLIB_INT_SourceFlagGet	Returns the status of the interrupt flag for the selected source.
	PLIB_INT_SourceFlagSet	Sets the status of the interrupt flag for the selected source.
	PLIB_INT_SourceIsEnabled	Gets the enable state of the interrupt source.
	PLIB_INT_VectorPriorityGet	Gets the priority of the interrupt vector.
	PLIB_INT_VectorPrioritySet	Sets the priority of the interrupt vector.

	PLIB_INT_VectorSubPriorityGet	Gets the sub-priority of the interrupt vector.
	PLIB_INT_VectorSubPrioritySet	Sets the sub-priority of the interrupt vector.

c) Other Status and Control Functions

	Name	Description
	PLIB_INT_CPUCurrentPriorityLevelGet	Gets the interrupt priority level at which the CPU is currently operating.
	PLIB_INT_ProximityTimerGet	Returns the value used by the temporal proximity timer as a reload value when the temporal proximity timer is triggered by an interrupt event.
	PLIB_INT_ProximityTimerSet	Sets the temporal proximity timer reload value. This value is used to reload the proximity timer after it has been triggered by an interrupt event.
	PLIB_INT_VectorGet	Returns the interrupt vector that is presented to the CPU.
	PLIB_INT_GetStateAndDisable	Disables the generation of interrupts to the CPU.
	PLIB_INT_ShadowRegisterGet	Gets the shadow register set assigned for an interrupt priority level.
	PLIB_INT_VariableVectorOffsetGet	Gets the offset specific to an interrupt source number.

d) Feature Existence Functions

	Name	Description
	PLIB_INT_ExistsCPUCurrentPriorityLevel	Identifies whether the CPUCurrentPriorityLevel feature exists on the Interrupts module.
	PLIB_INT_ExistsEnableControl	Identifies whether the EnableControl feature exists on the Interrupt module.
	PLIB_INT_ExistsExternalINTEdgeSelect	Identifies whether the ExternalINTEdgeSelect feature exists on the Interrupts module.
	PLIB_INT_ExistsINTCPUPriority	Identifies whether the INTCPUPriority feature exists on the Interrupt module.
	PLIB_INT_ExistsINTCPUVector	Identifies whether the INTCPUVector feature exists on the Interrupt module.
	PLIB_INT_ExistsProximityTimerControl	Identifies whether the ProximityTimerControl feature exists on the Interrupts module.
	PLIB_INT_ExistsProximityTimerEnable	Identifies whether the ProximityTimerEnable feature exists on the Interrupts module.
	PLIB_INT_ExistsSingleVectorShadowSet	Identifies whether the SingleVectorShadowSet feature exists on the Interrupt module.
	PLIB_INT_ExistsSourceControl	Identifies whether the SourceControl feature exists on the Interrupt module.
	PLIB_INT_ExistsSourceFlag	Identifies whether the SourceFlag feature exists on the Interrupt module.
	PLIB_INT_ExistsVectorPriority	Identifies whether the VectorPriority feature exists on the Interrupt module.
	PLIB_INT_ExistsVectorSelect	Identifies whether the VectorSelect feature exists on the Interrupt module.
	PLIB_INT_ExistsShadowRegisterAssign	Identifies whether the ShadowRegisterAssign feature exists on the Interrupts module.
	PLIB_INT_ExistsVariableOffset	Identifies whether the VariableOffset feature exists on the Interrupt module.
	PLIB_INT_ExistsSoftwareNMI	Identifies whether the SoftwareNMI feature exists on the Interrupt module.

e) Data Types and Constants

	Name	Description
	INT_EXTERNAL_SOURCES	Lists the possible external sources that can cause an interrupt to occur.
	INT_PRIORITY_LEVEL	Lists the possible interrupt priority levels.
	INT_SOURCE	Lists the possible sources that can cause an interrupt to occur.
	INT_SUBPRIORITY_LEVEL	Lists the possible interrupt sub priority levels.
	INT_VECTOR	Lists the possible interrupt vectors.
	INT_STATE_GLOBAL	Data type defining the global interrupt state.
	INT_SHADOW_REGISTER	Lists the possible shadow register sets.
	INT_VECTOR_SPACING	Lists the possible interrupt vector spacing.

Description

This section describes the Application Programming Interface (API) functions of the Interrupt Peripheral Library.

Refer to each section for a detailed description.

a) General Configuration Functions

PLIB_INT_Disable Function

Disables the generation of interrupts to the CPU.

File

plib_int.h

C

```
void PLIB_INT_Disable(INT_MODULE_ID index);
```

Returns

None.

Description

This function disables the generation of interrupts to the CPU.

Remarks

This function implements an operation of the EnableControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsEnableControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_Disable( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

void PLIB_INT_Disable (INT_MODULE_ID index)

PLIB_INT_Enable Function

Enables the generation of interrupts to the CPU.

File

plib_int.h

C

```
void PLIB_INT_Enable(INT_MODULE_ID index);
```

Returns

None.

Description

This function enables the generation of interrupts to the CPU.

Remarks

This function implements an operation of the EnableControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsEnableControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_Enable( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

void PLIB_INT_Enable (INT_MODULE_ID index)

PLIB_INT_ExternalFallingEdgeSelect Function

Selects the falling edge as the edge polarity of the external interrupt.

File

plib_int.h

C

```
void PLIB_INT_ExternalFallingEdgeSelect(INT_MODULE_ID index, INT_EXTERNAL_SOURCES source);
```

Returns

None.

Description

This function selects the falling edge as the edge polarity of the external interrupt.

Remarks

This function implements an operation of the ExternalINTEdgeSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsExternalINTEdgeSelect function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_ExternalFallingEdgeSelect( INT_ID_0,
                                    (INT_EXTERNAL_INT_SOURCE0 |
                                    INT_EXTERNAL_INT_SOURCE1) );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
source	One or more of the values from INT_EXTERNAL_SOURCES. Values can be combined using a bitwise "OR" operation.

Function

void PLIB_INT_ExternalFallingEdgeSelect (INT_MODULE_ID index, INT_EXTERNAL_SOURCES source)

PLIB_INT_ExternalRisingEdgeSelect Function

Selects the rising edge as the edge polarity of the external interrupt.

File

plib_int.h

C

```
void PLIB_INT_ExternalRisingEdgeSelect(INT_MODULE_ID index, INT_EXTERNAL_SOURCES source);
```

Returns

None.

Description

This function selects the rising edge as the edge polarity of the external interrupt.

Remarks

This function implements an operation of the ExternalINTEdgeSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsExternalINTEdgeSelect function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_ExternalRisingEdgeSelect( INT_ID_0,
                                   ( INT_EXTERNAL_INT_SOURCE0 |
                                       INT_EXTERNAL_INT_SOURCE1 ) );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
source	One or more of the values from INT_EXTERNAL_SOURCES. Values can be combined using a bitwise "OR" operation.

Function

void PLIB_INT_ExternalRisingEdgeSelect (INT_MODULE_ID index,
INT_EXTERNAL_SOURCES source)

PLIB_INT_IsEnabled Function

Identifies if interrupts are currently enabled or disabled at the top level.

File

plib_int.h

C

```
bool PLIB_INT_IsEnabled(INT_MODULE_ID index);
```

Returns

- true - If the interrupts are currently enabled
- false - If the interrupts are currently disabled

Description

This function identifies if interrupts are enabled or disabled at the top level.

Remarks

This function implements an operation of the EnableControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsEnableControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
status = PLIB_INT_IsEnabled( INT_ID_0 );
```

Function

bool PLIB_INT_IsEnabled (INT_MODULE_ID index)

PLIB_INT_MultiVectorSelect Function

Configures the Interrupt Controller for Multiple Vector mode.

File

plib_int.h

C

```
void PLIB_INT_MultiVectorSelect(INT_MODULE_ID index);
```

Returns

None.

Description

This function configures the Interrupt Controller for Multiple Vector mode. Interrupt requests will serviced at the calculated vector addresses. The CPU vectors to the unique address for each vector number.

Remarks

While the user can, during run-time, reconfigure the interrupt controller from Single Vector mode to Multiple Vector mode, such action is strongly discouraged, as it may result in undefined behavior.

This function implements an operation of the VectorSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsVectorSelect function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_MultiVectorSelect( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

void PLIB_INT_MultiVectorSelect(INT_MODULE_ID index)

PLIB_INT_PriorityGet Function

Returns the priority level of the latest interrupt presented to the CPU.

File

plib_int.h

C

```
INT_PRIORITY_LEVEL PLIB_INT_PriorityGet(INT_MODULE_ID index);
```

Returns

One of the possible values from INT_PRIORITY_LEVEL.

Description

This function returns the priority level of the latest interrupt presented to the CPU.

Remarks

This value should only be used when the interrupt controller is configured for single vector mode using the function PLIB_INT_SingleVectorSelect.

This function implements an operation of the INTCPUPriority feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsINTCPUPriority function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
INT_PRIORITY_LEVEL level = PLIB_INT_RequestedPriorityLevelGet( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

INT_PRIORITY_LEVEL PLIB_INT_PriorityGet (INT_MODULE_ID index)

PLIB_INT_ProximityTimerDisable Function

Disables the interrupt temporal-proximity timer.

File

plib_int.h

C

```
void PLIB_INT_ProximityTimerDisable(INT_MODULE_ID index);
```

Returns

None.

Description

This function disables the interrupt temporal-proximity timer.

Remarks

This function implements an operation of the ProximityTimerEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsProximityTimerEnable function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_ProximityTimerDisable(INT_PRIORITY_LEVEL3);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

void PLIB_INT_ProximityTimerDisable(INT_MODULE_ID index)

PLIB_INT_ProximityTimerEnable Function

Enables the interrupt temporal-proximity timer and selects the priority levels that start the timer.

File

plib_int.h

C

```
void PLIB_INT_ProximityTimerEnable(INT_MODULE_ID index, INT_PRIORITY_LEVEL priority);
```

Returns

None.

Description

This function enables the interrupt temporal-proximity timer and selects the priority levels that start the timer. One of the possible values from PLIB_INT_PRIORITY_LEVEL can be selected. Interrupts of that priority and lower start the temporal proximity timer.

Remarks

This function implements an operation of the ProximityTimerEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsProximityTimerEnable function in your application to determine whether this feature is available.

Choosing INT_PRIORITY_0 disables the proximity timer (exactly the same as if PLIB_INT_ProximityTimerDisable had been called.

Preconditions

None.

Example

```
//Interrupts of group priority 3 or lower start the temporal proximity timer
PLIB_INT_ProximityTimerEnable( INT_ID_0, INT_PRIORITY_LEVEL3 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
priority	One of possible values from INT_PRIORITY_LEVEL.

Function

void PLIB_INT_ProximityTimerEnable (INT_MODULE_ID index,
INT_PRIORITY_LEVEL priority)

PLIB_INT_SingleVectorSelect Function

Configures the Interrupt Controller for Single Vector mode.

File

plib_int.h

C

```
void PLIB_INT_SingleVectorSelect(INT_MODULE_ID index);
```

Returns

None.

Description

The function configures the Interrupt Controller for Single Vector mode. All interrupt requests will serviced at one vector address. The CPU vectors to the same address for all interrupt sources.

Remarks

While the user can, during run-time, reconfigure the Interrupt Controller from Single Vector mode to Multiple Vector mode, such action is strongly discouraged, as it may result in undefined behavior.

This function implements an operation of the VectorSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsVectorSelect function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_SingleVectorSelect( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

void PLIB_INT_SingleVectorSelect (INT_MODULE_ID index)

PLIB_INT_SingleVectorShadowSetDisable Function

Disables the Shadow Register Set in Single Vector mode.

File

plib_int.h

C

```
void PLIB_INT_SingleVectorShadowSetDisable(INT_MODULE_ID index);
```

Returns

None.

Description

This function disables usage of the "shadow" set of processor registers when operating in Single Vector mode.

Remarks

This function implements an operation of the SingleVectorShadowSet feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsSingleVectorShadowSet function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_SingleVectorShadowSetEnable( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

void PLIB_INT_SingleVectorShadowSetDisable (INT_MODULE_ID index)

PLIB_INT_SingleVectorShadowSetEnable Function

Enables the Shadow Register Set in Single Vector mode.

File

plib_int.h

C

```
void PLIB_INT_SingleVectorShadowSetEnable(INT_MODULE_ID index);
```

Returns

None.

Description

This function enables usage of the "shadow" set of processor registers when operating in Single Vector mode.

Remarks

This function implements an operation of the SingleVectorShadowSet feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsSingleVectorShadowSet function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_SingleVectorShadowSetEnable( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

void PLIB_INT_SingleVectorShadowSetEnable (INT_MODULE_ID index)

PLIB_INT_SetState Function

Restores the status of CPU interrupts based on the value passed into the function.

File

plib_int.h

C

```
void PLIB_INT_SetState(INT_MODULE_ID index, INT_STATE_GLOBAL interrupt_state);
```

Returns

None.

Description

This function will use the value passed in, to set the state of global interrupts.

Remarks

This function should be paired with the use of PLIB_INT_GetStateAndDisable. The value returned from PLIB_INT_GetStateAndDisable should be passed into this function.

Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsEnableControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
INT_STATE_GLOBAL interrupt_value;

interrupt_value = PLIB_INT_GetStateAndDisable( INT_ID_0 );

PLIB_INT_SetState(INT_ID_0, interrupt_value);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
interrupt_state	value returned from previous call to PLIB_INT_GetStateAndDisable.

Function

void PLIB_INT_SetState (INT_MODULE_ID index, INT_STATE_GLOBAL interrupt_state)

PLIB_INT_ShadowRegisterAssign Function

Assigns a shadow register set for an interrupt priority level.

File

plib_int.h

C

```
void PLIB_INT_ShadowRegisterAssign(INT_MODULE_ID index, INT_PRIORITY_LEVEL priority, INT_SHADOW_REGISTER
shadowRegister);
```

Returns

None.

Description

The function assigns a shadow register set for an interrupt priority level.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsShadowRegisterAssign function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_ShadowRegisterAssign( INT_ID_0, INT_PRIORITY_LEVEL5, INT_SHADOW_REGISTER_5 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all devices that have only one Interrupt module).
priority	Interrupt priority level for the shadow register set that is to be assigned.
shadowRegister	Shadow register set number.

Function

void PLIB_INT_ShadowRegisterAssign (INT_MODULE_ID index,
INT_PRIORITY_LEVEL priority,
INT_SHADOW_REGISTER shadowRegister)

PLIB_INT_VariableVectorOffsetSet Function

Sets the offset specific to an interrupt source number.

File

plib_int.h

C

```
void PLIB_INT_VariableVectorOffsetSet(INT_MODULE_ID index, INT_VECTOR vector, uint32_t offset);
```

Returns

None.

Description

The function sets the offset specific to an interrupt source number.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsVariableOffset function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Set 200 bytes offset
PLIB_INT_VariableVectorOffsetSet ( INT_ID_0, INT_VECTOR_USB1, 200 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
vector	Interrupt source, one of the possible value from INT_VECTOR enum.
offset	Offset in number of bytes.

Function

void PLIB_INT_VariableVectorOffsetSet (INT_MODULE_ID index, INT_VECTOR source, uint32_t offset)

PLIB_INT_SoftwareNMITrigger Function

Triggers software NMI.

File

plib_int.h

C

```
void PLIB_INT_SoftwareNMITrigger(INT_MODULE_ID index);
```

Returns

None.

Description

This function triggers the software NMI.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_INT_ExistsSoftwareNMI in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_SoftwareNMITrigger( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

void PLIB_INT_SoftwareNMITrigger(INT_MODULE_ID index)

b) Interrupt Source Control Functions

PLIB_INT_SourceDisable Function

Disables the interrupt source

File

plib_int.h

C

```
void PLIB_INT_SourceDisable(INT_MODULE_ID index, INT_SOURCE source);
```

Returns

None.

Description

This function disables the given interrupt source.

Remarks

This function implements an operation of the SourceControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsSourceControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_SourceDisable(INT_ID_0,INT_SOURCE_TIMER_1);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
source	One of the possible values from INT_SOURCE.

Function

void PLIB_INT_SourceDisable (INT_MODULE_ID index, INT_SOURCE source)

PLIB_INT_SourceEnable Function

Enables the interrupt source.

File

plib_int.h

C

```
void PLIB_INT_SourceEnable(INT_MODULE_ID index, INT_SOURCE source);
```

Returns

None.

Description

This function enables the interrupt source. The interrupt flag is set when the interrupt request is sampled. The pending interrupt request will not cause further processing if the interrupt is not enabled using this function or if interrupts are not enabled (on processors that support the PLIB_INT_Enable feature).

Remarks

This function implements an operation of the SourceControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsSourceControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_SourceEnable(INT_ID_0,INT_SOURCE_TIMER_1);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
source	One of the possible values from INT_SOURCE.

Function

void PLIB_INT_SourceEnable (INT_MODULE_ID index, INT_SOURCE source)

PLIB_INT_SourceFlagClear Function

Clears the status of the interrupt flag for the selected source.

File

plib_int.h

C

```
void PLIB_INT_SourceFlagClear(INT_MODULE_ID index, INT_SOURCE source);
```

Returns

None.

Description

This function clears the status of the interrupt flag for the selected source. The flag is set when the interrupt request is identified. The pending interrupt request will not cause further processing if the interrupt is not enabled using the function PLIB_INT_InterruptSourceEnable or if interrupts are not enabled (on processors that support the PLIB_INT_Enable feature).

Remarks

This function implements an operation of the SourceFlag feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsSourceFlag function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_INT_SourceFlagGet(INT_ID_0,INT_SOURCE_TIMER_1))
{
    PLIB_INT_SourceFlagClear(INT_ID_0,INT_SOURCE_TIMER_1);
}
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
source	One of the possible values from INT_SOURCE.

Function

void PLIB_INT_SourceFlagClear (INT_MODULE_ID index, INT_SOURCE source)

PLIB_INT_SourceFlagGet Function

Returns the status of the interrupt flag for the selected source.

File

plib_int.h

C

```
bool PLIB_INT_SourceFlagGet(INT_MODULE_ID index, INT_SOURCE source);
```

Returns

- true - If the interrupt request is recognized for the source
- false - If the interrupt request is not recognized for the source

Description

This function returns the status of the interrupt flag for the selected source. The flag is set when the interrupt request is recognized. The pending interrupt request will not cause further processing if the interrupt is not enabled using the function PLIB_INT_InterruptSourceEnable or if interrupts are not enabled (on processors that support the PLIB_INT_Enable feature).

Remarks

This function implements an operation of the SourceFlag feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsSourceFlag function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_INT_SourceFlagGet(INT_ID_0, INT_SOURCE_TIMER_1))
{
    PLIB_INT_SourceFlagClear(INT_ID_0, INT_SOURCE_TIMER_1);
```

```
}
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
source	One of the possible values from INT_SOURCE.

Function

bool PLIB_INT_SourceFlagGet (INT_MODULE_ID index, INT_SOURCE source)

PLIB_INT_SourceFlagSet Function

Sets the status of the interrupt flag for the selected source.

File

plib_int.h

C

```
void PLIB_INT_SourceFlagSet(INT_MODULE_ID index, INT_SOURCE source);
```

Returns

None.

Description

This function sets the status of the interrupt flag for the selected source. This function will not be used during normal operation of the system. It is used to generate test interrupts for debug and testing purposes.

Remarks

This function implements an operation of the SourceFlag feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsSourceFlag function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_SourceFlagSet(INT_ID_0,INT_SOURCE_TIMER_1);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
source	One of the possible values from INT_SOURCE.

Function

void PLIB_INT_SourceFlagSet (INT_MODULE_ID index, INT_SOURCE source)

PLIB_INT_SourceIsEnabled Function

Gets the enable state of the interrupt source.

File

plib_int.h

C

```
bool PLIB_INT_SourceIsEnabled(INT_MODULE_ID index, INT_SOURCE source);
```

Returns

- true - If the interrupt source is enabled
- false - If the interrupt source is disabled

Description

This function gets the enable state of the interrupt source.

Remarks

This function implements an operation of the SourceControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsSourceControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_INT_SourceIsEnabled(INT_ID_0,INT_SOURCE_TIMER_1) != true)
{
    PLIB_INT_SourceEnable(INT_ID_0,INT_SOURCE_TIMER_1);
}
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
source	One of the possible values from INT_SOURCE.

Function

bool PLIB_INT_SourceIsEnabled (INT_MODULE_ID index, INT_SOURCE source)

PLIB_INT_VectorPriorityGet Function

Gets the priority of the interrupt vector.

File

plib_int.h

C

```
INT_PRIORITY_LEVEL PLIB_INT_VectorPriorityGet(INT_MODULE_ID index, INT_VECTOR vector);
```

Returns

- priority - One of the possible values from INT_PRIORITY_LEVEL

Description

Gets the priority of the interrupt vector. The priority is one of the possible values from INT_PRIORITY_LEVEL

Remarks

This function implements an operation of the VectorPriority feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsVectorPriority function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
INT_PRIORITY_LEVEL level;
level = PLIB_INT_VectorPriorityGet(INT_ID_0, INT_VECTOR_T1);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
vector	One of the possible values from INT_VECTOR

Function

PLIB_INT_PRIORITY_LEVEL INT_VectorPriorityGet (INT_MODULE_ID index, INT_VECTOR vector)

PLIB_INT_VectorPrioritySet Function

Sets the priority of the interrupt vector.

File

plib_int.h

C

```
void PLIB_INT_VectorPrioritySet(INT_MODULE_ID index, INT_VECTOR vector, INT_PRIORITY_LEVEL priority);
```

Returns

None.

Description

Sets the priority of the interrupt vector. The priority is one of the possible values from INT_PRIORITY_LEVEL.

Remarks

This function implements an operation of the VectorPriority feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsVectorPriority function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_VectorPrioritySet(INT_ID_0, INT_VECTOR_T1, INT_PRIORITY_LEVEL4);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
vector	One of the possible values from INT_VECTOR
priority	One of the possible values from INT_PRIORITY_LEVEL

Function

void PLIB_INT_VectorPrioritySet(INT_MODULE_ID index,
INT_VECTOR vector,
INT_PRIORITY_LEVEL priority)

PLIB_INT_VectorSubPriorityGet Function

Gets the sub-priority of the interrupt vector.

File

plib_int.h

C

```
INT_SUBPRIORITY_LEVEL PLIB_INT_VectorSubPriorityGet(INT_MODULE_ID index, INT_VECTOR vector);
```

Returns

- priority - One of the possible values from INT_SUBPRIORITY_LEVEL

Description

This function gets the sub-priority of the interrupt vector. The priority is one of the possible values from INT_SUBPRIORITY_LEVEL.

Remarks

This function implements an operation of the VectorPriority feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsVectorPriority function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
INT_SUBPRIORITY_LEVEL level;
level = PLIB_INT_VectorSubPriorityGet(INT_ID_0, INT_VECTOR_T1);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
vector	One of the possible values from INT_VECTOR

Function

INT_SUBPRIORITY_LEVEL PLIB_INT_VectorSubPriorityGet (INT_MODULE_ID index,
INT_VECTOR vector)

PLIB_INT_VectorSubPrioritySet Function

Sets the sub-priority of the interrupt vector.

File

plib_int.h

C

```
void PLIB_INT_VectorSubPrioritySet(INT_MODULE_ID index, INT_VECTOR vector, INT_SUBPRIORITY_LEVEL
subPriority);
```

Returns

None.

Description

This function sets the sub priority of the interrupt vector. The sub-priority is one of the possible values from INT_SUBPRIORITY_LEVEL.

Remarks

This function implements an operation of the VectorPriority feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsVectorPriority function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_VectorSubPrioritySet(INT_ID_0, INT_VECTOR_T1, INT_SUBPRIORITY_LEVEL1);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
vector	One of the possible values from INT_VECTOR
subPriority	One of the possible values from INT_SUBPRIORITY_LEVEL

Function

void PLIB_INT_VectorSubPrioritySet (INT_MODULE_ID index,
INT_VECTOR vector,
INT_SUBPRIORITY_LEVEL subPriority)

c) Other Status and Control Functions

PLIB_INT_CPUCurrentPriorityLevelGet Function

Gets the interrupt priority level at which the CPU is currently operating.

File

plib_int.h

C

```
INT_PRIORITY_LEVEL PLIB_INT_CPUCurrentPriorityLevelGet(INT_MODULE_ID index);
```

Returns

- priority - The current interrupt priority of the CPU. Range (0 - 15)

Description

This function gets the interrupt priority level at which the CPU is currently operating.

Remarks

User interrupts are disabled when the CPU priority is more than 7.

This function implements an operation of the CPUCurrentPriorityLevel feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsCPUCurrentPriorityLevel function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
INT_PRIORITY_LEVEL currentCPUPriority;
currentCPUPriority = PLIB_INT_CPUCurrentPriorityLevelGet( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

INT_PRIORITY_LEVEL PLIB_INT_CPUCurrentPriorityLevelGet (INT_MODULE_ID index)

PLIB_INT_ProximityTimerGet Function

Returns the value used by the temporal proximity timer as a reload value when the temporal proximity timer is triggered by an interrupt event.

File

plib_int.h

C

```
uint32_t PLIB_INT_ProximityTimerGet(INT_MODULE_ID index);
```

Returns

Timer reload value.

Description

This function returns the value used by the temporal proximity timer as a reload value when the temporal proximity timer is triggered by an interrupt event.

Remarks

This function implements an operation of the ProximityTimerControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsProximityTimerControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t timer;

timer = PLIB_INT_ProximityTimerGet( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

uint32_t PLIB_INT_ProximityTimerGet (INT_MODULE_ID index)

PLIB_INT_ProximityTimerSet Function

Sets the temporal proximity timer reload value. This value is used to reload the proximity timer after it has been triggered by an interrupt event.

File

plib_int.h

C

```
void PLIB_INT_ProximityTimerSet(INT_MODULE_ID index, uint32_t timerreloadvalue);
```

Returns

None.

Description

This function sets the temporal proximity timer reload value. This value is used to reload the proximity timer after it has been triggered by an interrupt event.

Remarks

This function implements an operation of the ProximityTimerControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsProximityTimerControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_INT_ProximityTimerSet(INT_ID_0, 0x12345678);
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
timerReloadValue	Timer reload value.

Function

void PLIB_INT_ProximityTimerSet (INT_MODULE_ID index, uint32_t timerReloadValue)

PLIB_INT_VectorGet Function

Returns the interrupt vector that is presented to the CPU.

File

plib_int.h

C

```
INT_VECTOR PLIB_INT_VectorGet(INT_MODULE_ID index);
```

Returns

One of the possible values from INT_VECTOR.

Description

This function returns the interrupt vector that is presented to the CPU.

Remarks

This value should only be used when the interrupt controller is configured for single vector mode using the function PLIB_INT_MultiVectorDisable.

This function implements an operation of the INTCPUVector feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsINTCPUVector function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
INT_VECTOR level = PLIB_INT_VectorGet( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

INT_VECTOR PLIB_INT_VectorGet (INT_MODULE_ID index)

PLIB_INT_GetStateAndDisable Function

Disables the generation of interrupts to the CPU.

File

plib_int.h

C

```
INT_STATE_GLOBAL PLIB_INT_GetStateAndDisable(INT_MODULE_ID index);
```

Returns

Value of CP0 Status register before interrupts were disabled globally.

Description

This function disables the generation of interrupts to the CPU.

Remarks

This function should be paired with the use of PLIB_INT_SetState. The value returned from this function should be passed into PLIB_INT_SetState.

Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsEnableControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
INT_STATE_GLOBAL interrupt_value;

interrupt_value = PLIB_INT_GetStateAndDisable( INT_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).

Function

INT_STATE_GLOBAL PLIB_INT_GetStateAndDisable (INT_MODULE_ID index)

PLIB_INT_ShadowRegisterGet Function

Gets the shadow register set assigned for an interrupt priority level.

File

plib_int.h

C

```
INT_SHADOW_REGISTER PLIB_INT_ShadowRegisterGet(INT_MODULE_ID index, INT_PRIORITY_LEVEL priority);
```

Returns

None.

Description

The function gets the shadow register set assigned for an interrupt priority level.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsShadowRegisterAssign function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
INT_SHADOW_REGISTER shadowReg;

shadowReg = PLIB_INT_ShadowRegisterGet( INT_ID_0, INT_PRIORITY_LEVEL5 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
priority	Interrupt priority level for the shadow register set that is to be assigned.

Function

INT_SHADOW_REGISTER PLIB_INT_ShadowRegisterGet (INT_MODULE_ID index,
INT_PRIORITY_LEVEL priority)

PLIB_INT_VariableVectorOffsetGet Function

Gets the offset specific to an interrupt source number.

File

plib_int.h

C

```
uint32_t PLIB_INT_VariableVectorOffsetGet(INT_MODULE_ID index, INT_VECTOR vector);
```

Returns

Offset value.

Description

The function gets the offset specific to an interrupt source number.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use the PLIB_INT_ExistsVariableOffset function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t offset;

offset = PLIB_INT_VariableVectorOffsetGet ( INT_ID_0, INT_VECTOR_USB1 );
```

Parameters

Parameters	Description
index	Identifier for the module instance to be configured (it should be INT_ID_0 for all of the devices that have only one Interrupt module).
vector	Interrupt source, one of the possible value from INT_VECTOR enum.

Function

uint32_t PLIB_INT_VariableVectorOffsetGet (INT_MODULE_ID index, INT_VECTOR vector)

d) Feature Existence Functions

PLIB_INT_ExistsCPUCurrentPriorityLevel Function

Identifies whether the CPUCurrentPriorityLevel feature exists on the Interrupts module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsCPUCurrentPriorityLevel(INT_MODULE_ID index);
```

Returns

- true - The CPUCurrentPriorityLevel feature is supported on the device
- false - The CPUCurrentPriorityLevel feature is not supported on the device

Description

This function identifies whether the CPUCurrentPriorityLevel feature is available on the Interrupt module. When this function returns true, this function is supported on the device:

- PLIB_INT_CPUCurrentPriorityLevelGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsCPUCurrentPriorityLevel(INT_MODULE_ID index)

PLIB_INT_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsEnableControl(INT_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_Enable
- PLIB_INT_Disable
- PLIB_INT_IsEnabled
- PLIB_INT_SetState
- PLIB_INT_GetStateAndDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsEnableControl(INT_MODULE_ID index)

PLIB_INT_ExistsExternalINTEdgeSelect Function

Identifies whether the ExternalINTEdgeSelect feature exists on the Interrupts module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsExternalINTEdgeSelect(INT_MODULE_ID index);
```

Returns

- true - The ExternalINTEdgeSelect feature is supported on the device
- false - The ExternalINTEdgeSelect feature is not supported on the device

Description

This function identifies whether the ExternalINTEdgeSelect feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_ExternalRisingEdgeSelect
- PLIB_INT_ExternalFallingEdgeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsExternalINTEdgeSelect(INT_MODULE_ID index)

PLIB_INT_ExistsINTCPUPriority Function

Identifies whether the INTCPUPriority feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsINTCPUPriority(INT_MODULE_ID index);
```

Returns

- true - The INTCPUPriority feature is supported on the device
- false - The INTCPUPriority feature is not supported on the device

Description

This function identifies whether the INTCPUPriority feature is available on the Interrupt module. When this function returns true, this function is supported on the device:

- PLIB_INT_PriorityGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsINTCPUPriority(INT_MODULE_ID index)

PLIB_INT_ExistsINTCPUVector Function

Identifies whether the INTCPUVector feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsINTCPUVector(INT_MODULE_ID index);
```

Returns

- true - The INTCPUVector feature is supported on the device
- false - The INTCPUVector feature is not supported on the device

Description

This function identifies whether the INTCPUVector feature is available on the Interrupt module. When this function returns true, this function is supported on the device:

- PLIB_INT_VectorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsINTCPUVector(INT_MODULE_ID index)

PLIB_INT_ExistsProximityTimerControl Function

Identifies whether the ProximityTimerControl feature exists on the Interrupts module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsProximityTimerControl(INT_MODULE_ID index);
```

Returns

- true - The ProximityTimerControl feature is supported on the device
- false - The ProximityTimerControl feature is not supported on the device

Description

This function identifies whether the ProximityTimerControl feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_ProximityTimerSet
- PLIB_INT_ProximityTimerGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsProximityTimerControl(INT_MODULE_ID index)

PLIB_INT_ExistsProximityTimerEnable Function

Identifies whether the ProximityTimerEnable feature exists on the Interrupts module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsProximityTimerEnable(INT_MODULE_ID index);
```

Returns

- true - The ProximityTimerEnable feature is supported on the device
- false - The ProximityTimerEnable feature is not supported on the device

Description

This function identifies whether the ProximityTimerEnable feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_ProximityTimerEnable
- PLIB_INT_ProximityTimerDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsProximityTimerEnable(INT_MODULE_ID index)

PLIB_INT_ExistsSingleVectorShadowSet Function

Identifies whether the SingleVectorShadowSet feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsSingleVectorShadowSet(INT_MODULE_ID index);
```

Returns

- true - The SingleVectorShadowSet feature is supported on the device
- false - The SingleVectorShadowSet feature is not supported on the device

Description

This function identifies whether the SingleVectorShadowSet feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_SingleVectorShadowSetDisable
- PLIB_INT_SingleVectorShadowSetEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsSingleVectorShadowSet(INT_MODULE_ID index)

PLIB_INT_ExistsSourceControl Function

Identifies whether the SourceControl feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsSourceControl(INT_MODULE_ID index);
```

Returns

- true - The SourceControl feature is supported on the device
- false - The SourceControl feature is not supported on the device

Description

This function identifies whether the SourceControl feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_SourceEnable
- PLIB_INT_SourceDisable
- PLIB_INT_SourceIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsSourceControl(INT_MODULE_ID index)

PLIB_INT_ExistsSourceFlag Function

Identifies whether the SourceFlag feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsSourceFlag(INT_MODULE_ID index);
```

Returns

- true - The SourceFlag feature is supported on the device
- false - The SourceFlag feature is not supported on the device

Description

This function identifies whether the SourceFlag feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_SourceFlagGet
- PLIB_INT_SourceFlagSet
- PLIB_INT_SourceFlagClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsSourceFlag(INT_MODULE_ID index)

PLIB_INT_ExistsVectorPriority Function

Identifies whether the VectorPriority feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsVectorPriority(INT_MODULE_ID index);
```

Returns

- true - The VectorPriority feature is supported on the device
- false - The VectorPriority feature is not supported on the device

Description

This function identifies whether the VectorPriority feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_VectorPrioritySet
- PLIB_INT_VectorPriorityGet
- PLIB_INT_VectorSubPrioritySet
- PLIB_INT_VectorSubPriorityGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsVectorPriority(INT_MODULE_ID index)

PLIB_INT_ExistsVectorSelect Function

Identifies whether the VectorSelect feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsVectorSelect(INT_MODULE_ID index);
```

Returns

- true - The VectorSelect feature is supported on the device
- false - The VectorSelect feature is not supported on the device

Description

This function identifies whether the VectorSelect feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_MultiVectorSelect
- PLIB_INT_SingleVectorSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsVectorSelect(INT_MODULE_ID index)

PLIB_INT_ExistsShadowRegisterAssign Function

Identifies whether the ShadowRegisterAssign feature exists on the Interrupts module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsShadowRegisterAssign(INT_MODULE_ID index);
```

Returns

- true - The ShadowRegisterAssign feature is supported on the device
- false - The ShadowRegisterAssign feature is not supported on the device

Description

This function identifies whether the ShadowRegisterAssign feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_ShadowRegisterAssign
- PLIB_INT_ShadowRegisterGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsShadowRegisterAssign(INT_MODULE_ID index)

PLIB_INT_ExistsVariableOffset Function

Identifies whether the VariableOffset feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsVariableOffset(INT_MODULE_ID index);
```

Returns

- true - The VariableOffset feature is supported on the device
- false - The VariableOffset feature is not supported on the device

Description

This function identifies whether the VariableOffset feature is available on the Interrupt module. When this function returns true, these functions are supported on the device:

- PLIB_INT_VariableOffsetSet
- PLIB_INT_VariableOffsetGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsVariableOffset(INT_MODULE_ID index)

PLIB_INT_ExistsSoftwareNMI Function

Identifies whether the SoftwareNMI feature exists on the Interrupt module.

File

plib_int.h

C

```
bool PLIB_INT_ExistsSoftwareNMI(INT_MODULE_ID index);
```

Returns

- true - The SoftwareNMI feature is supported on the device
- false - The SoftwareNMI feature is not supported on the device

Description

This function identifies whether the SoftwareNMI feature is available on the Interrupt module. When this function returns true, this function is supported on the device:

- PLIB_INT_SoftwareNMITrigger

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_INT_ExistsSoftwareNMI(INT_MODULE_ID index)

e) Data Types and Constants

INT_EXTERNAL_SOURCES Enumeration

Lists the possible external sources that can cause an interrupt to occur.

File

plib_int_help.h

C

```
typedef enum {
  INT_EXTERNAL_INT_SOURCE0,
  INT_EXTERNAL_INT_SOURCE1,
  INT_EXTERNAL_INT_SOURCE2,
  INT_EXTERNAL_INT_SOURCE3,
  INT_EXTERNAL_INT_SOURCE4
} INT_EXTERNAL_SOURCES;
```

Members

Members	Description
INT_EXTERNAL_INT_SOURCE0	External Interrupt Source 0

INT_EXTERNAL_INT_SOURCE1	External Interrupt Source 1
INT_EXTERNAL_INT_SOURCE2	External Interrupt Source 2
INT_EXTERNAL_INT_SOURCE3	External Interrupt Source 3
INT_EXTERNAL_INT_SOURCE4	External Interrupt Source 4

Description

External Interrupt Sources

This enumeration lists the possible external sources that can cause an interrupt to occur.

Remarks

This enumeration is processor-specific and is defined in the processor-specific header files (see processor.h).

INT_PRIORITY_LEVEL Enumeration

Lists the possible interrupt priority levels.

File

plib_int_help.h

C

```
typedef enum {
  INT_PRIORITY_LEVEL0,
  INT_PRIORITY_LEVEL1,
  INT_PRIORITY_LEVEL2,
  INT_PRIORITY_LEVEL3,
  INT_PRIORITY_LEVEL4,
  INT_PRIORITY_LEVEL5,
  INT_PRIORITY_LEVEL6,
  INT_PRIORITY_LEVEL7
} INT_PRIORITY_LEVEL;
```

Members

Members	Description
INT_PRIORITY_LEVEL0	Disabled
INT_PRIORITY_LEVEL1	Priority 1
INT_PRIORITY_LEVEL2	Priority 2
INT_PRIORITY_LEVEL3	Priority 3
INT_PRIORITY_LEVEL4	Priority 4
INT_PRIORITY_LEVEL5	Priority 5
INT_PRIORITY_LEVEL6	Priority 6
INT_PRIORITY_LEVEL7	Priority 7

Description

Priority Level

This enumeration lists the possible interrupt priority levels that can be selected for each source.

Remarks

This enumeration is processor-specific and is defined in the processor-specific header files (see processor.h).

INT_SOURCE Enumeration

Lists the possible sources that can cause an interrupt to occur.

File

plib_int_help.h

C

```
typedef enum {
  INT_SOURCE_SOFTWARE_0,
  INT_SOURCE_SOFTWARE_1,
  INT_SOURCE_EXTERNAL_0,

INT_SOURCE_DMA_5	Direct Memory Access Channel 5 interrupt
INT_SOURCE_DMA_6	Direct Memory Access Channel 6 interrupt
INT_SOURCE_DMA_7	Direct Memory Access Channel 7 interrupt
INT_SOURCE_FLASH_CONTROL	Flash Control Event interrupt
INT_SOURCE_USB_1	Universal Serial Bus 1 interrupt
INT_SOURCE_CAN_1	Controller Area Network 1 interrupt
INT_SOURCE_CAN_2	Controller Area Network 2 interrupt
INT_SOURCE_ETH_1	Ethernet interrupt
INT_SOURCE_ADC_FAULT	ADC Fault interrupt
INT_SOURCE_CRYPTO	Crypto interrupt
INT_SOURCE_SPI_5_RECEIVE	SPI 5 Receive Done interrupt
INT_SOURCE_SPI_5_TRANSMIT	SPI 5 Transmit Done interrupt
INT_SOURCE_SPI_6_ERROR	SPI 6 Error interrupt
INT_SOURCE_SPI_6_RECEIVE	SPI 6 Receive Done interrupt
INT_SOURCE_SPI_6_TRANSMIT	SPI 6 Transmit Done interrupt

Description

Interrupt Source

This enumeration lists the possible sources that can cause an interrupt to occur.

Remarks

This enumeration is processor-specific and is defined in the processor-specific header files (see processor.h).

INT_SUBPRIORITY_LEVEL Enumeration

Lists the possible interrupt sub priority levels.

File

plib_int_help.h

C

```
typedef enum {
  INT_SUBPRIORITY_LEVEL0,
  INT_SUBPRIORITY_LEVEL1,
  INT_SUBPRIORITY_LEVEL2,
  INT_SUBPRIORITY_LEVEL3
} INT_SUBPRIORITY_LEVEL;
```

Members

Members	Description
INT_SUBPRIORITY_LEVEL0	Sub Priority 0
INT_SUBPRIORITY_LEVEL1	Sub Priority 1
INT_SUBPRIORITY_LEVEL2	Sub Priority 2
INT_SUBPRIORITY_LEVEL3	Sub Priority 3

Description

Sub Priority Level

This enumeration lists the possible interrupt sub priority levels that can be selected for each source.

Remarks

This enumeration (INT_SUBPRIORITY_LEVEL) is processor-specific and is defined in the processor-specific header files (see processor.h).

INT_VECTOR Enumeration

Lists the possible interrupt vectors.

File

plib_int_help.h

C

```
typedef enum {
  INT_VECTOR_CT,
  INT_VECTOR_CS0,
  INT_VECTOR_CS1,

Description

Interrupt Vectors

This enumeration lists the possible interrupt vectors.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

INT_STATE_GLOBAL Type

Data type defining the global interrupt state.

File

plib_int.h

C

```
typedef uint32_t INT_STATE_GLOBAL;
```

Description

INT global state type definition

This data type is used for interrupt enable and disable functions.

Remarks

None.

INT_SHADOW_REGISTER Enumeration

Lists the possible shadow register sets.

File

plib_int_help.h

C

```
typedef enum {
  INT_SHADOW_REGISTER_0,
  INT_SHADOW_REGISTER_1,
  INT_SHADOW_REGISTER_2,
  INT_SHADOW_REGISTER_3,
  INT_SHADOW_REGISTER_4,
  INT_SHADOW_REGISTER_5,
  INT_SHADOW_REGISTER_6,
  INT_SHADOW_REGISTER_7
} INT_SHADOW_REGISTER;
```

Members

Members	Description
INT_SHADOW_REGISTER_0	Shadow register set 0
INT_SHADOW_REGISTER_1	Shadow register set 1
INT_SHADOW_REGISTER_2	Shadow register set 2
INT_SHADOW_REGISTER_3	Shadow register set 3
INT_SHADOW_REGISTER_4	Shadow register set 4
INT_SHADOW_REGISTER_5	Shadow register set 5
INT_SHADOW_REGISTER_6	Shadow register set 6
INT_SHADOW_REGISTER_7	Shadow register set 7

Description

Shadow Register Sets

This enumeration lists the possible shadow register sets.

Remarks

This feature may not be available on all the devices. Refer to the specific device header files for availability.

INT_VECTOR_SPACING Enumeration

Lists the possible interrupt vector spacing.

File

plib_int_help.h

C

```
typedef enum {
  INT_VECTOR_SPACING_0,
  INT_VECTOR_SPACING_8,
  INT_VECTOR_SPACING_16,
  INT_VECTOR_SPACING_32,
  INT_VECTOR_SPACING_64,
  INT_VECTOR_SPACING_128,
  INT_VECTOR_SPACING_256,
  INT_VECTOR_SPACING_512
} INT_VECTOR_SPACING;
```

Members

Members	Description
INT_VECTOR_SPACING_0	0 Byte Vector Spacing
INT_VECTOR_SPACING_8	8 Byte Vector Spacing
INT_VECTOR_SPACING_16	16 Byte Vector Spacing
INT_VECTOR_SPACING_32	32 Byte Vector Spacing
INT_VECTOR_SPACING_64	64 Byte Vector Spacing
INT_VECTOR_SPACING_128	128 Byte Vector Spacing
INT_VECTOR_SPACING_256	256 Byte Vector Spacing
INT_VECTOR_SPACING_512	512 Byte Vector Spacing

Description

Interrupt Vector Spacing

This enumeration lists the possible interrupt vector spacing, which can be provided between two interrupt vectors.

Remarks

This feature may not be available in all the devices. Refer to the specific device header files for availability.

Functions

	Name	Description
	PLIB_INT_CPUCurrentPriorityLevelGet	Gets the interrupt priority level at which the CPU is currently operating.
	PLIB_INT_Disable	Disables the generation of interrupts to the CPU.
	PLIB_INT_Enable	Enables the generation of interrupts to the CPU.
	PLIB_INT_ExistsCPUCurrentPriorityLevel	Identifies whether the CPUCurrentPriorityLevel feature exists on the Interrupts module.
	PLIB_INT_ExistsEnableControl	Identifies whether the EnableControl feature exists on the Interrupt module.
	PLIB_INT_ExistsExternalINTEdgeSelect	Identifies whether the ExternalINTEdgeSelect feature exists on the Interrupts module.
	PLIB_INT_ExistsINTCPUPriority	Identifies whether the INTCPUPriority feature exists on the Interrupt module.
	PLIB_INT_ExistsINTCPUVector	Identifies whether the INTCPUVector feature exists on the Interrupt module.
	PLIB_INT_ExistsProximityTimerControl	Identifies whether the ProximityTimerControl feature exists on the Interrupts module.
	PLIB_INT_ExistsProximityTimerEnable	Identifies whether the ProximityTimerEnable feature exists on the Interrupts module.
	PLIB_INT_ExistsShadowRegisterAssign	Identifies whether the ShadowRegisterAssign feature exists on the Interrupts module.
	PLIB_INT_ExistsSingleVectorShadowSet	Identifies whether the SingleVectorShadowSet feature exists on the Interrupt module.
	PLIB_INT_ExistsSoftwareNMI	Identifies whether the SoftwareNMI feature exists on the Interrupt module.
	PLIB_INT_ExistsSourceControl	Identifies whether the SourceControl feature exists on the Interrupt module.
	PLIB_INT_ExistsSourceFlag	Identifies whether the SourceFlag feature exists on the Interrupt module.
	PLIB_INT_ExistsVariableOffset	Identifies whether the VariableOffset feature exists on the Interrupt module.
	PLIB_INT_ExistsVectorPriority	Identifies whether the VectorPriority feature exists on the Interrupt module.
	PLIB_INT_ExistsVectorSelect	Identifies whether the VectorSelect feature exists on the Interrupt module.
	PLIB_INT_ExternalFallingEdgeSelect	Selects the falling edge as the edge polarity of the external interrupt.
	PLIB_INT_ExternalRisingEdgeSelect	Selects the rising edge as the edge polarity of the external interrupt.
	PLIB_INT_GetStateAndDisable	Disables the generation of interrupts to the CPU.
	PLIB_INT_IsEnabled	Identifies if interrupts are currently enabled or disabled at the top level.
	PLIB_INT_MultiVectorSelect	Configures the Interrupt Controller for Multiple Vector mode.
	PLIB_INT_PriorityGet	Returns the priority level of the latest interrupt presented to the CPU.
	PLIB_INT_ProximityTimerDisable	Disables the interrupt temporal-proximity timer.
	PLIB_INT_ProximityTimerEnable	Enables the interrupt temporal-proximity timer and selects the priority levels that start the timer.
	PLIB_INT_ProximityTimerGet	Returns the value used by the temporal proximity timer as a reload value when the temporal proximity timer is triggered by an interrupt event.
	PLIB_INT_ProximityTimerSet	Sets the temporal proximity timer reload value. This value is used to reload the proximity timer after it has been triggered by an interrupt event.
	PLIB_INT_SetState	Restores the status of CPU interrupts based on the value passed into the function.
	PLIB_INT_ShadowRegisterAssign	Assigns a shadow register set for an interrupt priority level.
	PLIB_INT_ShadowRegisterGet	Gets the shadow register set assigned for an interrupt priority level.
	PLIB_INT_SingleVectorSelect	Configures the Interrupt Controller for Single Vector mode.
	PLIB_INT_SingleVectorShadowSetDisable	Disables the Shadow Register Set in Single Vector mode.

	PLIB_INT_SingleVectorShadowSetEnable	Enables the Shadow Register Set in Single Vector mode.
	PLIB_INT_SoftwareNMITrigger	Triggers software NMI.
	PLIB_INT_SourceDisable	Disables the interrupt source
	PLIB_INT_SourceEnable	Enables the interrupt source.
	PLIB_INT_SourceFlagClear	Clears the status of the interrupt flag for the selected source.
	PLIB_INT_SourceFlagGet	Returns the status of the interrupt flag for the selected source.
	PLIB_INT_SourceFlagSet	Sets the status of the interrupt flag for the selected source.
	PLIB_INT_SourceIsEnabled	Gets the enable state of the interrupt source.
	PLIB_INT_VariableVectorOffsetGet	Gets the offset specific to an interrupt source number.
	PLIB_INT_VariableVectorOffsetSet	Sets the offset specific to an interrupt source number.
	PLIB_INT_VectorGet	Returns the interrupt vector that is presented to the CPU.
	PLIB_INT_VectorPriorityGet	Gets the priority of the interrupt vector.
	PLIB_INT_VectorPrioritySet	Sets the priority of the interrupt vector.
	PLIB_INT_VectorSubPriorityGet	Gets the sub-priority of the interrupt vector.
	PLIB_INT_VectorSubPrioritySet	Sets the sub-priority of the interrupt vector.

Types

	Name	Description
	INT_STATE_GLOBAL	Data type defining the global interrupt state.

Description

Interrupt Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Interrupt Peripheral Library for Microchip microcontrollers. The definitions in this file are for the Interrupt Controller module.

File Name

plib_int.h

Company

Microchip Technology Inc.

plib_int_help.h

Enumerations

	Name	Description
	INT_EXTERNAL_SOURCES	Lists the possible external sources that can cause an interrupt to occur.
	INT_PRIORITY_LEVEL	Lists the possible interrupt priority levels.
	INT_SHADOW_REGISTER	Lists the possible shadow register sets.
	INT_SOURCE	Lists the possible sources that can cause an interrupt to occur.
	INT_SUBPRIORITY_LEVEL	Lists the possible interrupt sub priority levels.
	INT_VECTOR	Lists the possible interrupt vectors.
	INT_VECTOR_SPACING	Lists the possible interrupt vector spacing.

Section

Interrupt Controller Definitions - Processor-Specific Enumerations

****

****

This section defines Interrupt Controller enumerations that are
processor-specific.

NVM Peripheral Library

This section describes the Non-volatile Memory (NVM) Peripheral Library.

Introduction

This library provides a low-level abstraction of the Non-Volatile Memory (NVM)component (Flash and EEPROM) on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences from one microcontroller variant to another.

Description

Flash Program Memory

The Flash program memory is readable, writeable and erasable during normal operation over the entire operating voltage range.

A read from program memory is executed at one byte/word at a time depending on the width of the data bus.

A write to the program memory is executed in either blocks of specific sizes or a single word depending on the type of processor used.

An erase is performed in blocks. A bulk erase may be performed from user code depending on the type of processor supporting the operation.

Writing or erasing program memory will cease instruction fetches until the operation is complete thus restricting memory access and therefore preventing code execution. This is controlled by an internal programming timer.

There are three processor dependant methods for Flash program memory modification.

- Run-Time Self Programming (RTSP)
- In-Circuit Serial Programming (ICSP)
- EJTAG programming

Note: This topic covers the RTSP techniques.

EEPROM Memory

The EEPROM memory is the data storage memory.

On device power-up, power is disconnected from the EEPROM and the EEPROM will be in its lowest power mode. When it is enabled, power is applied to the EEPROM, but it will be ready for the access only after a power-up delay. Once ready for access, all read and write operations are executed using the Data EEPROM registers.

Write/Read/Erase operations are possible in words.

A bulk erase may be performed to erase the full EEPROM.

Using the Library

This topic describes the basic architecture of the NVM Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_nvm.h`

The interface to the NVM library is defined in the `plib_nvm.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the NVM library must include `peripheral.h`.

Library File:

The NVM peripheral library is part of the processor-specific peripheral library archive (`.a`) file installed with the compiler. Libraries in this archive are automatically available to the linker (in the default search path) for any project built using the Microchip compiler.

Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

Hardware Abstraction Model

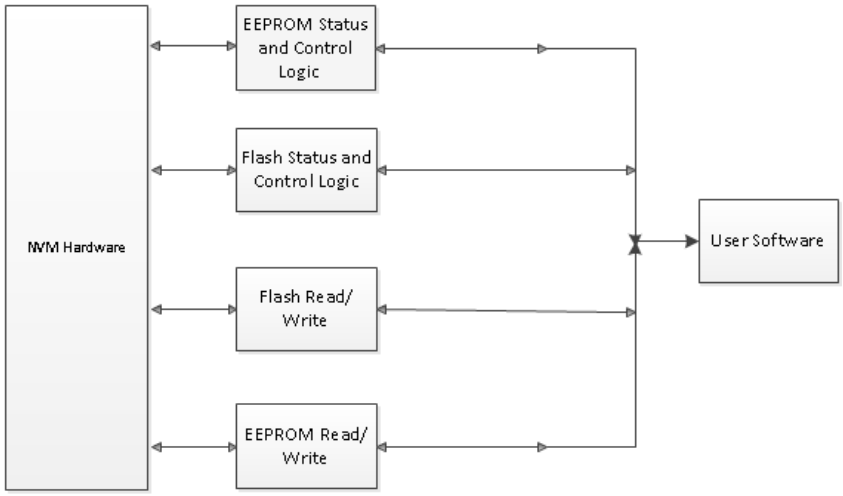
This library provides a low-level abstraction of the NVM module on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

Abstraction Model

The NVM Peripheral Library provides interface routines to interact with the blocks shown in the diagram.

NVM Software Abstraction Block Diagram



The **Flash Status and Control** logic ensures that the Flash memory is configured appropriately for modification. It also provides the status of the different operations in progress as well as errors, if any. It also decides if the operation is for Flash program memory or the special device Configuration registers.

The **Flash Read/Write** block ensures that the user data is written to/read from the program memory holding latches. It provides a layer of abstraction over the sequence of processor specific instructions which are required to access this data. Depending on the processor type, either block or Word programming options are available.

The **EEPROM Status and Control** logic ensures that the EEPROM is configured appropriately for access and also provides the status of the different operations in progress, as well as errors, if any.

The **EEPROM Read/Write** block ensures that the user data is written to/read from the data EEPROM. All of the EEPROM operations are word programmable with the exception of the bulk erase, which erases the entire EEPROM.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the NVM module

Library Interface Section	Description
Flash Memory Configuration and Status Functions	Provides Flash memory setup, configuration, and status control interface routines.
Flash Memory Functions	Provides Flash memory interface routines.
Other Flash Memory Functions	Provides additional functions for Boot page and Flash memory.
EEPROM Configuration and Status Functions	Provides EEPROM setup, configuration, and status control interface routines.
EEPROM Operation Functions	Provides interface routines for EEPROM operations.
Feature Existence Functions	Determine whether or not certain features are available.

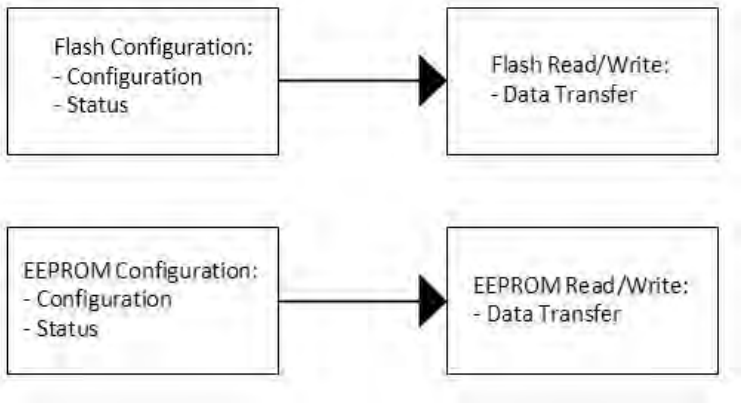
How the Library Works

The usage model for this library is explained in the following sections.

Description

Each of the blocks in the diagram correspond to the library interface section.

Usage Model



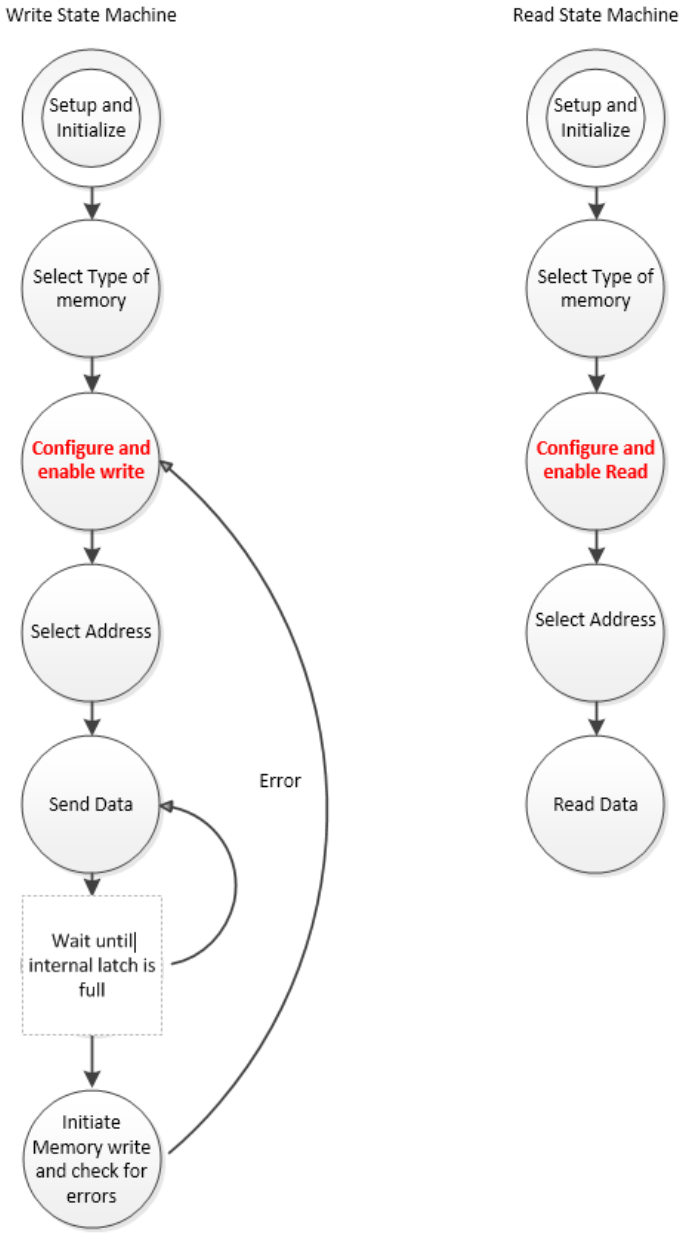
State Machine

This topic describes the NVM Write and Read state machine.

Description

The following state machine is for the NVM Read and Write during the normal operation. This state machine is provided to give a general idea of the usage model of the peripheral library. Refer to the usage model for more detailed steps for the scenario that is being used.

NVM Write and Read State Machine



State	Associated Function
Setup and Initialization	Refer to mode of NVM for detailed instructions of setup.
Select Type of memory	Once the NVM has been appropriately set up and initialized, the state machine waits for the application to select the type of memory to be accessed, either Memory region (Flash/EEPROM) or the corresponding configuration registers.
Configure and enable write/read	Configures the registers and enables the write/read operation.
Select Address	The application provides the write/read address from which to access memory.
Send Data/Read Data	When the application is polling it can fill data/read data into the internal holding registers and initiate write via PLIB_NVM_FlashWriteStart(NVM_ID_0) or PLIB_NVM_EEPROMWriteStart(NVM_ID_0).
Read Error/Write Status	The error/write status is available to the application through the PLIB_NVM_FlashWriteCycleHasCompleted(NVM_ID_0) or PLIB_NVM_EEPROMOperationHasCompleted(NVM_ID_0) functions and other status/error APIs.

Note: Refer to the mode used for the NVM for the setup and initialization steps.

Flash Operations

This topic describes Flash operations.

Description

Note: Flash program memory operations vary across microcontrollers. Please refer to the **"Flash Controller"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine which features are supported by the device in use.

Flash Read Operation Setup

Do the following set up Flash read operation:

1. Provide the Flash program memory from which the data memory has to be read via the API PLIB_NVM_FlashRead function. This address is then updated in the respective address registers or the Table Pointers depending on the device.
2. Ensure the alignment of the address as specified by the specific device data sheet.
3. The size of the data read depends upon the microcontroller in use. For details, please refer to the specific device data sheet.

Example: Flash Program Memory Read

```
// Determine the address from which to read
#define MY_FLASH_BASE_ADDRESS      0xA0007862 // Or any address in Flash to read

uint32_t    address = MY_FLASH_BASE_ADDRESS;
// The Data Available at the memory location
size_t    DataToBeRead;

// where, MY_NVM_INSTANCE - is a specific instance of the hardware peripheral.
// where, address         - The address in the memory from which to read.
DataToBeRead = PLIB_NVM_FlashRead(NVM_ID_0, address);
```

EEPROM Operations

This topic describes EEPROM operations.

Description

Note: EEPROM operations vary across microcontrollers. Please refer to the **"Data EEPROM"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine which features are supported by the device in use.

Before accessing the EEPROM at full speed, it is necessary to program configuration values into the Data EEPROM controller after enabling it. Refer to **"EEPROM Configuration Write Operation Setup"** in Flash Operations for more information.

EEPROM Read Operation Setup

Prior to reading the Data EEPROM, the Data EEPROM must be enabled and ready. There can be no ongoing command when a new command is issued to the Data EEPROM.

Do the following to execute a Data EEPROM read operation:

1. Load the Data EEPROM address to be read. The address must be on a 32-bit boundary and the last two bits must be '00'.
2. Select the read operation command.
3. Enable for read access.
4. Start the read operation.
5. Wait until the read cycle is complete.
6. Read the data from the intermediate register.

Example: EEPROM Read

```
if (PLIB_NVM_EEPROMIsReady( NVM_ID_0 ))
{
    // There should be no ongoing operation.
    if (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ))
    {
        // Set address on 32-bit boundary, last two bits must be '00'
        uint32_t ADDR = 0x0100;
        // Load Data EEPROM read command
        PLIB_NVM_EEPROMOperationSelect( NVM_ID_0 , EEPROM_WORD_READ_OPERATION);
        // Load address and check if it is valid
        if(true ==PLIB_NVM_EEPROMAddress( NVM_ID_0 , ADDR ))
        {
```

```
            // Enable access for read
            PLIB_NVM_EEPROMReadEnable( NVM_ID_0 );
            // Start the read operation
            PLIB_NVM_EEPROMReadStart( NVM_MODULE_ID index );
            // Wait until read is complete
            while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
            // Read the data
            *ee_data = PLIB_NVM_EEPROMRead( NVM_ID_0 );
        }
    }
}
```

EEPROM Write Operation Setup

Prior to writing to the Data EEPROM, the Data EEPROM must be enabled and ready. There can be no ongoing command when a new command is issued to the Data EEPROM.

Do the following to execute a Data EEPROM write operation:

1. Load the Data EEPROM address where data has to be stored. The address must be on a 32-bit boundary so that the last two bits must be '00'.
2. Select the write operation command.
3. Enable for write access.
4. Write data into the intermediate register.
5. Execute the Data EEPROM unlock sequence.
6. Start the write operation.
7. Wait until the write cycle is complete.

Example: EEPROM Write

```
if (PLIB_NVM_EEPROMIsReady( NVM_ID_0 ))
{
    // There should be no ongoing operation.
    if (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ))
    {
        // Set address on 32-bit boundary, last two bits must be '00'
        uint32_t ADDR = 0x0100;
        //Keys to unlock EEPROM
        uint32_t key1 = 0xEDB7;
        uint32_t key2 = 0x1248;
        // Load Data EEPROM write command
        PLIB_NVM_EEPROMOperationSelect( NVM_ID_0 , EEPROM_WORD_WRITE_OPERATION);
        // Load address and check if it is valid
        if(true ==PLIB_NVM_EEPROMAddress( NVM_ID_0 , ADDR ))
        {
            // Enable access to write
            PLIB_NVM_EEPROMWriteEnable( NVM_ID_0 );
            // Load data to intermediate register
            PLIB_NVM_EEPROMDataToWrite ( NVM_ID_0 , ee_data ) ;
            // Unlock the EEPROM
            PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key1);
            PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key2);
            // Start the write operation
            PLIB_NVM_EEPROMWriteStart( NVM_MODULE_ID index );
            // Wait until write is complete
            while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
        }
    }
}
```

EEPROM Forced Word Erase Operation Setup

Under normal conditions, there is no need to attempt a Forced Word Erase. The Data EEPROM has internal logic which automatically manages all read, erase, and write command sequences.

If a verification error occurs during a write to the Data EEPROM, the user can attempt a Forced Word Erase operation to recover the Data EEPROM word storage location.

The Word Erase operation is similar to the write operation.

Example: EEPROM Word Erase

```
if (PLIB_NVM_EEPROMIsReady( NVM_ID_0 ))
{
   // There should be no ongoing operation.
    if (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ))
```

```
    {
        // Set address on 32-bit boundary, last two bits must be '00'
        uint32_t ADDR = 0x0100;
        //Keys to unlock EEPROM
        uint32_t key1 = 0xEDB7;
        uint32_t key2 = 0x1248;
        // Load Data EEPROM forced word erase command
        PLIB_NVM_EEPROMOperationSelect( NVM_ID_0 , EEPROM_FORCED_WORD_ERASE_OPERATION);
        // Load address and check if it is valid
        if(true ==PLIB_NVM_EEPROMAddress( NVM_ID_0 , ADDR ))
        {
            // Enable access to write
            PLIB_NVM_EEPROMWriteEnable( NVM_ID_0 );
            // Unlock the EEPROM
            PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key1);
            PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key2);
            // Start the write operation
            PLIB_NVM_EEPROMEraseStart( NVM_MODULE_ID index );
            // Wait until write is complete
            while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
    }
}
```

EEPROM Bulk Erase Operation Setup

Prior to erasing the entire Data EEPROM, the Data EEPROM must be enabled and ready. There can be no ongoing command when a new command is issued to the Data EEPROM.

The Bulk Erase operation is similar to the write operation except the EEPROM operation is selected for Bulk erase and the data or address does not need to be loaded.

Example: EEPROM Bulk Erase

```
    if (PLIB_NVM_EEPROMIsReady( NVM_ID_0 ))
    {
        // There should be no ongoing operation.
        if (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ))
        {
            //Keys to unlock EEPROM
            uint32_t key1 = 0xEDB7;
            uint32_t key2 = 0x1248;
            // Load Data EEPROM forced word erase command
            PLIB_NVM_EEPROMOperationSelect( NVM_ID_0 , EEPROM_ERASE_ALL_OPERATION);
            // Enable access to write
            PLIB_NVM_EEPROMWriteEnable( NVM_ID_0 );
            // Unlock the EEPROM
            PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key1);
            PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key2);
            // Start the write operation
            PLIB_NVM_EEPROMEraseStart( NVM_MODULE_ID index );
            // Wait until write is complete
            while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
        }
    }
```

EEPROM Configuration Write Operation Setup

Before accessing the EEPROM at full speed, it is necessary to program configuration values into the Data EEPROM controller after enabling it. This is done through the Configuration Write operation. The configuration values to be written to the Data EEPROM Controller are stored in the DEVEE1 through DEVEE8 registers. Eight consecutive word write cycles should be performed with the EEPROM Configuration Write mode operation selected.

Miscellaneous Functions

This topic describes miscellaneous features.

Description

Note: Features vary across microcontrollers. Please refer to the **"Flash Controller"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine which features are supported by the device in use.

This section will detail out a few niche and processor-specific APIs provided by this library.

Stop in Idle Mode

The PLIB_NVM_EEPROMStopInIdleEnable and PLIB_NVM_EEPROMStopInIdleDisable functions cater to this functionality. These functions ensure that EEPROM operations are discontinued or continued in Idle mode.

Low Voltage Detection

The PLIB_NVM_LowVoltageIsDetected and PLIB_NVM_LowVoltageEventIsActive functions support low-voltage error detection and triggering of a Flash memory low-voltage event.

Long Write/Erase Cycle Detection

The PLIB_NVM_EEPROMNextWriteCycleIsLong function allows the application to know whether the next EEPROM Write/Erase cycle is long.

Configuring the Library

The library is configured for the supported NVM module when the processor is chosen in the MPLAB X IDE.

Building the Library

This section list the files that are available in the `src` folder of the NVM driver. It lists which files need to be included in the build based on either a hardware feature present on the board or configuration option selected by the system.

Library Interface

a) Flash Memory Configuration and Status Functions

	Name	Description
	PLIB_NVM_LowVoltageEventIsActive	Provides low voltage detection status.
	PLIB_NVM_LowVoltageIsDetected	Provides low voltage error detection status.
	PLIB_NVM_MemoryModifyEnable	Allows write cycles to Flash memory.
	PLIB_NVM_MemoryModifyInhibit	Inhibits write cycles to Flash memory.
	PLIB_NVM_MemoryOperationSelect	Selects the operation to be performed on Flash memory.

b) Flash Memory Operation Functions

	Name	Description
	PLIB_NVM_DataBlockSourceAddress	Takes the address parameter in the argument and loads the base address from which data has to be copied into Flash memory.
	PLIB_NVM_FlashAddressToModify	Modifies the Flash memory address.
	PLIB_NVM_FlashEraseStart	Performs erase operation on the selected Flash memory area.
	PLIB_NVM_FlashProvideData	Provides the data to be written into Flash memory.
	PLIB_NVM_FlashProvideQuadData	Provides the quad data to be written into Flash memory.
	PLIB_NVM_FlashRead	Read the specified address of Flash memory.
	PLIB_NVM_FlashWriteKeySequence	Copies the mandatory KEY sequence into the respective registers.
	PLIB_NVM_FlashWriteStart	Performs a write operation on the Flash memory row selected.
	PLIB_NVM_FlashWriteCycleHasCompleted	Provides the status of the Flash write cycle.
	PLIB_NVM_WriteOperationHasTerminated	Provides the status of the Flash write operation or sequence.

c) Other Flash Memory Functions

	Name	Description
	PLIB_NVM_FlashSwapLockSelect	Selects the kind of Flash swap lock required.
	PLIB_NVM_FlashSwapLockStatusGet	Get the status of Swap lock bits.
	PLIB_NVM_FlashWriteProtectMemoryAreaRange	Sets the address below which physical memory will be write protected.
	PLIB_NVM_BootPageWriteProtectionDisable	Write protection for selected boot page is disabled.
	PLIB_NVM_BootPageWriteProtectionEnable	Locks the selected boot page.
	PLIB_NVM_IsBootMemoryLocked	Provides lock status of boot page write-protect bits.
	PLIB_NVM_IsBootPageWriteProtected	Provides write protection status for boot memory page.
	PLIB_NVM_IsProgramFlashMemoryLocked	Provides lock status of Program Flash Write-Protect register.
	PLIB_NVM_LockBootMemory	Locks the boot write-protect bits.
	PLIB_NVM_LockProgramFlashMemory	Lock the Program Flash write-protect register.
	PLIB_NVM_ProgramFlashBank1LowerRegion	Maps Flash Bank 1 to the lower mapped region.
	PLIB_NVM_ProgramFlashBank2LowerRegion	Maps the bank 2 to lower mapped region.

	PLIB_NVM_ProgramFlashBank2IsLowerRegion	Gives the status of Program Flash Bank mapping.
	PLIB_NVM_BootFlashBank1LowerRegion	Maps Boot Flash Bank 1 to lower mapped region.
	PLIB_NVM_BootFlashBank2IsLowerRegion	Gives the status of Boot Flash Bank mapping.
	PLIB_NVM_BootFlashBank2LowerRegion	Maps Boot Flash Bank 2 to the lower mapped region.

d) EEPROM Configuration and Status Functions

	Name	Description
	PLIB_NVM_EEPROMEnable	Enables the EEPROM memory.
	PLIB_NVM_EEPROMDisable	Disables the EEPROM memory.
	PLIB_NVM_EEPROMIsReady	Provides the availability status of the EEPROM.
	PLIB_NVM_EEPROMStopInIdleEnable	Discontinues EEPROM operation when device enters Idle mode.
	PLIB_NVM_EEPROMStopInIdleDisable	Continues EEPROM operation when device enters Idle mode.
	PLIB_NVM_EEPROMStopInIdleIsEnabled	Returns Stop in Idle mode status of the EEPROM operation.
	PLIB_NVM_EEPROMOperationSelect	Selects the operation to be performed on the EEPROM.
	PLIB_NVM_EEPROMWriteEnable	Allows write or erase operation to the EEPROM.
	PLIB_NVM_EEPROMReadEnable	Allows read operation to the EEPROM.
	PLIB_NVM_EEPROMWriteIsEnabled	Returns EEPROM Write permission status.
	PLIB_NVM_EEPROMReadIsEnabled	Returns EEPROM read permission status.
	PLIB_NVM_EEPROMNextWriteCycleIsLong	Informs whether the next write or erase cycle of the EEPROM is long.
	PLIB_NVM_EEPROMErrorGet	Returns the EEPROM operation error.
	PLIB_NVM_EEPROMErrorClear	Clears the EEPROM operation error.

e) EEPROM Operation Functions

	Name	Description
	PLIB_NVM_EEPROMAddress	EEPROM address where operation has to be performed.
	PLIB_NVM_EEPROMDataToWrite	Accepts the data to be written into the EEPROM.
	PLIB_NVM_EEPROMKeySequenceWrite	Write mandatory KEY sequence to unlock the EEPROM write or erase protection.
	PLIB_NVM_EEPROMEraseStart	Initiates EEPROM erase cycle.
	PLIB_NVM_EEPROMWriteStart	Initiates a EEPROM write cycle.
	PLIB_NVM_EEPROMReadStart	Initiates a EEPROM read cycle.
	PLIB_NVM_EEPROMOperationHasCompleted	Provides the status of the EEPROM write or erase or read cycle.
	PLIB_NVM_EEPROMRead	Read the EEPROM data.
	PLIB_NVM_EEPROMOperationAbort	Aborts the current EEPROM operation.

f) Feature Existence Functions

	Name	Description
	PLIB_NVM_ExistsAddressModifyControl	Identifies whether the AddressModifyControl feature exists on the NVM module.
	PLIB_NVM_ExistsBootPageWriteProtect	Identifies whether the BootPageWriteProtect feature exists on the NVM module.
	PLIB_NVM_ExistsFlashBankRegionSelect	Identifies whether the FlashBankRegionSelect feature exists on the NVM module.
	PLIB_NVM_ExistsFlashWPMemoryRangeProvide	Identifies whether the FlashWPMemoryRangeProvide feature exists on the NVM module.
	PLIB_NVM_ExistsKeySequence	Identifies whether the KeySequence feature exists on the NVM module.
	PLIB_NVM_ExistsLockBootSelect	Identifies whether the LockBootSelect feature exists on the NVM module.
	PLIB_NVM_ExistsLockPFMSelect	Identifies whether the LockPFMSelect feature exists on the NVM module.
	PLIB_NVM_ExistsLowVoltageError	Identifies whether the LowVoltageError feature exists on the NVM module.
	PLIB_NVM_ExistsLowVoltageStatus	Identifies whether the LowVoltageStatus feature exists on the NVM module.
	PLIB_NVM_ExistsMemoryModificationControl	Identifies whether the MemoryModificationControl feature exists on the NVM module.
	PLIB_NVM_ExistsOperationMode	Identifies whether the OperationMode feature exists on the NVM module.
	PLIB_NVM_ExistsProvideData	Identifies whether the ProvideData feature exists on the NVM module.
	PLIB_NVM_ExistsProvideQuadData	Identifies whether the ProvideQuadData feature exists on the NVM module.
	PLIB_NVM_ExistsSourceAddress	Identifies whether the SourceAddress feature exists on the NVM module.
	PLIB_NVM_ExistsWriteErrorStatus	Identifies whether the WriteErrorStatus feature exists on the NVM module.
	PLIB_NVM_ExistsWriteOperation	Identifies whether the WriteOperation feature exists on the NVM module.

	PLIB_NVM_ExistsBootFlashBankRegion	Identifies whether the BootFlashBankRegion feature exists on the NVM module.
	PLIB_NVM_ExistsSwapLockControl	Identifies whether the SwapLockControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMAddressControl	Identifies whether the EEPROMAddressControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMDataControl	Identifies whether the EEPROMDataControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMEnableControl	Identifies whether the EEPROMEnableControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMEnableOperationControl	Identifies whether the EEPROMEnableOperationControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMErrorStatus	Identifies whether the EEPROMErrorStatus feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMKeySequence	Identifies whether the EEPROMKeySequence feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMLongWriteStatus	Identifies whether the EEPROMLongWriteStatus feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMOperationAbortControl	Identifies whether the EEPROMOperationAbortControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMOperationModeControl	Identifies whether the EEPROMOperationModeControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMStartOperationControl	Identifies whether the EEPROMStartOperationControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMStopInIdleControl	Identifies whether the EEPROMStopInIdleControl feature exists on the NVM module.

g) Data Types and Constants

	Name	Description
	NVM_BOOT_MEMORY_AREA	Lists the different possible boot memory region.
	NVM_BOOT_MEMORY_PAGE	Lists the different NVM boot memory pages.
	NVM_OPERATION_MODE	Lists the different Flash operation modes.
	NVM_MODULE_ID	Possible instances of the NVM module.
	NVM_FLASH_SWAP_LOCK_TYPE	Lists the possible type of Flash swap lock.
	EEPROM_ERROR	Lists the different EEPROM operation errors.
	EEPROM_OPERATION_MODE	Lists the different EEPROM operation modes.

Description

This section describes the Application Programming Interface (API) functions of the NVM Peripheral Library.

Refer to each section for a detailed description.

a) Flash Memory Configuration and Status Functions

PLIB_NVM_LowVoltageEventIsActive Function

Provides low voltage detection status.

File

plib_nvm.h

C

```
bool PLIB_NVM_LowVoltageEventIsActive(NVM_MODULE_ID index);
```

Returns

- 1 - Low Voltage Event is active
- 0 - Low Voltage Event is not active

Description

This function provides detection of low voltage event, if any.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsLowVoltageStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
status = PLIB_NVM_LowVoltageEventIsActive(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_LowVoltageEventIsActive(NVM_MODULE_ID index)

PLIB_NVM_LowVoltageIsDetected Function

Provides low voltage error detection status.

File

plib_nvm.h

C

```
bool PLIB_NVM_LowVoltageIsDetected(NVM_MODULE_ID index);
```

Returns

- 1 - Low Voltage detection and possible data corruption
- 0 - Voltage Level Acceptable for programming

Description

This function provides detection of low voltage error status.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsLowVoltageStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
status = PLIB_NVM_LowVoltageIsDetected(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_LowVoltageIsDetected(NVM_MODULE_ID index)

PLIB_NVM_MemoryModifyEnable Function

Allows write cycles to Flash memory.

File

plib_nvm.h

C

```
void PLIB_NVM_MemoryModifyEnable(NVM_MODULE_ID index);
```

Returns

None.

Description

This function allows changing the write control (WR) bit and disables writing into the SWAP and NVMOP bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsMemoryModificationControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_MemoryModifyEnable(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_MemoryModifyEnable(NVM_MODULE_ID index)

PLIB_NVM_MemoryModifyInhibit Function

Inhibits write cycles to Flash memory.

File

plib_nvm.h

C

```
void PLIB_NVM_MemoryModifyInhibit(NVM_MODULE_ID index);
```

Returns

None.

Description

This function disables the writing in the write control (WR) bit and enables writing into the SWAP and NVMOP bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsMemoryModificationControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_MemoryModifyInhibit(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_MemoryModifyInhibit(NVM_MODULE_ID index)

PLIB_NVM_MemoryOperationSelect Function

Selects the operation to be performed on Flash memory.

File

plib_nvm.h

C

```
void PLIB_NVM_MemoryOperationSelect(NVM_MODULE_ID index, NVM_OPERATION_MODE operationmode);
```

Returns

None.

Description

This function selects the operation to be performed on Flash memory.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsOperationMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_MemoryOperationSelect(MY_NVM_INSTANCE, NVM_MEMORY_ROW_PROGRAM_OPERATION);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_MemoryOperationSelect(NVM_MODULE_ID index,
NVM_OPERATION_TYPE_SELECT operationmode)

b) Flash Memory Operation Functions

PLIB_NVM_DataBlockSourceAddress Function

Takes the address parameter in the argument and loads the base address from which data has to be copied into Flash memory.

File

plib_nvm.h

C

```
void PLIB_NVM_DataBlockSourceAddress(NVM_MODULE_ID index, uint32_t address);
```

Returns

None.

Description

This function takes the address parameter in the argument and loads the base address from which data has to be copied into Flash memory. This is to copy a row of data directly into Flash in one iteration without handling any intermediate holding registers.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsSourceAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t    address = MY_RAM_BASE_ADDRESS;
PLIB_NVM_DataBlockSourceAddress(MY_NVM_INSTANCE, address);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	The starting address in the user data memory from which data will be written

Function

void PLIB_NVM_DataBlockSourceAddress(NVM_MODULE_ID index, uint32_t address)

PLIB_NVM_FlashAddressToModify Function

Modifies the Flash memory address.

File

plib_nvm.h

C

```
void PLIB_NVM_FlashAddressToModify(NVM_MODULE_ID index, uint32_t address);
```

Returns

None.

Description

This function takes the address parameter in the argument and loads the address that will be modified by the actual write operation. The write or erase operation following this will write or erase the user data into or from the Flash program memory.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsAddressModifyControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t    address = MY_FLASH_BASE_ADDRESS;
PLIB_NVM_FlashAddressToModify(MY_NVM_INSTANCE, address);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	The starting address in the memory from which data will be written. This address should be a physical address.

Function

void PLIB_NVM_FlashAddressToModify(NVM_MODULE_ID index, uint32_t address)

PLIB_NVM_FlashEraseStart Function

Performs erase operation on the selected Flash memory area.

File

plib_nvm.h

C

```
void PLIB_NVM_FlashEraseStart(NVM_MODULE_ID index);
```

Returns

None.

Description

This function Performs erase operation on the selected Flash memory region.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsWriteOperation in your application to determine whether this feature is available.

Preconditions

- The Address of the page to be erased must be provided using PLIB_NVM_FlashAddressToModify
- Erase Operation should be selected using PLIB_NVM_MemoryOperationSelect
- The module should be configured to access Flash memory using PLIB_NVM_MemoryModifyEnable
- The unlock key sequence should be provided using PLIB_NVM_FlashWriteKeySequence

Example

```
PLIB_NVM_FlashEraseStart(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_FlashEraseStart(NVM_MODULE_ID index)

PLIB_NVM_FlashProvideData Function

Provides the data to be written into Flash memory.

File

plib_nvm.h

C

```
void PLIB_NVM_FlashProvideData(NVM_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

This function provides the user data to intermediate registers before being written into Flash memory.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsProvideData in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t DataToWrite;
PLIB_NVM_FlashProvideData(MY_NVM_INSTANCE, DataToWrite);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Data to be written

Function

void PLIB_NVM_FlashProvideData(NVM_MODULE_ID index, uint32_t data)

PLIB_NVM_FlashProvideQuadData Function

Provides the quad data to be written into Flash memory.

File

plib_nvm.h

C

```
void PLIB_NVM_FlashProvideQuadData(NVM_MODULE_ID index, uint32_t * data);
```

Returns

None.

Description

This function provides the user quad data to intermediate registers before being written into Flash memory.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsProvideQuadData in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t  DataToWrite[4];
PLIB_NVM_FlashProvideQuadData(MY_NVM_INSTANCE, &DataToWrite);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Address pointing to the data to be written.

Function

void PLIB_NVM_FlashProvideQuadData(NVM_MODULE_ID index, uint32_t *data);

PLIB_NVM_FlashRead Function

Read the specified address of Flash memory.

File

plib_nvm.h

C

```
uint32_t PLIB_NVM_FlashRead(NVM_MODULE_ID index, uint32_t address);
```

Returns

Data value read at the memory address.

Description

This function takes the address parameter in the argument and loads the read address to the appropriate register. The read operation provides data from the given address.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsWriteOperation in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t    DataToBeRead;
```

```
DataToBeRead = PLIB_NVM_FlashRead(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	The address in the memory from which to read

Function

uint32_t PLIB_NVM_FlashRead(NVM_MODULE_ID index, uint32_t address)

PLIB_NVM_FlashWriteKeySequence Function

Copies the mandatory KEY sequence into the respective registers.

File

plib_nvm.h

C

```
void PLIB_NVM_FlashWriteKeySequence(NVM_MODULE_ID index, uint32_t keysequence);
```

Returns

None.

Description

This function copies the mandatory KEY sequence into the respective registers.

Remarks

Without the KEY sequence write or erase operation will not be executed.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsKeySequence in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_FlashWriteKeySequence(MY_NVM_INSTANCE, keysequence);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
keysequence	Mandatory KEY sequence depending on the controller type

Function

void PLIB_NVM_FlashWriteKeySequence(NVM_MODULE_ID index, uint32_t keysequence)

PLIB_NVM_FlashWriteStart Function

Performs a write operation on the Flash memory row selected.

File

plib_nvm.h

C

```
void PLIB_NVM_FlashWriteStart(NVM_MODULE_ID index);
```

Returns

None.

Description

This function performs a write operation on the Flash memory row selected.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsWriteOperation in your application to determine whether this feature is available.

Preconditions

- The Address of the page to be written must be provided using PLIB_NVM_FlashAddressToModify
- Erase Operation should be selected using PLIB_NVM_MemoryOperationSelect
- The module should be configured to access Flash memory using PLIB_NVM_MemoryModifyEnable
- The unlock key sequence should be provided using PLIB_NVM_FlashWriteKeySequence

Example

```
PLIB_NVM_FlashWriteStart(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_FlashWriteStart(NVM_MODULE_ID index)

PLIB_NVM_FlashWriteCycleHasCompleted Function

Provides the status of the Flash write cycle.

File

plib_nvm.h

C

```
bool PLIB_NVM_FlashWriteCycleHasCompleted(NVM_MODULE_ID index);
```

Returns

- 0 - Write or erase cycle is incomplete
- 1 - Write or erase cycle has completed

Description

This function provides the status of the Flash write cycle that was initiated by a write or erase operation.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsWriteOperation in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
status = PLIB_NVM_FlashWriteCycleHasCompleted(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_FlashWriteCycleHasCompleted(NVM_MODULE_ID index)

PLIB_NVM_WriteOperationHasTerminated Function

Provides the status of the Flash write operation or sequence.

File

plib_nvm.h

C

```
bool PLIB_NVM_WriteOperationHasTerminated(NVM_MODULE_ID index);
```

Returns

- 1 - Write operation prematurely terminated
- 0 - Write operation completed

Description

This function provides the status of the Flash write operation or sequence that was initiated by a write or erase operation.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsWriteErrorStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
status = PLIB_NVM_WriteOperationHasTerminated(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_WriteOperationHasTerminated(NVM_MODULE_ID index)

c) Other Flash Memory Functions

PLIB_NVM_FlashSwapLockSelect Function

Selects the kind of Flash swap lock required.

File

plib_nvm.h

C

```
void PLIB_NVM_FlashSwapLockSelect(NVM_MODULE_ID index, NVM_FLASH_SWAP_LOCK_TYPE lockType);
```

Returns

None.

Description

This function allows user to select which swap bits will be writable.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsSwapLockControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_FlashSwapLockSelect(MY_NVM_INSTANCE, NVM_FLASH_SWAP_UNLOCKED);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
lockType	One of the value from NVM_FLASH_SWAP_LOCK_TYPE enum to identify which swap bit will be locked

Function

void PLIB_NVM_FlashSwapLockSelect
(
NVM_MODULE_ID index,
NVM_FLASH_SWAP_LOCK_TYPE lockType
)

PLIB_NVM_FlashSwapLockStatusGet Function

Get the status of Swap lock bits.

File

plib_nvm.h

C

```
NVM_FLASH_SWAP_LOCK_TYPE PLIB_NVM_FlashSwapLockStatusGet(NVM_MODULE_ID index);
```

Returns

- NVM_FLASH_SWAP_LOCK_TYPE - The lock status of Flash swap bits.

Description

This function allows user to get the status of swap lock bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsSwapLockControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
NVM_FLASH_SWAP_LOCK_TYPE lockStatus;
lockStatus = PLIB_NVM_FlashSwapLockStatusGet(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured.

Function

NVM_FLASH_SWAP_LOCK_TYPE PLIB_NVM_FlashSwapLockStatusGet
(
NVM_MODULE_ID index
)

PLIB_NVM_FlashWriteProtectMemoryAreaRange Function

Sets the address below which physical memory will be write protected.

File

plib_nvm.h

C

```
void PLIB_NVM_FlashWriteProtectMemoryAreaRange(NVM_MODULE_ID index, uint32_t address);
```

Returns

None.

Description

This function sets the address below which physical memory will be protected. Physical memory below address 0x1Dxxxxxx is write protected, where 'xxxxxx' is specified by "address" parameter. When "address" has a value of '0', write protection is disabled for the entire program Flash. If the specified address falls within the page, the entire page and all pages below the current page will be protected.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsFlashWPMemoryRangeProvide in your application to determine whether this feature is available.

Preconditions

The unlock key sequence should be provided using PLIB_NVM_FlashWriteKeySequence.

Example

```
PLIB_NVM_FlashWriteProtectMemoryAreaRange(MY_NVM_INSTANCE, WRITE_PROTECT_PAGE_ADDRESS);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	Flash program write-protect (Page) address

Function

void PLIB_NVM_FlashWriteProtectMemoryAreaRange(NVM_MODULE_ID index, uint32_t address);

PLIB_NVM_BootPageWriteProtectionDisable Function

Write protection for selected boot page is disabled.

File

plib_nvm.h

C

```
void PLIB_NVM_BootPageWriteProtectionDisable(NVM_MODULE_ID index, NVM_BOOT_MEMORY_PAGE bootPage);
```

Returns

None.

Description

This function disables Write protection for selected boot page.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsBootPageWriteProtect in your application to determine whether this feature is available.

Preconditions

Unlock key sequence should be provided using API PLIB_NVM_FlashWriteKeySequence.

Example

```
PLIB_NVM_BootPageWriteProtectionDisable(MY_NVM_INSTANCE, LOWER_BOOT_ALIAS_PAGE4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
bootPage	Selects the boot page for which write protection has to be disabled

Function

void PLIB_NVM_BootPageWriteProtectionDisable(NVM_MODULE_ID index, NVM_BOOT_MEMORY_PAGE bootPage);

PLIB_NVM_BootPageWriteProtectionEnable Function

Locks the selected boot page.

File

plib_nvm.h

C

```
void PLIB_NVM_BootPageWriteProtectionEnable(NVM_MODULE_ID index, NVM_BOOT_MEMORY_PAGE bootPage);
```

Returns

None.

Description

This function locks the selected boot page.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsBootPageWriteProtect in your application to determine whether this feature is available.

Preconditions

Unlock key sequence should be provided using API PLIB_NVM_FlashWriteKeySequence.

Example

```
PLIB_NVM_BootPageWriteProtectionEnable(MY_NVM_INSTANCE, LOWER_BOOT_ALIAS_PAGE4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
bootPage	Selects the boot page which has to be locked

Function

void PLIB_NVM_BootPageWriteProtectionEnable(NVM_MODULE_ID index, NVM_BOOT_MEMORY_PAGE bootPage);

PLIB_NVM_IsBootMemoryLocked Function

Provides lock status of boot page write-protect bits.

File

plib_nvm.h

C

```
bool PLIB_NVM_IsBootMemoryLocked(NVM_MODULE_ID index, NVM_BOOT_MEMORY_AREA memoryArea);
```

Returns

- 1 - Selected boot alias write-protect bits are locked
- 0 - Selected boot alias write-protect bits are not locked

Description

This function provides lock status of boot page write-protect bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsLockBootSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
status = PLIB_NVM_IsBootMemoryLocked(MY_NVM_INSTANCE, LOWER_BOOT_ALIAS_AREA);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
memoryArea	Selects between the Lower or Upper Boot Alias area

Function

bool PLIB_NVM_IsBootMemoryLocked(NVM_MODULE_ID index, NVM_BOOT_MEMORY_AREA memoryArea);

PLIB_NVM_IsBootPageWriteProtected Function

Provides write protection status for boot memory page.

File

plib_nvm.h

C

```
bool PLIB_NVM_IsBootPageWriteProtected(NVM_MODULE_ID index, NVM_BOOT_MEMORY_PAGE bootPage);
```

Returns

- 1 - Selected boot region is write protected
- 0 - Selected boot region is not write protected

Description

This function provides write protection status for selected boot memory page.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsBootPageWriteProtect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
status = PLIB_NVM_IsBootPageWriteProtected(MY_NVM_INSTANCE, LOWER_BOOT_ALIAS_PAGE4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
bootPage	Selects the boot page region

Function

bool PLIB_NVM_IsBootPageWriteProtected(NVM_MODULE_ID index, NVM_BOOT_MEMORY_PAGE bootPage);

PLIB_NVM_IsProgramFlashMemoryLocked Function

Provides lock status of Program Flash Write-Protect register.

File

plib_nvm.h

C

```
bool PLIB_NVM_IsProgramFlashMemoryLocked(NVM_MODULE_ID index);
```

Returns

- 1 - Program Flash write-protect register is locked
- 0 - Program Flash write-protect register is not locked

Description

This function provides lock status of Program Flash Write-Protect (NVMPWP) register.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsLockPFMSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
    status = PLIB_NVM_IsProgramFlashMemoryLocked(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_IsProgramFlashMemoryLocked(NVM_MODULE_ID index);

PLIB_NVM_LockBootMemory Function

Locks the boot write-protect bits.

File

plib_nvm.h

C

```
void PLIB_NVM_LockBootMemory(NVM_MODULE_ID index, NVM_BOOT_MEMORY_AREA memoryArea);
```

Returns

None.

Description

This function locks the given (lower or upper alias) boot write-protect bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsLockBootSelect in your application to determine whether this feature is available.

Preconditions

The unlock key sequence should be provided using PLIB_NVM_FlashWriteKeySequence.

Example

```
PLIB_NVM_LockBootMemory(MY_NVM_INSTANCE, LOWER_BOOT_ALIAS_AREA);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
memoryArea	Selects between Lower or Upper Boot Alias area

Function

void PLIB_NVM_LockBootMemory(NVM_MODULE_ID index, NVM_BOOT_MEMORY_AREA memoryArea);

PLIB_NVM_LockProgramFlashMemory Function

Lock the Program Flash write-protect register.

File

plib_nvm.h

C

```
void PLIB_NVM_LockProgramFlashMemory(NVM_MODULE_ID index);
```

Returns

None.

Description

This function locks the Program Flash Write-Protect register (NVMPWP).

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsLockPFMSelect in your application to determine whether this feature is available.

Preconditions

Unlock key sequence should be provided using API PLIB_NVM_FlashWriteKeySequence.

Example

```
PLIB_NVM_LockProgramFlashMemory(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_LockProgramFlashMemory(NVM_MODULE_ID index);

PLIB_NVM_ProgramFlashBank1LowerRegion Function

Maps Flash Bank 1 to the lower mapped region.

File

plib_nvm.h

C

```
void PLIB_NVM_ProgramFlashBank1LowerRegion(NVM_MODULE_ID index);
```

Returns

None.

Description

This function maps Program Flash Bank 1 to the lower mapped region and programs Flash Bank 2 to the upper mapped region.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsFlashBankRegionSelect in your application to determine whether this feature is available.

Preconditions

The WREN bit in the NVMCON register should be set to '0' using PLIB_NVM_MemoryModifyInhibit before swapping the memory regions.

Example

```
PLIB_NVM_ProgramFlashBank1LowerRegion(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_ProgramFlashBank1LowerRegion(NVM_MODULE_ID index);

PLIB_NVM_ProgramFlashBank2LowerRegion Function

Maps the bank 2 to lower mapped region.

File

plib_nvm.h

C

```
void PLIB_NVM_ProgramFlashBank2LowerRegion(NVM_MODULE_ID index);
```

Returns

None.

Description

This function maps Program Flash Bank 2 to the lower mapped region and Program Flash Bank 1 to the upper mapped region.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsFlashBankRegionSelect in your application to determine whether this feature is available.

Preconditions

The WREN bit in the NVMCON register should be set to '0' using PLIB_NVM_MemoryModifyInhibit before swapping the memory regions.

Example

```
PLIB_NVM_ProgramFlashBank2LowerRegion(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_ProgramFlashBank2LowerRegion(NVM_MODULE_ID index);

PLIB_NVM_ProgramFlashBank2IsLowerRegion Function

Gives the status of Program Flash Bank mapping.

File

plib_nvm.h

C

```
bool PLIB_NVM_ProgramFlashBank2IsLowerRegion(NVM_MODULE_ID index);
```

Returns

- 1 - Program Flash Bank 2 is mapped to the lower mapped region and Program Flash Bank 1 is mapped to the upper mapped region
- 0 - Program Flash Bank 1 is mapped to the lower mapped region and Program Flash Bank 2 is mapped to the upper mapped region

Description

This function tells which Program Flash Bank is mapped to which region.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsFlashBankRegionSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(!PLIB_NVM_ProgramFlashBank2IsLowerRegion(MY_NVM_INSTANCE))
PLIB_NVM_ProgramFlashBank2LowerRegion(NVM_MODULE_ID index);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_ProgramFlashBank2IsLowerRegion(NVM_MODULE_ID index);

PLIB_NVM_BootFlashBank1LowerRegion Function

Maps Boot Flash Bank 1 to lower mapped region.

File

plib_nvm.h

C

```
void PLIB_NVM_BootFlashBank1LowerRegion(NVM_MODULE_ID index);
```

Returns

None.

Description

This function maps Boot Flash Bank 1 to the lower mapped region and Boot Flash Bank 2 to the upper mapped region.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsBootFlashBankRegion in your application to determine whether this feature is available.

Preconditions

The WREN bit in the NVMCON register should be set to '0' using PLIB_NVM_MemoryModifyInhibit before swapping the memory regions.

Example

```
PLIB_NVM_BootFlashBank1LowerRegion(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_BootFlashBank1LowerRegion(NVM_MODULE_ID index);

PLIB_NVM_BootFlashBank2IsLowerRegion Function

Gives the status of Boot Flash Bank mapping.

File

plib_nvm.h

C

```
bool PLIB_NVM_BootFlashBank2IsLowerRegion(NVM_MODULE_ID index);
```

Returns

- 1 - Boot Flash Bank 2 is mapped to the lower mapped region and Boot Flash Bank 1 is mapped to the upper mapped region
- 0 - Boot Flash Bank 1 is mapped to the lower mapped region and Boot Flash Bank 2 is mapped to the upper mapped region

Description

This function tells which Boot Flash Bank is mapped to which region.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsBootFlashBankRegion in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(!PLIB_NVM_BootFlashBank2IsLowerRegion(MY_NVM_INSTANCE))
PLIB_NVM_BootFlashBank2LowerRegion(NVM_MODULE_ID index);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_BootFlashBank2IsLowerRegion(NVM_MODULE_ID index);

PLIB_NVM_BootFlashBank2LowerRegion Function

Maps Boot Flash Bank 2 to the lower mapped region.

File

plib_nvm.h

C

```
void PLIB_NVM_BootFlashBank2LowerRegion(NVM_MODULE_ID index);
```

Returns

None.

Description

This function maps Boot Flash Bank 2 to the lower mapped region and Boot Flash Bank 1 to the upper mapped region.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsBootFlashBankRegion in your application to determine whether this feature is available.

Preconditions

The WREN bit in the NVMCON register should be set to '0' using PLIB_NVM_MemoryModifyInhibit before swapping the memory regions.

Example

```
PLIB_NVM_BootFlashBank2LowerRegion(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_BootFlashBank2LowerRegion(NVM_MODULE_ID index);

d) EEPROM Configuration and Status Functions

PLIB_NVM_EEPROMEnable Function

Enables the EEPROM memory.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMEnable(NVM_MODULE_ID index);
```

Returns

None.

Description

This function enables the EEPROM memory for access.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_EEPROMEnable(MY_NVM_INSTANCE);
if(PLIB_NVM_EEPROMIsReady(MY_NVM_INSTANCE))
    {
        //Perform operation
    }
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMEnable(NVM_MODULE_ID index)

PLIB_NVM_EEPROMDisable Function

Disables the EEPROM memory.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMDisable(NVM_MODULE_ID index);
```

Returns

None.

Description

This function disables EEPROM memory access.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMEnableControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation.

Example

```
if(PLIB_NVM_EEPROMOperationHasCompleted)
    {
        PLIB_NVM_EEPROMDisable(MY_NVM_INSTANCE);
    }
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMDisable(NVM_MODULE_ID index)

PLIB_NVM_EEPROMIsReady Function

Provides the availability status of the EEPROM.

File

plib_nvm.h

C

```
bool PLIB_NVM_EEPROMIsReady(NVM_MODULE_ID index);
```

Returns

- true - EEPROM is ready to use
- false - EEPROM is not yet ready to use

Description

This function provides the ready status of the EEPROM which was initiated by PLIB_NVM_EEPROMEnable.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_EEPROMEnable(MY_NVM_INSTANCE);
if(PLIB_NVM_EEPROMIsReady(MY_NVM_INSTANCE))
    {
        //Perform operation
    }
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_EEPROMIsReady(NVM_MODULE_ID index)

PLIB_NVM_EEPROMStopInIdleEnable Function

Discontinues EEPROM operation when device enters Idle mode.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMStopInIdleEnable(NVM_MODULE_ID index);
```

Returns

None.

Description

This function discontinues EEPROM operation when device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMStopInIdleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_EEPROMStopInIdleEnable(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMStopInIdleEnable(NVM_MODULE_ID index)

PLIB_NVM_EEPROMStopInIdleDisable Function

Continues EEPROM operation when device enters Idle mode.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMStopInIdleDisable(NVM_MODULE_ID index);
```

Returns

None.

Description

This function continues EEPROM operation when device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMStopInIdleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_EEPROMStopInIdleDisable(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMStopInIdleDisable(NVM_MODULE_ID index)

PLIB_NVM_EEPROMStopInIdleIsEnabled Function

Returns Stop in Idle mode status of the EEPROM operation.

File

plib_nvm.h

C

```
bool PLIB_NVM_EEPROMStopInIdleIsEnabled(NVM_MODULE_ID index);
```

Returns

- true - EEPROM discontinues operation when the device enters Idle mode
- false - EEPROM continues operation when the device enters Idle mode

Description

This function returns whether the EEPROM continues or discontinues operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMStopInIdleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool sidl_status;
sidl_status = PLIB_NVM_EEPROMStopInIdleIsEnabled(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_EEPROMStopInIdleIsEnabled(NVM_MODULE_ID index)

PLIB_NVM_EEPROMOperationSelect Function

Selects the operation to be performed on the EEPROM.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMOperationSelect(NVM_MODULE_ID index, EEPROM_OPERATION_MODE mode);
```

Returns

None.

Description

This function selects the operation to be performed on the EEPROM from the set of operations available from the enum EEPROM_OPERATION_MODE.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMOperationModeControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation.

Example

```
PLIB_NVM_EEPROMOperationSelect(MY_NVM_INSTANCE, EEPROM_WORD_READ_OPERATION);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMOperationSelect(NVM_MODULE_ID index , EEPROM_OPERATION_MODE mode)

PLIB_NVM_EEPROMWriteEnable Function

Allows write or erase operation to the EEPROM.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMWriteEnable(NVM_MODULE_ID index);
```

Returns

None.

Description

This function enables write or erase operations on the EEPROM and inhibits read.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMEnableOperationControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation.

Example

```
PLIB_NVM_EEPROMWriteEnable(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMWriteEnable(NVM_MODULE_ID index)

PLIB_NVM_EEPROMReadEnable Function

Allows read operation to the EEPROM.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMReadEnable(NVM_MODULE_ID index);
```

Returns

None.

Description

This function enables read operations on the EEPROM and inhibits write or erase.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMEnableOperationControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation.

Example

```
PLIB_NVM_EEPROMReadEnable(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMReadEnable(NVM_MODULE_ID index)

PLIB_NVM_EEPROMWriteIsEnabled Function

Returns EEPROM Write permission status.

File

plib_nvm.h

C

```
bool PLIB_NVM_EEPROMWriteIsEnabled(NVM_MODULE_ID index);
```

Returns

- true - EEPROM write or erase is enabled
- false - EEPROM write or erase is not enabled

Description

This function returns whether or not the EEPROM write or erase.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMEnableOperationControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation.

Example

```
if(PLIB_NVM_EEPROMWriteIsEnabled(MY_NVM_INSTANCE))
{
    //perform write or erase
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_EEPROMWriteIsEnabled(NVM_MODULE_ID index)

PLIB_NVM_EEPROMReadIsEnabled Function

Returns EEPROM read permission status.

File

plib_nvm.h

C

```
bool PLIB_NVM_EEPROMReadIsEnabled(NVM_MODULE_ID index);
```

Returns

- true - EEPROM read is enabled.
- false - EEPROM read is not enabled.

Description

This function returns whether or not the EEPROM read is enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMEnableOperationControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation.

Example

```
if(PLIB_NVM_EEPROMReadIsEnabled(MY_NVM_INSTANCE))
{
    //perform read
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_EEPROMReadIsEnabled(NVM_MODULE_ID index)

PLIB_NVM_EEPROMNextWriteCycleIsLong Function

Informs whether the next write or erase cycle of the EEPROM is long.

File

plib_nvm.h

C

```
bool PLIB_NVM_EEPROMNextWriteCycleIsLong(NVM_MODULE_ID index);
```

Returns

false - Next write/Erase cycle will not take more time to complete. true - Next write/Erase cycle will take more time to complete.

Description

This function informs whether the next write or erase cycle of the EEPROM is long (i.e., the next write or erase to the EEPROM address (passed by PLIB_NVM_EEPROMAddress) will require more time (~20 ms) than usual).

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMLongWriteStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_NVM_EEPROMNextWriteCycleIsLong( MY_NVM_INSTANCE ))
{
    //stays here for ~20ms, better skip to other task for this time.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_EEPROMNextWriteCycleIsLong(NVM_MODULE_ID index)

PLIB_NVM_EEPROMErrorGet Function

Returns the EEPROM operation error.

File

plib_nvm.h

C

```
EEPROM_ERROR PLIB_NVM_EEPROMErrorGet(NVM_MODULE_ID index);
```

Returns

EEPROM_ERROR.

Description

This function returns the EEPROM operation error.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMErrorStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
EEPROM_ERROR error;
error = PLIB_NVM_EEPROMErrorGet(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

EEPROM_ERROR PLIB_NVM_EEPROMErrorGet(NVM_MODULE_ID index)

PLIB_NVM_EEPROMErrorClear Function

Clears the EEPROM operation error.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMErrorClear(NVM_MODULE_ID index);
```

Returns

None.

Description

This function clears the EEPROM operation error.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMErrorStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_EEPROMErrorClear(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMErrorClear(NVM_MODULE_ID index)

e) EEPROM Operation Functions

PLIB_NVM_EEPROMAddress Function

EEPROM address where operation has to be performed.

File

plib_nvm.h

C

```
bool PLIB_NVM_EEPROMAddress(NVM_MODULE_ID index, uint32_t address);
```

Returns

- true - EEPROM address is valid
- false - EEPROM address is invalid, please check if it is in the EEPROM address boundary and last two bits are '00'

Description

This function accepts the EEPROM address upon which to operate. Lower two bits of the address must always be '00'; otherwise, an error will occur when operation is started on EEPROM.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMAddressControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation.

Example

```
uint32_t  address = MY_EEPROM_ADDRESS;
// Load address and check if it is valid
if(true ==PLIB_NVM_EEPROMAddress( NVM_ID_0 , address ))
{
    //Perform operation
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	The address of the EEPROM from or to which data will be read or written. This address should be a physical address.

Function

bool PLIB_NVM_EEPROMAddress(NVM_MODULE_ID index, uint32_t address)

PLIB_NVM_EEPROMDataToWrite Function

Accepts the data to be written into the EEPROM.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMDataToWrite(NVM_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

This function accepts data to be written into the EEPROM.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMDataControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation.

Example

```
PLIB_NVM_EEPROMDataToWrite(MY_NVM_INSTANCE, DATA);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Data to be written

Function

void PLIB_NVM_EEPROMDataToWrite (NVM_MODULE_ID index , uint32_t data)

PLIB_NVM_EEPROMKeySequenceWrite Function

Write mandatory KEY sequence to unlock the EEPROM write or erase protection.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMKeySequenceWrite(NVM_MODULE_ID index, uint32_t keysequence);
```

Returns

None.

Description

Without the KEY sequence write or erase operation will not be executed. Writing the KEY 0xEDB7 followed by writing the another KEY 0x1248 will unlock the EEPROM control register for write or erase operations. Writing any other value will lock the EEPROM control register. The unlock sequence is not necessary for a read operation.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMKeySequence in your application to determine whether this feature is available.

Preconditions

Interrupts should be disabled when writing the unlock sequence to the EEKEY register to prevent a disruption of the unlock sequence.

Example

```
//EEPROM is locked.
uint32_t key1 = 0xEDB7;
uint32_t key2 = 0x1248;
PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key1);
PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key2);
//EEPROM is now unlocked.
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
keysequence	Mandatory KEY sequence depending on the controller type

Function

void PLIB_NVM_EEPROMKeySequenceWrite (NVM_MODULE_ID index , uint32_t keysequence)

PLIB_NVM_EEPROMEraseStart Function

Initiates EEPROM erase cycle.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMEraseStart(NVM_MODULE_ID index);
```

Returns

None.

Description

This function initiates the EEPROM erase cycle.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMStartOperationControl in your application to determine whether this feature is available.

Preconditions

PLIB_NVM_EEPROMWriteEnable should be called.

Example

```
// Enable write or erase operation
PLIB_NVM_EEPROMWriteEnable( NVM_ID_0 );
// unlock
PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key1);
PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key2);
// Start the erase operation
PLIB_NVM_EEPROMEraseStart( NVM_MODULE_ID index );
// Wait until erase is complete
while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMEraseStart(NVM_MODULE_ID index)

PLIB_NVM_EEPROMWriteStart Function

Initiates a EEPROM write cycle.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMWriteStart(NVM_MODULE_ID index);
```

Returns

None.

Description

This function initiates the EEPROM write cycle.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMStartOperationControl in your application to determine whether this feature is available.

Preconditions

EEPROM write should be enabled through PLIB_NVM_EEPROMWriteEnable.

Example

```
// Enable write operation
PLIB_NVM_EEPROMWriteEnable( NVM_ID_0 );
// Provide data
PLIB_NVM_EEPROMDataToWrite ( NVM_ID_0 , ee_data ) ;
// unlock
PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key1);
PLIB_NVM_EEPROMKeySequenceWrite(MY_NVM_INSTANCE, key2);
// Start the write operation
PLIB_NVM_EEPROMWriteStart( NVM_MODULE_ID index );
// Wait until write is complete
while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMWriteStart(NVM_MODULE_ID index)

PLIB_NVM_EEPROMReadStart Function

Initiates a EEPROM read cycle.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMReadStart(NVM_MODULE_ID index);
```

Returns

None.

Description

This function initiates the EEPROM read cycle.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMStartOperationControl in your application to determine whether this feature is available.

Preconditions

EEPROM read should be enabled through PLIB_NVM_EEPROMReadEnable.

Example

```
// Enable read operation
PLIB_NVM_EEPROMReadEnable( NVM_ID_0 );
// Start the read cycle
PLIB_NVM_EEPROMReadStart( NVM_MODULE_ID index );
// Wait until read is complete
while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
// Read the data
ee_data = PLIB_NVM_EEPROMRead( NVM_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMReadStart(NVM_MODULE_ID index)

PLIB_NVM_EEPROMOperationHasCompleted Function

Provides the status of the EEPROM write or erase or read cycle.

File

plib_nvm.h

C

```
bool PLIB_NVM_EEPROMOperationHasCompleted(NVM_MODULE_ID index);
```

Returns

- true - Write or erase cycle has completed
- false - Write or erase cycle has not completed

Description

This function provides the status of the EEPROM write or erase or read operation status.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMStartOperationControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Start the erase operation
PLIB_NVM_EEPROMEraseStart( NVM_MODULE_ID index );
// Wait until erase is complete
while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_NVM_EEPROMOperationHasCompleted(NVM_MODULE_ID index)

PLIB_NVM_EEPROMRead Function

Read the EEPROM data.

File

plib_nvm.h

C

```
uint32_t PLIB_NVM_EEPROMRead(NVM_MODULE_ID index);
```

Returns

32-bit EEPROM data.

Description

This function returns the EERPOM data that is been fetched by performing the EEPROM read operation sequence.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMDataControl in your application to determine whether this feature is available.

Preconditions

This API will have no affect if there is any ongoing EEPROM operation, or may return junk data.

Example

```
uint32_t EEPROM_Data;
// Start the read operation
PLIB_NVM_EEPROMReadStart( NVM_MODULE_ID index );
// Wait until read is complete
while (PLIB_NVM_EEPROMOperationHasCompleted( NVM_ID_0 ));
// Now read the data
EEPROM_Data = PLIB_NVM_EEPROMRead( NVM_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_NVM_EEPROMRead(NVM_MODULE_ID index)

PLIB_NVM_EEPROMOperationAbort Function

Aborts the current EEPROM operation.

File

plib_nvm.h

C

```
void PLIB_NVM_EEPROMOperationAbort(NVM_MODULE_ID index);
```

Returns

None.

Description

This function aborts the on-going write or erase operation as soon as possible.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_NVM_ExistsEEPROMOperationAbortControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_NVM_EEPROMOperationAbort(MY_NVM_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_NVM_EEPROMOperationAbort(NVM_MODULE_ID index)

f) Feature Existence Functions

PLIB_NVM_ExistsAddressModifyControl Function

Identifies whether the AddressModifyControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsAddressModifyControl(NVM_MODULE_ID index);
```

Returns

- true - The AddressModifyControl feature is supported on the device
- false - The AddressModifyControl feature is not supported on the device

Description

This function identifies whether the AddressModifyControl feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_FlashAddressToModify

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsAddressModifyControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsBootPageWriteProtect Function

Identifies whether the BootPageWriteProtect feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsBootPageWriteProtect(NVM_MODULE_ID index);
```

Returns

- true - The BootPageWriteProtect feature is supported on the device
- false - The BootPageWriteProtect feature is not supported on the device

Description

This function identifies whether the BootPageWriteProtect feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_BootPageWriteProtectionEnable
- PLIB_NVM_BootPageWriteProtectionDisable
- PLIB_NVM_IsBootPageWriteProtected

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsBootPageWriteProtect(NVM_MODULE_ID index)

PLIB_NVM_ExistsFlashBankRegionSelect Function

Identifies whether the FlashBankRegionSelect feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsFlashBankRegionSelect(NVM_MODULE_ID index);
```

Returns

- true - The FlashBankRegionSelect feature is supported on the device
- false - The FlashBankRegionSelect feature is not supported on the device

Description

This function identifies whether the FlashBankRegionSelect feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_ProgramFlashBank1LowerRegion
- PLIB_NVM_ProgramFlashBank2LowerRegion

- PLIB_NVM_ProgramFlashBank2IsLowerRegion

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsFlashBankRegionSelect(NVM_MODULE_ID index)

PLIB_NVM_ExistsFlashWPMemoryRangeProvide Function

Identifies whether the FlashWPMemoryRangeProvide feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsFlashWPMemoryRangeProvide(NVM_MODULE_ID index);
```

Returns

- true - The FlashWPMemoryRangeProvide feature is supported on the device
- false - The FlashWPMemoryRangeProvide feature is not supported on the device

Description

This function identifies whether the FlashWPMemoryRangeProvide feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_FlashWriteProtectMemoryAreaRange

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsFlashWPMemoryRangeProvide(NVM_MODULE_ID index)

PLIB_NVM_ExistsKeySequence Function

Identifies whether the KeySequence feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsKeySequence(NVM_MODULE_ID index);
```

Returns

- true - The KeySequence feature is supported on the device
- false - The KeySequence feature is not supported on the device

Description

This function identifies whether the KeySequence feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_FlashWriteKeySequence

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsKeySequence(NVM_MODULE_ID index)

PLIB_NVM_ExistsLockBootSelect Function

Identifies whether the LockBootSelect feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsLockBootSelect(NVM_MODULE_ID index);
```

Returns

- true - The LockBootSelect feature is supported on the device
- false - The LockBootSelect feature is not supported on the device

Description

This function identifies whether the LockBootSelect feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_LockBootMemory
- PLIB_NVM_IsBootMemoryLocked

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsLockBootSelect(NVM_MODULE_ID index)

PLIB_NVM_ExistsLockPFMSelect Function

Identifies whether the LockPFMSelect feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsLockPFMSelect(NVM_MODULE_ID index);
```

Returns

- true - The LockPFMSelect feature is supported on the device
- false - The LockPFMSelect feature is not supported on the device

Description

This function identifies whether the LockPFMSelect feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_LockProgramFlashMemory
- PLIB_NVM_IsProgramFlashMemoryLocked

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsLockPFMSelect(NVM_MODULE_ID index)

PLIB_NVM_ExistsLowVoltageError Function

Identifies whether the LowVoltageError feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsLowVoltageError(NVM_MODULE_ID index);
```

Returns

- true - The LowVoltageStatus feature is supported on the device
- false - The LowVoltageStatus feature is not supported on the device

Description

This function identifies whether the LowVoltageStatus feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_LowVoltageIsDetected

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsLowVoltageError(NVM_MODULE_ID index)

PLIB_NVM_ExistsLowVoltageStatus Function

Identifies whether the LowVoltageStatus feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsLowVoltageStatus(NVM_MODULE_ID index);
```

Returns

- true - The LowVoltageStatus feature is supported on the device
- false - The LowVoltageStatus feature is not supported on the device

Description

This function identifies whether the LowVoltageStatus feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_LowVoltageEventIsActive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsLowVoltageStatus(NVM_MODULE_ID index)

PLIB_NVM_ExistsMemoryModificationControl Function

Identifies whether the MemoryModificationControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsMemoryModificationControl(NVM_MODULE_ID index);
```

Returns

- true - The MemoryModificationControl feature is supported on the device
- false - The MemoryModificationControl feature is not supported on the device

Description

This function identifies whether the MemoryModificationControl feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_MemoryModifyEnable
- PLIB_NVM_MemoryModifyInhibit

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsMemoryModificationControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsOperationMode Function

Identifies whether the OperationMode feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsOperationMode(NVM_MODULE_ID index);
```

Returns

- true - The OperationMode feature is supported on the device
- false - The OperationMode feature is not supported on the device

Description

This function identifies whether the OperationMode feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_MemoryOperationSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsOperationMode(NVM_MODULE_ID index)

PLIB_NVM_ExistsProvideData Function

Identifies whether the ProvideData feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsProvideData(NVM_MODULE_ID index);
```

Returns

- true - The ProvideData feature is supported on the device
- false - The ProvideData feature is not supported on the device

Description

This function identifies whether the ProvideData feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_FlashProvideData

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsProvideData(NVM_MODULE_ID index)

PLIB_NVM_ExistsProvideQuadData Function

Identifies whether the ProvideQuadData feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsProvideQuadData(NVM_MODULE_ID index);
```

Returns

- true - The ProvideQuadData feature is supported on the device
- false - The ProvideQuadData feature is not supported on the device

Description

This function identifies whether the ProvideQuadData feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_FlashProvideQuadData

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsProvideQuadData(NVM_MODULE_ID index)

PLIB_NVM_ExistsSourceAddress Function

Identifies whether the SourceAddress feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsSourceAddress(NVM_MODULE_ID index);
```

Returns

- true - The SourceAddress feature is supported on the device
- false - The SourceAddress feature is not supported on the device

Description

This function identifies whether the SourceAddress feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_DataBlockSourceAddress

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsSourceAddress(NVM_MODULE_ID index)

PLIB_NVM_ExistsWriteErrorStatus Function

Identifies whether the WriteErrorStatus feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsWriteErrorStatus(NVM_MODULE_ID index);
```

Returns

- true - The WriteErrorStatus feature is supported on the device
- false - The WriteErrorStatus feature is not supported on the device

Description

This function identifies whether the WriteErrorStatus feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_WriteOperationHasTerminated

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsWriteErrorStatus(NVM_MODULE_ID index)

PLIB_NVM_ExistsWriteOperation Function

Identifies whether the WriteOperation feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsWriteOperation(NVM_MODULE_ID index);
```

Returns

- true - The WriteOperation feature is supported on the device
- false - The WriteOperation feature is not supported on the device

Description

This function identifies whether the WriteOperation feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_FlashRead
- PLIB_NVM_FlashWriteStart
- PLIB_NVM_FlashEraseStart
- PLIB_NVM_FlashWriteCycleHasCompleted

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsWriteOperation(NVM_MODULE_ID index)

PLIB_NVM_ExistsBootFlashBankRegion Function

Identifies whether the BootFlashBankRegion feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsBootFlashBankRegion(NVM_MODULE_ID index);
```

Returns

- true - The BootFlashBankRegion feature is supported on the device
- false - The BootFlashBankRegion feature is not supported on the device

Description

This function identifies whether the BootFlashBankRegion feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_BootFlashBank1LowerRegion
- PLIB_NVM_BootFlashBank2LowerRegion
- PLIB_NVM_BootFlashBank2IsLowerRegion

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsBootFlashBankRegion(NVM_MODULE_ID index)

PLIB_NVM_ExistsSwapLockControl Function

Identifies whether the SwapLockControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsSwapLockControl(NVM_MODULE_ID index);
```

Returns

- true - The SwapLockControl feature is supported on the device
- false - The SwapLockControl feature is not supported on the device

Description

This function identifies whether the SwapLockControl feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_FlashSwapLockSelect
- PLIB_NVM_FlashSwapLockStatusGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsSwapLockControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMAddressControl Function

Identifies whether the EEPROMAddressControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMAddressControl(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMAddressControl feature is supported on the device
- false - The EEPROMAddressControl feature is not supported on the device

Description

This function identifies whether the EEPROMAddressControl feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_EEPROMAddress

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMAddressControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMDataControl Function

Identifies whether the EEPROMDataControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMDataControl(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMDataControl feature is supported on the device
- false - The EEPROMDataControl feature is not supported on the device

Description

This function identifies whether the EEPROMDataControl feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_EEPROMDataToWrite
- PLIB_NVM_EEPROMRead

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMDataControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMEnableControl Function

Identifies whether the EEPROMEnableControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMEnableControl(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMEnableControl feature is supported on the device
- false - The EEPROMEnableControl feature is not supported on the device

Description

This function identifies whether the EEPROMEnableControl feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_EEPROMEnable
- PLIB_NVM_EEPROMDisable
- PLIB_NVM_EEPROMIsReady

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMEnableControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMEnableOperationControl Function

Identifies whether the EEPROMEnableOperationControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMEnableOperationControl(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMEnableOperationControl feature is supported on the device
- false - The EEPROMEnableOperationControl feature is not supported on the device

Description

This function identifies whether the EEPROMEnableOperationControl feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_EEPROMWriteEnable
- PLIB_NVM_EEPROMWriteIsEnabled
- PLIB_NVM_EEPROMReadEnable
- PLIB_NVM_EEPROMReadIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMEnableOperationControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMErrorStatus Function

Identifies whether the EEPROMErrorStatus feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMErrorStatus(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMErrorStatus feature is supported on the device
- false - The EEPROMErrorStatus feature is not supported on the device

Description

This function identifies whether the EEPROMErrorStatus feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_EEPROMErrorGet
- PLIB_NVM_EEPROMErrorClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMErrorStatus(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMKeySequence Function

Identifies whether the EEPROMKeySequence feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMKeySequence(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMKeySequence feature is supported on the device
- false - The EEPROMKeySequence feature is not supported on the device

Description

This function identifies whether the EEPROMKeySequence feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_EEPROMKeySequenceWrite

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMKeySequence(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMLongWriteStatus Function

Identifies whether the EEPROMLongWriteStatus feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMLongWriteStatus(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMLongWriteStatus feature is supported on the device
- false - The EEPROMLongWriteStatus feature is not supported on the device

Description

This function identifies whether the EEPROMLongWriteStatus feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_EEPROMNextWriteCycleIsLong

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMLongWriteStatus(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMOperationAbortControl Function

Identifies whether the EEPROMOperationAbortControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMOperationAbortControl(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMOperationAbortControl feature is supported on the device
- false - The EEPROMOperationAbortControl feature is not supported on the device

Description

This function identifies whether the EEPROMOperationAbortControl feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_EEPROMOperationAbort

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMOperationAbortControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMOperationModeControl Function

Identifies whether the EEPROMOperationModeControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMOperationModeControl(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMOperationModeControl feature is supported on the device
- false - The EEPROMOperationModeControl feature is not supported on the device

Description

This function identifies whether the EEPROMOperationModeControl feature is available on the NVM module. When this function returns true, this function is supported on the device:

- PLIB_NVM_EEPROMOperationSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMOperationModeControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMStartOperationControl Function

Identifies whether the EEPROMStartOperationControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMStartOperationControl(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMStartOperationControl feature is supported on the device
- false - The EEPROMStartOperationControl feature is not supported on the device

Description

This function identifies whether the EEPROMStartOperationControl feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_EEPROMReadStart
- PLIB_NVM_EEPROMWriteStart
- PLIB_NVM_EEPROMEraseStart
- PLIB_NVM_EEPROMOperationHasCompleted

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMStartOperationControl(NVM_MODULE_ID index)

PLIB_NVM_ExistsEEPROMStopInIdleControl Function

Identifies whether the EEPROMStopInIdleControl feature exists on the NVM module.

File

plib_nvm.h

C

```
bool PLIB_NVM_ExistsEEPROMStopInIdleControl(NVM_MODULE_ID index);
```

Returns

- true - The EEPROMStopInIdleControl feature is supported on the device
- false - The EEPROMStopInIdleControl feature is not supported on the device

Description

This function identifies whether the EEPROMStopInIdleControl feature is available on the NVM module. When this function returns true, these functions are supported on the device:

- PLIB_NVM_EEPROMStopInIdleEnable
- PLIB_NVM_EEPROMStopInIdleDisable
- PLIB_NVM_EEPROMStopInIdleIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_NVM_ExistsEEPROMStopInIdleControl(NVM_MODULE_ID index)

g) Data Types and Constants

NVM_BOOT_MEMORY_AREA Enumeration

Lists the different possible boot memory region.

File

plib_nvm_help.h

C

```
typedef enum {
  LOWER_BOOT_ALIAS_AREA,
  UPPER_BOOT_ALIAS_AREA,
  LOWER_BOOT_MEMORY_AREA_NOT_SUPPORTED
} NVM_BOOT_MEMORY_AREA;
```

Members

Members	Description
LOWER_BOOT_ALIAS_AREA	Lower boot alias region
UPPER_BOOT_ALIAS_AREA	Upper boot alias region
LOWER_BOOT_MEMORY_AREA_NOT_SUPPORTED	Lower boot alias region is not supported

Description

NVM Boot Memory Area

This enumeration lists the different possible boot memory region.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

NVM_BOOT_MEMORY_PAGE Enumeration

Lists the different NVM boot memory pages.

File

plib_nvm_help.h

C

```
typedef enum {
  LOWER_BOOT_ALIAS_PAGE4,
```

```
  LOWER_BOOT_ALIAS_PAGE3,
  LOWER_BOOT_ALIAS_PAGE2,
  LOWER_BOOT_ALIAS_PAGE1,
  LOWER_BOOT_ALIAS_PAGE0,
  UPPER_BOOT_ALIAS_PAGE4,
  UPPER_BOOT_ALIAS_PAGE3,
  UPPER_BOOT_ALIAS_PAGE2,
  UPPER_BOOT_ALIAS_PAGE1,
  UPPER_BOOT_ALIAS_PAGE0,
  LOWER_BOOT_MEMORY_PAGE_NOT_SUPPORTED
} NVM_BOOT_MEMORY_PAGE;
```

Members

Members	Description
LOWER_BOOT_ALIAS_PAGE4	Lower boot alias page 4
LOWER_BOOT_ALIAS_PAGE3	Lower boot alias page 3
LOWER_BOOT_ALIAS_PAGE2	Lower boot alias page 2
LOWER_BOOT_ALIAS_PAGE1	Lower boot alias page 1
LOWER_BOOT_ALIAS_PAGE0	Lower boot alias page 0
UPPER_BOOT_ALIAS_PAGE4	Upper boot alias page 4
UPPER_BOOT_ALIAS_PAGE3	Upper boot alias page 3
UPPER_BOOT_ALIAS_PAGE2	Upper boot alias page 2
UPPER_BOOT_ALIAS_PAGE1	Upper boot alias page 1
UPPER_BOOT_ALIAS_PAGE0	Upper boot alias page 0
LOWER_BOOT_MEMORY_PAGE_NOT_SUPPORTED	Lower boot memory page not supported

Description

NVM Boot Memory Page

This enumeration lists the different NVM boot memory page details.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

NVM_OPERATION_MODE Enumeration

Lists the different Flash operation modes.

File

plib_nvm_help.h

C

```
typedef enum {
  WORD_PROGRAM_OPERATION,
  ROW_PROGRAM_OPERATION,
  PAGE_ERASE_OPERATION,
  FLASH_ERASE_OPERATION,
  UPPER_FLASH_REGION_ERASE_OPERATION,
  LOWER_FLASH_REGION_ERASE_OPERATION,
  QUAD_WORD_PROGRAM_OPERATION,
  NO_OPERATION
} NVM_OPERATION_MODE;
```

Members

Members	Description
WORD_PROGRAM_OPERATION	Word Program Operation
ROW_PROGRAM_OPERATION	Row Program Operation
PAGE_ERASE_OPERATION	Page Erase Operation
FLASH_ERASE_OPERATION	Flash Erase Operation
UPPER_FLASH_REGION_ERASE_OPERATION	Upper Flash Region Erase Operation
LOWER_FLASH_REGION_ERASE_OPERATION	Lower Flash Region Erase Operation
QUAD_WORD_PROGRAM_OPERATION	Quad Word Program Operation
NO_OPERATION	No Operation

Description

NVM Operation Mode

This enumeration lists the different Flash operation modes.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

NVM_MODULE_ID Enumeration

Possible instances of the NVM module.

File

plib_nvm_help.h

C

```
typedef enum {
  NVM_ID_0,
  NVM_NUMBER_OF_MODULES
} NVM_MODULE_ID;
```

Members

Members	Description
NVM_ID_0	NVM Module 0 ID
NVM_NUMBER_OF_MODULES	Number of available NVM modules.

Description

NVM Module ID

This data type defines the possible instances of the NVM module.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

NVM_FLASH_SWAP_LOCK_TYPE Enumeration

Lists the possible type of Flash swap lock.

File

plib_nvm_help.h

C

```
typedef enum {
  NVM_FLASH_SWAP_UNLOCKED = 0x0,
  NVM_FLASH_SWAP_LOCKED = 0x1,
  NVM_FLASH_SWAP_LOCKED_UNTIL_RESET = 0x3
} NVM_FLASH_SWAP_LOCK_TYPE;
```

Members

Members	Description
NVM_FLASH_SWAP_UNLOCKED = 0x0	Program Flash Bank and Boot Flash Bank region swapping is Not locked
NVM_FLASH_SWAP_LOCKED = 0x1	Program Flash Bank and Boot Flash Bank region swapping is locked
NVM_FLASH_SWAP_LOCKED_UNTIL_RESET = 0x3	Program Flash Bank and Boot Flash Bank region swapping is locked until device is reset

Description

NVM Flash Swap Lock

This enumeration lists the possible type of Flash swap lock.

Remarks

This feature may not be available on all the devices. Refer to the specific device header files for availability.

EEPROM_ERROR Enumeration

Lists the different EEPROM operation errors.

File

plib_nvm_help.h

C

```
typedef enum {
  NO_ERROR,
  VERIFY_ERROR,
  INVALID_OPERATION,
  BOR_ERROR
} EEPROM_ERROR;
```

Members

Members	Description
NO_ERROR	No error has occurred
VERIFY_ERROR	Error occurred during verification
INVALID_OPERATION	Operation selected and executed are not the same
BOR_ERROR	BOR has suspended EEPROM operation

Description

EEPROM operation error

This enumeration lists the different EEPROM operation errors.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

EEPROM_OPERATION_MODE Enumeration

Lists the different EEPROM operation modes.

File

plib_nvm_help.h

C

```
typedef enum {
  EEPROM_WORD_READ_OPERATION,
  EEPROM_WORD_WRITE_OPERATION,
  EEPROM_FORCED_WORD_ERASE_OPERATION,
  EEPROM_ERASE_ALL_OPERATION,
  EEPROM_CONFIG_WRITE_OPERATION
} EEPROM_OPERATION_MODE;
```

Members

Members	Description
EEPROM_WORD_READ_OPERATION	Word read operation
EEPROM_WORD_WRITE_OPERATION	Word write operation
EEPROM_FORCED_WORD_ERASE_OPERATION	Page erase operation. Under normal conditions, there is no need to attempt a Forced Word Erase. The Data EEPROM has internal logic which automatically manages all read/erase/write command sequences. Software execution of the Forced Word Erase operation should be used in response to write verification error, VERIFY_ERROR
EEPROM_ERASE_ALL_OPERATION	Bulk erase operation. Unlike the read command, the bulk erase command cannot be aborted by software. During an erase cycle, any software attempt to write to the EECON register will be ignored
EEPROM_CONFIG_WRITE_OPERATION	Write to configuration registers operation. Before accessing the EEPROM at full speed, it is necessary to program configuration values into the Data EEPROM controller after enabling it. This is done through the Configuration Write operation

Description

EEPROM Operation Mode

This enumeration lists the different EEPROM operation modes.

Remarks

This enumeration is processor specific and is defined in the processor- specific header files.

NVM PLIB Interface Header for NVM common definitions.

Functions

	Name	Description
	PLIB_NVM_BootFlashBank1LowerRegion	Maps Boot Flash Bank 1 to lower mapped region.
	PLIB_NVM_BootFlashBank2IsLowerRegion	Gives the status of Boot Flash Bank mapping.
	PLIB_NVM_BootFlashBank2LowerRegion	Maps Boot Flash Bank 2 to the lower mapped region.
	PLIB_NVM_BootPageWriteProtectionDisable	Write protection for selected boot page is disabled.
	PLIB_NVM_BootPageWriteProtectionEnable	Locks the selected boot page.
	PLIB_NVM_DataBlockSourceAddress	Takes the address parameter in the argument and loads the base address from which data has to be copied into Flash memory.
	PLIB_NVM_EEPROMAddress	EEPROM address where operation has to be performed.
	PLIB_NVM_EEPROMDataToWrite	Accepts the data to be written into the EEPROM.
	PLIB_NVM_EEPROMDisable	Disables the EEPROM memory.
	PLIB_NVM_EEPROMEnable	Enables the EEPROM memory.
	PLIB_NVM_EEPROMEraseStart	Initiates EEPROM erase cycle.
	PLIB_NVM_EEPROMErrorClear	Clears the EEPROM operation error.
	PLIB_NVM_EEPROMErrorGet	Returns the EEPROM operation error.
	PLIB_NVM_EEPROMIsReady	Provides the availability status of the EEPROM.
	PLIB_NVM_EEPROMKeySequenceWrite	Write mandatory KEY sequence to unlock the EEPROM write or erase protection.
	PLIB_NVM_EEPROMNextWriteCycleIsLong	Informs whether the next write or erase cycle of the EEPROM is long.
	PLIB_NVM_EEPROMOperationAbort	Aborts the current EEPROM operation.
	PLIB_NVM_EEPROMOperationHasCompleted	Provides the status of the EEPROM write or erase or read cycle.
	PLIB_NVM_EEPROMOperationSelect	Selects the operation to be performed on the EEPROM.
	PLIB_NVM_EEPROMRead	Read the EEPROM data.
	PLIB_NVM_EEPROMReadEnable	Allows read operation to the EEPROM.
	PLIB_NVM_EEPROMReadIsEnabled	Returns EEPROM read permission status.
	PLIB_NVM_EEPROMReadStart	Initiates a EEPROM read cycle.
	PLIB_NVM_EEPROMStopInIdleDisable	Continues EEPROM operation when device enters Idle mode.
	PLIB_NVM_EEPROMStopInIdleEnable	Discontinues EEPROM operation when device enters Idle mode.
	PLIB_NVM_EEPROMStopInIdleIsEnabled	Returns Stop in Idle mode status of the EEPROM operation.
	PLIB_NVM_EEPROMWriteEnable	Allows write or erase operation to the EEPROM.
	PLIB_NVM_EEPROMWriteIsEnabled	Returns EEPROM Write permission status.
	PLIB_NVM_EEPROMWriteStart	Initiates a EEPROM write cycle.
	PLIB_NVM_ExistsAddressModifyControl	Identifies whether the AddressModifyControl feature exists on the NVM module.
	PLIB_NVM_ExistsBootFlashBankRegion	Identifies whether the BootFlashBankRegion feature exists on the NVM module.

	PLIB_NVM_ExistsBootPageWriteProtect	Identifies whether the BootPageWriteProtect feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMAddressControl	Identifies whether the EEPROMAddressControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMDataControl	Identifies whether the EEPROMDataControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMEnableControl	Identifies whether the EEPROMEnableControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMEnableOperationControl	Identifies whether the EEPROMEnableOperationControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMErrorStatus	Identifies whether the EEPROMErrorStatus feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMKeySequence	Identifies whether the EEPROMKeySequence feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMLongWriteStatus	Identifies whether the EEPROMLongWriteStatus feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMOperationAbortControl	Identifies whether the EEPROMOperationAbortControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMOperationModeControl	Identifies whether the EEPROMOperationModeControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMStartOperationControl	Identifies whether the EEPROMStartOperationControl feature exists on the NVM module.
	PLIB_NVM_ExistsEEPROMStopInIdleControl	Identifies whether the EEPROMStopInIdleControl feature exists on the NVM module.
	PLIB_NVM_ExistsFlashBankRegionSelect	Identifies whether the FlashBankRegionSelect feature exists on the NVM module.
	PLIB_NVM_ExistsFlashWPMemoryRangeProvide	Identifies whether the FlashWPMemoryRangeProvide feature exists on the NVM module.
	PLIB_NVM_ExistsKeySequence	Identifies whether the KeySequence feature exists on the NVM module.
	PLIB_NVM_ExistsLockBootSelect	Identifies whether the LockBootSelect feature exists on the NVM module.
	PLIB_NVM_ExistsLockPFMSelect	Identifies whether the LockPFMSelect feature exists on the NVM module.
	PLIB_NVM_ExistsLowVoltageError	Identifies whether the LowVoltageError feature exists on the NVM module.
	PLIB_NVM_ExistsLowVoltageStatus	Identifies whether the LowVoltageStatus feature exists on the NVM module.
	PLIB_NVM_ExistsMemoryModificationControl	Identifies whether the MemoryModificationControl feature exists on the NVM module.
	PLIB_NVM_ExistsOperationMode	Identifies whether the OperationMode feature exists on the NVM module.
	PLIB_NVM_ExistsProvideData	Identifies whether the ProvideData feature exists on the NVM module.
	PLIB_NVM_ExistsProvideQuadData	Identifies whether the ProvideQuadData feature exists on the NVM module.
	PLIB_NVM_ExistsSourceAddress	Identifies whether the SourceAddress feature exists on the NVM module.
	PLIB_NVM_ExistsSwapLockControl	Identifies whether the SwapLockControl feature exists on the NVM module.
	PLIB_NVM_ExistsWriteErrorStatus	Identifies whether the WriteErrorStatus feature exists on the NVM module.
	PLIB_NVM_ExistsWriteOperation	Identifies whether the WriteOperation feature exists on the NVM module.
	PLIB_NVM_FlashAddressToModify	Modifies the Flash memory address.
	PLIB_NVM_FlashEraseStart	Performs erase operation on the selected Flash memory area.
	PLIB_NVM_FlashProvideData	Provides the data to be written into Flash memory.
	PLIB_NVM_FlashProvideQuadData	Provides the quad data to be written into Flash memory.
	PLIB_NVM_FlashRead	Read the specified address of Flash memory.
	PLIB_NVM_FlashSwapLockSelect	Selects the kind of Flash swap lock required.
	PLIB_NVM_FlashSwapLockStatusGet	Get the status of Swap lock bits.
	PLIB_NVM_FlashWriteCycleHasCompleted	Provides the status of the Flash write cycle.
	PLIB_NVM_FlashWriteKeySequence	Copies the mandatory KEY sequence into the respective registers.
	PLIB_NVM_FlashWriteProtectMemoryAreaRange	Sets the address below which physical memory will be write protected.
	PLIB_NVM_FlashWriteStart	Performs a write operation on the Flash memory row selected.
	PLIB_NVM_IsBootMemoryLocked	Provides lock status of boot page write-protect bits.
	PLIB_NVM_IsBootPageWriteProtected	Provides write protection status for boot memory page.
	PLIB_NVM_IsProgramFlashMemoryLocked	Provides lock status of Program Flash Write-Protect register.
	PLIB_NVM_LockBootMemory	Locks the boot write-protect bits.
	PLIB_NVM_LockProgramFlashMemory	Lock the Program Flash write-protect register.
	PLIB_NVM_LowVoltageEventIsActive	Provides low voltage detection status.

	PLIB_NVM_LowVoltageIsDetected	Provides low voltage error detection status.
	PLIB_NVM_MemoryModifyEnable	Allows write cycles to Flash memory.
	PLIB_NVM_MemoryModifyInhibit	Inhibits write cycles to Flash memory.
	PLIB_NVM_MemoryOperationSelect	Selects the operation to be performed on Flash memory.
	PLIB_NVM_ProgramFlashBank1LowerRegion	Maps Flash Bank 1 to the lower mapped region.
	PLIB_NVM_ProgramFlashBank2IsLowerRegion	Gives the status of Program Flash Bank mapping.
	PLIB_NVM_ProgramFlashBank2LowerRegion	Maps the bank 2 to lower mapped region.
	PLIB_NVM_WriteOperationHasTerminated	Provides the status of the Flash write operation or sequence.

Description

Non-Volatile Memory (NVM) Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the NVM PLIB for all families of Microchip microcontrollers..The definitions in this file are common to NVM peripheral.

File Name

plib_nvm.h

Company

Microchip Technology Inc.

plib_nvm_help.h

Defines the NVM Peripheral Library data types.

Enumerations

	Name	Description
	EEPROM_ERROR	Lists the different EEPROM operation errors.
	EEPROM_OPERATION_MODE	Lists the different EEPROM operation modes.
	NVM_BOOT_MEMORY_AREA	Lists the different possible boot memory region.
	NVM_BOOT_MEMORY_PAGE	Lists the different NVM boot memory pages.
	NVM_FLASH_SWAP_LOCK_TYPE	Lists the possible type of Flash swap lock.
	NVM_MODULE_ID	Possible instances of the NVM module.
	NVM_OPERATION_MODE	Lists the different Flash operation modes.

Description

NVM Peripheral Library Constants Header

This header file contains the definitions of the data types and constants that make up the interface to the NVM Peripheral Library for Microchip microcontrollers. The definitions in this file are for NVM module.

File Name

plib_nvm_help.h

Company

Microchip Technology Inc.

Output Compare Peripheral Library

This section describes the Output Compare Peripheral Library.

Introduction

This library provides a low-level abstraction of the Output Compare Peripheral Library that is available on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

The Output Compare module is primarily used to generate a single pulse or a series of pulses in response to selected time base events.

Output Compare module operation essentially requires a timer and one or two compare values. Users have an option to select either a 32-bit timer or a 16-bit timer. The timer can be programmed to count at a desired frequency and count up to a desired period value. Details regarding timer operation and setup can be found in the Timer Peripheral Library. The Output Compare module compares the value of the timer with the compare values depending on the selected operating mode. When a compare match occurs between a timer value and compare values, the Output Compare module outputs a change of state on its output pins in accordance with the chosen Output Compare compare mode logic. Either a single pulse or a sequence of pulses may be generated.

Some of the key operating modes of the OC module are:

- Single Compare Set High/Low modes: In these compare modes, a compare match between the timer and the buffer (primary compare value) sets the output High/Low. The output remains at the same state after compare match event unless the module is disabled or the mode is changed.
- Single Compare Toggle mode: Output toggles state at every compare match event between the timer and the buffer (primary compare value)
- Dual compare Single/Continuous Pulse modes: These modes require two compare values. Leading edge of output pulse is generated during compare match of the incrementing timer and the buffer (primary compare value). Trailing edge of output pulse results when a compare match occurs between the incrementing timer and the pulse width value (secondary compare value). The output may be a single pulse or a sequence of pulses.
- Pulse-Width Modulation (PWM) modes: In this mode, output goes high when a compare match occurs between timer and the pulse width value (duty cycle). The output is reset back to its initial state when the timer resets after attaining its maximum count.

The Output Compare module also provides programmable interrupt generation on a compare match event. In PWM mode, hardware-based Fault detection and automatic output disable features are provided.

Figure 1 shows a block diagram of the Output Compare module. A compare match between the timer value and the compare values generates a pulse at the output.

Figure 1: Output Compare Module Block Diagram

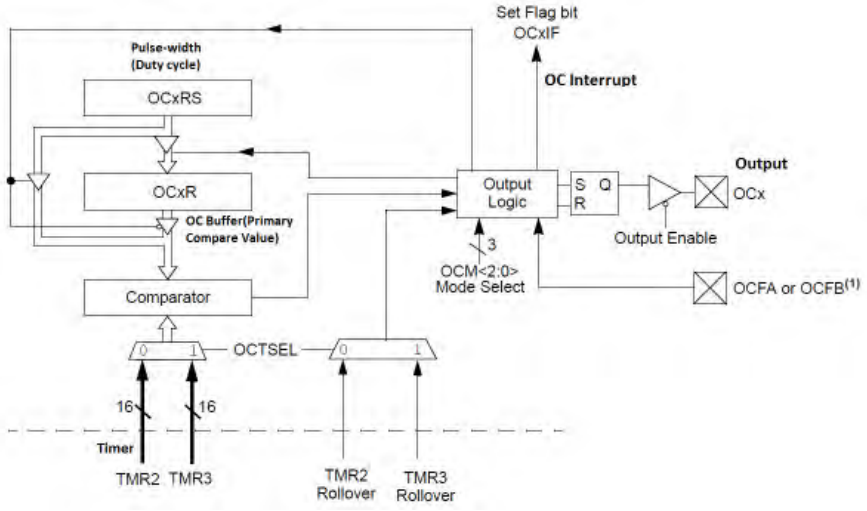

Figure 2 shows a block diagram of the Output Compare module with dedicated timers, present on some devices. It facilitates the use of multiple Output Compare modules operating synchronously or the use of an asynchronous trigger to generate a pulse.

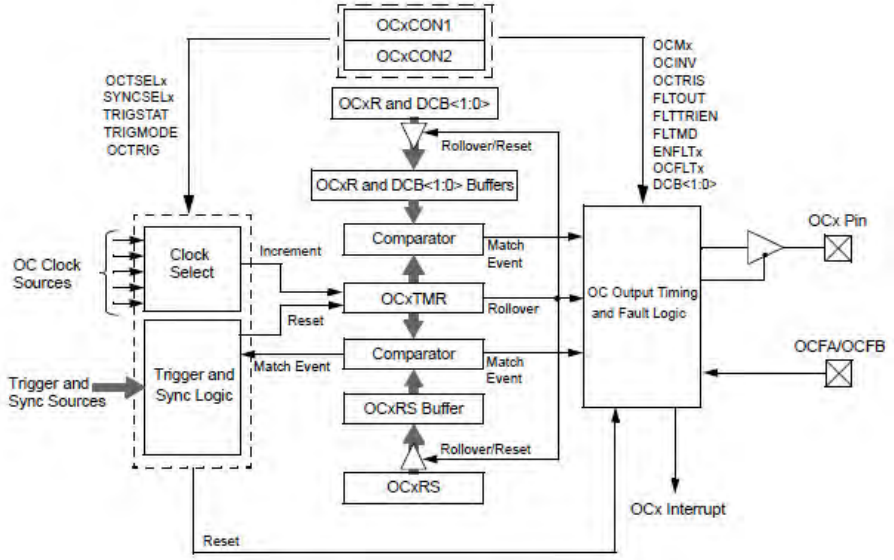
Figure 2: Output Compare Module Block Diagram with Dedicated Timers



Using the Library

This topic describes the basic architecture of the Output Compare Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_oc.h`

The interface to the Output Compare Peripheral library is defined in the `plib_oc.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Output Compare Peripheral Library must include `peripheral.h`.

Library File:

The Output Compare Peripheral library archive (`.a`) file is installed with MPLAB Harmony.

Please refer to the What is MPLAB Harmony? section for how the Peripheral interacts with the framework.

Hardware Abstraction Model

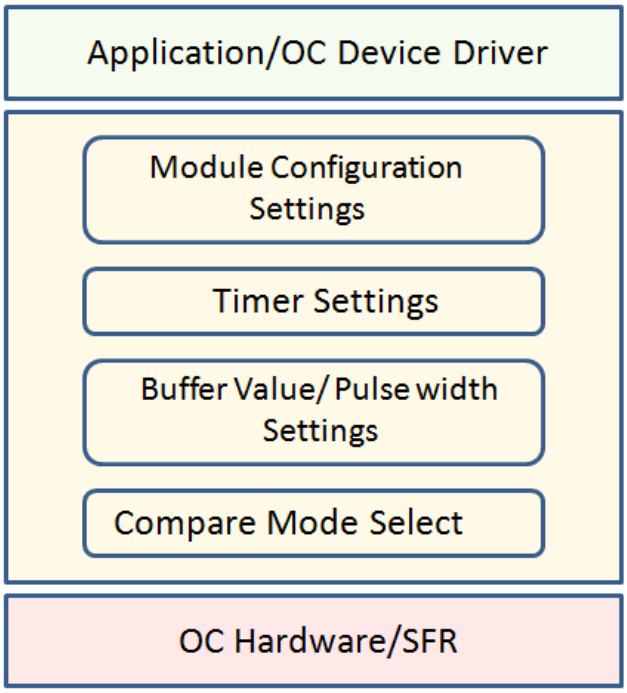
This library provides the low-level abstraction of the Output Compare module on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in the software and introduces the library interface.

Note: The interface provided is a superset of all the functionality of the available Output Compare modules on the device. Refer to the **"Output Compare"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine the set of functions that are supported for each Output Compare module on your device.

Description

The Output Compare Peripheral Library is used to simplify low-level access to the Output Compare module without having the need to directly interact the module's registers. The function names are generic and lead to easier access to the Output Compare module on different devices.

Output Compare module Software Abstraction Block Diagram



The Output Compare module can be described from a software standpoint as having functions to configure the module itself, to select the timer, set the buffer and pulse width values, and select the mode of operation. The desired nature of the output pulse is thus obtained.

A 16-bit or a 32-bit timer can be selected for the output compare time base. In some devices, the Output Compare module can be synchronized to an external input source. The Output Compare module can also operate asynchronously, based on a trigger by an input source. The Output Compare module entails the use of some functions dealing with Timer set up. These details can be found in Timer Peripheral Library.

Functions have been provided to set buffer values and pulse-width values. Pulse-width values are used only in Dual compare and PWM modes. In PWM mode, the buffer value provides the initial duty cycle for the first time period, while all later time cycles employ the 'pulse-width' value as the duty cycle value.

Compare modes:

- Single Compare Level Mode: Sets the output of Output Compare module at either 'High' or 'Low' at a compare match event
- Single Compare Toggle Mode: Toggles the output of OC module at each compare match event. This mode will produce continuous pulses.
- Dual Compare Mode: Output Compare module output is driven 'High' on compare match with buffer value and driven 'Low' on a compare match with the pulse-width value. The output can be either a single pulse or a continuous stream of pulses.
- PWM Mode: In Edge-aligned PWM mode, the Output Compare module output is driven 'High' whenever the timer resets, and is driven 'Low' on a compare match with the pulse-width value. Faults may or may not be enabled. In Center-aligned PWM mode, the Output Compare module output is driven 'High' on a compare match with the buffer value and driven 'Low' on a compare match with the pulse-width value.

Note: In PWM mode, it is vital that the user selects the mode of operation before selecting a Fault input.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Output Compare module.

Library Interface Section	Description
General Setup Functions	Provides setup, configuration and status control interface routines.
Compare Mode Functions	Provides Compare mode interface routines.
Timer Functions	Provides Timer interface routines.
Power-Saving Modes Functions	Provides Power-Saving modes interface routines.
Faults Functions	Provides Faults interface routines.
Feature Existence Functions	Provides interface routines that determine whether or not certain features are available.

How the Library Works

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine the supported modes.

All of the interface functions in this library are classified according to:

- General Setup: These routines deal with general setup of Output Compare module
- Compare/PWM Mode: These routines facilitate the selection of a Compare/PWM mode and setting up the compare values
- Timer: These functions deal with configuring the timer, selection of the clock source, and setting up a synchronous or asynchronous mode of operation for the OC module
- Power-Saving Modes:
  - Sleep Mode: The Output Compare module output is driven to the same state as it was in prior to the device entering Sleep mode. In PWM Fault mode, Fault detection is active. A Fault forces output of the OC module to tri-state or to a fixed predetermined state.
  - Idle Mode: The Output Compare module can be configured to suspend its operations or continue its operations. If the Output Compare module suspends its operations, it has the same behavior as it does in Sleep mode.
- Faults: These functions are used to select Fault inputs and identify occurrences of Faults when the Output Compare module functions in PWM mode
- Exists: These functions notify whether or not a particular feature is present on a device

The following sections provide examples that depict the use of interface functions to perform general tasks such as initialization and set up of the Output Compare module and setting up the Output Compare module in different compare modes.

Single Compare Set High Mode

The Single Compare Set High mode sets the output of the Output Compare module 'High' at a compare match event. This section illustrates the steps required to configure the Output Compare module in Single Compare Set High mode.

Example:

```
/* This example illustrates setting up Output Compare Module in Single Compare Set High
mode */

/* Configure Timer2 in 16-bit mode. Refer to Timer Peripheral Library for the
API */

/* Disable OC module */
PLIB_OC_Disable(MY_OC_ID);

/* Select Timer2 as time base */
PLIB_OC_TimerSelect(MY_OC_ID, OC_TIMER_16BIT_TMR2);

/* Set period of time base. Refer to Timer Peripheral Library for the API */

/* Select compare mode */
PLIB_OC_ModeSelect(MY_OC_ID, OC_SET_HIGH_SINGLE_PULSE_MODE);

/* Set buffer size to 16-bits */
PLIB_OC_BufferSizeSelect(MY_OC_ID, OC_BUFFER_SIZE_16BIT);

/* Set buffer value */
PLIB_OC_Buffer16BitSet(MY_OC_ID, 0x00FF);

/* Configure interrupts associated with Output Compare module. Refer to
Timer Peripheral Library for the API */

/* Enable Timer2. Refer to Timer Peripheral Library for the API */

/* Enable the Output Compare module */
PLIB_OC_Enable(MY_OC_ID);
```

Single Compare Toggle Mode

The Single Compare Toggle mode toggles the output of the Output Compare module at each compare match event. This section illustrates the steps required to configure the Output Compare module in Single Compare Toggle mode.

Example:

```
/* This example illustrates setting up Output Compare Module in Single Compare Toggle mode */
```

```
/* Configure Timer2 in 16-bit mode. Refer to Timer Peripheral Library for
the API */

/* Disable OC module */
PLIB_OC_Disable(MY_OC_ID);

/* Select Timer2 as time base */
PLIB_OC_TimerSelect(MY_OC_ID, OC_TIMER_16BIT_TMR2);

/* Set period of time base. Refer to Timer Peripheral Library for the API */

/* Select compare mode */
PLIB_OC_ModeSelect(MY_OC_ID, OC_TOGGLE_CONTINOUS_PULSE_MODE);

/* Set buffer size to 16-bits */
PLIB_OC_BufferSizeSelect(MY_OC_ID, OC_BUFFER_SIZE_16BIT);

/* Set Buffer Value */
PLIB_OC_Buffer16BitSet(MY_OC_ID, 0x00FF);

/* Configure interrupts associated with Output Compare module. Refer to
Interrupts Peripheral Library for the API */

/* Enable Timer2. Refer to Timer Peripheral Library for the API */

/* Enable Output Compare module */
PLIB_OC_Enable(MY_OC_ID);
```

Dual Compare Continuous Mode

In this mode, the Output Compare module output is driven 'High' on a compare match with the buffer value and driven 'Low' on a compare match with the pulse-width value. A continuous stream of pulses is generated. This section illustrates the steps required to configure the Output Compare module in Dual Compare Continuous Pulse mode.

Example:

```
/* This example illustrates setting up Output Compare Module in Dual Compare Continuous Pulse mode */

/* Configure Timer2 in 16-bit mode. Refer to Timer Peripheral Library for
the API */

/* Disable OC module */
PLIB_OC_Disable(MY_OC_ID);

/* Select Timer2 as time base */
PLIB_OC_TimerSelect(MY_OC_ID, OC_TIMER_16BIT_TMR2);

/* Set period of time base. Refer to Timer Peripheral Library for the API */

/* Select compare mode */
PLIB_OC_ModeSelect(MY_OC_ID, OC_DUAL_COMPARE_CONTINUOUS_PULSE_MODE);

/* Set buffer size to 16-bits */
PLIB_OC_BufferSizeSelect(MY_OC_ID, OC_BUFFER_SIZE_16BIT);

/* Set buffer(primary compare) value */
PLIB_OC_Buffer16BitSet(MY_OC_ID, 0x00FF);

/*Set pulse width(secondary compare) value */
PLIB_OC_PulseWidth16BitSet(MY_OC_ID, 0x0FFF);

/* Configure interrupts associated with Output Compare module. Refer to
Interrupts Peripheral Library for the API */

/* Enable Timer2. Refer to Timer Peripheral Library for the API */

/* Enable the Output Compare module */
PLIB_OC_Enable(MY_OC_ID);
```

PWM Mode with Enabled Faults

This section illustrates the steps required to configure the Output Compare module in PWM mode.

Note: In PWM mode, it is vital that the user selects the mode of operation before selecting a Fault input.

Example:

This section illustrates the steps required to configure the Output Compare module in PWM mode with Fault protection. This mode can be selected using PLIB_OC_ModeSelect or PLIB_OC_FaultInputSelect.

```
/* Configure Timer2 in 16-bit mode. Refer to Timer Peripheral Library for the API */

/* Disable OC module */
PLIB_OC_Disable(MY_OC_ID);

/* Select Timer2 as time base */
PLIB_OC_TimerSelect(MY_OC_ID, OC_TIMER_16BIT_TMR2);

/* Set period of time base. Refer to Timer Peripheral Library for the API */

/* Select compare mode. PWM with fault protection mode is selected ,
   fault selection is preset in the hardware*/

PLIB_OC_ModeSelect(MY_OC_ID, OC_COMPARE_PWM_MODE_WITH_FAULT_PROTECTION );
/*or use PLIB_OC_FaultInputSelect(MY_OC_ID, OC_FAULT_PRESET) to achieve the same*/

/* Set buffer size to 16-bits. Refer to Timer Peripheral Library for the API */
PLIB_OC_BufferSizeSelect(MY_OC_ID, OC_BUFFER_SIZE_16BIT);

/* Set buffer (initial duty cycle) Value */
PLIB_OC_Buffer16BitSet(MY_OC_ID, 0x00FF);

/*Set pulse width (Duty cycle) value */
PLIB_OC_PulseWidth16BitSet(MY_OC_ID, 0x0FFF);

/* Configure interrupts associated with Output Compare module. Refer to
Interrupts Peripheral Library for the API */

/* Enable Timer2. Refer to Timer Peripheral Library for the API */

/* Enable OC module */
PLIB_OC_Enable(MY_OC_ID);

/* Check for PWM Fault */
while(!PLIB_OC_FaultHasOccurred(MY_OC_ID))
{
    /* If no PWM fault, continue normal operation*/
}
```

Configuring the Library

The library is configured for the supported Output Compare module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Setup Functions

	Name	Description
	PLIB_OC_Disable	Disable the Output Compare module.
	PLIB_OC_Enable	Enables the Output Compare module.
	PLIB_OC_IsEnabled	Checks whether the Output Compare module is enabled or not.

b) Compare Mode Functions

	Name	Description
	PLIB_OC_ModeSelect	Selects the compare mode for the Output Compare module.
	PLIB_OC_Buffer16BitSet	Sets a 16-bit primary compare value for compare operations.
	PLIB_OC_Buffer32BitSet	Sets a 32-bit primary compare value for compare operations.
	PLIB_OC_BufferSizeSelect	Sets the buffer size and pulse width to 16-bits or 32-bits.
	PLIB_OC_PulseWidth16BitSet	Sets a 16-bit pulse width for Output Compare module output.
	PLIB_OC_PulseWidth32BitSet	Sets a 32-bit pulse width for Output Compare module output.

c) Timer Functions

	Name	Description
	PLIB_OC_TimerSelect	Selects a clock source for the Output Compare module.
	PLIB_OC_AlternateClockDisable	Selects Timer 2/3, instead of the alternate clock source.
	PLIB_OC_AlternateClockEnable	Selects the alternate clock source.
	PLIB_OC_AlternateTimerSelect	Selects an alternate timer as a clock source for the Output Compare module.

d) Power-Saving Modes Functions

	Name	Description
	PLIB_OC_StopInIdleDisable	Output Compare module continues operating when the device enters Idle mode.
	PLIB_OC_StopInIdleEnable	Discontinues Output Compare module operation when the device enters Idle mode.

e) Faults Functions

	Name	Description
	PLIB_OC_FaultHasOccurred	Checks if a PWM fault has occurred.
	PLIB_OC_FaultInputSelect	Enables/Disables the Fault input for the Output Compare PWM mode.

f) Feature Existence Functions

	Name	Description
	PLIB_OC_ExistsAlternateClock	Identifies whether the AlternateClock feature exists on the Output Compare module.
	PLIB_OC_ExistsBufferSize	Identifies whether the BufferSize feature exists on the Output Compare module.
	PLIB_OC_ExistsBufferValue	Identifies whether the BufferValue feature exists on the Output Compare module.
	PLIB_OC_ExistsCompareModeSelect	Identifies whether the CompareModeSelect feature exists on the Output Compare module.
	PLIB_OC_ExistsEnableControl	Identifies whether the EnableControl feature exists on the Output Compare module.
	PLIB_OC_ExistsFaultInput	Identifies whether the FaultInput feature exists on the Output Compare module.
	PLIB_OC_ExistsFaultStatus	Identifies whether the FaultStatus feature exists on the Output Compare module.
	PLIB_OC_ExistsPulseWidth	Identifies whether the PulseWidth feature exists on the Output Compare module.
	PLIB_OC_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the Output Compare module.
	PLIB_OC_ExistsTimerSelect	Identifies whether the TimerSelect feature exists on the Output Compare module.
	PLIB_OC_ExistsAlternateTimerSelect	Identifies whether the AlternateTimerSelect feature exists on the Output Compare module.

g) Data Types and Constants

	Name	Description
	OC_16BIT_TIMERS	Lists different 16 bit time bases for Output Compare module.
	OC_BUFFER_SIZE	Lists different buffer sizes for compare value.
	OC_COMPARE_MODES	Lists the different compare modes for the Output Compare module.
	OC_FAULTS	Lists different fault sources for Output Compare module
	OC_MODULE_ID	OC_MODULE_ID This enumeration defines number of modules which are available on the microcontroller. This is the super set of all the possible instances that might be available on Microchip microcontrollers. Refer to the specific device data sheet to determine the correct number of modules defined for the desired microcontroller.
	OC_ALT_TIMERS	Lists the different 16-bit alternate timers for the Output Compare module.

Description

This section describes the Application Programming Interface (API) functions of the Output Compare Peripheral Library.

Refer to each section for a detailed description.

a) General Setup Functions

PLIB_OC_Disable Function

Disable the Output Compare module.

File

plib_oc.h

C

```
void PLIB_OC_Disable(OC_MODULE_ID index);
```

Returns

None.

Description

This function disables the Output Compare module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_OC_ID OC_ID_1

PLIB_OC_Disable(MY_OC_ID);
```

Parameters

Parameters	Description
index	Identifies the Output Compare module

Function

void PLIB_OC_Disable(OC_MODULE_ID index)

PLIB_OC_Enable Function

Enables the Output Compare module.

File

plib_oc.h

C

```
void PLIB_OC_Enable(OC_MODULE_ID index);
```

Returns

None.

Description

This function enables the Output Compare module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

The module should be appropriately configured before being enabled.

Example

```
#define MY_OC_ID OC_ID_1

//Do all the other configurations before enabling.

PLIB_OC_Enable(MY_OC_ID);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module

Function

void PLIB_OC_Enable(OC_MODULE_ID index)

PLIB_OC_IsEnabled Function

Checks whether the Output Compare module is enabled or not.

File

plib_oc.h

C

```
bool PLIB_OC_IsEnabled(OC_MODULE_ID index);
```

Returns

Boolean

- true - The Output Compare module is enabled
- false - The Output Compare module is not enabled

Description

The function returns the enable status of the Output Compare module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_OC_ID OC_ID_1

if(PLIB_OC_IsEnabled(MY_OC_ID))
{
//Take respective actions
}
else
{
//Take respective actions
}
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module

Function

bool PLIB_OC_IsEnabled(OC_MODULE_ID index)

b) Compare Mode Functions

PLIB_OC_ModeSelect Function

Selects the compare mode for the Output Compare module.

File

plib_oc.h

C

```
void PLIB_OC_ModeSelect(OC_MODULE_ID index, OC_COMPARE_MODES cmpMode);
```

Returns

None.

Description

This function selects the compare mode for the Output Compare module.

Remarks

If PLIB_OC_FaultInputSelect is called after PLIB_OC_ModeSelect, the mode selected by the PLIB_OC_ModeSelect function will be overwritten as the PLIB_OC_FaultInputSelect function selects the PWM mode with or without Fault protection.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsCompareModeSelect in your application to determine whether this feature is available.

Preconditions

The Output Compare module must be turned off before a new mode is selected. The Output Compare module is turned off through the PLIB_OC_ModeSelect(MY_OC_ID,OC_COMPARE_TURN_OFF_MODE) function. Refer to the enumeration description for information on different modes and preconditions.

Example

```
#define MY_OC_ID OC_ID_1
// Dual compare continuous pulse mode is selected
PLIB_OC_ModeSelect(MY_OC_ID, OC_DUAL_COMPARE_CONTINUOUS_PULSE_MODE );
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
cmpMode	Identifies the compare mode for Output Compare module

Function

void PLIB_OC_ModeSelect(OC_MODULE_ID index, OC_COMPARE_MODES cmpMode)

PLIB_OC_Buffer16BitSet Function

Sets a 16-bit primary compare value for compare operations.

File

plib_oc.h

C

```
void PLIB_OC_Buffer16BitSet(OC_MODULE_ID index, uint16_t val16Bit);
```

Returns

None.

Description

This function sets a 16-bit primary compare value for compare operations in all modes except PWM modes.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsBufferValue in your application to determine whether this feature is available.

Preconditions

The PWM mode of operation should not be selected. The buffer size should be set to 16-bits by the PLIB_OC_BufferSizeSelect function.

Example

```
#define MY_OC_ID OC_ID_1

PLIB_OC_Buffer16BitSet(MY_OC_ID, 0x00FF);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
val16Bit	Sets a 16-bit primary compare value

Function

void PLIB_OC_Buffer16BitSet(OC_MODULE_ID index, uint16_t val16Bit)

PLIB_OC_Buffer32BitSet Function

Sets a 32-bit primary compare value for compare operations.

File

plib_oc.h

C

```
void PLIB_OC_Buffer32BitSet(OC_MODULE_ID index, uint32_t val32Bit);
```

Returns

None.

Description

This function sets a 32-bit primary compare value for compare operations in all modes except PWM modes.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsBufferValue in your application to determine whether this feature is available.

Preconditions

The PWM mode of operation should not be selected. The buffer size should be set to 32-bits by the PLIB_OC_BufferSizeSelect function.

Example

```
#define MY_OC_ID OC_ID_1

PLIB_OC_Buffer32BitSet(MY_OC_ID, 0x000000FF);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
val32Bit	Sets a 32-bit primary compare value

Function

void PLIB_OC_Buffer32BitSet(OC_MODULE_ID index, uint32_t val32Bit)

PLIB_OC_BufferSizeSelect Function

Sets the buffer size and pulse width to 16-bits or 32-bits.

File

plib_oc.h

C

```
void PLIB_OC_BufferSizeSelect(OC_MODULE_ID index, OC_BUFFER_SIZE size);
```

Returns

None.

Description

This function sets the size of the buffer and pulse width to 16-bits or 32-bits. The choice is made based on whether a 16-bit timer or a 32-bit timer is selected.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsBufferSize in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_OC_ID OC_ID_1
// Buffer size and pulse width size are set to 32-bits
PLIB_OC_BufferSizeSelect(MY_OC_ID, OC_BUFFER_SIZE_32BIT);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
size	Identifies the size of compare value

Function

void PLIB_OC_BufferSizeSelect(OC_MODULE_ID index, OC_BUFFER_SIZE size)

PLIB_OC_PulseWidth16BitSet Function

Sets a 16-bit pulse width for Output Compare module output.

File

plib_oc.h

C

```
void PLIB_OC_PulseWidth16BitSet(OC_MODULE_ID index, uint16_t pulseWidth);
```

Returns

None.

Description

This function sets a 16-bit pulse width for the Output Compare module in dual compare modes. A dual compare mode can be selected using the PLIB_OC_ModeSelect function. Secondary compare match event (pulse width) decides the trailing (falling) edge of the Output Compare module output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsPulseWidth in your application to determine whether this feature is available.

Preconditions

Dual compare operation should be selected. The buffer size should be set to 16-bits by the PLIB_OC_BufferSizeSelect function.

Example

```
#define MY_OC_ID OC_ID_1

PLIB_OC_PulseWidth16BitSet(MY_OC_ID, 0x0FFF);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
pulseWidth	Pulse width value

Function

void PLIB_OC_PulseWidth16BitSet(OC_MODULE_ID index,uint16_t pulseWidth)

PLIB_OC_PulseWidth32BitSet Function

Sets a 32-bit pulse width for Output Compare module output.

File

plib_oc.h

C

```
void PLIB_OC_PulseWidth32BitSet(OC_MODULE_ID index, uint32_t pulseWidth);
```

Returns

None.

Description

This function sets a 32-bit pulse width for Output Compare module in dual compare modes. A dual compare mode can be selected using PLIB_OC_ModeSelect function. Secondary compare match event (pulse width) decides the trailing (falling) edge of the Output Compare module output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsPulseWidth in your application to determine whether this feature is available.

Preconditions

Dual compare operation should be selected. The buffer size should be set to 32-bits by the PLIB_OC_BufferSizeSelect function.

Example

```
#define MY_OC_ID OC_ID_1

PLIB_OC_PulseWidth32BitSet(MY_OC_ID, 0x00000FFF);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
pulseWidth	Pulse width value

Function

void PLIB_OC_PulseWidth32BitSet(OC_MODULE_ID index,uint32_t pulseWidth)

c) Timer Functions

PLIB_OC_TimerSelect Function

Selects a clock source for the Output Compare module.

File

plib_oc.h

C

```
void PLIB_OC_TimerSelect(OC_MODULE_ID index, OC_16BIT_TIMERS tmr);
```

Returns

None.

Description

This function selects a clock source for the Output Compare module if the 16-bit time base is set.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsTimerSelect in your application to determine whether this feature is available.

Preconditions

The 16-bit time base needs to be set.

Example

```
#define MY_OC_ID OC_ID_1
// 16-bit Timer2 is selected
PLIB_OC_TimerSelect(MY_OC_ID, OC_TIMER_16BIT_TMR2);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
tmr	Identifies the timer

Function

void PLIB_OC_TimerSelect(OC_MODULE_ID index, OC_16BIT_TIMERS tmr)

PLIB_OC_AlternateClockDisable Function

Selects Timer 2/3, instead of the alternate clock source.

File

plib_oc.h

C

```
void PLIB_OC_AlternateClockDisable(OC_MODULE_ID index);
```

Returns

None.

Description

This function selects Timer2/Timer3, instead of the alternate clock source.

Remarks

The feature is not supported on all devices. Please refer to the specific device data sheet to determine availability. A system unlock must be performed before this function can be executed. This function applies to all input capture modules, regardless of the OC_MODULE_ID passed in the call.

Preconditions

A system unlock PLIB_DEVCON_SystemUnlock must be performed before this function can be executed.

Example

```
// Call system service to unlock oscillator
#define MY_OC_ID OC_ID_1
PLIB_OC_AlternateClockDisable( MY_OC_ID );
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module

Function

void PLIB_OC_AlternateClockDisable(OC_MODULE_ID index)

PLIB_OC_AlternateClockEnable Function

Selects the alternate clock source.

File

plib_oc.h

C

```
void PLIB_OC_AlternateClockEnable(OC_MODULE_ID index);
```

Returns

None.

Description

This function selects the alternate clock source instead of Timer2/Timer3.

Remarks

The feature is not supported on all devices. Please refer to the specific device data sheet to determine availability. A system unlock must be performed before this function can be executed. This function applies to all input capture modules, regardless of the OC_MODULE_ID passed in the call.

Preconditions

A system unlock PLIB_DEVCON_SystemUnlock must be performed before this function can be executed.

Example

```
// Call system service to unlock oscillator
#define MY_OC_ID OC_ID_1
PLIB_OC_AlternateClockEnable( MY_OC_ID );
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module

Function

void PLIB_OC_AlternateClockEnable(OC_MODULE_ID index)

PLIB_OC_AlternateTimerSelect Function

Selects an alternate timer as a clock source for the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_AlternateTimerSelect(OC_MODULE_ID index, OC_ALT_TIMERS tmr);
```

Returns

- true - Alternate timer selected successfully
- false - Alternate timer selection failure, select an appropriate alternate timer for the Output Compare module index

Description

This function selects an alternate timer as a clock source for the Output Compare module.

- OC_ID_1,OC_ID_2,OC_ID_3: Can use Timer4 or Timer5 as alternate timers
- OC_ID_4,OC_ID_5,OC_ID_6: Can use Timer2 or Timer3 as alternate timers
- OC_ID_7,OC_ID_8,OC_ID_9: Can use Timer6 or Timer7 as alternate timers

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsAlternateTimerSelect in your application to determine whether this feature is available.

Preconditions

The 16-bit time base needs to be set. The PLIB_OC_AlternateClockEnable function should be called for the Output Compare module to enable the alternate clock selection.

Example

```
#define MY_OC_ID   OC_ID_1
bool result;

//Enabling alternate timer selection
PLIB_OC_AlternateClockEnable( MY_OC_ID );

// 16-bit Timer4 is selected as the clock source for Output Compare module 1
result = PLIB_OC_AlternateTimerSelect(MY_OC_ID, OC_ALT_TIMER_TMR4);

if(false == result)
{
    // Selected alternate timer does not available for the desired Output
    // Compare module.
    // Select the appropriate alternate timer.
}
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
tmr	Identifies the alternate timer

Function

bool PLIB_OC_AlternateTimerSelect(OC_MODULE_ID index, OC_ALT_TIMERS tmr)

d) Power-Saving Modes Functions

PLIB_OC_StopInIdleDisable Function

Output Compare module continues operating when the device enters Idle mode.

File

plib_oc.h

C

```
void PLIB_OC_StopInIdleDisable(OC_MODULE_ID index);
```

Returns

None.

Description

The function continues Output Compare module operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_OC_ID OC_ID_1

PLIB_OC_StopInIdleDisable(MY_OC_ID);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module

Function

void PLIB_OC_StopInIdleDisable(OC_MODULE_ID index)

PLIB_OC_StopInIdleEnable Function

Discontinues Output Compare module operation when the device enters Idle mode.

File

plib_oc.h

C

```
void PLIB_OC_StopInIdleEnable(OC_MODULE_ID index);
```

Returns

None.

Description

This function discontinues Output Compare module operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_OC_ID OC_ID_1

PLIB_OC_StopInIdleEnable(MY_OC_ID);
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module

Function

void PLIB_OC_StopInIdleEnable(OC_MODULE_ID index)

e) Faults Functions

PLIB_OC_FaultHasOccurred Function

Checks if a PWM fault has occurred.

File

plib_oc.h

C

```
bool PLIB_OC_FaultHasOccurred(OC_MODULE_ID index);
```

Returns

- true - PWM Fault has occurred
- false - No PWM fault has occurred

Description

This function returns 'true' if a PWM Fault has occurred and 'false' if no Fault condition exists.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsFaultStatus in your application to determine whether this feature is available.

Preconditions

This function should be used only in Edge or Center-Aligned PWM mode set by the PLIB_OC_ModeSelect() function.

Example

```
#define MY_OC_ID OC_ID_1
if(!PLIB_OC_FaultHasOccurred(MY_OC_ID))
{
    // Do some operation
};
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module

Function

bool PLIB_OC_FaultHasOccurred(OC_MODULE_ID index)

PLIB_OC_FaultInputSelect Function

Enables/Disables the Fault input for the Output Compare PWM mode.

File

plib_oc.h

C

```
void PLIB_OC_FaultInputSelect(OC_MODULE_ID index, OC_FAULTS flt);
```

Returns

None.

Description

This function enables/disables the Fault input for the Output Compare PWM mode.

If some other mode was selected using PLIB_OC_ModeSelect, the mode selected by PLIB_OC_ModeSelect will be overwritten as PLIB_OC_FaultInputSelect selects PWM mode with/without Fault protection.

Fault input is valid if the fault pin is enabled in the hardware. If a logic '0' is detected on the OCFA/OCFB pin, the selected PWM output pin(s) are placed in the tri-state. The user may elect to provide a pull-down or pull-up resistor on the PWM pin to provide for a desired state if a Fault condition occurs. The shutdown of the PWM output is immediate and is not tied to the device clock source. Fault occurrence can be detected by calling the function PLIB_OC_FaultHasOccurred. The Output Compare module will be disabled until the following conditions are met: • The external Fault condition has been removed • The PWM mode is re-enabled

Remarks

This function selects the PWM mode of the Output Compare module with Fault protection or without Fault protection.

These modes can be selected using PLIB_OC_ModeSelect also.

If any other Output Compare mode is selected prior to this function, that mode will be overwritten as this feature is available for PWM mode only.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OC_ExistsFaultInput in your application to determine whether this feature is available.

Preconditions

Fault pin: OCFA for OC_ID_1 to OC_ID_4 , OCFB for OC_ID_5 in MX devices. OCFA for OC_ID_1 to OC_ID_3 and OC_ID_7 to OC_ID_9 , OCFB for OC_ID_4 to OC_ID_6 in MZ devices. should be enabled in the hardware if enabling the fault input, that is if selecting the OC_FAULT_PRESET.

Example

```
#define MY_OC_ID OC_ID_1
// Fault pin is enabled in the hardware
// This function selects PWM with fault protection mode for MY_OC_ID instance.
PLIB_OC_FaultInputSelect(MY_OC_ID, OC_FAULT_PRESET);
// Output Compare fault input is now enabled for Output Compare Module
```

Parameters

Parameters	Description
index	Identifies the desired Output Compare module
flt	Identifies the Output Compare module Fault input

Function

void PLIB_OC_FaultInputSelect(OC_MODULE_ID index, OC_FAULTS flt)

f) Feature Existence Functions

PLIB_OC_ExistsAlternateClock Function

Identifies whether the AlternateClock feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsAlternateClock(OC_MODULE_ID index);
```

Returns

- true - The AlternateClock feature is supported on the device
- false - The AlternateClock feature is not supported on the device

Description

This function identifies whether the AlternateClock feature is available on the Output Compare module. When this function returns true, these functions are supported on the device:

- PLIB_OC_AlternateClockEnable
- PLIB_OC_AlternateClockDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OC_ExistsAlternateClock(OC_MODULE_ID index)

PLIB_OC_ExistsBufferSize Function

Identifies whether the BufferSize feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsBufferSize(OC_MODULE_ID index);
```

Returns

- true - If the BufferSize feature is supported on the device
- false - If the BufferSize feature is not supported on the device

Description

This function identifies whether the BufferSize feature is available on the Output Compare module. When this function returns true, this function is supported on the device:

- PLIB_OC_BufferSizeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsBufferSize(OC_MODULE_ID index)

PLIB_OC_ExistsBufferValue Function

Identifies whether the BufferValue feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsBufferValue(OC_MODULE_ID index);
```

Returns

- true - If the BufferValue feature is supported on the device
- false - If the BufferValue feature is not supported on the device

Description

This function identifies whether the BufferValue feature is available on the Output Compare module. When this function returns true, these functions are supported on the device:

- PLIB_OC_Buffer32BitSet
- PLIB_OC_Buffer16BitSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsBufferValue(OC_MODULE_ID index)

PLIB_OC_ExistsCompareModeSelect Function

Identifies whether the CompareModeSelect feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsCompareModeSelect(OC_MODULE_ID index);
```

Returns

- true - If the CompareModeSelect feature is supported on the device
- false - If the CompareModeSelect feature is not supported on the device

Description

This function identifies whether the CompareModeSelect feature is available on the Output Compare module. When this function returns true, this function is supported on the device:

- PLIB_OC_ModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsCompareModeSelect(OC_MODULE_ID index)

PLIB_OC_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsEnableControl(OC_MODULE_ID index);
```

Returns

- true - If the EnableControl feature is supported on the device
- false - If the EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the Output Compare module. When this function returns true, these functions are supported on the device:

- PLIB_OC_Enable
- PLIB_OC_Disable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsEnableControl(OC_MODULE_ID index)

PLIB_OC_ExistsFaultInput Function

Identifies whether the FaultInput feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsFaultInput(OC_MODULE_ID index);
```

Returns

- true - If the FaultInput feature is supported on the device
- false - If the FaultInput feature is not supported on the device

Description

This function identifies whether the FaultInput feature is available on the Output Compare module. When this function returns true, this function is supported on the device:

- PLIB_OC_FaultInputSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsFaultInput(OC_MODULE_ID index)

PLIB_OC_ExistsFaultStatus Function

Identifies whether the FaultStatus feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsFaultStatus(OC_MODULE_ID index);
```

Returns

- true - If the FaultStatus feature is supported on the device
- false - If the FaultStatus feature is not supported on the device

Description

This function identifies whether the FaultStatus feature is available on the Output Compare module. When this function returns true, this function is supported on the device:

- PLIB_OC_FaultHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsFaultStatus(OC_MODULE_ID index)

PLIB_OC_ExistsPulseWidth Function

Identifies whether the PulseWidth feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsPulseWidth(OC_MODULE_ID index);
```

Returns

- true - If the PulseWidth feature is supported on the device
- false - If the PulseWidth feature is not supported on the device

Description

This function identifies whether the PulseWidth feature is available on the Output Compare module. When this function returns true, these functions are supported on the device:

- PLIB_OC_PulseWidth32BitSet
- PLIB_OC_PulseWidth16BitSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsPulseWidth(OC_MODULE_ID index)

PLIB_OC_ExistsStopInIdle Function

Identifies whether the StopInIdle feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsStopInIdle(OC_MODULE_ID index);
```

Returns

- true - If the StopInIdle feature is supported on the device
- false - If the StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the Output Compare module. When this function returns true, these functions are supported on the device:

- PLIB_OC_StopInIdleEnable
- PLIB_OC_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsStopInIdle(OC_MODULE_ID index)

PLIB_OC_ExistsTimerSelect Function

Identifies whether the TimerSelect feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsTimerSelect(OC_MODULE_ID index);
```

Returns

- true - If the TimerSelect feature is supported on the device
- false - If the TimerSelect feature is not supported on the device

Description

This function identifies whether the TimerSelect feature is available on the Output Compare module. When this function returns true, this function is supported on the device:

- PLIB_OC_TimerSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsTimerSelect(OC_MODULE_ID index)

PLIB_OC_ExistsAlternateTimerSelect Function

Identifies whether the AlternateTimerSelect feature exists on the Output Compare module.

File

plib_oc.h

C

```
bool PLIB_OC_ExistsAlternateTimerSelect(OC_MODULE_ID index);
```

Returns

- true - If the AlternateTimerSelect feature is supported on the device
- false - If the AlternateTimerSelect feature is not supported on the device

Description

This function identifies whether the AlternateTimerSelect feature is available on the Output Compare module. When this function returns true, this function is supported on the device:

- PLIB_OC_AlternateTimerSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_OC_ExistsAlternateTimerSelect(OC_MODULE_ID index)

g) Data Types and Constants

OC_16BIT_TIMERS Enumeration

Lists different 16 bit time bases for Output Compare module.

File

plib_oc_help.h

C

```
typedef enum {
  OC_TIMER_16BIT_TMR2,
  OC_TIMER_16BIT_TMR3
} OC_16BIT_TIMERS;
```

Members

Members	Description
OC_TIMER_16BIT_TMR2	Clock source of Timer2 is the clock source of Output Compare module
OC_TIMER_16BIT_TMR3	Clock source of Timer3 is the clock source of Output Compare module

Description

Output Compare 16-bit Timer Select

This enumeration lists different 16 bit time bases for Output Compare module. The time base is set by the PLIB_OC_TimerSelect function.

OC_BUFFER_SIZE Enumeration

Lists different buffer sizes for compare value.

File

plib_oc_help.h

C

```
typedef enum {
  OC_BUFFER_SIZE_16BIT,
  OC_BUFFER_SIZE_32BIT
} OC_BUFFER_SIZE;
```

Members

Members	Description
OC_BUFFER_SIZE_16BIT	Buffer size is 16-bits. Duty cycle and compare values will have 16-bit values.
OC_BUFFER_SIZE_32BIT	Buffer size is 32-bits. Duty cycle and compare values will have 32-bit values.

Description

Output Compare Buffer Size

This enumeration lists different buffer sizes for compare value and duty cycle value.

OC_COMPARE_MODES Enumeration

Lists the different compare modes for the Output Compare module.

File

plib_oc_help.h

C

```
typedef enum {
  OC_COMPARE_PWM_MODE_WITH_FAULT_PROTECTION,
  OC_COMPARE_PWM_MODE_WITHOUT_FAULT_PROTECTION,
  OC_COMPARE_PWM_EDGE_ALIGNED_MODE,
  OC_DUAL_COMPARE_CONTINUOUS_PULSE_MODE,
  OC_DUAL_COMPARE_SINGLE_PULSE_MODE,
```

```
  OC_TOGGLE_CONTINUOUS_PULSE_MODE,
  OC_SET_LOW_SINGLE_PULSE_MODE,
  OC_SET_HIGH_SINGLE_PULSE_MODE,
  OC_COMPARE_TURN_OFF_MODE
} OC_COMPARE_MODES;
```

Members

Members	Description
OC_COMPARE_PWM_MODE_WITH_FAULT_PROTECTION	Output Compare module output is PWM signal and is fault protected if fault protection pin is enabled. Fault protection is valid if the fault pin is enabled in the hardware. Fault pin: OCFA for OC_ID_1 to OC_ID_4 , OCFB for OC_ID_5 in MX devices. OCFA for OC_ID_1 to OC_ID_3 and OC_ID_7 to OC_ID_9 , OCFB for OC_ID_4 to OC_ID_6 in PIC32MZ devices. If a logic â€˜0â€™ is detected on the OCFA/OCFB pin, the selected PWM output pin(s) are placed in the tri-state. The user may elect to provide a pull-down or pull-up resistor on the PWM pin to provide for a desired state if a Fault condition occurs. The shutdown of the PWM output is immediate and is not tied to the device clock source. Fault occurrence can be detected by calling the function PLIB_OC_FaultHasOccurred. The Output Compare will be disabled until the following conditions are met: 1. The external Fault condition has been removed 2. The PWM mode is re-enabled
OC_COMPARE_PWM_MODE_WITHOUT_FAULT_PROTECTION	Output Compare module output is PWM signal and is not fault protected
OC_COMPARE_PWM_EDGE_ALIGNED_MODE	This element is obsolete and it will be removed from next release
OC_DUAL_COMPARE_CONTINUOUS_PULSE_MODE	Dual Compare, Continuous Pulse mode: Output Compare module output is driven high on compare match with primary compare value and driven low on compare match with secondary compare value. A continuous stream of pulses is generated unless the compare mode is changed or the module is disabled. If the secondary compare value is greater than time base period value, secondary compare match does not occur. As a consequence, Output Compare module output stays high.
OC_DUAL_COMPARE_SINGLE_PULSE_MODE	Dual Compare, Single Pulse mode: Output Compare module output is driven high on compare match with primary compare value and driven low on compare match with secondary compare value. If the secondary compare value is greater than time base period value, secondary compare match does not occur. As a consequence, Output Compare module output stays high until a mode change is made or module is disabled
OC_TOGGLE_CONTINUOUS_PULSE_MODE	Single Compare Toggle mode: Output Compare module output is initialized to Low. Output Compare module output toggles at every compare match event with primary compare value with a single peripheral bus clock cycle delay. This scheme generates a square wave with 50% duty cycle. An interrupt is generated each time the output toggles.
OC_SET_LOW_SINGLE_PULSE_MODE	Single Compare Set Low mode: A compare match event with primary compare value will set the output of Output Compare module 'Low' with a single peripheral bus clock cycle delay. Output stays Low unless Output Compare module is disabled or a new compare mode is chosen. An interrupt is generated at compare match event. Output Compare module output is initially forced High.
OC_SET_HIGH_SINGLE_PULSE_MODE	Single Compare Set High mode: A compare match event with primary compare value will set the output of Output Compare module 'High' with a single peripheral bus clock cycle delay. Output stays High unless Output Compare module is disabled or a new compare mode is chosen. An interrupt is generated at compare match event. Output Compare module output is initially forced Low.
OC_COMPARE_TURN_OFF_MODE	Turn OFF mode: Output Compare module is disabled but still draws current. This mode is used to temporarily turn OFF the Output Compare module before a new compare mode is selected

Description

Output Compare Compare Modes

This enumeration lists different compare modes for Output Compare module. The compare mode is set by the PLIB_OC_ModeSelect function.

OC_FAULTS Enumeration

Lists different fault sources for Output Compare module

File

plib_oc_help.h

C

```
typedef enum {
  OC_FAULT_PRESET,
  OC_FAULT_DISABLE
} OC_FAULTS;
```

Members

Members	Description
OC_FAULT_PRESET	Enable Fault protection. PWM operation with fault protection.
OC_FAULT_DISABLE	Disable Fault protection. PWM operation without faults.

Description

Output Compare Fault Select

This enumeration lists different fault sources for Output Compare module. The fault source is selected by the PLIB_OC_FaultInputSelect function.

OC_MODULE_ID Enumeration

File

plib_oc_help.h

C

```
typedef enum {
  OC_ID_1,
  OC_ID_2,
  OC_ID_3,
  OC_ID_4,
  OC_ID_5,
  OC_ID_6,
  OC_ID_7,
  OC_ID_8,
  OC_ID_9,
  OC_NUMBER_OF_MODULES
} OC_MODULE_ID;
```

Members

Members	Description
OC_NUMBER_OF_MODULES	The total number of modules available.

Description

OC_MODULE_ID

This enumeration defines number of modules which are available on the microcontroller. This is the super set of all the possible instances that might be available on Microchip microcontrollers.

Refer to the specific device data sheet to determine the correct number of modules defined for the desired microcontroller.

OC_ALT_TIMERS Enumeration

Lists the different 16-bit alternate timers for the Output Compare module.

File

plib_oc_help.h

C

```
typedef enum {
  OC_ALT_TIMER_TMR2,
  OC_ALT_TIMER_TMR3,
  OC_ALT_TIMER_TMR4,
  OC_ALT_TIMER_TMR5,
  OC_ALT_TIMER_TMR6,
  OC_ALT_TIMER_TMR7
} OC_ALT_TIMERS;
```

Members

Members	Description
OC_ALT_TIMER_TMR2	Select Timer2 as the alternate clock source for Output Compare module
OC_ALT_TIMER_TMR3	Select Timer3 as the alternate clock source for Output Compare module
OC_ALT_TIMER_TMR4	Select Timer4 as the alternate clock source for Output Compare module
OC_ALT_TIMER_TMR5	Select Timer5 as the alternate clock source for Output Compare module
OC_ALT_TIMER_TMR6	Select Timer6 as the alternate clock source for Output Compare module
OC_ALT_TIMER_TMR7	Select Timer7 as the alternate clock source for Output Compare module

Description

Output Compare 16-bit alternate Timer Select

This enumeration lists the different 16-bit timers for the Output Compare time base when the Output Compare module is configured with a 16-bit alternate timer resource.

Files

Files

Name	Description
plib_oc.h	This file contains the interface definition for the Output Compare Peripheral Library.
plib_oc_help.h	This is file plib_oc_help.h.

Description

This section lists the source and header files used by the library.

plib_oc.h

This file contains the interface definition for the Output Compare Peripheral Library.

Functions

	Name	Description
	PLIB_OC_AlternateClockDisable	Selects Timer 2/3, instead of the alternate clock source.
	PLIB_OC_AlternateClockEnable	Selects the alternate clock source.
	PLIB_OC_AlternateTimerSelect	Selects an alternate timer as a clock source for the Output Compare module.
	PLIB_OC_Buffer16BitSet	Sets a 16-bit primary compare value for compare operations.
	PLIB_OC_Buffer32BitSet	Sets a 32-bit primary compare value for compare operations.
	PLIB_OC_BufferSizeSelect	Sets the buffer size and pulse width to 16-bits or 32-bits.
	PLIB_OC_Disable	Disable the Output Compare module.
	PLIB_OC_Enable	Enables the Output Compare module.
	PLIB_OC_ExistsAlternateClock	Identifies whether the AlternateClock feature exists on the Output Compare module.
	PLIB_OC_ExistsAlternateTimerSelect	Identifies whether the AlternateTimerSelect feature exists on the Output Compare module.
	PLIB_OC_ExistsBufferSize	Identifies whether the BufferSize feature exists on the Output Compare module.
	PLIB_OC_ExistsBufferValue	Identifies whether the BufferValue feature exists on the Output Compare module.
	PLIB_OC_ExistsCompareModeSelect	Identifies whether the CompareModeSelect feature exists on the Output Compare module.
	PLIB_OC_ExistsEnableControl	Identifies whether the EnableControl feature exists on the Output Compare module.
	PLIB_OC_ExistsFaultInput	Identifies whether the FaultInput feature exists on the Output Compare module.
	PLIB_OC_ExistsFaultStatus	Identifies whether the FaultStatus feature exists on the Output Compare module.
	PLIB_OC_ExistsPulseWidth	Identifies whether the PulseWidth feature exists on the Output Compare module.
	PLIB_OC_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the Output Compare module.
	PLIB_OC_ExistsTimerSelect	Identifies whether the TimerSelect feature exists on the Output Compare module.
	PLIB_OC_FaultHasOccurred	Checks if a PWM fault has occurred.
	PLIB_OC_FaultInputSelect	Enables/Disables the Fault input for the Output Compare PWM mode.
	PLIB_OC_IsEnabled	Checks whether the Output Compare module is enabled or not.
	PLIB_OC_ModeSelect	Selects the compare mode for the Output Compare module.
	PLIB_OC_PulseWidth16BitSet	Sets a 16-bit pulse width for Output Compare module output.
	PLIB_OC_PulseWidth32BitSet	Sets a 32-bit pulse width for Output Compare module output.

	PLIB_OC_StopInIdleDisable	Output Compare module continues operating when the device enters Idle mode.
	PLIB_OC_StopInIdleEnable	Discontinues Output Compare module operation when the device enters Idle mode.
	PLIB_OC_TimerSelect	Selects a clock source for the Output Compare module.

Description

Output Compare Module Peripheral Library Interface Header

This library provides a low-level abstraction of the Output Compare module on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences between one microcontroller variant and another.

Oscillator Peripheral Library

This section describes the Oscillator Peripheral Library.

Introduction

This library provides a low-level abstraction of the Oscillator module on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

The Oscillator is the heart of the microcontroller and provides the clock on which the core and the peripherals run.

For all of the oscillators present on a Microchip microcontroller, two kinds of configurations exist:

- Through Configuration bits
- At execution time

The first is through 'Configuration bits', which is a one-time configuration done during the programming of the device. These one-time configurations are programmed in the code memory.

The other is 'Execution time' configuration, which deals with features that are allowed to be changed during run-time. This peripheral library provides functions which deal only with the 'execution time' configurable features of the Oscillator module.

Certain Oscillator module features can only be selected through 'Configuration bits'. However, most of the features can be altered during run-time by using the functions provided in this library.

Using the Library

This topic describes the basic architecture of the Oscillator Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_osc.h`

The interface to the Oscillator Peripheral Library is defined in the `plib_osc.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Oscillator Peripheral Library must include `peripheral.h`.

Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

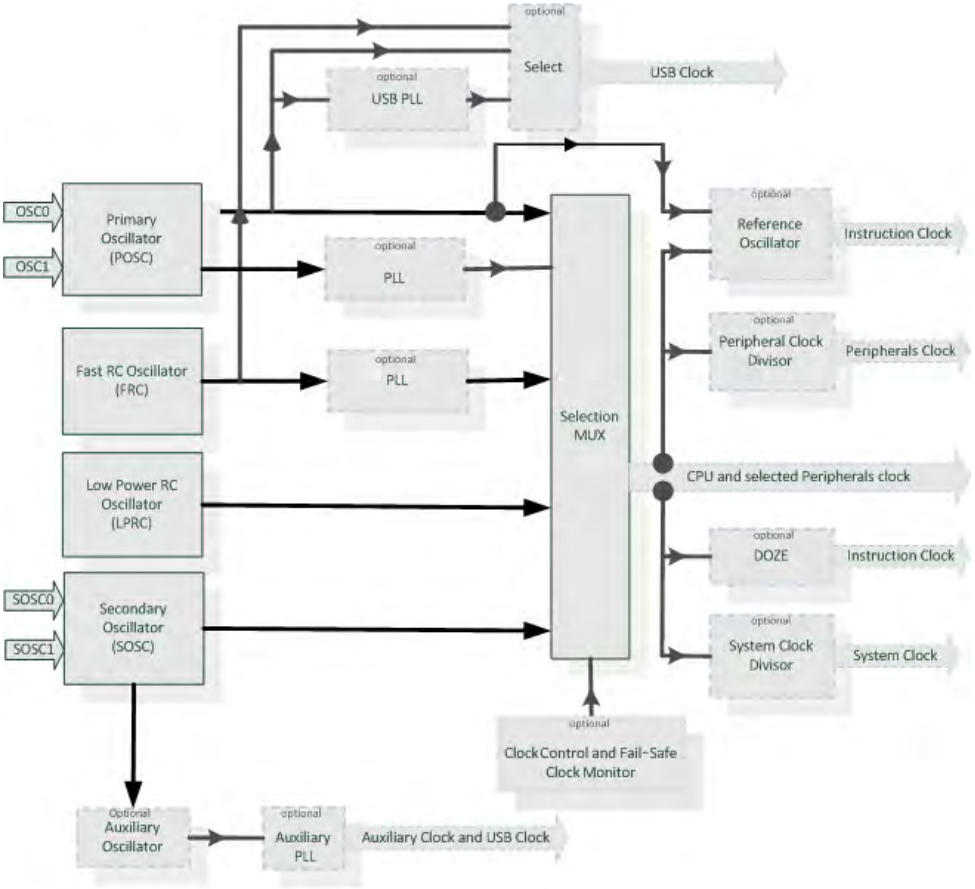
Hardware Abstraction Model

This library provides a low-level abstraction of the Oscillator module on Microchip microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

Hardware Abstraction Model

The Oscillator hardware model is shown in the following figure. The blocks represented in dashed lines may not be present in all microcontrollers. Refer to the **"Oscillator"** chapter in the specific device data sheet to determine availability.



To understand the Oscillator module and how each feature is mapped in this library, it is important to understand the following terminology.

Clock Source

A clock source is hardware that generates oscillations, which may be internal or external.

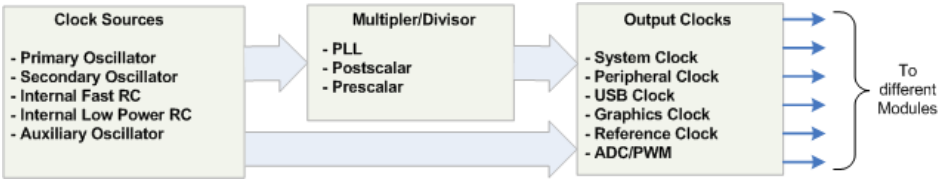
Divisor and Multiplier/PLL

These are hardware modules that can scale the clock. The rate at which the scaling is done may be fixed or configurable.

Clock Outputs

Clock outputs means output lines from the Oscillator module, which may route to different modules of the device or to the CPU (i.e., the system clock).

The following diagram provides a simplified explanation and the relationship between the previously mentioned terms. In most cases, there are multiple clock source options available for each of the clock outputs. However, not all the clock sources are available for all the output clocks. Scaling is an optional feature in most of the cases.



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Output Compare module.

Library Interface Section	Description
General Setup Functions	Provides General Configurations • Operation on a `WAIT` instruction • System clock source selection
Primary Oscillator Setup Functions	Provides Configuration Routines for the Primary Oscillator: • Primary Oscillator Sleep Enable

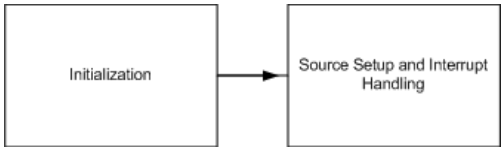
Secondary Oscillator Setup Functions	Provides Configuration Routines for the Secondary Oscillator: • Secondary Oscillator Enable/Disable • Secondary Oscillator Ready Indicator
Auxiliary Oscillator Setup Functions	Provides Configuration Routines for the Auxiliary Oscillator Configuration: • Reference Clock Source for Auxiliary Clock • Auxiliary Oscillator Mode Selection
Reference Oscillator Setup Functions	Provides Configuration Routines for the Reference Oscillator Configuration: • Reference Oscillator Output Enable/Disable • Select Reference Oscillator Output Divider • Reference Oscillator Clock Source Selection • Configure Reference Oscillator in Sleep Mode
Fast RC (FRC) Oscillator Setup Functions	Provides Configuration Routines for FRC Oscillator: • FRC Oscillator clock divider selection • FRC Oscillator tuning
Oscillator Switch Setup Functions	Provides Configuration Routines for Oscillator Switch and New Oscillator Selection: • Initiate an oscillator switch • Select the new oscillator • Get the current oscillator selection bits
Doze Setup Functions	Provides Configuration Routines for Doze mode Configuration • Enable/Disable Doze mode • Select DOZE (CPU Peripheral Clock Ratio) bits
USB and Display Clock Setup Functions	Provides Configuration Routines for USB and Display Clock Configuration: • Select FRC as USB Clock • Select Graphics Controller Clock • Display Module Clock Divider Selection
PLL Setup Functions	Provides Configuration Routines for PLL (Including USB and Auxiliary PLL) • PLL Multiplier • PLL Output Divider • 96 MHz PLL Enable for USB/Graphics Clock • Auxiliary PLL Input Divider • Auxiliary PLL Output Divider • Auxiliary PLL Multiplier • Auxiliary PLL Enable/Disable • PLL and USB PLL Lock Status
Peripheral Clock Setup Functions	Provides Configuration Routines for the Peripheral Clock • Set Peripheral Block Clock Divisor
Clock Fail Monitoring Functions	Provides Routines for Clock Fail Monitoring • Clock Fail Detect Status
Feature Existence Functions	Provides interface routines that determine whether certain features are available.

How the Library Works

The library can be used to control the Oscillator module. The usage model is explained in this section.

Description

The following diagram shows the major components of the usage model:



Oscillator Selection and Switching

Note: The device Configuration options change with the microcontroller family. Refer to the **"Oscillator"** chapter in the specific device data sheet for possible device configurations.

On devices that allow it, the oscillator selection can be overridden at run-time using the Oscillator Peripheral Library, as shown in the following code example:

```
//Do the configuration bit settings
OSC_SYS_TYPE currOsc;
OSC_SYS_TYPE newOsc=OSC_PRIMARY;

//get the current oscillator
currOsc =  PLIB_OSC_CurrentSysClockGet(OSC_ID_0);

//check if the current oscillator is same as new oscillator
if(currOsc != newOsc)
{
    // Unlock the Oscillator Registers
    PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);

    //set the new oscillator request to Fast RC oscillator
    PLIB_OSC_SysClockSelect ( OSC_ID_0, newOsc );
}
```

Example: Oscillator Selection Change During Run-time

In the event the clock switch did not complete, the clock switch logic can be reset by calling the following API:

```
bool oscSwitch_st;

oscSwitch_st = PLIB_OSC_ClockSwitchingIsComplete(OSC_ID_0);

if(!oscSwitch_st)
{
    // Unlock the Oscillator Registers
    PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);

    PLIB_OSC_ClockSwitchingAbort(OSC_ID_0);
}
```

Example: Oscillator Switch Abort

This will abandon the clock switch process, stop and reset the oscillator start-up timer (if applicable), and stop the PLL (if applicable). The clock switch process can be aborted at any time. A clock switch that is already in progress can also be aborted by performing a second clock switch.

Clock Sources

This section explains the available clock sources and their setup.

The following clock sources are available in Microchip microcontrollers:

- Primary Oscillator (Posc)
- Secondary Oscillator (Sosc)
- Internal Fast RC (FRC) Oscillator
- Internal Low-Power RC (LPRC) Oscillator

Primary Oscillator (Posc)

The Primary Oscillator has several operating modes (refer to the **"Oscillator"** chapter in the specific device data sheet for exact operating modes). The selection of the operating mode is done using the device Configuration registers during device programming. During run-time this can be changed using the oscillator switch option. However, changing the operating mode from High Gain (HC) to External Clock (EC) or External Resonator(XT) is not possible.

If a PLL is available, the PLL input divider can only be programmed during device programming. However, the PLL output divider and the PLL multiplier can be changed during run-time using the PLL functions described in the PLL section.

Secondary Oscillator (Sosc)

The optional Secondary Oscillator is designed specifically for low-power operation with an external crystal. The Secondary Oscillator is enabled in hardware by the device Configuration bits. Once it is enabled in hardware, it can be switched on during software run-time.

```
bool oscSecondary_st;

oscSecondary_st = PLIB_OSC_SecondaryIsEnabled(OSC_ID_0);
if(oscSecondary_st)
{
   // Unlock the Oscillator Registers
   PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);

   PLIB_OSC_SecondaryDisable(OSC_ID_0);
}
```

Internal Fast RC (FRC) Oscillator

The FRC Oscillator is a fast user-trimmable internal RC oscillator with a user-selectable input divider, PLL multiplier, and output divider. See the **"Oscillator"** chapter in the specific device data sheet for more information on the FRC oscillator.

Once the FRC oscillator is selected using the device Configuration registers or an oscillator switch is initiated selecting the FRC as a new oscillator, the FRC Oscillator PLL divider can be changed during run-time.

```
OSC_FRC_DIV FRCDivisor;

//Get the current divider value for FRC
FRCDivisor = PLIB_OSC_FRCDivisorGet(OSC_ID_0);

if(FRCDivisor != OSC_FRC_DIV_4)
{
    // Unlock the Oscillator Registers
    PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);

    PLIB_OSC_FRCDivisorSelect ( OSC_ID_0, OSC_FRC_DIV_4 );
}
```

Internal Low-Power RC (LPRC) Oscillator

The LPRC Oscillator is separate from the FRC Oscillator. It oscillates at a nominal frequency of 31.25 kHz (this value is device-dependent). The LPRC Oscillator can act as the clock source for the Power-up Timer (PWRT), Watchdog Timer (WDT), Fail-Safe Clock Monitor (FSCM), and PLL reference circuits. It can also be used to provide a low-frequency clock source option for the device in those applications where power consumption is critical and timing accuracy is not required.

The LPRC remains enabled after power on in the following conditions:

- Fail-safe clock monitoring is enabled
- Watchdog Timer is enabled
- LPRC is selected as the system clock

PLL Configuration

```
OSC_SYSPLL_OUT_DIV PLLOutDiv;
OSC_SYSPLL_MULTIPLIER pll_multiply;

// Unlock the Oscillator Registers
PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);

pll_multiply = PLIB_OSC_SysPLLMultiplierGet(OSC_ID_0);
if(pll_multiply != 15)
{
    PLIB_OSC_SysPLLMultiplierSelect(OSC_ID_0, 15);
}
PLLOutDiv = PLIB_OSC_SysPLLOutputDivisorGet(OSC_ID_0);

if(PLLOutDiv != OSC_SYSPLL_OUT_DIV_8)
{
    PLIB_OSC_SysPLLOutputDivisorSelect(OSC_ID_0, OSC_SYSPLL_OUT_DIV_8);
}
```

Fail-Safe Clock Monitor

Fail-Safe Clock Monitor (FSCM)

The Fail-Safe Clock Monitor (FSCM) is designed to allow continued device operation if the current oscillator fails. It is intended for use with the Primary Oscillator (Posc) and automatically switches to the FRC oscillator if a Posc failure is detected. The switch to the FRC oscillator allows continued device operation and the ability to retry the Posc or to execute the appropriate for a clock failure.

The FSCM can be enabled in the device configuration during the programming of the device. During run-time, the clock failure status can be obtained as follows:

```
bool clockFail;

//Returns true if clock failure is detected.
clockFail = PLIB_OSC_ClockHasFailed(OSC_ID_0);
```

Internal FRC Oscillator Tuning

Tuning the Oscillator

Oscillator tuning will help compensate for temperature effects on the FRC frequency over a wide range of temperatures. The tuning step size is an approximation, the application is supposed to try different values to achieve the best result. In some of the devices there are different tuning modes available.

Direct Number Method

FRC tuning is based on the number specified by the PLIB_OSC_FRCTuningSelect function.

```
PLIB_OSC_FRCTuningModeSet(OSC_ID_0, OSC_TUNING_USING_NUMBER);

PLIB_OSC_FRCTuningSelect(OSC_ID_0, 0x11);
```

Sequential Dithering

To get the sequential dithering working, the client needs to set eight sequencer values. Value 0 is set using the PLIB_OSC_FRCTuningSelect function. The other seven values (values 1 through 7) are set using the PLIB_OSC_FRCTuningSequenceValueSet function.

```
// Unlock the Oscillator Registers
PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);

PLIB_OSC_FRCTuningModeSet(OSC_ID_0, OSC_TUNING_SEQ_DITHER);

PLIB_OSC_FRCTuningSelect(OSC_ID_0, 0x11);

PLIB_OSC_FRCTuningSequenceValueSet(OSC_ID_0, OSC_TUNING_SEQUENCER_1,
        OSC_FRC_TUNE_MINUS_2_25_PERCENT);

PLIB_OSC_FRCTuningSequenceValueSet(OSC_ID_0, OSC_TUNING_SEQUENCER_2,
        OSC_FRC_TUNE_MINUS_1_5_PERCENT);

PLIB_OSC_FRCTuningSequenceValueSet(OSC_ID_0, OSC_TUNING_SEQUENCER_3,
        OSC_FRC_TUNE_MINUS_0_375_PERCENT);

PLIB_OSC_FRCTuningSequenceValueSet(OSC_ID_0, OSC_TUNING_SEQUENCER_4,
        OSC_FRC_TUNE_PLUS_0_43_PERCENT);

PLIB_OSC_FRCTuningSequenceValueSet(OSC_ID_0, OSC_TUNING_SEQUENCER_5,
        OSC_FRC_TUNE_PLUS_1_29_PERCENT);

PLIB_OSC_FRCTuningSequenceValueSet(OSC_ID_0, OSC_TUNING_SEQUENCER_6,
        OSC_FRC_TUNE_PLUS_2_54_PERCENT);

PLIB_OSC_FRCTuningSequenceValueSet(OSC_ID_0, OSC_TUNING_SEQUENCER_7,
        OSC_FRC_TUNE_MINUS_3_PERCENT);

//Configure PWM (period, pulse width and turn on the module)
```

Pseudo-Random Number

Select the tuning mode. Then, configure the PWM module and set the period and pulse width. The Oscillator system generates a 4-bit number based on a pseudo-random number generation algorithm. It then uses this value to tune the FRC oscillator. The module will generate different frequencies corresponding to the generated pseudo-random numbers every eighth PWM cycle.

```
PLIB_OSC_FRCTuningModeSet(OSC_ID_0, OSC_TUNING_PSEUDO_RANDOM);

//15 bit Linear Feedback shift register value
PLIB_OSC_LinearFeedbackShiftRegSet(OSC_ID_0, 0x7FFF);

//Configure PWM (period, pulse width and turn on the module)
```

Configuring the Library

The library is configured for the supported Oscillator module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Setup Functions

	Name	Description
	PLIB_OSC_OnWaitActionGet	Gets the configured operation to be performed when a WAIT instruction is executed.
	PLIB_OSC_OnWaitActionSet	Selects the operation to be performed when a WAIT instruction is executed.
	PLIB_OSC_SlewDisable	Disables the selected type of slewing.
	PLIB_OSC_SlewDivisorStepGet	Get the slew divisor maximum step.

	PLIB_OSC_SlewDivisorStepSelect	Selects division steps used while slewing.
	PLIB_OSC_SlewEnable	Enables the selected type of slewing.
	PLIB_OSC_SlewIsEnabled	Returns 'true' if the reference oscillator is disabled in Idle mode.
	PLIB_OSC_SleepToStartupClockGet	Returns the clock used for the duration when the device wakes from sleep and the clock ready.
	PLIB_OSC_SleepToStartupClockSelect	Selects the clock duration for when the device wakes from sleep and the clock is ready.
	PLIB_OSC_DreamModeDisable	Disables the dream mode.
	PLIB_OSC_DreamModeEnable	Enables the dream mode.
	PLIB_OSC_DreamModeStatus	gets the status of the dream mode.

b) Primary Oscillator Setup Functions

	Name	Description
	PLIB_OSC_ClockIsReady	Get the ready status of clock.
	PLIB_OSC_ClockSlewingIsActive	Returns the status of clock slewing.
	PLIB_OSC_SystemClockDivisorGet	Get the system clock divisor value.
	PLIB_OSC_SystemClockDivisorSelect	Selects system clock divisor.

c) Secondary Oscillator Setup Functions

	Name	Description
	PLIB_OSC_SecondaryDisable	Disables the Secondary Oscillator.
	PLIB_OSC_SecondaryEnable	Enables the Secondary Oscillator.
	PLIB_OSC_SecondaryIsEnabled	Returns 'true' if the Secondary Oscillator is enabled.
	PLIB_OSC_SecondaryIsReady	Returns 'true' if the Secondary Oscillator is ready.

d) Reference Oscillator Setup Functions

	Name	Description
	PLIB_OSC_ReferenceOscBaseClockSelect	Sets the base clock for the reference oscillator.
	PLIB_OSC_ReferenceOscDisable	Disables the reference oscillator output.
	PLIB_OSC_ReferenceOscDivisorValueSet	Selects the reference oscillator divisor value.
	PLIB_OSC_ReferenceOscEnable	Enables the reference oscillator.
	PLIB_OSC_ReferenceOscIsEnabled	Gets the enable status of the reference oscillator output.
	PLIB_OSC_ReferenceOscSourceChangeIsActive	Returns 'true' if a reference oscillator source change request is active.
	PLIB_OSC_ReferenceOscStopInIdleDisable	Enables the reference oscillator in Idle mode.
	PLIB_OSC_ReferenceOscStopInIdleEnable	Configures the reference oscillator to stop operating in Idle mode.
	PLIB_OSC_ReferenceOscStopInIdleIsEnabled	Returns 'true' if the reference oscillator is disabled in Idle mode.
	PLIB_OSC_ReferenceOscStopInSleepDisable	Enables the reference oscillator in Sleep mode.
	PLIB_OSC_ReferenceOscStopInSleepEnable	Configures the reference oscillator to stop operating in Sleep mode.
	PLIB_OSC_ReferenceOscStopInSleepIsEnabled	Returns 'true' if the reference oscillator is disabled in Sleep mode.
	PLIB_OSC_ReferenceOscSwitchIsComplete	Returns 'true' if the reference oscillator base clock switching is complete.
	PLIB_OSC_ReferenceOscTrimSet	Sets the reference oscillator divisor trim value.
	PLIB_OSC_ReferenceOutputDisable	Disables the reference oscillator output.
	PLIB_OSC_ReferenceOutputEnable	Enables the reference oscillator output.
	PLIB_OSC_ReferenceOutputIsEnabled	Returns 'true' if the reference oscillator output is enabled.

e) Fast RC Oscillator Setup Functions

	Name	Description
	PLIB_OSC_FRCDivisorGet	Gets the FRC clock divisor.
	PLIB_OSC_FRCDivisorSelect	Sets the FRC clock divisor to the specified value.
	PLIB_OSC_FRCTuningSelect	Sets the FRC tuning value.

f) Oscillator Switch Setup Functions

	Name	Description
	PLIB_OSC_ClockSwitchingAbort	Aborts an oscillator switch.
	PLIB_OSC_ClockSwitchingIsComplete	Gets the oscillator switch progress status.
	PLIB_OSC_CurrentSysClockGet	Gets the current oscillator selected.
	PLIB_OSC_SysClockSelect	Selects the new oscillator.

g) USB and Display Clock Setup Functions

	Name	Description
	PLIB_OSC_UsbClockSourceGet	Gets the USB module clock source.
	PLIB_OSC_UsbClockSourceSelect	Sets the USB module clock source.

h) PLL Setup Functions

	Name	Description
	PLIB_OSC_PLLClockIsLocked	Gets the lock status for the clock and PLL selections.
	PLIB_OSC_PLLClockLock	Locks the clock and PLL selections.
	PLIB_OSC_PLLClockUnlock	Unlocks the clock and PLL selections.
	PLIB_OSC_PLLIsLocked	Returns 'true' if the selected PLL module is locked.
	PLIB_OSC_SysPLLFrequencyRangeGet	Gets the frequency range for the PLL module.
	PLIB_OSC_SysPLLFrequencyRangeSet	Sets the frequency range for the PLL module.
	PLIB_OSC_SysPLLInputClockSourceGet	Gets the input clock source for the PLL module.
	PLIB_OSC_SysPLLInputClockSourceSet	Sets the input clock source for the PLL module.
	PLIB_OSC_SysPLLInputDivisorGet	Gets the input divisor for the PLL.
	PLIB_OSC_SysPLLMultiplierGet	Gets the PLL multiplier.
	PLIB_OSC_SysPLLMultiplierSelect	Sets the PLL multiplier to the specified value.
	PLIB_OSC_SysPLLOutputDivisorGet	Gets the output divisor for the PLL.
	PLIB_OSC_SysPLLOutputDivisorSet	Sets the output divider for the PLL to the specified value.
	PLIB_OSC_SysPLLInputDivisorSet	Sets the input divider for the PLL to the specified value.
	PLIB_OSC_BTPLLClockOutDisable	Disables the Bluetooth PLL Clock Output.
	PLIB_OSC_BTPLLClockOutEnable	Enables the Bluetooth PLL clock Ouput.
	PLIB_OSC_BTPLLClockOutStatus	gets the status of the Bluetooth PLL clock Output.
	PLIB_OSC_BTPLLFrequencyRangeGet	Gets the frequency range for the Bluetooth PLL module.
	PLIB_OSC_BTPLLFrequencyRangeSet	Sets the frequency range for the Bluetooth PLL module.
	PLIB_OSC_BTPLLInputClockSourceGet	Gets the input clock source for the Bluetooth PLL module.
	PLIB_OSC_BTPLLInputClockSourceSet	Sets the input clock source for the Bluetooth PLL module.
	PLIB_OSC_BTPLLInputDivisorGet	Gets the input divisor for the Bluetooth PLL.
	PLIB_OSC_BTPLLInputDivisorSet	Sets the input divider for the Bluetooth PLL to the specified value.
	PLIB_OSC_BTPLLMultiplierGet	Gets the Bluetooth PLL multiplier.
	PLIB_OSC_BTPLLMultiplierSelect	Sets the Bluetooth PLL multiplier to the specified value.
	PLIB_OSC_BTPLLOutputDivisorGet	Gets the output divisor for the PLL.
	PLIB_OSC_BTPLLOutputDivisorSet	Sets the output divider for the Bluetooth PLL to the specified value.
	PLIB_OSC_ForceSPLLLockDisable	Disables the Force PLL Lock feature for specified PLL.
	PLIB_OSC_ForceSPLLLockEnable	Enables the Force PLL Lock feature for specified PLL.
	PLIB_OSC_ForceSPLLLockStatus	gets the status of the force PLL Lock bit of the specified PLL.
	PLIB_OSC_PLLBypassDisable	Disables the PLL Bypass.
	PLIB_OSC_PLLBypassEnable	Enables the PLL Bypass.
	PLIB_OSC_PLLBypassStatus	gets the status of the PLL Bypass.
	PLIB_OSC_UPLLFrequencyRangeGet	Gets the frequency range for the USB PLL module.
	PLIB_OSC_UPLLFrequencyRangeSet	Sets the frequency range for the USB PLL module.
	PLIB_OSC_UPLLInputDivisorGet	Gets the input divisor for the USB PLL.
	PLIB_OSC_UPLLInputDivisorSet	Sets the input divider for the USB PLL to the specified value.
	PLIB_OSC_UPLLMultiplierGet	Gets the USB PLL multiplier.
	PLIB_OSC_UPLLMultiplierSelect	Sets the USB PLL multiplier to the specified value.
	PLIB_OSC_UPLLOutputDivisorGet	Gets the output divisor for the PLL.
	PLIB_OSC_UPLLOutputDivisorSet	Sets the output divider for the USB PLL to the specified value.
	PLIB_OSC_ResetPLLAssert	Asserts the PLL reset for selected PLL.
	PLIB_OSC_ResetPLLDeassert	Deasserts the PLL reset for selected PLL.
	PLIB_OSC_ResetPLLStatus	gets the status of the PLL reset bit for the specified PLL.

i) Peripheral Clock Setup Functions

	Name	Description
	PLIB_OSC_PBClockDivisorGet	Gets the peripheral bus clock divisor.
	PLIB_OSC_PBClockDivisorIsReady	Checks whether the peripheral bus clock divisor is ready to be written.
	PLIB_OSC_PBClockDivisorSet	Sets the peripheral bus clock divisor to the specified value.
	PLIB_OSC_PBOutputClockDisable	Disables the peripheral bus output clock.
	PLIB_OSC_PBOutputClockEnable	Enables the peripheral bus output clock
	PLIB_OSC_PBOutputClockIsEnabled	Checks whether or not the peripheral bus clock output is enabled.

j) Clock Functions

	Name	Description
	PLIB_OSC_ClockHasFailed	Returns 'true' if the clock fails.
	PLIB_OSC_ClockStart	Starts the specified clock source.
	PLIB_OSC_ClockStop	Stops the specified clock source.
	PLIB_OSC_ClockStopStatus	returns the status of clock stop bit for the specified clock source.

k) Feature Existence Functions

	Name	Description
	PLIB_OSC_ExistsClockFail	Identifies whether the ClockFail feature exists on the Oscillator module.
	PLIB_OSC_ExistsFRCDivisor	Identifies whether the FRCDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsFRCTuning	Identifies whether the FRCTuning feature exists on the Oscillator module.
	PLIB_OSC_ExistsOnWaitAction	Identifies whether the OnWaitAction feature exists on the Oscillator module.
	PLIB_OSC_ExistsOscCurrentGet	Identifies whether the OscCurrentGet feature exists on the Oscillator module.
	PLIB_OSC_ExistsOscSelect	Identifies whether the OscSelect feature exists on the Oscillator module.
	PLIB_OSC_ExistsOscSwitchInit	Identifies whether the OscSwitchInit feature exists on the Oscillator module.
	PLIB_OSC_ExistsPBClockDivisor	Identifies whether the PBClockDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsPBClockOutputEnable	Identifies whether the PBClockOutputEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsPBClockReady	Identifies whether the PBClockReady feature exists on the Oscillator module.
	PLIB_OSC_ExistsPLLClockLock	Identifies whether the PLLClockLock feature exists on the Oscillator module.
	PLIB_OSC_ExistsPLLLockStatus	Identifies whether the PLLLockStatus feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscBaseClock	Identifies whether the ReferenceOscBaseClock feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscChange	Identifies whether the ReferenceOscChange feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscChangeActive	Identifies whether the ReferenceOscChangeActive feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscDivisor	Identifies whether the ReferenceOscDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscEnable	Identifies whether the ReferenceOscEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscStopInIdleEnable	Identifies whether the ReferenceOscStopInIdleEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscStopInSleep	Identifies whether the ReferenceOscStopInSleep feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscTrim	Identifies whether the ReferenceOscTrim feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOutputEnable	Identifies whether the ReferenceOutputEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsSecondaryEnable	Identifies whether the SecondaryEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsSecondaryReady	Identifies whether the SecondaryReady feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLFrequencyRange	Identifies whether the PLLFrequencyRange feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLInputClockSource	Identifies whether the PLLInputClockSource feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLInputDivisor	Identifies whether the PLLInputDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLMultiplier	Identifies whether the PLLMultiplier feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLOutputDivisor	Identifies whether the PLLOutputDivisor feature exists on the Oscillator module.

	PLIB_OSC_ExistsUsbClockSource	Identifies whether the UsbClockSource feature exists on the Oscillator module.
	PLIB_OSC_ExistsClockReadyStatus	Identifies whether the ClockReadyStatus feature exists on the Oscillator module.
	PLIB_OSC_ExistsClockSlewingStatus	Identifies whether the ClockSlewingStatus feature exists on the Oscillator module.
	PLIB_OSC_ExistsSleepToStartupClock	Identifies whether the SleepToStartupClock feature exists on the Oscillator module.
	PLIB_OSC_ExistsSlewDivisorStepControl	Identifies whether the SlewDivisorStepControl feature exists on the Oscillator module.
	PLIB_OSC_ExistsSlewEnableControl	Identifies whether the SlewEnableControl feature exists on the Oscillator module.
	PLIB_OSC_ExistsSystemClockDivisorControl	Identifies whether the SystemClockDivisorControl feature exists on the Oscillator module.
	PLIB_OSC_ExistsBTPLLClockOut	Identifies whether the BTPLLClockOut feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLFrequencyRange	Identifies whether the BTPLLFrequencyRange feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLInputClockSource	Identifies whether the BTPLLInputClockSource feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLInputDivisor	Identifies whether the BTPLLInputDivisor feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLMultiplier	Identifies whether the BTPLLMultiplier feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLOutputDivisor	Identifies whether the BTPLLOutputDivisor feature exists on the OSC module
	PLIB_OSC_ExistsClockDiagStatus	Identifies whether the ClockDiagStatus feature exists on the OSC module
	PLIB_OSC_ExistsDreamModeControl	Identifies whether the DreamModeControl feature exists on the OSC module
	PLIB_OSC_ExistsForceLock	Identifies whether the ForceLock feature exists on the OSC module
	PLIB_OSC_ExistsPLLBypass	Identifies whether the SPLLBypass feature exists on the OSC module
	PLIB_OSC_ExistsResetPLL	Identifies whether the ResetPLL feature exists on the OSC module
	PLIB_OSC_ExistsUPLLFrequencyRange	Identifies whether the UPLLFrequencyRange feature exists on the OSC module
	PLIB_OSC_ExistsUPLLInputDivisor	Identifies whether the UPLLInputDivisor feature exists on the OSC module
	PLIB_OSC_ExistsUPLLMultiplier	Identifies whether the UPLLMultiplier feature exists on the OSC module
	PLIB_OSC_ExistsUPLLOutputDivisor	Identifies whether the UPLLOutputDivisor feature exists on the OSC module

l) Data Types and Constants

	Name	Description
	OSC_PB_CLOCK_DIV_TYPE	Type of the oscillator PB Clock divisor value.
	OSC_REF_DIVISOR_TYPE	Reference oscillator divisor type.
	OSC_REFERENCE_MAX_DIV	Defines the reference clock output divisor maximum value.
	OSC_SYSPLL_MULTIPLIER_TYPE	Type of the oscillator system PLL multiplier value.
	OSC_FRC_DIV	Lists the possible Fast RC (FRC) Oscillator divider values.
	OSC_MODULE_ID	Possible instances of the OSC module.
	OSC_OPERATION_ON_WAIT	Lists the possible base clock values for the reference oscillator.
	OSC_PERIPHERAL_BUS	Lists the possible Peripheral buses.
	OSC_PLL_SELECT	Lists the PLLs in the Oscillator module.
	OSC_REFERENCE	Lists the possible reference oscillator.
	OSC_SYS_TYPE	Lists the possible oscillator type values.
	OSC_SYSPLL_FREQ_RANGE	Lists the possible PLL frequency range.
	OSC_SYSPLL_IN_CLK_SOURCE	Lists the possible input clock source for PLL module.
	OSC_SYSPLL_OUT_DIV	Lists the possible PLL output divider values.
	OSC_USBCLOCK_SOURCE	Lists the possible USB clock sources.
	OSC_CLOCK_ID	Lists the clock sources for which ready status can be checked.
	OSC_CLOCK_SLEW_TYPE	Lists the possible type of clock slewing.
	OSC_SLEEP_TO_STARTUP_CLK_TYPE	Lists the possible clock sources for sleep to start-up period.

Description

This section describes the Application Programming Interface (API) functions of the Oscillator Peripheral Library.

Refer to each section for a detailed description.

a) General Setup Functions

PLIB_OSC_OnWaitActionGet Function

Gets the configured operation to be performed when a WAIT instruction is executed.

File

plib_osc.h

C

```
OSC_OPERATION_ON_WAIT PLIB_OSC_OnWaitActionGet(OSC_MODULE_ID index);
```

Returns

On a WAIT action, one of the possible values of OSC_OPERATION_ON_WAIT.

Description

This function gets the configured operation that is to be performed when a WAIT instruction is executed.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsOnWaitAction in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_OSC_OnWaitActionGet(OSC_ID_0) == OSC_ON_WAIT_SLEEP)
{
    //Do some action
}
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_OPERATION_ON_WAIT PLIB_OSC_OnWaitActionGet (OSC_MODULE_ID index)

PLIB_OSC_OnWaitActionSet Function

Selects the operation to be performed when a WAIT instruction is executed.

File

plib_osc.h

C

```
void PLIB_OSC_OnWaitActionSet(OSC_MODULE_ID index, OSC_OPERATION_ON_WAIT onWait);
```

Returns

None.

Description

This function selects the operation to be performed when a WAIT instruction is executed.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsOnWaitAction in your application to determine whether this feature is available.

If this function is not called, the device will enter Idle mode on execution of a WAIT instruction.

Preconditions

None.

Example

```
PLIB_OSC_OnWaitActionSet(OSC_ID_0, OSC_ON_WAIT_SLEEP);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
onWait	Operation to be performed when a WAIT instruction is executed. One of the possible values of OSC_OPERATION_ON_WAIT.

Function

void PLIB_OSC_OnWaitActionSet (OSC_MODULE_ID index,
OSC_OPERATION_ON_WAIT onWait)

PLIB_OSC_SlewDisable Function

Disables the selected type of slewing.

File

plib_osc.h

C

```
void PLIB_OSC_SlewDisable(OSC_MODULE_ID index, OSC_CLOCK_SLEW_TYPE slewType);
```

Returns

None.

Description

This function disables slewing to an upward or downward frequency based on the selection.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSlewEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SlewDisable(OSC_ID_0, OSC_CLOCK_SLEW_DOWNWARD);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
slewType	One of the possible value from OSC_CLOCK_SLEW_TYPE

Function

void PLIB_OSC_SlewDisable (OSC_MODULE_ID index, OSC_CLOCK_SLEW_TYPE slewType)

PLIB_OSC_SlewDivisorStepGet Function

Get the slew divisor maximum step.

File

plib_osc.h

C

```
uint32_t PLIB_OSC_SlewDivisorStepGet(OSC_MODULE_ID index);
```

Returns

- slewSteps - Number of steps in which slewing is occurring

Description

This function returns the number of division steps used when slewing during a frequency change.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSlewDivisorStepControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t slewSteps;
slewSteps = PLIB_OSC_SlewDivisorStepGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint32_t PLIB_OSC_SlewDivisorStepGet

(

OSC_MODULE_ID index

)

PLIB_OSC_SlewDivisorStepSelect Function

Selects division steps used while slewing.

File

plib_osc.h

C

```
void PLIB_OSC_SlewDivisorStepSelect(OSC_MODULE_ID index, uint32_t slewSteps);
```

Returns

None.

Description

This API selects number of division steps to be used when slewing during a frequency change. If the number of steps chosen is 0, no divisor will be used while slewing. If the number of steps chosen is 1, slewing will start with divide by 2, and then no divisor. Similarly, if the number of steps chosen is 2, slewing will start with divisor 4. Then,after a few seconds the divisor will be 2, and then after a few more seconds no divisor will be used and so on. Therefore, the largest step would be equal to 2^(number of steps), and then the step size will reduce by half every few seconds.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSlewDivisorStepControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SlewDivisorStepSelect(OSC_ID_0, OSC_SLEW_DIVISOR_STEP_MAX_32);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
slewSteps	Number of steps in which slewing is desired

Function

void PLIB_OSC_SlewDivisorStepSelect

(
OSC_MODULE_ID index,
uint32_t slewSteps
)

PLIB_OSC_SlewEnable Function

Enables the selected type of slewing.

File

plib_osc.h

C

```
void PLIB_OSC_SlewEnable(OSC_MODULE_ID index, OSC_CLOCK_SLEW_TYPE slewType);
```

Returns

None.

Description

This function enables slewing to an upward or downward frequency based on the selection.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSlewEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SlewEnable(OSC_ID_0, OSC_CLOCK_SLEW_DOWNWARD);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
slewType	One of the possible value from OSC_CLOCK_SLEW_TYPE

Function

void PLIB_OSC_SlewEnable (OSC_MODULE_ID index, OSC_CLOCK_SLEW_TYPE slewType)

PLIB_OSC_SlewIsEnabled Function

Returns 'true' if the reference oscillator is disabled in Idle mode.

File

plib_osc.h

C

```
bool PLIB_OSC_SlewIsEnabled(OSC_MODULE_ID index, OSC_CLOCK_SLEW_TYPE slewType);
```

Returns

- true - The selected type of Slewing is enabled
- false - The selected type of Slewing is disabled

Description

This function returns 'true' if the reference oscillator is disabled in Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSlewEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool slewStatus;
slewStatus = PLIB_OSC_SlewIsEnabled(OSC_ID_0, OSC_CLOCK_SLEW_DOWNWARD);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
slewType	One of the possible value from OSC_CLOCK_SLEW_TYPE.

Function

bool PLIB_OSC_SlewIsEnabled (OSC_MODULE_ID index, OSC_CLOCK_SLEW_TYPE slewType)

PLIB_OSC_SleepToStartupClockGet Function

Returns the clock used for the duration when the device wakes from sleep and the clock ready.

File

plib_osc.h

C

```
OSC_SLEEP_TO_STARTUP_CLK_TYPE PLIB_OSC_SleepToStartupClockGet(OSC_MODULE_ID index);
```

Returns

- startupOsc - One of the possible values from OSC_SLEEP_TO_STARTUP_CLK_TYPE

Description

When a device enters Sleep mode, the source of the system clock usually stops and takes some time after waking up to start running at full speed. This function is to return the clock set for that duration in which the actual clock source is starting up.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSleepToStartupClock in your application to determine whether this feature is available.

Preconditions

None.

Example

```
OSC_SLEEP_TO_STARTUP_CLK_TYPE startupClk;
startupClk = PLIB_OSC_SleepToStartupClockGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_SLEEP_TO_STARTUP_CLK_TYPE PLIB_OSC_SleepToStartupClockGet
(
OSC_MODULE_ID index
)

PLIB_OSC_SleepToStartupClockSelect Function

Selects the clock duration for when the device wakes from sleep and the clock is ready.

File

plib_osc.h

C

```
void PLIB_OSC_SleepToStartupClockSelect(OSC_MODULE_ID index, OSC_SLEEP_TO_STARTUP_CLK_TYPE startupOsc);
```

Returns

None.

Description

When a device enters Sleep mode, the source of the system clock usually stops and takes some time after waking up to start running at full speed. This function allows the user to select a clock for that duration in which the actual clock source is starting up.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSleepToStartupClock in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SleepToStartupClockSelect(OSC_ID_0, OSC_SLEEP_TO_STARTUP_CLK_FRC);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
startupOsc	One of the possible values from OSC_SLEEP_TO_STARTUP_CLK_TYPE

Function

void PLIB_OSC_SleepToStartupClockSelect

(

OSC_MODULE_ID index,

OSC_SLEEP_TO_STARTUP_CLK_TYPE startupOsc

)

PLIB_OSC_DreamModeDisable Function

Disables the dream mode.

File

plib_osc.h

C

```
void PLIB_OSC_DreamModeDisable(OSC_MODULE_ID index);
```

Returns

None.

Description

This function is used to disable the dream mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsDreamModeControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_DreamModeDisable(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_DreamModeDisable (OSC_MODULE_ID index)

PLIB_OSC_DreamModeEnable Function

Enables the dream mode.

File

plib_osc.h

C

```
void PLIB_OSC_DreamModeEnable(OSC_MODULE_ID index);
```

Returns

None.

Description

This function is used to enable the dream mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsDreamModeControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_DreamModeEnable(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_DreamModeEnable (OSC_MODULE_ID index)

PLIB_OSC_DreamModeStatus Function

gets the status of the dream mode.

File

plib_osc.h

C

```
bool PLIB_OSC_DreamModeStatus(OSC_MODULE_ID index);
```

Returns

Status of dream mode bit.

Description

This function is used to get the status of the dream mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsDreamModeControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool drmMode = PLIB_OSC_DreamModeStatus(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

bool PLIB_OSC_DreamModeStatus (OSC_MODULE_ID index)

b) Primary Oscillator Setup Functions

PLIB_OSC_ClockIsReady Function

Get the ready status of clock.

File

plib_osc.h

C

```
bool PLIB_OSC_ClockIsReady(OSC_MODULE_ID index, OSC_CLOCK_ID clk);
```

Returns

- true - Indicates that the selected clock is running and is stable
- false - Indicates that the selected clock is either turned off or is still warming up

Description

This function returns the ready status of selected clock.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsClockReadyStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool clkReady;
clkReady = PLIB_OSC_ClockIsReady(OSC_ID_0, OSC_CLOCK_FAST_RC);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module.
clk	One of the values of OSC_CLOCK_ID.

Function

bool PLIB_OSC_ClockIsReady (OSC_MODULE_ID index, OSC_CLOCK_ID clk)

PLIB_OSC_ClockSlewingIsActive Function

Returns the status of clock slewing.

File

plib_osc.h

C

```
bool PLIB_OSC_ClockSlewingIsActive(OSC_MODULE_ID index);
```

Returns

- true - The clock frequency is being actively slewed to the new frequency.
- false - The clock switch has reached its final value

Description

This function returns the current status of clock switching slewing.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsClockSlewingStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_OSC_ClockSlewingIsActive(OSC_ID_0))
{
    //wait for clock switch to complete
}
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module.

Function

bool PLIB_OSC_ClockSlewingIsActive (OSC_MODULE_ID index)

PLIB_OSC_SystemClockDivisorGet Function

Get the system clock divisor value.

File

plib_osc.h

C

```
uint32_t PLIB_OSC_SystemClockDivisorGet(OSC_MODULE_ID index);
```

Returns

- systemClkDivisor - The value by which system clock is divided.

Description

This function returns the divisor set for system clock.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSystemClockDivisorControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t systemClkDivisor;
systemClkDivisor = PLIB_OSC_SystemClockDivisorGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint32_t PLIB_OSC_SystemClockDivisorGet
(
OSC_MODULE_ID index
)

PLIB_OSC_SystemClockDivisorSelect Function

Selects system clock divisor.

File

plib_osc.h

C

```
void PLIB_OSC_SystemClockDivisorSelect(OSC_MODULE_ID index, uint32_t systemClkDivisor);
```

Returns

None.

Description

This function selects the system clock divisor.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSystemClockDivisorControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SystemClockDivisorSelect(OSC_ID_0, OSC_SYSTEM_CLOCK_DIVIDED_BY_10);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
systemClkDivisor	The value by which the system clock is to be divided

Function

void PLIB_OSC_SystemClockDivisorSelect
(
OSC_MODULE_ID index,
uint32_t systemClkDivisor
)

c) Secondary Oscillator Setup Functions

PLIB_OSC_SecondaryDisable Function

Disables the Secondary Oscillator.

File

plib_osc.h

C

```
void PLIB_OSC_SecondaryDisable(OSC_MODULE_ID index);
```

Returns

None.

Description

This function disables the Secondary Oscillator.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSecondaryEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SecondaryDisable(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_SecondaryDisable (OSC_MODULE_ID index);

PLIB_OSC_SecondaryEnable Function

Enables the Secondary Oscillator.

File

plib_osc.h

C

```
void PLIB_OSC_SecondaryEnable(OSC_MODULE_ID index);
```

Returns

None.

Description

This function enables the Secondary Oscillator.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSecondaryEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SecondaryEnable(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_SecondaryEnable (OSC_MODULE_ID index)

PLIB_OSC_SecondaryIsEnabled Function

Returns 'true' if the Secondary Oscillator is enabled.

File

plib_osc.h

C

```
bool PLIB_OSC_SecondaryIsEnabled(OSC_MODULE_ID index);
```

Returns

- true - The Secondary Oscillator is enabled
- false - The Secondary Oscillator is disabled

Description

This function returns 'true' if the Secondary Oscillator is enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSecondaryEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool secOscEnable;

secOscEnable = PLIB_OSC_SecondaryIsEnabled(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

bool PLIB_OSC_SecondaryIsEnabled (OSC_MODULE_ID index);

PLIB_OSC_SecondaryIsReady Function

Returns 'true' if the Secondary Oscillator is ready.

File

plib_osc.h

C

```
bool PLIB_OSC_SecondaryIsReady(OSC_MODULE_ID index);
```

Returns

- true - Indicates that the Secondary Oscillator is running and is stable
- false - Indicates that the Secondary Oscillator is either turned off or is still warming up

Description

This function returns the ready status of the Secondary Oscillator.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSecondaryReady in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool secOscReady;

secOscReady = PLIB_OSC_SecondaryIsReady(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

bool PLIB_OSC_SecondaryIsReady (OSC_MODULE_ID index)

d) Reference Oscillator Setup Functions

PLIB_OSC_ReferenceOscBaseClockSelect Function

Sets the base clock for the reference oscillator.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscBaseClockSelect(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc,
OSC_REF_BASECLOCK refOscBaseClock);
```

Returns

None.

Description

This function sets the base clock for the reference oscillator. There are multiple clock sources by which the user can configure the module to output to the pin. Users can check the accuracy of the clock by probing the pin. Use the PLIB_OSC_ReferenceOscDivisorValueSet function to divide the clock if it is a very high value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscBaseClock in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOscBaseClockSelect(OSC_ID_0, OSC_REFERENCE_1, OSC_REF_BASECLOCK_PBCLK);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator
refOscBaseClk	One of the possible values of OSC_REF_BASECLOCK

Function

void PLIB_OSC_ReferenceOscBaseClockSelect (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc, OSC_REF_BASECLOCK refOscBaseClock)

PLIB_OSC_ReferenceOscDisable Function

Disables the reference oscillator output.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscDisable(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

None.

Description

This function disables output from the reference oscillator.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOscDisable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

void PLIB_OSC_ReferenceOscDisable (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscDivisorValueSet Function

Selects the reference oscillator divisor value.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscDivisorValueSet(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc,
OSC_REF_DIVISOR_TYPE refOscDivValue);
```

Returns

None.

Description

This function selects the reference oscillator divisor value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscDivisor in your application to determine whether this feature is available.

The value entered may not be the actual divisor. Please refer to the specific device data sheet to determine the actual divisor corresponding to the value entered.

Preconditions

None.

Example

```
// Select the clock source.
PLIB_OSC_ReferenceOscBaseClockSelect(OSC_ID_0, OSC_REFERENCE_1, OSC_REF_BASECLOCK_PBCLK);

PLIB_OSC_ReferenceOscDivisorValueSet(OSC_ID_0, OSC_REFERENCE_1, 128);

PLIB_OSC_ReferenceOscEnable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator
refOscDivValue	Value for Reference Oscillator Divisor (RODIV) field. If it is '0', the divider is not used.

Function

void PLIB_OSC_ReferenceOscDivisorValueSet (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc,
OSC_REF_DIVISOR_TYPE refOscDivValue)

PLIB_OSC_ReferenceOscEnable Function

Enables the reference oscillator.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscEnable(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

None.

Description

This function enables the reference oscillator.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscEnable in your application to determine whether this feature is available.

If the device has a reference clock output enable control, calling this function may not give the reference clock output. Use the PLIB_OSC_ReferenceOutputEnable function to enable the output.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOscEnable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

void PLIB_OSC_ReferenceOscEnable (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscIsEnabled Function

Gets the enable status of the reference oscillator output.

File

plib_osc.h

C

```
bool PLIB_OSC_ReferenceOscIsEnabled(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

- true - The reference oscillator is enabled
- false - The reference oscillator is disabled

Description

This function gets the enable status of the reference oscillator output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_OSC_ReferenceOscIsEnabled(OSC_ID_0, OSC_REFERENCE_1))
{
//Do some action
}
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

bool PLIB_OSC_ReferenceOscIsEnabled (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscSourceChangeIsActive Function

Returns 'true' if a reference oscillator source change request is active.

File

plib_osc.h

C

```
bool PLIB_OSC_ReferenceOscSourceChangeIsActive(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

- true - The reference oscillator change request is active
- false - The reference oscillator change request is not active

Description

This function returns 'true' if the reference oscillator source change is in progress. The software is not allowed to give a new source change request.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscChangeActive in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (!PLIB_OSC_ReferenceOscSourceChangeIsActive(OSC_ID_0, OSC_REFERENCE_1))
{
    //Allowed to change the reference clock source
}
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

bool PLIB_OSC_ReferenceOscSourceChangeIsActive (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscStopInIdleDisable Function

Enables the reference oscillator in Idle mode.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscStopInIdleDisable(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

None.

Description

This function enables the reference oscillator in Idle mode. The reference oscillator continues to run in Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscStopInIdleEnable in your application to determine whether this feature is available.

The default state of the device is the reference oscillator is enabled in Idle mode.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOsctopInSleepDisable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

void PLIB_OSC_ReferenceOscStopInIdleDisable (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscStopInIdleEnable Function

Configures the reference oscillator to stop operating in Idle mode.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscStopInIdleEnable(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

None.

Description

This function configures the reference oscillator to stop operating in Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscStopInIdleEnable in your application to determine whether this feature is available.

The default state of the device is reference oscillator enabled in Idle mode. Therefore, calling this function is necessary only if the PLIB_OSC_ReferenceOscStopInIdleDisable function was previously called, and the software wants to enable oscillator operation in Sleep mode.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOscStopInIdleEnable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

void PLIB_OSC_ReferenceOscStopInIdleEnable (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscStopInIdleIsEnabled Function

Returns 'true' if the reference oscillator is disabled in Idle mode.

File

plib_osc.h

C

```
bool PLIB_OSC_ReferenceOscStopInIdleIsEnabled(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

- true - The reference oscillator is disabled in Idle mode
- false - The reference oscillator is enabled in Idle mode

Description

This function returns 'true' if the reference oscillator is disabled in Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscStopInIdleEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool refOscIdle;

refOscIdle = PLIB_OSC_ReferenceOscStopInIdleIsEnabled(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

bool PLIB_OSC_ReferenceOscStopInIdleIsEnabled (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscStopInSleepDisable Function

Enables the reference oscillator in Sleep mode.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscStopInSleepDisable(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

None.

Description

This function enables the reference oscillator in Sleep mode. The reference oscillator continues to run in Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscStopInSleep in your application to determine whether this feature is available.

The reference clock output will be stopped in Sleep mode if the base clock selected is 'System Clock' or 'Peripheral Clock' regardless of this function.

The default state of the device is for the reference oscillator to be enabled in Sleep mode. Therefore, calling this function is necessary only if the PLIB_OSC_ReferenceOscStopInSleepEnable function was previously called, and the software wants to enable oscillator operation in Sleep mode.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOsctopInSleepDisable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

void PLIB_OSC_ReferenceOscStopInSleepDisable (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscStopInSleepEnable Function

Configures the reference oscillator to stop operating in Sleep mode.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscStopInSleepEnable(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

None.

Description

This function configures the reference oscillator to stop operating in Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscStopInSleep in your application to determine whether this feature is available.

The default state of the device is for the reference oscillator to be enabled in Sleep mode.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOscStopInSleepEnable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

void PLIB_OSC_ReferenceOscStopInSleepEnable (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscStopInSleepIsEnabled Function

Returns 'true' if the reference oscillator is disabled in Sleep mode.

File

plib_osc.h

C

```
bool PLIB_OSC_ReferenceOscStopInSleepIsEnabled(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

- true - The reference oscillator is disabled in Sleep mode
- false - The reference oscillator is enabled in Sleep mode

Description

This function returns 'true' if the reference oscillator is disabled in Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscStopInSleep in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool refOscSleep;

refOscSleep = PLIB_OSC_ReferenceOscStopInSleepIsEnabled(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

bool PLIB_OSC_ReferenceOscStopInSleepIsEnabled (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscSwitchIsComplete Function

Returns 'true' if the reference oscillator base clock switching is complete.

File

plib_osc.h

C

```
bool PLIB_OSC_ReferenceOscSwitchIsComplete(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

- true - The reference clock base clock switching is complete
- false - The reference clock base clock switching is not complete; switching is not started

Description

This function returns 'true' if the reference oscillator base clock switching is complete.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscChange in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool refOscIdle;

refOscIdle = PLIB_OSC_ReferenceOscSwitchIsComplete(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

bool PLIB_OSC_ReferenceOscSwitchIsComplete (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOscTrimSet Function

Sets the reference oscillator divisor trim value.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOscTrimSet(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc, OSC_REF_TRIM_TYPE
trimValue);
```

Returns

None.

Description

This function selects the reference oscillator divisor trim value. The value selected divided by OSC_REF_TRIM_MAX_VALUE will be added to the oscillator divisor value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOscTrim in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOscTrimSet(OSC_ID_0, OSC_REFERENCE_1, 50);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator
trimValue	Reference oscillator trim value

Function

void PLIB_OSC_ReferenceOscTrimSet (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc,
OSC_REF_TRIM_TYPE trimValue)

PLIB_OSC_ReferenceOutputDisable Function

Disables the reference oscillator output.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOutputDisable(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

None.

Description

This function disables the reference oscillator output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOutputEnable in your application to determine whether this feature is available.

The default state of the device is reference oscillator output disabled.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOutputDisable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

void PLIB_OSC_ReferenceOutputDisable (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOutputEnable Function

Enables the reference oscillator output.

File

plib_osc.h

C

```
void PLIB_OSC_ReferenceOutputEnable(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

None.

Description

This function enables the reference oscillator output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOutputEnable in your application to determine whether this feature is available.

The default state of the device is reference oscillator output disabled.

Preconditions

None.

Example

```
PLIB_OSC_ReferenceOutputEnable(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

void PLIB_OSC_ReferenceOutputEnable (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

PLIB_OSC_ReferenceOutputIsEnabled Function

Returns 'true' if the reference oscillator output is enabled.

File

plib_osc.h

C

```
bool PLIB_OSC_ReferenceOutputIsEnabled(OSC_MODULE_ID index, OSC_REFERENCE referenceOsc);
```

Returns

- true - The reference oscillator output is enabled
- false - The reference oscillator output is disabled

Description

This function returns 'true' if the reference oscillator output is enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsReferenceOutputEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool refOscIdle;

refOscIdle = PLIB_OSC_ReferenceOutputIsEnabled(OSC_ID_0, OSC_REFERENCE_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
referenceOsc	Identifies the desired reference oscillator

Function

bool PLIB_OSC_ReferenceOutputIsEnabled (OSC_MODULE_ID index, OSC_REFERENCE referenceOsc)

e) Fast RC Oscillator Setup Functions

PLIB_OSC_FRCDivisorGet Function

Gets the FRC clock divisor.

File

plib_osc.h

C

```
uint16_t PLIB_OSC_FRCDivisorGet(OSC_MODULE_ID index);
```

Returns

The FRC divisor value.

Description

This function gets the FRC clock divisor. The value returned will be direct number and not enum equivalent.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsFRCDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t divisorFRC;

divisorFRC = PLIB_OSC_FRCDivisorGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint16_t PLIB_OSC_FRCDivisorGet(OSC_MODULE_ID index)

PLIB_OSC_FRCDivisorSelect Function

Sets the FRC clock divisor to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_FRCDivisorSelect(OSC_MODULE_ID index, OSC_FRC_DIV divisorFRC);
```

Returns

None.

Description

This function sets the FRC clock divisor to the specified value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsFRCDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_FRCDivisorSelect ( OSC_ID_0, OSC_FRC_DIV_4 );
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
divisorFRC	One of the possible values from OSC_FRC_DIV

Function

void PLIB_OSC_FRCDivisorSelect (OSC_MODULE_ID index,
OSC_FRC_DIV divisorFRC)

PLIB_OSC_FRCTuningSelect Function

Sets the FRC tuning value.

File

plib_osc.h

C

```
void PLIB_OSC_FRCTuningSelect(OSC_MODULE_ID index, OSC_FRC_TUNE_TYPE tuningValue);
```

Returns

None.

Description

This function tunes the FRC oscillator to the value specified. The application is supposed to try different values and find the best one. If the device has different tuning modes, this function will be used differently. See the example provided for the PLIB_OSC_FRCTuningSequenceValueSet function for details.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsFRCTuning in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_FRCTuningSelect(OSC_ID_0, 0x05);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
tuningValue	Tuning value. One of the possible values from OSC_FRC_TUNE_TYPE.

Function

void PLIB_OSC_FRCTuningSelect (OSC_MODULE_ID index,
OSC_FRC_TUNE_TYPE tuningValue)

f) Oscillator Switch Setup Functions

PLIB_OSC_ClockSwitchingAbort Function

Aborts an oscillator switch.

File

plib_osc.h

C

```
void PLIB_OSC_ClockSwitchingAbort(OSC_MODULE_ID index);
```

Returns

None.

Description

This function aborts the oscillator switch to the selection specified by the new oscillator selection bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsOscSwitchInit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ClockSwitchingAbort(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_ClockSwitchingAbort (OSC_MODULE_ID index)

PLIB_OSC_ClockSwitchingIsComplete Function

Gets the oscillator switch progress status.

File

plib_osc.h

C

```
bool PLIB_OSC_ClockSwitchingIsComplete(OSC_MODULE_ID index);
```

Returns

- true - The oscillator switch is complete
- false - The oscillator switch is in progress

Description

This function gets the status of the oscillator switch progress.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsOscSwitchInit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SysClockSelect(OSC_ID_0, OSC_PRIMARY);

while(!PLIB_OSC_ClockSwitchingIsComplete(OSC_ID_0));
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

bool PLIB_OSC_ClockSwitchingIsComplete(OSC_MODULE_ID index);

PLIB_OSC_CurrentSysClockGet Function

Gets the current oscillator selected.

File

plib_osc.h

C

```
OSC_SYS_TYPE PLIB_OSC_CurrentSysClockGet(OSC_MODULE_ID index);
```

Returns

One of the possible values from OSC_SYS_TYPE.

Description

This function gets the current oscillator. If the application has not changed the oscillator selection, this will be same as the oscillator selected through the Configuration bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsOscCurrentGet in your application to determine whether this feature is available.

Preconditions

None.

Example

```
OSC_SYS_TYPE oscCurrent;

oscCurrent = PLIB_OSC_CurrentSysClockGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_SYS_TYPE PLIB_OSC_CurrentSysClockGet (OSC_MODULE_ID index)

PLIB_OSC_SysClockSelect Function

Selects the new oscillator.

File

plib_osc.h

C

```
void PLIB_OSC_SysClockSelect(OSC_MODULE_ID index, OSC_SYS_TYPE newOsc);
```

Returns

None.

Description

This function selects the new oscillator.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsOscSelect in your application to determine whether this feature is available.

This function adds the necessary delay (NOP instructions) after switching the oscillator. Therefore, the user need not add any delay as specified in the device data sheet.

Preconditions

None.

Example

```
PLIB_OSC_SysClockSelect(OSC_ID_0, OSC_PRIMARY);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
newOsc	One of the possible values from OSC_SYS_TYPE

Function

void PLIB_OSC_SysClockSelect (OSC_MODULE_ID index,
OSC_SYS_TYPE newOsc)

g) USB and Display Clock Setup Functions

PLIB_OSC_UsbClockSourceGet Function

Gets the USB module clock source.

File

plib_osc.h

C

```
OSC_USBCLOCK_SOURCE PLIB_OSC_UsbClockSourceGet(OSC_MODULE_ID index);
```

Returns

USB module clock source. One of the possible values from OSC_USBCLOCK_SOURCE.

Description

This function gets the USB module clock source.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUsbClockSource in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (SYS_OSC_USBCLK_FRC == PLIB_OSC_UsbClockSourceGet(OSC_ID_0))
{
//Do some action
}
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_USBCLOCK_SOURCE PLIB_OSC_UsbClockSourceGet (OSC_MODULE_ID index)

PLIB_OSC_UsbClockSourceSelect Function

Sets the USB module clock source.

File

plib_osc.h

C

```
void PLIB_OSC_UsbClockSourceSelect(OSC_MODULE_ID index, OSC_USBCLOCK_SOURCE usbClock);
```

Returns

None.

Description

This function sets the USB module clock source.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUsbClockSource in your application to determine whether this feature is available.

Before placing the USB module in Suspend mode, use this function to enable the FRC clock.

Preconditions

None.

Example

```
PLIB_OSC_UsbClockSourceSelect(OSC_ID_0, SYS_OSC_USBCLK_FRC);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
usbClock	Select the USB module clock source. One of the possible values from OSC_USBCLOCK_SOURCE.

Function

void PLIB_OSC_UsbClockSourceSelect (OSC_MODULE_ID index,
OSC_USBCLOCK_SOURCE usbClock)

h) PLL Setup Functions

PLIB_OSC_PLLClockIsLocked Function

Gets the lock status for the clock and PLL selections.

File

plib_osc.h

C

```
bool PLIB_OSC_PLLClockIsLocked(OSC_MODULE_ID index);
```

Returns

- true - The clock and PLL selections are locked
- false - The clock and PLL selections are not locked

Description

This function gets the lock status for the clock and PLL selections.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPLLClockLock in your application to determine whether this feature is available.

If the PLL does not stabilize properly during start-up, this function may not reflect the actual status of PLL lock, nor does it detect when the PLL loses lock during normal operation.

Preconditions

None.

Example

```
bool clockPLL_st;

clockPLL_st = PLIB_OSC_PLLClockIsLocked(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

bool PLIB_OSC_PLLClockIsLocked (OSC_MODULE_ID index)

PLIB_OSC_PLLClockLock Function

Locks the clock and PLL selections.

File

plib_osc.h

C

```
void PLIB_OSC_PLLClockLock(OSC_MODULE_ID index);
```

Returns

None.

Description

This function locks the clock and PLL selections.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPLLClockLock in your application to determine whether this feature is available.

The data given by this function is only valid if clock switching and monitoring are enabled. Otherwise Clock and PLL selections are never locked and may be modified.

Preconditions

The Fail-Safe Clock Monitor (FSCM) should be enabled.

Example

```
PLIB_OSC_PLLClockLock(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_PLLClockLock (OSC_MODULE_ID index)

PLIB_OSC_PLLClockUnlock Function

Unlocks the clock and PLL selections.

File

plib_osc.h

C

```
void PLIB_OSC_PLLClockUnlock(OSC_MODULE_ID index);
```

Returns

None.

Description

This function unlocks the clock and PLL selection so that the clock and PLL may be modified.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPLLClockLock in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_PLLClockUnlock(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_PLLClockUnlock (OSC_MODULE_ID index)

PLIB_OSC_PLLIsLocked Function

Returns 'true' if the selected PLL module is locked.

File

plib_osc.h

C

```
bool PLIB_OSC_PLLIsLocked(OSC_MODULE_ID index, OSC_PLL_SELECT pllselect);
```

Returns

- true - The PLL module is in lock or the PLL module start-up timer is satisfied
- false - The PLL module is out of lock, the PLL start-up timer is running, or the PLL module is disabled

Description

This function returns the lock status of the selected PLL module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPLLLockStatus in your application to determine whether this feature is available.

If the PLL does not stabilize properly during start-up, this function may not reflect the actual status of PLL lock, nor does it detect when the PLL loses lock during normal operation.

Preconditions

None.

Example

```
bool lockPLL_status;

lockPLL_status = PLIB_OSC_PLLIsLocked(OSC_ID_0, OSC_PLL_SYSTEM);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllselect	Selects the PLL module

Function

bool PLIB_OSC_PLLIsLocked (OSC_MODULE_ID index, OSC_PLL_SELECT pllselect)

PLIB_OSC_SysPLLFrequencyRangeGet Function

Gets the frequency range for the PLL module.

File

plib_osc.h

C

```
OSC_SYSPLL_FREQ_RANGE PLIB_OSC_SysPLLFrequencyRangeGet(OSC_MODULE_ID index);
```

Returns

- PLLFrequencyRange - One of the possible values from OSC_SYSPLL_FREQ_RANGE

Description

This function returns the frequency range set for the PLL module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLFrequencyRange in your application to determine whether this feature is available.

Preconditions

None.

Example

```
OSC_SYSPLL_FREQ_RANGE PLLFrequencyRange;
PLLFrequencyRange = PLIB_OSC_SysPLLFrequencyRangeGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_SYSPLL_FREQ_RANGE PLIB_OSC_SysPLLFrequencyRangeGet (OSC_MODULE_ID index)

PLIB_OSC_SysPLLFrequencyRangeSet Function

Sets the frequency range for the PLL module.

File

plib_osc.h

C

```
void PLIB_OSC_SysPLLFrequencyRangeSet(OSC_MODULE_ID index, OSC_SYSPLL_FREQ_RANGE PLLFrequencyRange);
```

Returns

None.

Description

This function sets the frequency range for the PLL module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLFrequencyRange in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SysPLLFrequencyRangeSet(OSC_ID_0, OSC_SYSPLL_FREQ_RANGE_5M_TO_10M);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLFrequencyRange	One of the possible values from OSC_SYSPLL_FREQ_RANGE

Function

void PLIB_OSC_SysPLLFrequencyRangeSet (OSC_MODULE_ID index,
OSC_SYSPLL_FREQ_RANGE PLLFrequencyRange)

PLIB_OSC_SysPLLInputClockSourceGet Function

Gets the input clock source for the PLL module.

File

plib_osc.h

C

```
OSC_SYSPLL_IN_CLK_SOURCE PLIB_OSC_SysPLLInputClockSourceGet(OSC_MODULE_ID index);
```

Returns

- PLLInClockSource - One of the possible values from OSC_SYSPLL_IN_CLK_SOURCE

Description

This function returns the input clock source for the PLL module

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLInputClockSource in your application to determine whether this feature is available.

Preconditions

None.

Example

```
OSC_SYSPLL_IN_CLK_SOURCE PLLInClockSource;
PLLInClockSource = PLIB_OSC_SysPLLInputClockSourceGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_SYSPLL_IN_CLK_SOURCE PLIB_OSC_SysPLLInputClockSourceGet (OSC_MODULE_ID index)

PLIB_OSC_SysPLLInputClockSourceSet Function

Sets the input clock source for the PLL module.

File

plib_osc.h

C

```
void PLIB_OSC_SysPLLInputClockSourceSet(OSC_MODULE_ID index, OSC_SYSPLL_IN_CLK_SOURCE PLLInClockSource);
```

Returns

None.

Description

This function sets the input clock source for the PLL module

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLInputClockSource in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SysPLLInputClockSourceSet(OSC_ID_0, OSC_SYSPLL_IN_CLK_SOURCE_FRC);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLInClockSource	One of the possible values from OSC_SYSPLL_IN_CLK_SOURCE

Function

void PLIB_OSC_SysPLLInputClockSourceSet (OSC_MODULE_ID index,
OSC_SYSPLL_IN_CLK_SOURCE PLLInClockSource)

PLIB_OSC_SysPLLInputDivisorGet Function

Gets the input divisor for the PLL.

File

plib_osc.h

C

```
uint16_t PLIB_OSC_SysPLLInputDivisorGet(OSC_MODULE_ID index);
```

Returns

The System PLL input divisor as a number.

Description

This function returns the input divisor for the PLL.

Remarks

The direct register value itself is returned instead of the register value equivalent.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLInputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t pllInDiv;
```

```
PLLInDiv = PLIB_OSC_SysPLLInputDivisorGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint16_t PLIB_OSC_SysPLLInputDivisorGet (OSC_MODULE_ID index)

PLIB_OSC_SysPLLMultiplierGet Function

Gets the PLL multiplier.

File

plib_osc.h

C

```
OSC_SYSPLL_MULTIPLIER_TYPE PLIB_OSC_SysPLLMultiplierGet(OSC_MODULE_ID index);
```

Returns

One of the possible values of PB clock divisor of type OSC_SYSPLL_MULTIPLIER_TYPE.

Description

This function returns the PLL multiplier.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLMultiplier in your application to determine whether this feature is available.

The actual multiplier value will be returned, and NOT the 'PLLMULT' field value. Refer to the specific device data sheet for information.

Preconditions

None.

Example

```
OSC_SYSPLL_MULTIPLIER_TYPE pll_multiply;

pll_multiply = PLIB_OSC_SysPLLMultiplierGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_SYSPLL_MULTIPLIER_TYPE PLIB_OSC_SysPLLMultiplierGet (OSC_MODULE_ID index)

PLIB_OSC_SysPLLMultiplierSelect Function

Sets the PLL multiplier to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_SysPLLMultiplierSelect(OSC_MODULE_ID index, OSC_SYSPLL_MULTIPLIER_TYPE pll_multiplier);
```

Returns

None.

Description

This function sets the PLL multiplier to the specified value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLMultiplier in your application to determine whether this feature is available.

Use the PLL Multiplier value directly for the parameter 'pll_multiplier', and NOT the value of the 'PLLMULT' field. Use of the PLL Multiplier value is not supported by the selected device, and therefore, library behavior is undefined. Refer to the specific device data sheet for information.

Preconditions

None.

Example

```
PLIB_OSC_SysPLLMultiplierSelect (OSC_ID_0, 0x08);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pll_multiplier	One of the possible values of PB clock divisor of type OSC_PLL_MUL_TYPE

Function

void PLIB_OSC_SysPLLMultiplierSelect (OSC_MODULE_ID index,
OSC_SYSPLL_MULTIPLIER_TYPE pll_multiplier)

PLIB_OSC_SysPLLOutputDivisorGet Function

Gets the output divisor for the PLL.

File

plib_osc.h

C

```
uint16_t PLIB_OSC_SysPLLOutputDivisorGet(OSC_MODULE_ID index);
```

Returns

System PLL output divisor value.

Description

This function returns the output divisor for the System PLL. The value is the actual divisor and not the enum value corresponding to it.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLOutputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t pllOutDiv;

pllOutDiv = PLIB_OSC_SysPLLOutputDivisorGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint16_t PLIB_OSC_SysPLLOutputDivisorGet (OSC_MODULE_ID index)

PLIB_OSC_SysPLLOutputDivisorSet Function

Sets the output divider for the PLL to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_SysPLLOutputDivisorSet(OSC_MODULE_ID index, OSC_SYSPLL_OUT_DIV PLLOutDiv);
```

Returns

None.

Description

This function sets the output divider for the PLL to the specified value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLOutputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SysPLLOutputDivisorSelect(OSC_ID_0, OSC_SYSPLL_OUT_DIV_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLOutDiv	One of the possible values from OSC_SYSPLL_OUT_DIV

Function

void PLIB_OSC_SysPLLOutputDivisorSet (OSC_MODULE_ID index,
OSC_SYSPLL_OUT_DIV PLLOutDiv)

PLIB_OSC_SysPLLInputDivisorSet Function

Sets the input divider for the PLL to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_SysPLLInputDivisorSet(OSC_MODULE_ID index, uint16_t PLLInDiv);
```

Returns

None.

Description

This function sets the input divider for the PLL to the specified value.

Remarks

Pass the direct divisor instead of the register value equivalent.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSysPLLInputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_SysPLLInputDivisorSet( OSC_ID_0, 3 );
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLInDiv	System PLL input divisor value

Function

void PLIB_OSC_SysPLLInputDivisorSet (OSC_MODULE_ID index,
uint16_t PLLInDiv)

PLIB_OSC_BTPLLClockOutDisable Function

Disables the Bluetooth PLL Clock Output.

File

plib_osc.h

C

```
void PLIB_OSC_BTPLLClockOutDisable(OSC_MODULE_ID index);
```

Returns

None.

Description

This function is used to disable the Bluetooth PLL clock output to SoC pin.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLClockOut in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_BTPLLClockOutDisable(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_BTPLLClockOutDisable (OSC_MODULE_ID index)

PLIB_OSC_BTPLLClockOutEnable Function

Enables the Bluetooth PLL clock Ouput.

File

plib_osc.h

C

```
void PLIB_OSC_BTPLLClockOutEnable(OSC_MODULE_ID index);
```

Returns

None.

Description

This function is used to enable the Bluetooth PLL clock Output to the SoC pin.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use

PLIB_OSC_ExistsBTPLLClockOut in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_BTPLLClockOutEnable(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

void PLIB_OSC_BTPLLClockOutEnable (OSC_MODULE_ID index)

PLIB_OSC_BTPLLClockOutStatus Function

gets the status of the Bluetooth PLL clock Output.

File

plib_osc.h

C

```
bool PLIB_OSC_BTPLLClockOutStatus(OSC_MODULE_ID index);
```

Returns

Status of Bluetooth PLL clock output.

Description

This function is used to get the status of the Bluetooth PLL clock Output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLClockOut in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool btpllClkOut = PLIB_OSC_BTPLLClockOutStatus(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

bool PLIB_OSC_BTPLLClockOutStatus (OSC_MODULE_ID index)

PLIB_OSC_BTPLLFrequencyRangeGet Function

Gets the frequency range for the Bluetooth PLL module.

File

plib_osc.h

C

```
OSC_BTPLL_FREQ_RANGE PLIB_OSC_BTPLLFrequencyRangeGet(OSC_MODULE_ID index);
```

Returns

- PLLFrequencyRange - One of the possible values from OSC_BTPLL_FREQ_RANGE

Description

This function returns the frequency range set for the Bluetooth PLL module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLFrequencyRange in your application to determine whether this feature is available.

Preconditions

None.

Example

```
OSC_BTPLL_FREQ_RANGE PLLFrequencyRange;
PLLFrequencyRange = PLIB_OSC_BTPLLFrequencyRangeGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_BTPLL_FREQ_RANGE PLIB_OSC_BTPLLFrequencyRangeGet (OSC_MODULE_ID index)

PLIB_OSC_BTPLLFrequencyRangeSet Function

Sets the frequency range for the Bluetooth PLL module.

File

plib_osc.h

C

```
void PLIB_OSC_BTPLLFrequencyRangeSet(OSC_MODULE_ID index, OSC_BTPLL_FREQ_RANGE PLLFrequencyRange);
```

Returns

None.

Description

This function sets the frequency range for the Bluetooth PLL module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLFrequencyRange in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_BTPLLFrequencyRangeSet(OSC_ID_0, OSC_BTPLL_FREQ_RANGE_5M_TO_10M);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLFrequencyRange	One of the possible values from OSC_BTPLL_FREQ_RANGE

Function

void PLIB_OSC_BTPLLFrequencyRangeSet (OSC_MODULE_ID index,
OSC_BTPLL_FREQ_RANGE PLLFrequencyRange)

PLIB_OSC_BTPLLInputClockSourceGet Function

Gets the input clock source for the Bluetooth PLL module.

File

plib_osc.h

C

```
OSC_SYSPLL_IN_CLK_SOURCE PLIB_OSC_BTPLLInputClockSourceGet(OSC_MODULE_ID index);
```

Returns

- PLLInClockSource - One of the possible values from OSC_BTPLL_IN_CLK_SOURCE

Description

This function returns the input clock source for the Bluetooth PLL module

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLInputClockSource in your application to determine whether this feature is available.

Preconditions

None.

Example

```
OSC_BTPLL_IN_CLK_SOURCE PLLInClockSource;
PLLInClockSource = PLIB_OSC_BTPLLInputClockSourceGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_BTPLL_IN_CLK_SOURCE PLIB_OSC_BTPLLInputClockSourceGet (OSC_MODULE_ID index)

PLIB_OSC_BTPLLInputClockSourceSet Function

Sets the input clock source for the Bluetooth PLL module.

File

plib_osc.h

C

```
void PLIB_OSC_BTPLLInputClockSourceSet(OSC_MODULE_ID index, OSC_BTPLL_IN_CLK_SOURCE PLLInClockSource);
```

Returns

None.

Description

This function sets the input clock source for the Bluetooth PLL module

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLInputClockSource in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_BTPLLInputClockSourceSet(OSC_ID_0, OSC_BTPLL_IN_CLK_SOURCE_FRC);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLInClockSource	One of the possible values from OSC_BTPLL_IN_CLK_SOURCE

Function

void PLIB_OSC_BTPLLInputClockSourceSet (OSC_MODULE_ID index,
OSC_BTPLL_IN_CLK_SOURCE PLLInClockSource)

PLIB_OSC_BTPLLInputDivisorGet Function

Gets the input divisor for the Bluetooth PLL.

File

plib_osc.h

C

```
uint16_t PLIB_OSC_BTPLLInputDivisorGet(OSC_MODULE_ID index);
```

Returns

The Bluetooth PLL input divisor as a number.

Description

This function returns the input divisor for the Bluetooth PLL.

Remarks

The direct register value itself is returned instead of the register value equivalent.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLInputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t pllInDiv;

PLLInDiv = PLIB_OSC_BTPLLInputDivisorGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint16_t PLIB_OSC_BTPLLInputDivisorGet (OSC_MODULE_ID index)

PLIB_OSC_BTPLLInputDivisorSet Function

Sets the input divider for the Bluetooth PLL to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_BTPLLInputDivisorSet(OSC_MODULE_ID index, uint16_t PLLInDiv);
```

Returns

None.

Description

This function sets the input divider for the Bluetooth PLL to the specified value.

Remarks

Pass the direct divisor instead of the register value equivalent.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLInputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_BTPLLInputDivisorSet( OSC_ID_0, 3 );
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLInDiv	USB PLL input divisor value

Function

void PLIB_OSC_BTPLLInputDivisorSet (OSC_MODULE_ID index, uint16_t PLLInDiv)

PLIB_OSC_BTPLLMultiplierGet Function

Gets the Bluetooth PLL multiplier.

File

plib_osc.h

C

```
OSC_SYSPLL_MULTIPLIER_TYPE PLIB_OSC_BTPLLMultiplierGet(OSC_MODULE_ID index);
```

Returns

One of the possible values of Bluetooth Multiplier of type OSC_SYSPLL_MULTIPLIER_TYPE.

Description

This function returns the Bluetooth PLL multiplier.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLMultiplier in your application to determine whether this feature is available.

The actual multiplier value will be returned, and NOT the 'BTPLLMULT' field value. Refer to the specific device data sheet for information.

Preconditions

None.

Example

```
OSC_SYSPLL_MULTIPLIER_TYPE pll_multiply;

pll_multiply = PLIB_OSC_BTPLLMultiplierGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_SYSPLL_MULTIPLIER_TYPE PLIB_OSC_BTPLLMultiplierGet (OSC_MODULE_ID index)

PLIB_OSC_BTPLLMultiplierSelect Function

Sets the Bluetooth PLL multiplier to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_BTPLLMultiplierSelect(OSC_MODULE_ID index, OSC_SYSPLL_MULTIPLIER_TYPE pll_multiplier);
```

Returns

None.

Description

This function sets the Bluetooth PLL multiplier to the specified value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLMultiplier in your application to determine whether this feature is available.

Use the USB PLL Multiplier value directly for the parameter 'pll_multiplier', and NOT the value of the 'BTPLLMULT' field. Use of the PLL Multiplier value is not supported by the selected device, and therefore, library behavior is undefined. Refer to the specific device data sheet for information.

Preconditions

None.

Example

```
PLIB_OSC_BTPLLMultiplierSelect (OSC_ID_0, 0x08);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pll_multiplier	One of the possible values between 0 and 255

Function

void PLIB_OSC_BTPLLMultiplierSelect (OSC_MODULE_ID index,
OSC_SYSPLL_MULTIPLIER_TYPE pll_multiplier)

PLIB_OSC_BTPLLOutputDivisorGet Function

Gets the output divisor for the PLL.

File

plib_osc.h

C

```
uint16_t PLIB_OSC_BTPLLOutputDivisorGet(OSC_MODULE_ID index);
```

Returns

Bluetooth PLL output divisor value.

Description

This function returns the output divisor for the Bluetooth PLL. The value is the actual divisor and not the enum value corresponding to it.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLOutputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t pllOutDiv;

pllOutDiv = PLIB_OSC_BTPLLOutputDivisorGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint16_t PLIB_OSC_BTPLLOutputDivisorGet (OSC_MODULE_ID index)

PLIB_OSC_BTPLLOutputDivisorSet Function

Sets the output divider for the Bluetooth PLL to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_BTPLLOutputDivisorSet(OSC_MODULE_ID index, OSC_BTPLL_OUT_DIV PLLOutDiv);
```

Returns

None.

Description

This function sets the output divider for the Bluetooth PLL to the specified value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsBTPLLOutputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_BTPLLOutputDivisorSelect(OSC_ID_0, OSC_BTPLL_OUT_DIV_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLOutDiv	One of the possible values from OSC_BTPLL_OUT_DIV

Function

void PLIB_OSC_BTPLLOutputDivisorSet (OSC_MODULE_ID index,
OSC_BTPLL_OUT_DIV PLLOutDiv)

PLIB_OSC_ForceSPLLLockDisable Function

Disables the Force PLL Lock feature for specified PLL.

File

plib_osc.h

C

```
void PLIB_OSC_ForceSPLLLockDisable(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

None.

Description

This function is used to disable the Force PLL Lock feature for the specified PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsForceLock in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ForceSPLLLockDisable(OSC_ID_0, OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL for which force locked to be disabled

Function

void PLIB_OSC_ForceSPLLLockDisable (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

PLIB_OSC_ForceSPLLLockEnable Function

Enables the Force PLL Lock feature for specified PLL.

File

plib_osc.h

C

```
void PLIB_OSC_ForceSPLLLockEnable(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

None.

Description

This function is used to enable the Force PLL Lock feature for the specified PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsForceLock in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ForceSPLLLockEnable(OSC_ID_0, OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL to be force locked

Function

void PLIB_OSC_ForceSPLLLockEnable (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

PLIB_OSC_ForceSPLLLockStatus Function

gets the status of the force PLL Lock bit of the specified PLL.

File

plib_osc.h

C

```
bool PLIB_OSC_ForceSPLLLockStatus(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

Status of Force PLL Lock Status for the specified PLL.

Description

This function is used to get the status of the force PLL Lock bit of the specified PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use

PLIB_OSC_ExistsForceLock in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool spllFLock = PLIB_OSC_ForceSPLLLockStatus(OSC_ID_0, OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL for which force lock status to be read.

Function

bool PLIB_OSC_ForceSPLLLockStatus (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

PLIB_OSC_PLLBypassDisable Function

Disables the PLL Bypass.

File

plib_osc.h

C

```
void PLIB_OSC_PLLBypassDisable(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

None.

Description

This function is used to disable the PLL Bypass for a specified PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSPLLBypass in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_PLLBypassDisable(OSC_ID_0, OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL for which bypass has to be disabled

Function

void PLIB_OSC_SPLLBypassDisable (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

PLIB_OSC_PLLBypassEnable Function

Enables the PLL Bypass.

File

plib_osc.h

C

```
void PLIB_OSC_PLLBypassEnable(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

None.

Description

This function is used to enable the PLL Bypass for a specified PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPLLBypass in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_PLLBypassEnable(OSC_ID_0, OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL for which bypass has to be enabled

Function

void PLIB_OSC_PLLBypassEnable (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

PLIB_OSC_PLLBypassStatus Function

gets the status of the PLL Bypass.

File

plib_osc.h

C

```
bool PLIB_OSC_PLLBypassStatus(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

Status of SPLL Bypass bit.

Description

This function is used to get the status of the PLL Bypass bit for a specified PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsSPLLBypass in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool spllBypass = PLIB_OSC_SPLLBypassStatus(OSC_ID_0. OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL whose Bypass status has to be read

Function

bool PLIB_OSC_SPLLBypassStatus (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

PLIB_OSC_UPLLFrequencyRangeGet Function

Gets the frequency range for the USB PLL module.

File

plib_osc.h

C

```
OSC_UPLL_FREQ_RANGE PLIB_OSC_UPLLFrequencyRangeGet(OSC_MODULE_ID index);
```

Returns

- PLLFrequencyRange - One of the possible values from OSC_UPLL_FREQ_RANGE

Description

This function returns the frequency range set for the USB PLL module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUPLLFrequencyRange in your application to determine whether this feature is available.

Preconditions

None.

Example

```
OSC_UPLL_FREQ_RANGE PLLFrequencyRange;
PLLFrequencyRange = PLIB_OSC_UPLLFrequencyRangeGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_UPLL_FREQ_RANGE PLIB_OSC_UPLLFrequencyRangeGet (OSC_MODULE_ID index)

PLIB_OSC_UPLLFrequencyRangeSet Function

Sets the frequency range for the USB PLL module.

File

plib_osc.h

C

```
void PLIB_OSC_UPLLFrequencyRangeSet(OSC_MODULE_ID index, OSC_UPLL_FREQ_RANGE PLLFrequencyRange);
```

Returns

None.

Description

This function sets the frequency range for the USB PLL module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUPLLFrequencyRange in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_UPLLFrequencyRangeSet(OSC_ID_0, OSC_UPLL_FREQ_RANGE_5M_TO_10M);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLFrequencyRange	One of the possible values from OSC_UPLL_FREQ_RANGE

Function

void PLIB_OSC_UPLLFrequencyRangeSet (OSC_MODULE_ID index,
OSC_UPLL_FREQ_RANGE PLLFrequencyRange)

PLIB_OSC_UPLLInputDivisorGet Function

Gets the input divisor for the USB PLL.

File

plib_osc.h

C

```
uint16_t PLIB_OSC_UPLLInputDivisorGet(OSC_MODULE_ID index);
```

Returns

The USB PLL input divisor as a number.

Description

This function returns the input divisor for the USB PLL.

Remarks

The direct register value itself is returned instead of the register value equivalent.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUPLLInputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t pllInDiv;

PLLInDiv = PLIB_OSC_UPLLInputDivisorGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint16_t PLIB_OSC_UPLLInputDivisorGet (OSC_MODULE_ID index)

PLIB_OSC_UPLLInputDivisorSet Function

Sets the input divider for the USB PLL to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_UPLLInputDivisorSet(OSC_MODULE_ID index, uint16_t PLLInDiv);
```

Returns

None.

Description

This function sets the input divider for the USB PLL to the specified value.

Remarks

Pass the direct divisor instead of the register value equivalent.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUPLLInputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_UPLLInputDivisorSet( OSC_ID_0, 3 );
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLInDiv	USB PLL input divisor value

Function

void PLIB_OSC_UPLLInputDivisorSet (OSC_MODULE_ID index,

uint16_t PLLInDiv)

PLIB_OSC_UPLLMultiplierGet Function

Gets the USB PLL multiplier.

File

plib_osc.h

C

```
OSC_SYSPLL_MULTIPLIER_TYPE PLIB_OSC_UPLLMultiplierGet(OSC_MODULE_ID index);
```

Returns

One of the possible values of USB Multiplier of type OSC_SYSPLL_MULTIPLIER_TYPE.

Description

This function returns the USB PLL multiplier.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUPLLMultiplier in your application to determine whether this feature is available.

The actual multiplier value will be returned, and NOT the 'UPLLMULT' field value. Refer to the specific device data sheet for information.

Preconditions

None.

Example

```
OSC_SYSPLL_MULTIPLIER_TYPE pll_multiply;

pll_multiply = PLIB_OSC_UPLLMultiplierGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

OSC_SYSPLL_MULTIPLIER_TYPE PLIB_OSC_UPLLMultiplierGet (OSC_MODULE_ID index)

PLIB_OSC_UPLLMultiplierSelect Function

Sets the USB PLL multiplier to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_UPLLMultiplierSelect(OSC_MODULE_ID index, OSC_SYSPLL_MULTIPLIER_TYPE pll_multiplier);
```

Returns

None.

Description

This function sets the USB PLL multiplier to the specified value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUPLLMultiplier in your application to determine whether this feature is available.

Use the USB PLL Multiplier value directly for the parameter 'pll_multiplier', and NOT the value of the 'UPLLMULT' field. Use of the PLL Multiplier value is not supported by the selected device, and therefore, library behavior is undefined. Refer to the specific device data sheet for information.

Preconditions

None.

Example

```
PLIB_OSC_UPLLMultiplierSelect (OSC_ID_0, 0x08);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pll_multiplier	One of the possible values between 0 and 255

Function

void PLIB_OSC_UPLLMultiplierSelect (OSC_MODULE_ID index,
OSC_SYSPLL_MULTIPLIER_TYPE pll_multiplier)

PLIB_OSC_UPLLOutputDivisorGet Function

Gets the output divisor for the PLL.

File

plib_osc.h

C

```
uint16_t PLIB_OSC_UPLLOutputDivisorGet(OSC_MODULE_ID index);
```

Returns

USB PLL output divisor value.

Description

This function returns the output divisor for the USB PLL. The value is the actual divisor and not the enum value corresponding to it.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUPLLOutputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t pllOutDiv;

pllOutDiv = PLIB_OSC_UPLLOutputDivisorGet(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

uint16_t PLIB_OSC_UPLLOutputDivisorGet (OSC_MODULE_ID index)

PLIB_OSC_UPLLOutputDivisorSet Function

Sets the output divider for the USB PLL to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_UPLLOutputDivisorSet(OSC_MODULE_ID index, OSC_UPLL_OUT_DIV PLLOutDiv);
```

Returns

None.

Description

This function sets the output divider for the USB PLL to the specified value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsUPLLOutputDivisor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_UPLLOutputDivisorSelect(OSC_ID_0, OSC_UPLL_OUT_DIV_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
PLLOutDiv	One of the possible values from OSC_UPLL_OUT_DIV

Function

void PLIB_OSC_UPLLOutputDivisorSet (OSC_MODULE_ID index,
OSC_UPLL_OUT_DIV PLLOutDiv)

PLIB_OSC_ResetPLLAssert Function

Asserts the PLL reset for selected PLL.

File

plib_osc.h

C

```
void PLIB_OSC_ResetPLLAssert(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

None.

Description

This function is used to assert the PLL reset for the selected PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use

PLIB_OSC_ExistsResetPLL in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ResetPLLAssert(OSC_ID_0, OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL for which reset to be asserted

Function

void PLIB_OSC_ResetPLLAssert (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

PLIB_OSC_ResetPLLDeassert Function

Deasserts the PLL reset for selected PLL.

File

plib_osc.h

C

```
void PLIB_OSC_ResetPLLDeassert(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

None.

Description

This function is used to deassert the PLL reset for the selected PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsResetPLL in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ResetPLLDeassert(OSC_ID_0, OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL for which reset to be deasserted

Function

void PLIB_OSC_ResetPLLDeassert (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

PLIB_OSC_ResetPLLStatus Function

gets the status of the PLL reset bit for the specified PLL.

File

plib_osc.h

C

```
bool PLIB_OSC_ResetPLLStatus(OSC_MODULE_ID index, OSC_PLL_SELECT pllSel);
```

Returns

Status of PLL reset bit for the specified PLL.

Description

This function is used to get the status of the PLL reset bit for the specified PLL.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsResetPLL in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool upllReset = PLIB_OSC_ResetPLLStatus(OSC_ID_0, OSC_PLL_USB);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
pllSel	PLL whose reset status to be checked

Function

bool PLIB_OSC_ResetPLLStatus (OSC_MODULE_ID index, OSC_PLL_SELECT pllSel)

i) Peripheral Clock Setup Functions

PLIB_OSC_PBClockDivisorGet Function

Gets the peripheral bus clock divisor.

File

plib_osc.h

C

```
OSC_PB_CLOCK_DIV_TYPE PLIB_OSC_PBClockDivisorGet(OSC_MODULE_ID index, OSC_PERIPHERAL_BUS
peripheralBusNumber);
```

Returns

One of the possible values of PB clock divisor of type OSC_PB_CLOCK_DIV_TYPE.

Description

This function returns the peripheral bus clock divisor.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPBClockDivisor in your application to determine whether this feature is available.

Actual Divisor value will be returned, NOT the 'PBDIV' field value. Refer the data sheet of the device for the detail.

Preconditions

None.

Example

```
OSC_PB_CLOCK_DIV_TYPE peripheralBusClkDiv;

peripheralBusClkDiv = PLIB_OSC_PBClockDivisorGet(OSC_ID_0,
                                                 OSC_PERIPHERAL_BUS_1);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

peripheralBusNumber	Identifies the desired peripheral bus

Function

OSC_PB_CLOCK_DIV_TYPE PLIB_OSC_PBClockDivisorGet (OSC_MODULE_ID index,
OSC_PERIPHERAL_BUS peripheralBusNumber)

PLIB_OSC_PBClockDivisorIsReady Function

Checks whether the peripheral bus clock divisor is ready to be written.

File

plib_osc.h

C

```
bool PLIB_OSC_PBClockDivisorIsReady(OSC_MODULE_ID index, OSC_PERIPHERAL_BUS peripheralBusNumber);
```

Returns

- true - The peripheral bus clock divisor can be written
- false - The peripheral bus clock divisor cannot be written

Description

This function checks whether the peripheral bus clock divisor is ready to be written.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPBClockReady in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_OSC_PBClockDivisorIsReady(OSC_ID_0, OSC_PERIPHERAL_BUS_1))
{
    PLIB_OSC_PBClockDivisorSet (OSC_ID_0, OSC_PERIPHERAL_BUS_1,
                                0x01);
}
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
peripheralBusNumber	Identifies the desired peripheral bus

Function

bool PLIB_OSC_PBClockDivisorIsReady(OSC_MODULE_ID index,
OSC_PERIPHERAL_BUS peripheralBusNumber)

PLIB_OSC_PBClockDivisorSet Function

Sets the peripheral bus clock divisor to the specified value.

File

plib_osc.h

C

```
void PLIB_OSC_PBClockDivisorSet(OSC_MODULE_ID index, OSC_PERIPHERAL_BUS peripheralBusNumber,
OSC_PB_CLOCK_DIV_TYPE peripheralBusClkDiv);
```

Returns

None.

Description

This function sets the peripheral bus clock divisor to the specified value.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPBClockDivisor in your application to determine whether this feature is available.

Use PB Divider value directly for the parameter 'peripheralBusClkDiv', and NOT the value of the 'PBDIV' field. Use of the PB Divider value is not supported by the selected device, and therefore, library behavior is undefined. Refer the the specific device data sheet for information.

Preconditions

Peripheral bus clock divisor should be ready to be written.

Example

```
PLIB_OSC_PBClockDivisorSet (OSC_ID_0, OSC_PERIPHERAL_BUS_1, 0x01);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
peripheralBusNumber	Identifies the desired peripheral bus
peripheralBusClkDiv	One of the possible values of PB clock divisor of type OSC_PB_CLOCK_DIV_TYPE

Function

void PLIB_OSC_PBClockDivisorSet(OSC_MODULE_ID index,
OSC_PERIPHERAL_BUS peripheralBusNumber,
OSC_PB_CLOCK_DIV_TYPE peripheralBusClkDiv)

PLIB_OSC_PBOutputClockDisable Function

Disables the peripheral bus output clock.

File

plib_osc.h

C

```
void PLIB_OSC_PBOutputClockDisable(OSC_MODULE_ID index, OSC_PERIPHERAL_BUS peripheralBusNumber);
```

Returns

None

Description

This function disables the peripheral bus output clock.

Remarks

The clock for peripheral bus 1 cannot be turned off.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPBClockOutputEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_PBOutputClockDisable (OSC_ID_0, OSC_PERIPHERAL_BUS_2);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
peripheralBusNumber	Identifies the desired peripheral bus

Function

void PLIB_OSC_PBOutputClockDisable(OSC_MODULE_ID index,
OSC_PERIPHERAL_BUS peripheralBusNumber)

PLIB_OSC_PBOutputClockEnable Function

Enables the peripheral bus output clock

File

plib_osc.h

C

```
void PLIB_OSC_PBOutputClockEnable(OSC_MODULE_ID index, OSC_PERIPHERAL_BUS peripheralBusNumber);
```

Returns

None

Description

This function enables the peripheral bus output clock

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPBClockOutputEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_PBOutputClockEnable (OSC_ID_0, OSC_PERIPHERAL_BUS_2);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
peripheralBusNumber	Identifies the desired peripheral bus

Function

void PLIB_OSC_PBOutputClockEnable(OSC_MODULE_ID index,
OSC_PERIPHERAL_BUS peripheralBusNumber)

PLIB_OSC_PBOutputClockIsEnabled Function

Checks whether or not the peripheral bus clock output is enabled.

File

plib_osc.h

C

```
bool PLIB_OSC_PBOutputClockIsEnabled(OSC_MODULE_ID index, OSC_PERIPHERAL_BUS peripheralBusNumber);
```

Returns

- true - The peripheral bus clock output is enabled
- false - The peripheral bus clock output is disabled

Description

This function checks whether or not the peripheral bus clock output is enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsPBClockOutputEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_OSC_PBOutputClockIsEnabled(OSC_ID_0, OSC_PERIPHERAL_BUS_2))
```

```
{
    PLIB_OSC_PBOutputClockDisable(OSC_ID_0, OSC_PERIPHERAL_BUS_2);
}
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
peripheralBusNumber	Identifies the desired peripheral bus

Function

bool PLIB_OSC_PBOutputClockIsEnabled(OSC_MODULE_ID index,
OSC_PERIPHERAL_BUS peripheralBusNumber)

j) Clock Functions

PLIB_OSC_ClockHasFailed Function

Returns 'true' if the clock fails.

File

plib_osc.h

C

```
bool PLIB_OSC_ClockHasFailed(OSC_MODULE_ID index);
```

Returns

- true - The FSCM detected a clock failure
- false - The no clock failure has been detected

Description

This function returns 'true' if the clock fails. Monitors the Fail-Safe Clock Monitor (FSCM).

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsClockFail in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool clockStatus;
clockStatus = PLIB_OSC_ClockHasFailed(OSC_ID_0);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module

Function

bool PLIB_OSC_ClockHasFailed (OSC_MODULE_ID index);

PLIB_OSC_ClockStart Function

Starts the specified clock source.

File

plib_osc.h

C

```
void PLIB_OSC_ClockStart(OSC_MODULE_ID index, OSC_CLOCK_DIAG clk);
```

Returns

None.

Description

This function is used to start a specified clock source if it has already been stopped.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsClockDiagStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ClockStart(OSC_ID_0, OSC_CLOCK_POSC_STOP);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
clk	Clock to be started

Function

void PLIB_OSC_ClockStart (OSC_MODULE_ID index, OSC_CLOCK_DIAG clk)

PLIB_OSC_ClockStop Function

Stops the specified clock source.

File

plib_osc.h

C

```
void PLIB_OSC_ClockStop(OSC_MODULE_ID index, OSC_CLOCK_DIAG clk);
```

Returns

None.

Description

This function is used to stop a specified clock source.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsClockDiagStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_OSC_ClockStop(OSC_ID_0, OSC_CLOCK_POSC_STOP);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
clk	Clock to be stopped

Function

void PLIB_OSC_ClockStop (OSC_MODULE_ID index, OSC_CLOCK_DIAG clk)

PLIB_OSC_ClockStopStatus Function

returns the status of clock stop bit for the specified clock source.

File

plib_osc.h

C

```
bool PLIB_OSC_ClockStopStatus(OSC_MODULE_ID index, OSC_CLOCK_DIAG clk);
```

Returns

Status of the clock stop bit for a specified clock source.

Description

This function is used to get the status of clock stop bit for the specified clock source.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_OSC_ExistsClockDiagStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool PoscStat = PLIB_OSC_ClockStart(OSC_ID_0, OSC_CLOCK_POSC_STOP);
```

Parameters

Parameters	Description
index	Identifies the desired oscillator module
clk	Clock source whose status to be checked

Function

bool PLIB_OSC_ClockStopStatus (OSC_MODULE_ID index, OSC_CLOCK_DIAG clk)

k) Feature Existence Functions

PLIB_OSC_ExistsClockFail Function

Identifies whether the ClockFail feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsClockFail(OSC_MODULE_ID index);
```

Returns

- true - If the ClockFail feature is supported on the device
- false - If the ClockFail feature is not supported on the device

Description

This function identifies whether the ClockFail feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ClockHasFailed

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsClockFail(OSC_MODULE_ID index)

PLIB_OSC_ExistsFRCDivisor Function

Identifies whether the FRCDivisor feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsFRCDivisor(OSC_MODULE_ID index);
```

Returns

- true - If the FRCDivisor feature is supported on the device
- false - If the FRCDivisor feature is not supported on the device

Description

This function identifies whether the FRCDivisor feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_FRCDivisorSelect
- PLIB_OSC_FRCDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsFRCDivisor(OSC_MODULE_ID index)

PLIB_OSC_ExistsFRCTuning Function

Identifies whether the FRCTuning feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsFRCTuning(OSC_MODULE_ID index);
```

Returns

- true - If the FRCTuning feature is supported on the device
- false - If the FRCTuning feature is not supported on the device

Description

This function identifies whether the FRCTuning feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_FRCTuningSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsFRCTuning(OSC_MODULE_ID index)

PLIB_OSC_ExistsOnWaitAction Function

Identifies whether the OnWaitAction feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsOnWaitAction(OSC_MODULE_ID index);
```

Returns

- true - If the OnWaitAction feature is supported on the device
- false - If the OnWaitAction feature is not supported on the device

Description

This function identifies whether the OnWaitAction feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_OnWaitActionSet
- PLIB_OSC_OnWaitActionGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsOnWaitAction(OSC_MODULE_ID index)

PLIB_OSC_ExistsOscCurrentGet Function

Identifies whether the OscCurrentGet feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsOscCurrentGet(OSC_MODULE_ID index);
```

Returns

- true - If the OscCurrentGet feature is supported on the device
- false - If the OscCurrentGet feature is not supported on the device

Description

This function identifies whether the OscCurrentGet feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_CurrentSysClockGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsOscCurrentGet(OSC_MODULE_ID index)

PLIB_OSC_ExistsOscSelect Function

Identifies whether the OscSelect feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsOscSelect(OSC_MODULE_ID index);
```

Returns

- true - If the OscSelect feature is supported on the device
- false - If the OscSelect feature is not supported on the device

Description

This function identifies whether the OscSelect feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SysClockSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsOscSelect(OSC_MODULE_ID index)

PLIB_OSC_ExistsOscSwitchInit Function

Identifies whether the OscSwitchInit feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsOscSwitchInit(OSC_MODULE_ID index);
```

Returns

- true - If the OscSwitchInit feature is supported on the device
- false - If the OscSwitchInit feature is not supported on the device

Description

This function identifies whether the OscSwitchInit feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ClockSwitchingAbort
- PLIB_OSC_ClockSwitchingIsComplete

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsOscSwitchInit(OSC_MODULE_ID index)

PLIB_OSC_ExistsPBClockDivisor Function

Identifies whether the PBClockDivisor feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsPBClockDivisor(OSC_MODULE_ID index);
```

Returns

- true - If the PBClockDivisor feature is supported on the device
- false - If the PBClockDivisor feature is not supported on the device

Description

This function identifies whether the PBClockDivisor feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_PBClockDivisorGet
- PLIB_OSC_PBClockDivisorSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsPBClockDivisor(OSC_MODULE_ID index)

PLIB_OSC_ExistsPBClockOutputEnable Function

Identifies whether the PBClockOutputEnable feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsPBClockOutputEnable(OSC_MODULE_ID index);
```

Returns

- true - If the PBClockOutputEnable feature is supported on the device
- false - If the PBClockOutputEnable feature is not supported on the device

Description

This function identifies whether the PBClockOutputEnable feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_PBOutputClockEnable
- PLIB_OSC_PBOutputClockDisable
- PLIB_OSC_PBOutputClockIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsPBClockOutputEnable(OSC_MODULE_ID index)

PLIB_OSC_ExistsPBClockReady Function

Identifies whether the PBClockReady feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsPBClockReady(OSC_MODULE_ID index);
```

Returns

- true - If the PBClockReady feature is supported on the device
- false - If the PBClockReady feature is not supported on the device

Description

This function identifies whether the PBClockReady feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_PBClockDivisorIsReady

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsPBClockReady(OSC_MODULE_ID index)

PLIB_OSC_ExistsPLLClockLock Function

Identifies whether the PLLClockLock feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsPLLClockLock(OSC_MODULE_ID index);
```

Returns

- true - If the PLLClockLock feature is supported on the device
- false - If the PLLClockLock feature is not supported on the device

Description

This function identifies whether the PLLClockLock feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_PLLClockLock
- PLIB_OSC_PLLClockUnlock
- PLIB_OSC_PLLClockIsLocked

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsPLLClockLock(OSC_MODULE_ID index)

PLIB_OSC_ExistsPLLLockStatus Function

Identifies whether the PLLLockStatus feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsPLLLockStatus(OSC_MODULE_ID index);
```

Returns

- true - If the PLLLockStatus feature is supported on the device
- false - If the PLLLockStatus feature is not supported on the device

Description

This function identifies whether the PLLLockStatus feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_PLLIsLocked

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsPLLLockStatus(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOscBaseClock Function

Identifies whether the ReferenceOscBaseClock feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOscBaseClock(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOscBaseClock feature is supported on the device
- false - If the ReferenceOscBaseClock feature is not supported on the device

Description

This function identifies whether the ReferenceOscBaseClock feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOscBaseClockSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOscBaseClock(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOscChange Function

Identifies whether the ReferenceOscChange feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOscChange(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOscChange feature is supported on the device
- false - If the ReferenceOscChange feature is not supported on the device

Description

This function identifies whether the ReferenceOscChange feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOscSwitchIsComplete

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOscChange(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOscChangeActive Function

Identifies whether the ReferenceOscChangeActive feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOscChangeActive(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOscChangeActive feature is supported on the device
- false - If the ReferenceOscChangeActive feature is not supported on the device

Description

This function identifies whether the ReferenceOscChangeActive feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOscSourceChangeIsActive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOscChangeActive(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOscDivisor Function

Identifies whether the ReferenceOscDivisor feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOscDivisor(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOscDivisor feature is supported on the device
- false - If the ReferenceOscDivisor feature is not supported on the device

Description

This function identifies whether the ReferenceOscDivisor feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOscDivisorValueSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOscDivisor(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOscEnable Function

Identifies whether the ReferenceOscEnable feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOscEnable(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOscEnable feature is supported on the device
- false - If the ReferenceOscEnable feature is not supported on the device

Description

This function identifies whether the ReferenceOscEnable feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOscEnable
- PLIB_OSC_ReferenceOscDisable
- PLIB_OSC_ReferenceOscIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOscEnable(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOscStopInIdleEnable Function

Identifies whether the ReferenceOscStopInIdleEnable feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOscStopInIdleEnable(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOscStopInIdleEnable feature is supported on the device
- false - If the ReferenceOscStopInIdleEnable feature is not supported on the device

Description

This function identifies whether the ReferenceOscStopInIdleEnable feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOscStopInIdleEnable
- PLIB_OSC_ReferenceOscStopInIdleDisable
- PLIB_OSC_ReferenceOscStopInIdleIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOscStopInIdleEnable(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOscStopInSleep Function

Identifies whether the ReferenceOscStopInSleep feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOscStopInSleep(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOscStopInSleep feature is supported on the device
- false - If the ReferenceOscStopInSleep feature is not supported on the device

Description

This function identifies whether the ReferenceOscStopInSleep feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOscStopInSleepEnable
- PLIB_OSC_ReferenceOscStopInSleepDisable
- PLIB_OSC_ReferenceOscStopInSleepIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOscStopInSleep(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOscTrim Function

Identifies whether the ReferenceOscTrim feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOscTrim(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOscTrim feature is supported on the device
- false - If the ReferenceOscTrim feature is not supported on the device

Description

This function identifies whether the ReferenceOscTrim feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOscTrimSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOscTrim(OSC_MODULE_ID index)

PLIB_OSC_ExistsReferenceOutputEnable Function

Identifies whether the ReferenceOutputEnable feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsReferenceOutputEnable(OSC_MODULE_ID index);
```

Returns

- true - If the ReferenceOutputEnable feature is supported on the device
- false - If the ReferenceOutputEnable feature is not supported on the device

Description

This function identifies whether the ReferenceOutputEnable feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ReferenceOutputEnable
- PLIB_OSC_ReferenceOutputDisable
- PLIB_OSC_ReferenceOutputIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsReferenceOutputEnable(OSC_MODULE_ID index)

PLIB_OSC_ExistsSecondaryEnable Function

Identifies whether the SecondaryEnable feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSecondaryEnable(OSC_MODULE_ID index);
```

Returns

- true - If the SecondaryEnable feature is supported on the device
- false - If the SecondaryEnable feature is not supported on the device

Description

This function identifies whether the SecondaryEnable feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SecondaryEnable
- PLIB_OSC_SecondaryDisable
- PLIB_OSC_SecondaryIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSecondaryEnable(OSC_MODULE_ID index)

PLIB_OSC_ExistsSecondaryReady Function

Identifies whether the SecondaryReady feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSecondaryReady(OSC_MODULE_ID index);
```

Returns

- true - If the SecondaryReady feature is supported on the device
- false - If the SecondaryReady feature is not supported on the device

Description

This function identifies whether the SecondaryReady feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SecondaryIsReady

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSecondaryReady(OSC_MODULE_ID index)

PLIB_OSC_ExistsSysPLLFrequencyRange Function

Identifies whether the PLLFrequencyRange feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSysPLLFrequencyRange(OSC_MODULE_ID index);
```

Returns

- true - If the PLLFrequencyRange feature is supported on the device
- false - If the PLLFrequencyRange feature is not supported on the device

Description

This function identifies whether the PLLFrequencyRange feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SysPLLFrequencyRangeSet
- PLIB_OSC_SysPLLFrequencyRangeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSysPLLFrequencyRange(OSC_MODULE_ID index)

PLIB_OSC_ExistsSysPLLInputClockSource Function

Identifies whether the PLLInputClockSource feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSysPLLInputClockSource(OSC_MODULE_ID index);
```

Returns

- true - If the PLLInputClockSource feature is supported on the device
- false - If the PLLInputClockSource feature is not supported on the device

Description

This function identifies whether the PLLInputClockSource feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SysPLLInputClockSourceSet
- PLIB_OSC_SysPLLInputClockSourceGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSysPLLInputClockSource(OSC_MODULE_ID index)

PLIB_OSC_ExistsSysPLLInputDivisor Function

Identifies whether the PLLInputDivisor feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSysPLLInputDivisor(OSC_MODULE_ID index);
```

Returns

- true - If the PLLInputDivisor feature is supported on the device
- false - If the PLLInputDivisor feature is not supported on the device

Description

This function identifies whether the PLLInputDivisor feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SysPLLInputDivisorSet
- PLIB_OSC_SysPLLInputDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSysPLLInputDivisor(OSC_MODULE_ID index)

PLIB_OSC_ExistsSysPLLMultiplier Function

Identifies whether the PLLMultiplier feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSysPLLMultiplier(OSC_MODULE_ID index);
```

Returns

- true - If the PLLMultiplier feature is supported on the device
- false - If the PLLMultiplier feature is not supported on the device

Description

This function identifies whether the PLLMultiplier feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SysPLLMultiplierSelect
- PLIB_OSC_SysPLLMultiplierGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSysPLLMultiplier(OSC_MODULE_ID index)

PLIB_OSC_ExistsSysPLLOutputDivisor Function

Identifies whether the PLLOutputDivisor feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSysPLLOutputDivisor(OSC_MODULE_ID index);
```

Returns

- true - If the PLLOutputDivisor feature is supported on the device
- false - If the PLLOutputDivisor feature is not supported on the device

Description

This function identifies whether the PLLOutputDivisor feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SysPLLOutputDivisorSet
- PLIB_OSC_SysPLLOutputDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSysPLLOutputDivisor(OSC_MODULE_ID index)

PLIB_OSC_ExistsUsbClockSource Function

Identifies whether the UsbClockSource feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsUsbClockSource(OSC_MODULE_ID index);
```

Returns

- true - If the UsbClockSource feature is supported on the device
- false - If the UsbClockSource feature is not supported on the device

Description

This function identifies whether the UsbClockSource feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_UsbClockSourceSelect
- PLIB_OSC_UsbClockSourceGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsUsbClockSource(OSC_MODULE_ID index)

PLIB_OSC_ExistsClockReadyStatus Function

Identifies whether the ClockReadyStatus feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsClockReadyStatus(OSC_MODULE_ID index);
```

Returns

- true - The ClockReadyStatus feature is supported on the device
- false - The ClockReadyStatus feature is not supported on the device

Description

This function identifies whether the ClockReadyStatus feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ClockIsReady

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsClockReadyStatus(OSC_MODULE_ID index)

PLIB_OSC_ExistsClockSlewingStatus Function

Identifies whether the ClockSlewingStatus feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsClockSlewingStatus(OSC_MODULE_ID index);
```

Returns

- true - The ClockSlewingStatus feature is supported on the device
- false - The ClockSlewingStatus feature is not supported on the device

Description

This function identifies whether the ClockSlewingStatus feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ClockSlewingIsActive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsClockSlewingStatus(OSC_MODULE_ID index)

PLIB_OSC_ExistsSleepToStartupClock Function

Identifies whether the SleepToStartupClock feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSleepToStartupClock(OSC_MODULE_ID index);
```

Returns

- true - The SleepToStartupClock feature is supported on the device
- false - The SleepToStartupClock feature is not supported on the device

Description

This function identifies whether the SleepToStartupClock feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SleepToStartupClockSelect
- PLIB_OSC_SleepToStartupClockGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSleepToStartupClock(OSC_MODULE_ID index)

PLIB_OSC_ExistsSlewDivisorStepControl Function

Identifies whether the SlewDivisorStepControl feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSlewDivisorStepControl(OSC_MODULE_ID index);
```

Returns

- true - The SlewDivisorStepControl feature is supported on the device
- false - The SlewDivisorStepControl feature is not supported on the device

Description

This function identifies whether the SlewDivisorStepControl feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SlewDivisorStepSelect
- PLIB_OSC_SlewDivisorStepGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSlewDivisorStepControl(OSC_MODULE_ID index)

PLIB_OSC_ExistsSlewEnableControl Function

Identifies whether the SlewEnableControl feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSlewEnableControl(OSC_MODULE_ID index);
```

Returns

- true - The SlewEnableControl feature is supported on the device
- false - The SlewEnableControl feature is not supported on the device

Description

This function identifies whether the SlewEnableControl feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SlewEnable
- PLIB_OSC_SlewDisable
- PLIB_OSC_SlewIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSlewEnableControl(OSC_MODULE_ID index)

PLIB_OSC_ExistsSystemClockDivisorControl Function

Identifies whether the SystemClockDivisorControl feature exists on the Oscillator module.

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsSystemClockDivisorControl(OSC_MODULE_ID index);
```

Returns

- true - The SystemClockDivisorControl feature is supported on the device
- false - The SystemClockDivisorControl feature is not supported on the device

Description

This function identifies whether the SystemClockDivisorControl feature is available on the Oscillator module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_SystemClockDivisorSelect
- PLIB_OSC_SystemClockDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsSystemClockDivisorControl(OSC_MODULE_ID index)

PLIB_OSC_ExistsBTPLLClockOut Function

Identifies whether the BTPLLClockOut feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsBTPLLClockOut(OSC_MODULE_ID index);
```

Returns

- true - The BTPLLClockOut feature is supported on the device
- false - The BTPLLClockOut feature is not supported on the device

Description

This function identifies whether the BTPLLClockOut feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_BTPLLClockOutEnable
- PLIB_OSC_BTPLLClockOutDisable
- PLIB_OSC_BTPLLClockOutStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsBTPLLClockOut(OSC_MODULE_ID index)

PLIB_OSC_ExistsBTPLLFrequencyRange Function

Identifies whether the BTPLLFrequencyRange feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsBTPLLFrequencyRange(OSC_MODULE_ID index);
```

Returns

- true - The BTPLLFrequencyRange feature is supported on the device
- false - The BTPLLFrequencyRange feature is not supported on the device

Description

This function identifies whether the BTPLLFrequencyRange feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_BTPLLFrequencyRangeSet
- PLIB_OSC_BTPLLFrequencyRangeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsBTPLLFrequencyRange(OSC_MODULE_ID index)

PLIB_OSC_ExistsBTPLLInputClockSource Function

Identifies whether the BTPLLInputClockSource feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsBTPLLInputClockSource(OSC_MODULE_ID index);
```

Returns

- true - The BTPLLInputClockSource feature is supported on the device
- false - The BTPLLInputClockSource feature is not supported on the device

Description

This function identifies whether the BTPLLInputClockSource feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_BTPLLInputClockSourceSet
- PLIB_OSC_BTPLLInputClockSourceGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsBTPLLInputClockSource(OSC_MODULE_ID index)

PLIB_OSC_ExistsBTPLLInputDivisor Function

Identifies whether the BTPLLInputDivisor feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsBTPLLInputDivisor(OSC_MODULE_ID index);
```

Returns

- true - The BTPLLInputDivisor feature is supported on the device
- false - The BTPLLInputDivisor feature is not supported on the device

Description

This function identifies whether the BTPLLInputDivisor feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_BTPLLInputDivisorSet
- PLIB_OSC_BTPLLInputDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsBTPLLInputDivisor(OSC_MODULE_ID index)

PLIB_OSC_ExistsBTPLLMultiplier Function

Identifies whether the BTPLLMultiplier feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsBTPLLMultiplier(OSC_MODULE_ID index);
```

Returns

- true - The BTPLLMultiplier feature is supported on the device
- false - The BTPLLMultiplier feature is not supported on the device

Description

This function identifies whether the BTPLLMultiplier feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_BTPLLMultiplierSelect
- PLIB_OSC_BTPLLMultiplierGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsBTPLLMultiplier(OSC_MODULE_ID index)

PLIB_OSC_ExistsBTPLLOutputDivisor Function

Identifies whether the BTPLLOutputDivisor feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsBTPLLOutputDivisor(OSC_MODULE_ID index);
```

Returns

- true - The BTPLLOutputDivisor feature is supported on the device
- false - The BTPLLOutputDivisor feature is not supported on the device

Description

This function identifies whether the BTPLLOutputDivisor feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_BTPLLOutputDivisorSet
- PLIB_OSC_BTPLLOutputDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsBTPLLOutputDivisor(OSC_MODULE_ID index)

PLIB_OSC_ExistsClockDiagStatus Function

Identifies whether the ClockDiagStatus feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsClockDiagStatus(OSC_MODULE_ID index);
```

Returns

- true - The ClockDiagStatus feature is supported on the device
- false - The ClockDiagStatus feature is not supported on the device

Description

This function identifies whether the ClockDiagStatus feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ClockStop
- PLIB_OSC_ClockStart
- PLIB_OSC_ClockStopStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsClockDiagStatus(OSC_MODULE_ID index)

PLIB_OSC_ExistsDreamModeControl Function

Identifies whether the DreamModeControl feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsDreamModeControl(OSC_MODULE_ID index);
```

Returns

- true - The DreamModeControl feature is supported on the device
- false - The DreamModeControl feature is not supported on the device

Description

This function identifies whether the DreamModeControl feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_DreamModeEnable
- PLIB_OSC_DreamModeDisable

- PLIB_OSC_DreamModeStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsDreamModeControl(OSC_MODULE_ID index)

PLIB_OSC_ExistsForceLock Function

Identifies whether the ForceLock feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsForceLock(OSC_MODULE_ID index);
```

Returns

- true - The ForceLock feature is supported on the device
- false - The ForceLock feature is not supported on the device

Description

This function identifies whether the ForceLock feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ForceSPLLLockEnable
- PLIB_OSC_ForceSPLLLockDisable
- PLIB_OSC_ForceSPLLLockStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsForceLock(OSC_MODULE_ID index)

PLIB_OSC_ExistsPLLBypass Function

Identifies whether the SPLLBypass feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsPLLBypass(OSC_MODULE_ID index);
```

Returns

- true - The PLLBypass feature is supported on the device

- false - The PLLBypass feature is not supported on the device

Description

This function identifies whether the PLLBypass feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_PLLBypassEnable
- PLIB_OSC_PLLBypassDisable
- PLIB_OSC_PLLBypassStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsPLLBypass(OSC_MODULE_ID index)

PLIB_OSC_ExistsResetPLL Function

Identifies whether the ResetPLL feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsResetPLL(OSC_MODULE_ID index);
```

Returns

- true - The ResetPLL feature is supported on the device
- false - The ResetPLL feature is not supported on the device

Description

This function identifies whether the ResetPLL feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_ResetPLLAssert
- PLIB_OSC_ResetPLLDeassert
- PLIB_OSC_ResetPLLStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsResetPLL(OSC_MODULE_ID index)

PLIB_OSC_ExistsUPLLFrequencyRange Function

Identifies whether the UPLLFrequencyRange feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsUPLLFrequencyRange(OSC_MODULE_ID index);
```

Returns

- true - The UPLLFrequencyRange feature is supported on the device
- false - The UPLLFrequencyRange feature is not supported on the device

Description

This function identifies whether the UPLLFrequencyRange feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_UPLLFrequencyRangeSet
- PLIB_OSC_UPLLFrequencyRangeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsUPLLFrequencyRange(OSC_MODULE_ID index)

PLIB_OSC_ExistsUPLLInputDivisor Function

Identifies whether the UPLLInputDivisor feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsUPLLInputDivisor(OSC_MODULE_ID index);
```

Returns

- true - The UPLLInputDivisor feature is supported on the device
- false - The UPLLInputDivisor feature is not supported on the device

Description

This function identifies whether the UPLLInputDivisor feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_UPLLInputDivisorSet
- PLIB_OSC_UPLLInputDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsUPLLInputDivisor(OSC_MODULE_ID index)

PLIB_OSC_ExistsUPLLMultiplier Function

Identifies whether the UPLLMultiplier feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsUPLLMultiplier(OSC_MODULE_ID index);
```

Returns

- true - The UPLLMultiplier feature is supported on the device
- false - The UPLLMultiplier feature is not supported on the device

Description

This function identifies whether the UPLLMultiplier feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_UPLLMultiplierSelect
- PLIB_OSC_UPLLMultiplierGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsUPLLMultiplier(OSC_MODULE_ID index)

PLIB_OSC_ExistsUPLLOutputDivisor Function

Identifies whether the UPLLOutputDivisor feature exists on the OSC module

File

plib_osc.h

C

```
bool PLIB_OSC_ExistsUPLLOutputDivisor(OSC_MODULE_ID index);
```

Returns

- true - The UPLLOutputDivisor feature is supported on the device
- false - The UPLLOutputDivisor feature is not supported on the device

Description

This function identifies whether the UPLLOutputDivisor feature is available on the OSC module. When this function returns true, these functions are supported on the device:

- PLIB_OSC_UPLLOutputDivisorSet
- PLIB_OSC_UPLLOutputDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_OSC_ExistsUPLLOutputDivisor(OSC_MODULE_ID index)

I) Data Types and Constants

OSC_PB_CLOCK_DIV_TYPE Macro

Type of the oscillator PB Clock divisor value.

File

plib_osc_help.h

C

```
#define OSC_PB_CLOCK_DIV_TYPE SFR_TYPE
```

Description

Oscillator Peripheral Bus Clock Divisor Value Type

This macro defines the type of the oscillator PB Clock divisor value.

Remarks

None.

OSC_REF_DIVISOR_TYPE Macro

Reference oscillator divisor type.

File

plib_osc_help.h

C

```
#define OSC_REF_DIVISOR_TYPE SFR_TYPE
```

Description

Reference oscillator divisor type

This macro defines the reference oscillator divisor type. Please refer to the specific device data sheet to determine the possible values of this type.

Remarks

None.

OSC_REFERENCE_MAX_DIV Macro

Defines the reference clock output divisor maximum value.

File

plib_osc_help.h

C

```
#define OSC_REFERENCE_MAX_DIV 65534
```

Description

Reference clock output divisor maximum

This macro defines the reference clock output divisor maximum value.

Remarks

None.

OSC_SYSPLL_MULTIPLIER_TYPE Macro

Type of the oscillator system PLL multiplier value.

File

plib_osc_help.h

C

```
#define OSC_SYSPLL_MULTIPLIER_TYPE SFR_TYPE
```

Description

Oscillator System PLL Multiplier Value Type

This macro defines the type of the oscillator system PLL multiplier value.

Remarks

None.

OSC_FRC_DIV Enumeration

Lists the possible Fast RC (FRC) Oscillator divider values.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_FRC_DIV_1,
  OSC_FRC_DIV_2,
  OSC_FRC_DIV_4,
  OSC_FRC_DIV_8,
  OSC_FRC_DIV_16,
  OSC_FRC_DIV_32,
  OSC_FRC_DIV_64,
  OSC_FRC_DIV_256
} OSC_FRC_DIV;
```

Members

Members	Description
OSC_FRC_DIV_1	Fast RC Oscillator output Divide by 1
OSC_FRC_DIV_2	Fast RC Oscillator output Divide by 2
OSC_FRC_DIV_4	Fast RC Oscillator output Divide by 4
OSC_FRC_DIV_8	Fast RC Oscillator output Divide by 8
OSC_FRC_DIV_16	Fast RC Oscillator output Divide by 16
OSC_FRC_DIV_32	Fast RC Oscillator output Divide by 32
OSC_FRC_DIV_64	Fast RC Oscillator output Divide by 64
OSC_FRC_DIV_256	Fast RC Oscillator output Divide by 256

Description

FRC divider.

This enumeration lists the possible FRC Oscillator divider values.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_MODULE_ID Enumeration

Possible instances of the OSC module.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_ID_0
} OSC_MODULE_ID;
```

Members

Members	Description
OSC_ID_0	first instance of the OSC

Description

OSC module ID

This data type defines the possible instances of the Oscillator module.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_OPERATION_ON_WAIT Enumeration

Lists the possible base clock values for the reference oscillator.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_REF_BASECLOCK_SYSCLK,
  OSC_REF_BASECLOCK_PBCLK,
  OSC_REF_BASECLOCK_PRIMARY,
  OSC_REF_BASECLOCK_FRC,
  OSC_REF_BASECLOCK_LPRC,
  OSC_REF_BASECLOCK_SOSC,
  OSC_REF_BASECLOCK_USBCLK,
  OSC_REF_BASECLOCK_SYSPLLOUT,
  OSC_ON_WAIT_IDLE,
  OSC_ON_WAIT_SLEEP
} OSC_OPERATION_ON_WAIT;
```

Members

Members	Description
OSC_REF_BASECLOCK_SYSCLK	The base clock for reference clock is System Clock
OSC_REF_BASECLOCK_PBCLK	The base clock for reference clock is Peripheral Clock
OSC_REF_BASECLOCK_PRIMARY	The base clock for reference clock is Primary Oscillator
OSC_REF_BASECLOCK_FRC	The base clock for reference clock is FRC Oscillator
OSC_REF_BASECLOCK_LPRC	The base clock for reference clock is internal Low-Power RC
OSC_REF_BASECLOCK_SOSC	The base clock for reference clock is Secondary Oscillator
OSC_REF_BASECLOCK_USBCLK	The base clock for reference clock is USB Clock
OSC_REF_BASECLOCK_SYSPLLOUT	The base clock for reference clock is System PLL output
OSC_ON_WAIT_IDLE	Idle on Wait Instruction
OSC_ON_WAIT_SLEEP	Idle on Sleep Instruction

Description

Base clock for reference oscillator.

This enumeration lists the possible base clock values for the reference oscillator.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_PERIPHERAL_BUS Enumeration

Lists the possible Peripheral buses.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_PERIPHERAL_BUS_1,
  OSC_PERIPHERAL_BUS_2,
  OSC_PERIPHERAL_BUS_3,
  OSC_PERIPHERAL_BUS_4,
  OSC_PERIPHERAL_BUS_5,
  OSC_PERIPHERAL_BUS_6,
  OSC_PERIPHERAL_BUS_7,
  OSC_PERIPHERAL_BUS_8
} OSC_PERIPHERAL_BUS;
```

Members

Members	Description
OSC_PERIPHERAL_BUS_1	Peripheral bus 1
OSC_PERIPHERAL_BUS_2	Peripheral bus 2
OSC_PERIPHERAL_BUS_3	Peripheral bus 3
OSC_PERIPHERAL_BUS_4	Peripheral bus 4
OSC_PERIPHERAL_BUS_5	Peripheral bus 5
OSC_PERIPHERAL_BUS_6	Peripheral bus 6
OSC_PERIPHERAL_BUS_7	Peripheral bus 7
OSC_PERIPHERAL_BUS_8	Peripheral bus 8

Description

Peripheral Buses

This enumeration lists the possible peripheral buses available in the device

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_PLL_SELECT Enumeration

Lists the PLLs in the Oscillator module.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_PLL_SYSTEM,
  OSC_PLL_USB
} OSC_PLL_SELECT;
```

Members

Members	Description
OSC_PLL_SYSTEM	Select system PLL
OSC_PLL_USB	Select USB PLL

Description

Oscillator PLL selection.

This enumeration lists the available PLLs in the Oscillator module.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_REFERENCE Enumeration

Lists the possible reference oscillator.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_REFERENCE_1,
  OSC_REFERENCE_2,
  OSC_REFERENCE_3,
  OSC_REFERENCE_4
} OSC_REFERENCE;
```

Members

Members	Description
OSC_REFERENCE_1	Reference Oscillator 1
OSC_REFERENCE_2	Reference Oscillator 2
OSC_REFERENCE_3	Reference Oscillator 3
OSC_REFERENCE_4	Reference Oscillator 4

Description

Reference Oscillators

This enumeration lists the possible reference oscillator instances available in the device.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_SYS_TYPE Enumeration

Lists the possible oscillator type values.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_FRC,
  OSC_FRC_WITH_PLL,
  OSC_PRIMARY,
  OSC_PRIMARY_WITH_PLL,
  OSC_SECONDARY,
  OSC_LPRC,
  OSC_FRC_DIV_BY_16,
  OSC_FRC_BY_FRCDIV
} OSC_SYS_TYPE;
```

Members

Members	Description
OSC_FRC	Fast RC Oscillator. This includes the 8 MHz oscillator
OSC_FRC_WITH_PLL	Fast RC Oscillator with PLL
OSC_PRIMARY	Primary Oscillator
OSC_PRIMARY_WITH_PLL	Fast RC Oscillator with PLL and PostScaler. Includes the 8MHz oscillator
OSC_SECONDARY	Secondary Oscillator
OSC_LPRC	Low Power RC Oscillator
OSC_FRC_DIV_BY_16	Low-Power Fast RC Oscillator with PostScaler
OSC_FRC_BY_FRCDIV	Fast RC Oscillator divided by FRCDIV bits

Description

Oscillator type.

This enumeration lists the possible oscillator type values.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_SYSPLL_FREQ_RANGE Enumeration

Lists the possible PLL frequency range.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_SYSPLL_FREQ_RANGE_BYPASS,
  OSC_SYSPLL_FREQ_RANGE_5M_TO_10M,
  OSC_SYSPLL_FREQ_RANGE_8M_TO_16M,
  OSC_SYSPLL_FREQ_RANGE_13M_TO_26M,
  OSC_SYSPLL_FREQ_RANGE_21M_TO_42M,
  OSC_SYSPLL_FREQ_RANGE_34M_TO_68M
} OSC_SYSPLL_FREQ_RANGE;
```

Members

Members	Description
OSC_SYSPLL_FREQ_RANGE_BYPASS	PLL freq range bypass
OSC_SYSPLL_FREQ_RANGE_5M_TO_10M	PLL frequency range is 5 MHz to 10 MHz
OSC_SYSPLL_FREQ_RANGE_8M_TO_16M	PLL frequency range is 8 MHz to 16 MHz
OSC_SYSPLL_FREQ_RANGE_13M_TO_26M	PLL frequency range is 13 MHz to 26 MHz
OSC_SYSPLL_FREQ_RANGE_21M_TO_42M	PLL frequency range is 21 MHz to 42 MHz
OSC_SYSPLL_FREQ_RANGE_34M_TO_68M	PLL frequency range is 34 MHz to 68 MHz

Description

System PLL Frequency Range

This enumeration lists the possible frequency range for PLL module available in the device.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_SYSPLL_IN_CLK_SOURCE Enumeration

Lists the possible input clock source for PLL module.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_SYSPLL_IN_CLK_SOURCE_FRC,
  OSC_SYSPLL_IN_CLK_SOURCE_PRIMARY
} OSC_SYSPLL_IN_CLK_SOURCE;
```

Members

Members	Description
OSC_SYSPLL_IN_CLK_SOURCE_FRC	FRC is input clock source for PLL module
OSC_SYSPLL_IN_CLK_SOURCE_PRIMARY	Primary clock is the input clock source for PLL module

Description

System PLL Input Clock Source

This enumeration lists the possible input clock source for PLL module available in the device.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_SYSPLL_OUT_DIV Enumeration

Lists the possible PLL output divider values.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_SYSPLL_OUT_DIV_1,
  OSC_SYSPLL_OUT_DIV_2,
  OSC_SYSPLL_OUT_DIV_4,
  OSC_SYSPLL_OUT_DIV_8,
  OSC_SYSPLL_OUT_DIV_16,
  OSC_SYSPLL_OUT_DIV_32,
  OSC_SYSPLL_OUT_DIV_64,
  OSC_SYSPLL_OUT_DIV_256
} OSC_SYSPLL_OUT_DIV;
```

Members

Members	Description
OSC_SYSPLL_OUT_DIV_1	Divide by 1
OSC_SYSPLL_OUT_DIV_2	Divide by 2
OSC_SYSPLL_OUT_DIV_4	Divide by 4
OSC_SYSPLL_OUT_DIV_8	Divide by 8
OSC_SYSPLL_OUT_DIV_16	Divide by 16
OSC_SYSPLL_OUT_DIV_32	Divide by 32
OSC_SYSPLL_OUT_DIV_64	Divide by 64
OSC_SYSPLL_OUT_DIV_256	Divide by 256

Description

PLL Output divider.

This enumeration lists the possible PLL output divider values.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_USBCLOCK_SOURCE Enumeration

Lists the possible USB clock sources.

File

plib_osc_help.h

C

```
typedef enum {
  SYS_OSC_USBCLK_PRIMARY,
  SYS_OSC_USBCLK_FRC
} OSC_USBCLOCK_SOURCE;
```

Members

Members	Description
SYS_OSC_USBCLK_PRIMARY	USB clock source is primary oscillator
SYS_OSC_USBCLK_FRC	USB clock source isFRC oscillator

Description

USB clock sources.

This enumeration lists the the possible USB clock sources.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files.

OSC_CLOCK_ID Enumeration

Lists the clock sources for which ready status can be checked.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_CLOCK_FAST_RC,
  OSC_CLOCK_PRIMARY_OSC,
  OSC_CLOCK_SECONDARY_OSC,
  OSC_CLOCK_LOW_POWER_RC,
  OSC_CLOCK_SYSTEM_PLL
} OSC_CLOCK_ID;
```

Members

Members	Description
OSC_CLOCK_FAST_RC	Fast RC Oscillator
OSC_CLOCK_PRIMARY_OSC	Primary Oscillator
OSC_CLOCK_SECONDARY_OSC	Secondary Oscillator
OSC_CLOCK_LOW_POWER_RC	Low Power RC Oscillator
OSC_CLOCK_SYSTEM_PLL	System PLL

Description

OSC Clock ID

This enumeration lists all the possible clock sources for which the ready status can be checked.

Remarks

This feature may not be available in all the devices. Refer to the specific device header files for availability.

OSC_CLOCK_SLEW_TYPE Enumeration

Lists the possible type of clock slewing.

File

plib_osc_help.h

C

```
typedef enum {
  OSC_CLOCK_SLEW_DOWNWARD,
  OSC_CLOCK_SLEW_UPWARD
} OSC_CLOCK_SLEW_TYPE;
```

Members

Members	Description
OSC_CLOCK_SLEW_DOWNWARD	Slewing to a lower clock frequency
OSC_CLOCK_SLEW_UPWARD	Slewing to a higher clock frequency

Description

OSC Clock Slew Rate

This enumeration lists the possible type of clock slewing.

Remarks

This feature may not be available in all the devices. Refer to the specific device header files for availability.

OSC_SLEEP_TO_STARTUP_CLK_TYPE Enumeration

Lists the possible clock sources for sleep to start-up period.

File

plib_osc_help.h

C

```
typedef enum {
```

```
    OSC_SLEEP_TO_STARTUP_CLK_FRC,
    OSC_SLEEP_TO_STARTUP_NO_ADDITIONAL_CLK
} OSC_SLEEP_TO_STARTUP_CLK_TYPE;
```

Members

Members	Description
OSC_SLEEP_TO_STARTUP_CLK_FRC	FRC will be used after wakeup from sleep until selected clock is ready
OSC_SLEEP_TO_STARTUP_NO_ADDITIONAL_CLK	No additional clock will be used after wakeup from sleep, selected clock will be used directly once it is ready

Description

Sleep to Speed Startup Clock

This enumeration lists the possible clock sources that can be used from the time when the device wakes from sleep until the actual clock source is ready to be used.

Remarks

This feature may not be available in all the devices. Check device specific header files for availability.

Files

Files

Name	Description
plib_osc.h	Defines the Oscillator (OSC) Peripheral Library interface.
plib_osc_help.h	Defines the Oscillator Peripheral Library data types.

Description

plib_osc.h

Defines the Oscillator (OSC) Peripheral Library interface.

Functions

	Name	Description
	PLIB_OSC_BTPLLClockOutDisable	Disables the Bluetooth PLL Clock Output.
	PLIB_OSC_BTPLLClockOutEnable	Enables the Bluetooth PLL clock Ouput.
	PLIB_OSC_BTPLLClockOutStatus	gets the status of the Bluetooth PLL clock Output.
	PLIB_OSC_BTPLLFrequencyRangeGet	Gets the frequency range for the Bluetooth PLL module.
	PLIB_OSC_BTPLLFrequencyRangeSet	Sets the frequency range for the Bluetooth PLL module.
	PLIB_OSC_BTPLLInputClockSourceGet	Gets the input clock source for the Bluetooth PLL module.
	PLIB_OSC_BTPLLInputClockSourceSet	Sets the input clock source for the Bluetooth PLL module.
	PLIB_OSC_BTPLLInputDivisorGet	Gets the input divisor for the Bluetooth PLL.
	PLIB_OSC_BTPLLInputDivisorSet	Sets the input divider for the Bluetooth PLL to the specified value.
	PLIB_OSC_BTPLLMultiplierGet	Gets the Bluetooth PLL multiplier.
	PLIB_OSC_BTPLLMultiplierSelect	Sets the Bluetooth PLL multiplier to the specified value.
	PLIB_OSC_BTPLLOutputDivisorGet	Gets the output divisor for the PLL.
	PLIB_OSC_BTPLLOutputDivisorSet	Sets the output divider for the Bluetooth PLL to the specified value.
	PLIB_OSC_ClockHasFailed	Returns 'true' if the clock fails.
	PLIB_OSC_ClockIsReady	Get the ready status of clock.
	PLIB_OSC_ClockSlewingIsActive	Returns the status of clock slewing.
	PLIB_OSC_ClockStart	Starts the specified clock source.
	PLIB_OSC_ClockStop	Stops the specified clock source.
	PLIB_OSC_ClockStopStatus	returns the status of clock stop bit for the specified clock source.
	PLIB_OSC_ClockSwitchingAbort	Aborts an oscillator switch.
	PLIB_OSC_ClockSwitchingIsComplete	Gets the oscillator switch progress status.
	PLIB_OSC_CurrentSysClockGet	Gets the current oscillator selected.
	PLIB_OSC_DreamModeDisable	Disables the dream mode.

	PLIB_OSC_DreamModeEnable	Enables the dream mode.
	PLIB_OSC_DreamModeStatus	gets the status of the dream mode.
	PLIB_OSC_ExistsBTPLLClockOut	Identifies whether the BTPLLClockOut feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLFrequencyRange	Identifies whether the BTPLLFrequencyRange feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLInputClockSource	Identifies whether the BTPLLInputClockSource feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLInputDivisor	Identifies whether the BTPLLInputDivisor feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLMultiplier	Identifies whether the BTPLLMultiplier feature exists on the OSC module
	PLIB_OSC_ExistsBTPLLOutputDivisor	Identifies whether the BTPLLOutputDivisor feature exists on the OSC module
	PLIB_OSC_ExistsClockDiagStatus	Identifies whether the ClockDiagStatus feature exists on the OSC module
	PLIB_OSC_ExistsClockFail	Identifies whether the ClockFail feature exists on the Oscillator module.
	PLIB_OSC_ExistsClockReadyStatus	Identifies whether the ClockReadyStatus feature exists on the Oscillator module.
	PLIB_OSC_ExistsClockSlewingStatus	Identifies whether the ClockSlewingStatus feature exists on the Oscillator module.
	PLIB_OSC_ExistsDreamModeControl	Identifies whether the DreamModeControl feature exists on the OSC module
	PLIB_OSC_ExistsForceLock	Identifies whether the ForceLock feature exists on the OSC module
	PLIB_OSC_ExistsFRCDivisor	Identifies whether the FRCDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsFRCTuning	Identifies whether the FRCTuning feature exists on the Oscillator module.
	PLIB_OSC_ExistsOnWaitAction	Identifies whether the OnWaitAction feature exists on the Oscillator module.
	PLIB_OSC_ExistsOscCurrentGet	Identifies whether the OscCurrentGet feature exists on the Oscillator module.
	PLIB_OSC_ExistsOscSelect	Identifies whether the OscSelect feature exists on the Oscillator module.
	PLIB_OSC_ExistsOscSwitchInit	Identifies whether the OscSwitchInit feature exists on the Oscillator module.
	PLIB_OSC_ExistsPBClockDivisor	Identifies whether the PBClockDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsPBClockOutputEnable	Identifies whether the PBClockOutputEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsPBClockReady	Identifies whether the PBClockReady feature exists on the Oscillator module.
	PLIB_OSC_ExistsPLLBypass	Identifies whether the SPLLBypass feature exists on the OSC module
	PLIB_OSC_ExistsPLLClockLock	Identifies whether the PLLClockLock feature exists on the Oscillator module.
	PLIB_OSC_ExistsPLLLockStatus	Identifies whether the PLLLockStatus feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscBaseClock	Identifies whether the ReferenceOscBaseClock feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscChange	Identifies whether the ReferenceOscChange feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscChangeActive	Identifies whether the ReferenceOscChangeActive feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscDivisor	Identifies whether the ReferenceOscDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscEnable	Identifies whether the ReferenceOscEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscStopInIdleEnable	Identifies whether the ReferenceOscStopInIdleEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscStopInSleep	Identifies whether the ReferenceOscStopInSleep feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOscTrim	Identifies whether the ReferenceOscTrim feature exists on the Oscillator module.
	PLIB_OSC_ExistsReferenceOutputEnable	Identifies whether the ReferenceOutputEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsResetPLL	Identifies whether the ResetPLL feature exists on the OSC module
	PLIB_OSC_ExistsSecondaryEnable	Identifies whether the SecondaryEnable feature exists on the Oscillator module.
	PLIB_OSC_ExistsSecondaryReady	Identifies whether the SecondaryReady feature exists on the Oscillator module.
	PLIB_OSC_ExistsSleepToStartupClock	Identifies whether the SleepToStartupClock feature exists on the Oscillator module.
	PLIB_OSC_ExistsSlewDivisorStepControl	Identifies whether the SlewDivisorStepControl feature exists on the Oscillator module.
	PLIB_OSC_ExistsSlewEnableControl	Identifies whether the SlewEnableControl feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLFrequencyRange	Identifies whether the PLLFrequencyRange feature exists on the Oscillator module.

	PLIB_OSC_ExistsSysPLLInputClockSource	Identifies whether the PLLInputClockSource feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLInputDivisor	Identifies whether the PLLInputDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLMultiplier	Identifies whether the PLLMultiplier feature exists on the Oscillator module.
	PLIB_OSC_ExistsSysPLLOutputDivisor	Identifies whether the PLLOutputDivisor feature exists on the Oscillator module.
	PLIB_OSC_ExistsSystemClockDivisorControl	Identifies whether the SystemClockDivisorControl feature exists on the Oscillator module.
	PLIB_OSC_ExistsUPLLFrequencyRange	Identifies whether the UPLLFrequencyRange feature exists on the OSC module
	PLIB_OSC_ExistsUPLLInputDivisor	Identifies whether the UPLLInputDivisor feature exists on the OSC module
	PLIB_OSC_ExistsUPLLMultiplier	Identifies whether the UPLLMultiplier feature exists on the OSC module
	PLIB_OSC_ExistsUPLLOutputDivisor	Identifies whether the UPLLOutputDivisor feature exists on the OSC module
	PLIB_OSC_ExistsUsbClockSource	Identifies whether the UsbClockSource feature exists on the Oscillator module.
	PLIB_OSC_ForceSPLLLockDisable	Disables the Force PLL Lock feature for specified PLL.
	PLIB_OSC_ForceSPLLLockEnable	Enables the Force PLL Lock feature for specified PLL.
	PLIB_OSC_ForceSPLLLockStatus	gets the status of the force PLL Lock bit of the specified PLL.
	PLIB_OSC_FRCDivisorGet	Gets the FRC clock divisor.
	PLIB_OSC_FRCDivisorSelect	Sets the FRC clock divisor to the specified value.
	PLIB_OSC_FRCTuningSelect	Sets the FRC tuning value.
	PLIB_OSC_OnWaitActionGet	Gets the configured operation to be performed when a WAIT instruction is executed.
	PLIB_OSC_OnWaitActionSet	Selects the operation to be performed when a WAIT instruction is executed.
	PLIB_OSC_PBClockDivisorGet	Gets the peripheral bus clock divisor.
	PLIB_OSC_PBClockDivisorIsReady	Checks whether the peripheral bus clock divisor is ready to be written.
	PLIB_OSC_PBClockDivisorSet	Sets the peripheral bus clock divisor to the specified value.
	PLIB_OSC_PBOutputClockDisable	Disables the peripheral bus output clock.
	PLIB_OSC_PBOutputClockEnable	Enables the peripheral bus output clock
	PLIB_OSC_PBOutputClockIsEnabled	Checks whether or not the peripheral bus clock output is enabled.
	PLIB_OSC_PLLBypassDisable	Disables the PLL Bypass.
	PLIB_OSC_PLLBypassEnable	Enables the PLL Bypass.
	PLIB_OSC_PLLBypassStatus	gets the status of the PLL Bypass.
	PLIB_OSC_PLLClockIsLocked	Gets the lock status for the clock and PLL selections.
	PLIB_OSC_PLLClockLock	Locks the clock and PLL selections.
	PLIB_OSC_PLLClockUnlock	Unlocks the clock and PLL selections.
	PLIB_OSC_PLLIsLocked	Returns 'true' if the selected PLL module is locked.
	PLIB_OSC_ReferenceOscBaseClockSelect	Sets the base clock for the reference oscillator.
	PLIB_OSC_ReferenceOscDisable	Disables the reference oscillator output.
	PLIB_OSC_ReferenceOscDivisorValueSet	Selects the reference oscillator divisor value.
	PLIB_OSC_ReferenceOscEnable	Enables the reference oscillator.
	PLIB_OSC_ReferenceOscIsEnabled	Gets the enable status of the reference oscillator output.
	PLIB_OSC_ReferenceOscSourceChangeIsActive	Returns 'true' if a reference oscillator source change request is active.
	PLIB_OSC_ReferenceOscStopInIdleDisable	Enables the reference oscillator in Idle mode.
	PLIB_OSC_ReferenceOscStopInIdleEnable	Configures the reference oscillator to stop operating in Idle mode.
	PLIB_OSC_ReferenceOscStopInIdleIsEnabled	Returns 'true' if the reference oscillator is disabled in Idle mode.
	PLIB_OSC_ReferenceOscStopInSleepDisable	Enables the reference oscillator in Sleep mode.
	PLIB_OSC_ReferenceOscStopInSleepEnable	Configures the reference oscillator to stop operating in Sleep mode.
	PLIB_OSC_ReferenceOscStopInSleepIsEnabled	Returns 'true' if the reference oscillator is disabled in Sleep mode.
	PLIB_OSC_ReferenceOscSwitchIsComplete	Returns 'true' if the reference oscillator base clock switching is complete.
	PLIB_OSC_ReferenceOscTrimSet	Sets the reference oscillator divisor trim value.
	PLIB_OSC_ReferenceOutputDisable	Disables the reference oscillator output.
	PLIB_OSC_ReferenceOutputEnable	Enables the reference oscillator output.
	PLIB_OSC_ReferenceOutputIsEnabled	Returns 'true' if the reference oscillator output is enabled.
	PLIB_OSC_ResetPLLAssert	Asserts the PLL reset for selected PLL.
	PLIB_OSC_ResetPLLDeassert	Deasserts the PLL reset for selected PLL.
	PLIB_OSC_ResetPLLStatus	gets the status of the PLL reset bit for the specified PLL.
	PLIB_OSC_SecondaryDisable	Disables the Secondary Oscillator.
	PLIB_OSC_SecondaryEnable	Enables the Secondary Oscillator.

	PLIB_OSC_SecondaryIsEnabled	Returns 'true' if the Secondary Oscillator is enabled.
	PLIB_OSC_SecondaryIsReady	Returns 'true' if the Secondary Oscillator is ready.
	PLIB_OSC_SleepToStartupClockGet	Returns the clock used for the duration when the device wakes from sleep and the clock ready.
	PLIB_OSC_SleepToStartupClockSelect	Selects the clock duration for when the device wakes from sleep and the clock is ready.
	PLIB_OSC_SlewDisable	Disables the selected type of slewing.
	PLIB_OSC_SlewDivisorStepGet	Get the slew divisor maximum step.
	PLIB_OSC_SlewDivisorStepSelect	Selects division steps used while slewing.
	PLIB_OSC_SlewEnable	Enables the selected type of slewing.
	PLIB_OSC_SlewIsEnabled	Returns 'true' if the reference oscillator is disabled in Idle mode.
	PLIB_OSC_SysClockSelect	Selects the new oscillator.
	PLIB_OSC_SysPLLFrequencyRangeGet	Gets the frequency range for the PLL module.
	PLIB_OSC_SysPLLFrequencyRangeSet	Sets the frequency range for the PLL module.
	PLIB_OSC_SysPLLInputClockSourceGet	Gets the input clock source for the PLL module.
	PLIB_OSC_SysPLLInputClockSourceSet	Sets the input clock source for the PLL module.
	PLIB_OSC_SysPLLInputDivisorGet	Gets the input divisor for the PLL.
	PLIB_OSC_SysPLLInputDivisorSet	Sets the input divider for the PLL to the specified value.
	PLIB_OSC_SysPLLMultiplierGet	Gets the PLL multiplier.
	PLIB_OSC_SysPLLMultiplierSelect	Sets the PLL multiplier to the specified value.
	PLIB_OSC_SysPLLOutputDivisorGet	Gets the output divisor for the PLL.
	PLIB_OSC_SysPLLOutputDivisorSet	Sets the output divider for the PLL to the specified value.
	PLIB_OSC_SystemClockDivisorGet	Get the system clock divisor value.
	PLIB_OSC_SystemClockDivisorSelect	Selects system clock divisor.
	PLIB_OSC_UPLLFrequencyRangeGet	Gets the frequency range for the USB PLL module.
	PLIB_OSC_UPLLFrequencyRangeSet	Sets the frequency range for the USB PLL module.
	PLIB_OSC_UPLLInputDivisorGet	Gets the input divisor for the USB PLL.
	PLIB_OSC_UPLLInputDivisorSet	Sets the input divider for the USB PLL to the specified value.
	PLIB_OSC_UPLLMultiplierGet	Gets the USB PLL multiplier.
	PLIB_OSC_UPLLMultiplierSelect	Sets the USB PLL multiplier to the specified value.
	PLIB_OSC_UPLLOutputDivisorGet	Gets the output divisor for the PLL.
	PLIB_OSC_UPLLOutputDivisorSet	Sets the output divider for the USB PLL to the specified value.
	PLIB_OSC_UsbClockSourceGet	Gets the USB module clock source.
	PLIB_OSC_UsbClockSourceSelect	Sets the USB module clock source.

Description

Oscillator Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Oscillator (OSC) Peripheral Library for Microchip microcontrollers. The definitions in this file are for the Oscillator module.

File Name

plib_osc.h

Company

Microchip Technology Inc.

plib_osc_help.h

Defines the Oscillator Peripheral Library data types.

Enumerations

	Name	Description
	OSC_CLOCK_ID	Lists the clock sources for which ready status can be checked.
	OSC_CLOCK_SLEW_TYPE	Lists the possible type of clock slewing.
	OSC_FRC_DIV	Lists the possible Fast RC (FRC) Oscillator divider values.
	OSC_MODULE_ID	Possible instances of the OSC module.
	OSC_OPERATION_ON_WAIT	Lists the possible base clock values for the reference oscillator.

	OSC_PERIPHERAL_BUS	Lists the possible Peripheral buses.
	OSC_PLL_SELECT	Lists the PLLs in the Oscillator module.
	OSC_REFERENCE	Lists the possible reference oscillator.
	OSC_SLEEP_TO_STARTUP_CLK_TYPE	Lists the possible clock sources for sleep to start-up period.
	OSC_SYS_TYPE	Lists the possible oscillator type values.
	OSC_SYSPLL_FREQ_RANGE	Lists the possible PLL frequency range.
	OSC_SYSPLL_IN_CLK_SOURCE	Lists the possible input clock source for PLL module.
	OSC_SYSPLL_OUT_DIV	Lists the possible PLL output divider values.
	OSC_USBCLOCK_SOURCE	Lists the possible USB clock sources.

Macros

	Name	Description
	OSC_PB_CLOCK_DIV_TYPE	Type of the oscillator PB Clock divisor value.
	OSC_REF_DIVISOR_TYPE	Reference oscillator divisor type.
	OSC_REFERENCE_MAX_DIV	Defines the reference clock output divisor maximum value.
	OSC_SYSPLL_MULTIPLIER_TYPE	Type of the oscillator system PLL multiplier value.

Description

Oscillator Peripheral Library Interface Header

This header file contains the definitions of the data types and constants that make up the interface to the Oscillator Peripheral Library for Microchip microcontrollers. The definitions in this file are for the Oscillator module.

File Name

plib_osc_help.h

Company

Microchip Technology Inc.

PMP Peripheral Library

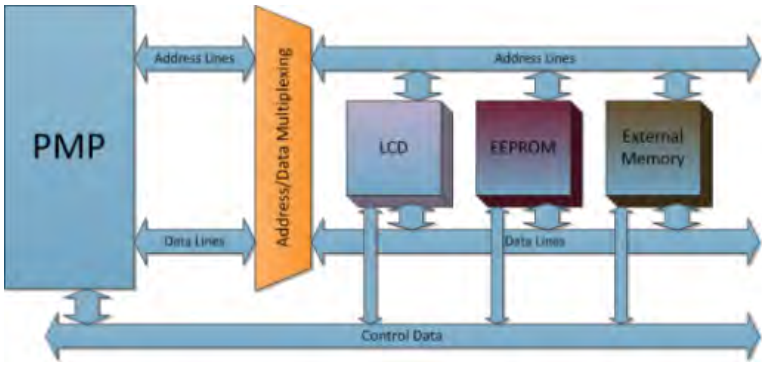
This section describes the Parallel Master Port (PMP) Peripheral Library.

Introduction

This library provides a low-level abstraction of the Parallel Master Port (PMP) module on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

The following diagram shows a block diagram of the PMP module and how it interacts with other peripherals.



Using the Library

This topic describes the basic architecture of the PMP Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_pmp.h`

The interface to the PMP Peripheral library is defined in the `plib_pmp.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the PMP Peripheral Library must include `peripheral.h`.

Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

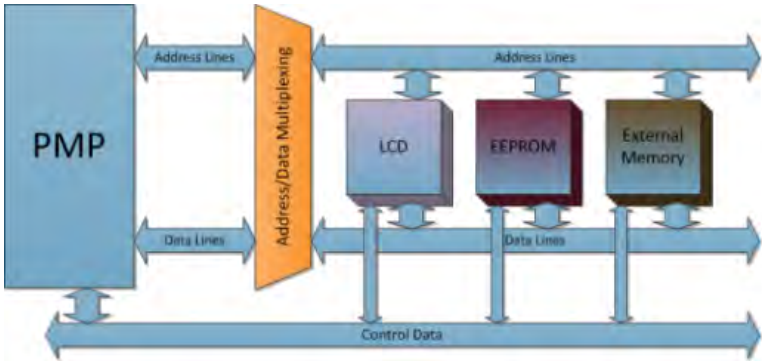
Hardware Abstraction Model

This library provides a low-level abstraction of the Parallel Master Port (PMP) module on Microchip's microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

The PMP module provides interface routines to interact with external peripherals such as LCD, EEPROM, Flash memory, etc., as shown in the following diagram. The diagram shows the PMP module acting as a master. The PMP module can be easily configured to act as a slave. The address and data lines can be multiplexed to suit the application. The address and data buffers are up to 2-byte (16-bit) buffers for data transmitted or received by the parallel interface to the PMP bus over the data and address lines synchronized with control logic including the read and write strobe.

PMP Hardware Abstraction Model Diagram



The desired timing wait states to suit different peripheral timings can also be programmed using the PMP module.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the PMP module

Library Interface Section	Description
General Initialization Functions	Provides configuration for: • Interrupt mode • Address Incrementing mode • Stop-in-Idle operation • Operating mode • Multiplexing mode • Chip Select mode
Wait States Initialization Functions	Provides configuration routines to tune the wait states of the PMP module.
Data Read and Write Functions	Provides functions for receiving the data from another module when operating in Master or Slave mode. Also provides routines for transmitting data from the module when operating in Master or Slave mode.
Address Handling	Provides functions to set the PMP module to point to the desired addresses.
Port Configuration	Provides functions for configuring the PMP pins either for PMP purpose or general purpose.
Polarity Configuration	Provides routines for configuring the PMP pins polarity either as active-high or active-low.
Error Status/Control Functions	Provides functions and status for error handling (either as a master or a slave).
General Status Functions	Provides status of the PMP module.

Note: The enhanced feature APIs are not available on all devices. Please refer to the specific device data sheet to determine the availability of these enhanced features.

How the Library Works

Provides information on how the library works.

Description

Before enabling the PMP module, the caller must initialize basic parameters such as wait states timings, and interrupt mode features (see the Initialization section).

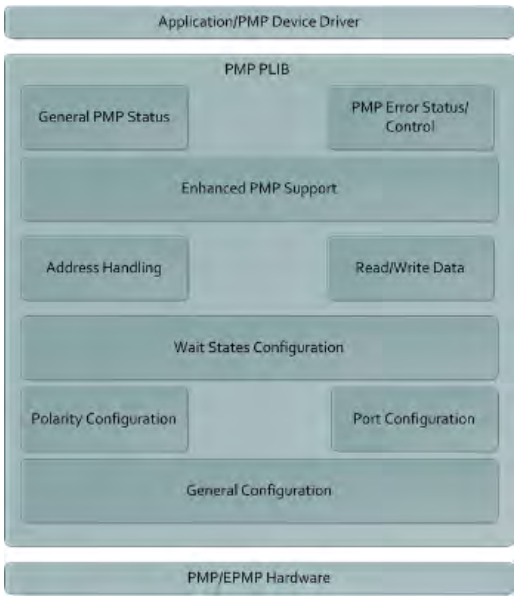
After the module has been enabled, it can begin monitoring the bus as a slave device waiting to be addressed by an external master (see the Operating as a Slave section). A slave device only transfers data on the bus when it has been addressed by a master. If the module is used to start a transfer, it is operating as a master. A master addresses a slave and controls the transfer of data by providing the clock (see the Operating as a Master section).

Some operations in the PMP peripheral library initiate actions on the PMP bus that require time to complete. Also, some events occur asynchronously on the bus. In each of these cases, the module causes either a "master", "slave", or "error" interrupt. The State Machine section describes the different states that can cause an interrupt and show what causes the transition from one state to another. The Handling Errors section describes the various errors that can occur and how to deal with them.

Usage Model

The following diagram shows the high level organization of the PMP Peripheral Library usage model. The items in the diagram correspond to the groupings in the Library Interface section.

PMP Library Usage Model



Initialization

This section describes the general initialization of the PMP module.

Description

The important configurations to look for are as follows.

Operating Mode

Depending on the device, the PMP module can function in Master modes 1 or 2, buffered/enhanced slave mode or the legacy slave mode. To set the PMP module in the appropriate mode, use PLIB_PMP_OperationModeSelect.

Multiplexing Mode

Depending on the application requirement or hardware arrangement, the data lines can be used to multiplex the addressing information. Various multiplexing modes supported are listed by PMP_MUX_MODE. Use PLIB_PMP_MultiplexModeSelect to select the appropriate multiplexing mode.

Chip Select Mode

As needed, the Chip Select lines can be made to function as Chip Select or as address lines. Use PLIB_PMP_ChipSelectFunctionSelect to select the required functionality of Chip Select lines.

Interrupt Mode

PMP generates interrupts based on the option selected for the interrupt mode. Interrupts can be enabled, disabled, generated at the end of a read or write cycle, or when other events occur. Use the PLIB_PMP_InterruptModeSelect to select these options.

Address Increment Mode

After every read/write cycle, the PMP module can be configured to automatically increment or decrement the address it is accessing. Use PLIB_PMP_AddressIncrementModeSelect to select this option.

To initialize the PMP module, perform the following sequence:

1. Select the desired initialization options using the General Initialization Functions (see the Library Interface section) to select the desired operation of the following features:
   - Operating mode
   - Multiplexing mode
   - Chip Select mode
   - Interrupt mode
   - Address Incrementing mode
   - Stop-in-Idle operation
2. Program the wait states of the PMP module. Refer to Wait States Initialization Functions in the Library Interface section for an example.
3. If operating in Master mode, set the desired address (8-bit in this case, the size may vary depending on the application) using PLIB_PMP_AddressSet.
4. If running in an interrupt-driven environment, clear any pending interrupts and enable the appropriate (master, slave, and error) PMP interrupts.

Note: Refer to the **"Interrupt Controller"** chapter in the specific device data sheet for details.

5. Enable the module for operation using PLIB_PMP_Enable.

Example

```
// Configure General PMP Options
// Select the PMP operation mode
PLIB_PMP_OperationModeSelect( PMP_ID_0, PMP_MASTER_READ_WRITE_STROBES_INDEPENDENT  );
// Set the multiplexing to none. Address and data lines are not multiplexed.
PLIB_PMP_MultiplexModeSelect( PMP_ID_0, PMP_MUX_NONE );
// Select the function of chip-select lines
PLIB_PMP_ChipSelectFunctionSelect( PMP_ID_0, PMCS1_PMCS2_AS_ADDRESS_LINES );
// Select the interrupt mode
PLIB_PMP_InterruptModeSelect( PMP_ID_0, PMP_INTERRUPT_NONE );
// disable the auto increment/decrement of address after each read/write
PLIB_PMP_AddressIncrementModeSelect( PMP_ID_0, PMP_ADDRESS_INCREMENT_DECREMENT_DISABLE );
// Enable stop in Idle mode.
PLIB_PMP_StopInIdleEnable( PMP_ID_0 );
// Set Desired Wait State Values
// Set the data wait states
PLIB_PMP_WaitStatesDataSetUpSelect( PMP_ID_0, PMP_DATA_WAIT_FOUR );
// Set the strobe wait states
PLIB_PMP_WaitStatesStrobeSelect( PMP_ID_0, PMP_STROBE_WAIT_1 );
// Set the data hold wait states.
PLIB_PMP_WaitStatesDataHoldSelect( PMP_ID_0, PMP_DATA_HOLD_1 );
// Set the appropriate address (MASTER only)
PLIB_PMP_AddressSet ( PMP_ID_0, 0x12 );

// Optional:  Clear and enable interrupts before enabling the PMP module.
// Enable the module
PLIB_PMP_Enable( PMP_ID_0 );
```

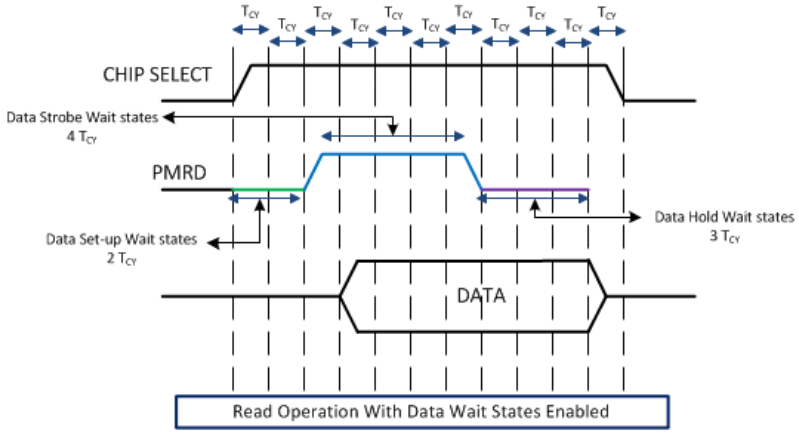
Note: Refer to the **"Interrupt Controller"** chapter in the specific device data sheet for details on how to clear and enable the PMP module interrupts.

Wait States Initialization

This section describes set up and initialization of the wait states for the PMP module.

Description

In Master mode, the user can control the duration of the read, write and address cycles by configuring the module Wait states. One Wait state period is equivalent to one peripheral bus clock cycles. The following figure shows an example of a Master Read operation using Wait states.



Wait States

Wait states can be added to the beginning, middle and end of any read or write cycle using the corresponding bits in the PMP Configuration. The wait states differ depending on which PMP mode you are in, but setting the wait states is the same per mode and device, as shown in the following example.

Initializing Wait States

The following sequence can be used to set up the wait states for the PMP Master mode.

Preconditions:

None.

Process:

1. Set the data hold time using PLIB_PMP_WaitStatesDataHoldSelect.
2. Set the strobe wait time using PLIB_PMP_WaitStatesStrobeSelect.
3. Set the data wait time using PLIB_PMP_WaitStatesDataSetUpSelect.

Example

```
// Set the data wait states
PLIB_PMP_WaitStatesDataSetUpSelect( PMP_ID_0, PMP_DATA_WAIT_ONE );
// Set the strobe wait states
PLIB_PMP_WaitStatesStrobeSelect( PMP_ID_0, PMP_STROBE_WAIT_1 );
// Set the data hold wait states.
PLIB_PMP_WaitStatesDataHoldSelect( PMP_ID_0, PMP_DATA_HOLD_1 );
```

Operating as a Master

This section describes how to set up the PMP module to operate as a master.

Description

The PMP module, while acting as a master, waits for its input or output buffers to be read or written. Once the buffers have been manipulated, the appropriate action takes place.

A PMP bus transfer always begins with reading or writing to the appropriate PMP input/output buffers. A read from a PMP input buffer performs a PMP read. A write to a PMP output buffer performs a PMP write. The address pins associated with the transfer will have the value that is inside the address register of the PMP module. These steps are summarized as follows.

Summary of Steps

- Set up the proper PMP address
- Send or read data bytes

Each of these steps making up a transfer will take some time to complete. By monitoring the busy bit of the PMP module, the user application can determine whether the transfer is complete. The completion of each step can cause a PMP interrupt.

Sending a Data Byte

The following sequence can be used to send a data byte and repeated to send an arbitrary number of data bytes.

Preconditions:

- The address of the destination must be configured in the PMP module
- The proper control signals are configured for PMP operation
- The PMP module is configured for the desired Master mode
- The PMP module is enabled

Process:

1. Ensure that the PMP module is not busy by using PLIB_PMP_PortIsBusy.
2. Write the output data buffer using PLIB_PMP_MasterSend.

Example:

```
uint8_t data = 'a';
// Set the destination address to be written
PLIB_PMP_AddressSet(PMP_ID_0, 0x1234 );
// Check to see if the PMP is busy, and then send the byte
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
  {
    // Send the data
    PLIB_PMP_MasterSend( PMP_ID_0, data );
  }
```

Receiving a Data byte

The following sequence can be used to send a data byte and repeated to send an arbitrary number of data bytes.

Preconditions:

- The address of the destination must be configured in the PMP module
- The proper control signal are configured for PMP operation

Process:

1. Ensure that the PMP module is not busy by using PLIB_PMP_PortIsBusy.
2. Write the output data buffer using PLIB_PMP_MasterReceive.

Example:

```
uint8_t data;
// Set the source address
PLIB_PMP_AddressSet(PMP_ID_0, 0x1234 );
// Check to see the PMP is not busy, and then read the data
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
  {
    // receive the data
    data = PLIB_PMP_MasterReceive( PMP_ID_0 );
  }
```

Operating as a Slave

This section describes how to set up the PMP module to operate as a slave.

Description

The PMP module while acting as a slave, waits for read or write strobes to occur. Once the buffers have been manipulated, the appropriate action takes place.

Summary of Steps

- Check to see if data is available to be read
- Prepare output buffer for slave read

Each of these steps making up a transfer will take some time to complete. By monitoring the busy bit of the PMP module, the user application can determine whether the transfer is complete. The completion of each step can cause a PMP interrupt.

Reading Available Data

The following sequence can be used to receive a data byte and repeated to receive an arbitrary number of data bytes.

Preconditions:

- The address of the destination must be set in the PMP module
- The proper control signals are initialized for PMP operation

Process:

1. Check to see if data is available using PLIB_PMP_InputBufferXIsFull.
2. Read the available data using PLIB_PMP_InputBufferXByteReceive.

Example:

```
uint8_t data;
// Check to see if data is available, and then receive the byte
if(PLIB_PMP_InputBufferXIsFull( PMP_ID_0, 1))
  {
    // Receive the data from buffer one.
    data = PLIB_PMP_InputBufferXByteReceive( PMP_ID_0, 1 );
  }
```

Preparing Output Buffer for Slave Write

The following sequence can be used to send a data byte and repeated to send an arbitrary number of data bytes.

Preconditions:

The proper control signals are initialized for PMP operation.

Process:

1. Ensure that the output buffer to be written is empty by using PLIB_PMP_OutputBufferXIsEmpty.
2. Write the output data buffer using PLIB_PMP_OutputBufferXByteSend.

Example:

```
 uint8_t data;
// Check to see if output buffer is available, and then send the byte
if(PLIB_PMP_OutputBufferXIsEmpty( PMP_ID_0, 1))
  {
    // Fill the output buffer-1 with the data to be sent
    PLIB_PMP_OutputBufferXByteSend( PMP_ID_0, 1, value);
  }
```

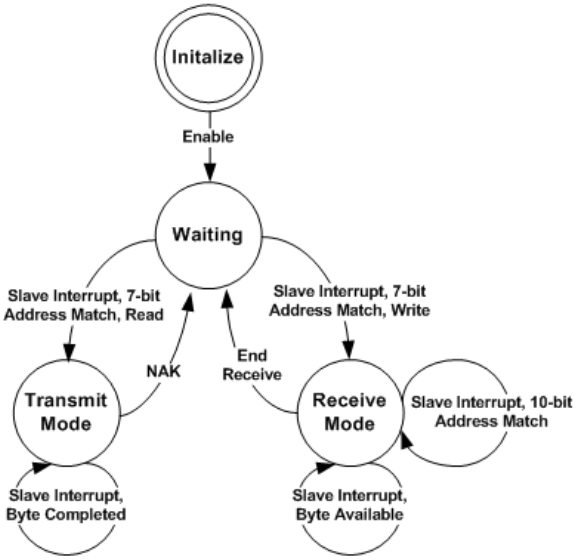
State Machine

The PMP state machine can be used in either a polled or an interrupt-driven manner. However, in both cases, software must check the state of the master, slave, and error interrupt flags to identify when a state transition occurs.

Description

The PMP module has one basic interrupt that is triggered when data has been written or read. In Buffered Slave mode, this interrupt can be set to wait until an 'X' amount of buffers are written or read. This interrupt must be cleared in software, but can also be used in DMA transactions to trigger the next DMA transfer.

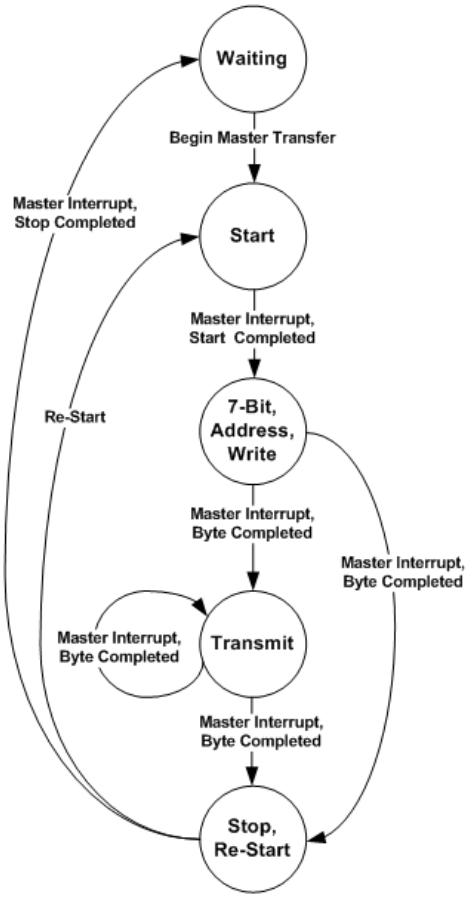
The PMP module will not start generating interrupts (setting the PMP interrupt flags, even if interrupts are disabled) until it is properly configured and enabled. After that, interrupts are generated as described in subsequent sections. Software has to respond appropriately once the interrupt has occurred (the flag has been set) to allow the state machine to advance to the next state. These actions are described in the following sections for the state machine diagram to which they refer.



Slave Mode State Machine

Slave-Mode State Transitions

In Slave mode, state transitions occur under hardware control automatically or in response to an interrupt. Software must respond appropriately to ensure that the PMP module continues to operate correctly. Basically, if a read/write strobe occurs, the appropriate read/write occurs, which in turn sets the interrupt.



Master Mode State Machine

Master-Mode State Transitions

In Master mode, state transitions occur under hardware control automatically or in response to an interrupt. Software must respond appropriately to ensure that the PMP module continues to operate correctly. Basically, if an input or output register is manipulated, the appropriate read/write happens, which in turn sets the interrupt. The PMP module can also be configured to have read/write strobes indicating whether a read/write has completed.

Handling Errors

There are two basic types of errors that can occur during various slave PMP operations:

- Input Buffer Overrun
- Output Buffer Underflow

This section provides information on handling these types of errors.

Description

Handling Input Buffer Overrun Errors

An input buffer overflow error occurs when the software is not reading or clearing the input buffers fast enough for the master PMP device attached to it. When this occurs, the master write is not allowed and the "input buffer overflow" status bit is set. This can be identified by calling PLIB_PMP_InputOverflowHasOccurred. Additional attempts to write to the input buffer will not be allowed until the overflow error is cleared by calling PLIB_PMP_InputOverflowClear. This type of error should be either avoided by having proper communication techniques with the PMP Master device or checked using PLIB_PMP_InputBuffersAreFull, which informs the controller that no buffers have data in them (overflow) .

Interrupts: The input buffer overflow error does not trigger an interrupt.

Handling Output Buffer Underflow Errors

An output buffer underflow error occurs when the software is not writing to the output buffers fast enough for the master PMP device attached to it. When this occurs, the master read is not allowed and the "output buffer underflow" status bit is set. This can be identified by calling PLIB_PMP_OutputUnderflowHasOccurred. Additional attempts to read from the output buffer will not be allowed until the overflow error is cleared by calling PLIB_PMP_OutputUnderflowClear. This sort of error should be either avoided by having proper communication techniques with the PMP Master device, or checked using PLIB_PMP_OutputBuffersAreEmpty, which informs the controller that buffers have data in them (underflow) .

Interrupts: The input buffer overflow error does not trigger an interrupt.

Other Features

This section provides information on additional features that may be available. These features are not available on all devices. Please refer to the **"Parallel Master Port (PMP)"** chapter in the specific device data sheet to determine which features are supported by your device.

Description

Operation During Sleep Mode

When the device enters Sleep mode, the system clock is disabled. The consequences of Sleep mode depend on which mode the PMP module is configured in at the time that Sleep mode is invoked.

Master

If the device enters Sleep mode while the PMP module is operating in Master mode, PMP operation will be suspended in its current state until clock execution resumes. As this may cause unexpected control pin timings, users should avoid invoking Sleep mode when continuous use of the module is needed.

Slave

While the PMP module is inactive, but enabled for any Slave mode operation, any read or write operations occurring at that time will be able to complete without the use of the microcontroller clock. Once the operation is completed, the module will issue an interrupt.

This interrupt may be used to wake the device from Sleep or Idle modes, depending on the configuration and capabilities of the device. Refer to the specific device data sheet or the related peripheral section in the reference manual to determine the capabilities of your device.

Operation During Idle Mode

When the device enters Idle mode, the system clock sources remain functional and the CPU stops code execution. PMP operation during Idle mode can be controlled using the PLIB_PMP_StopInIdleEnable or the PLIB_PMP_StopInIdleDisable. By default, the PMP module continues to operate in Idle mode and provide full functionality.

Configuring the Library

The library is configured for the supported PMP module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Initialization Functions

	Name	Description
	PLIB_PMP_AddressIncrementModeGet	Gets the increment mode being used with the address of the PMP module.
	PLIB_PMP_AddressIncrementModeSelect	Configures the increment mode being used with the address of the PMP module.
	PLIB_PMP_AddressLatchStrobeDisable	Disables the specific address latch strobe.
	PLIB_PMP_AddressLatchStrobeEnable	Enables the specific address latch strobe.
	PLIB_PMP_ChipSelectFunctionSelect	Defines the functionality of the pins intended to be used as Chip Select.
	PLIB_PMP_ChipSelectXDisable	Configures the Chip Select.
	PLIB_PMP_ChipSelectXEnable	Configures the Chip Select.
	PLIB_PMP_ChipSelectXIsActive	Gets the current status of the specified Chip Select.
	PLIB_PMP_DataSizeSelect	Enables data transfer size for the PMP module.
	PLIB_PMP_Disable	Disables the specific PMP module.
	PLIB_PMP_Enable	Enables the specific PMP module.
	PLIB_PMP_InputBufferTypeSelect	Selects the input buffer based on the input passed.
	PLIB_PMP_InterruptModeGet	Gets the current configured interrupt mode being used with the PMP module.
	PLIB_PMP_InterruptModeSelect	Configures the interrupt request mode being used with the PMP module.
	PLIB_PMP_MultiplexModeGet	Gets the current multiplexing mode configured between the address and data of the PMP module.
	PLIB_PMP_MultiplexModeSelect	Configures the multiplexing between the address and data of the PMP module.
	PLIB_PMP_OperationModeGet	Gets the current operation mode of the PMP module.
	PLIB_PMP_OperationModeSelect	Configures the operation mode of the PMP module.
	PLIB_PMP_StopInIdleDisable	Enables the PMP module to continue operation in Idle mode.
	PLIB_PMP_StopInIdleEnable	Discontinues PMP module operation when the device enters Idle mode.
	PLIB_PMP_DualModeReadAddressGet	Gets the current read address of the PMP module.

	PLIB_PMP_DualModeReadAddressSet	Sets the address to be written in Dual mode.
	PLIB_PMP_DualModeWriteAddressGet	Gets the current write address of the PMP module.
	PLIB_PMP_DualModeWriteAddressSet	Sets the address to be written in Dual mode.
	PLIB_PMP_DualModeMasterReceive	Receives the data in the Master Dual mode.
	PLIB_PMP_DualBufferEnable	Enables PMP dual Read/Write buffer.
	PLIB_PMP_DualBufferDisable	Disables the specific PMP module.
	PLIB_PMP_DualModeMasterSend	Sends the specified data in Dual Master mode.

b) Enhanced General Initialization Functions

	Name	Description
	PLIB_PMP_ReadChipSelectXDisable	Configures the Read Chip Select.
	PLIB_PMP_ReadChipSelectXEnable	Configures the Read Chip Select.
	PLIB_PMP_WriteChipSelectXDisable	Configures the Write Chip Select.
	PLIB_PMP_WriteChipSelectXEnable	Configures the Write Chip Select.

c) General Status Functions

	Name	Description
	PLIB_PMP_IsEnabled	Checks whether or not the PMP module is enabled.
	PLIB_PMP_DualBufferIsEnabled	Checks whether or not the PMP module is enabled.
	PLIB_PMP_PortIsBusy	Identifies if the (Master mode) PMP port is busy.
	PLIB_PMP_InputOverflowHasOccurred	Identifies if there was a receiver overflow error.
	PLIB_PMP_OutputUnderflowHasOccurred	Identifies if there was an output buffer sent out with no data.

d) Error Status/Control Functions

	Name	Description
	PLIB_PMP_InputOverflowClear	Clears a PMP Overflow error.
	PLIB_PMP_OutputUnderflowClear	Clears a PMP output underflow error.

e) Data Read and Write Functions

	Name	Description
	PLIB_PMP_InputBuffersAreFull	Gets the state of the input buffers.
	PLIB_PMP_InputBufferXByteReceive	Data to be received in Byte mode.
	PLIB_PMP_InputBufferXIsFull	Gets the state of the identified input buffer.
	PLIB_PMP_IsDataReceived	Checks and returns if the data has been received in the specified buffer in Slave mode.
	PLIB_PMP_IsDataTransmitted	Checks and returns if the data has been transmitted from the specified buffer in Slave mode.
	PLIB_PMP_MasterReceive	Receives the data in Master mode.
	PLIB_PMP_MasterSend	Sends the specified data in Master mode.
	PLIB_PMP_OutputBuffersAreEmpty	Gets the state of the output buffers.
	PLIB_PMP_OutputBufferXByteSend	Data to be transmitted in Byte mode.
	PLIB_PMP_OutputBufferXIsEmpty	Gets the state of the input buffer.
	PLIB_PMP_SlaveReceive	Receives the data in Slave mode.
	PLIB_PMP_SlaveSend	Sends the specified data in Slave mode.
	PLIB_PMP_ReadCycleIsStarted	Checks whether or not the read cycle on PMP bus is enabled.
	PLIB_PMP_ReadCycleStart	Starts a read cycle on the PMP bus.

f) Wait States Initialization Functions

	Name	Description
	PLIB_PMP_WaitStatesDataHoldSelect	Configures the data hold states (after data transfer) needed to be used with the PMP module.
	PLIB_PMP_WaitStatesDataSetUpSelect	Configures the data wait states (before the data transfer) needed to be used with the PMP module.
	PLIB_PMP_WaitStatesStrobeSelect	Configures the strobe wait states (during the data transfer) needed to be used with the PMP module.

g) Address Handling Functions

	Name	Description
	PLIB_PMP_AddressGet	Gets the current address of the PMP module.
	PLIB_PMP_AddressLinesA0A1Get	Gets the value of the address lines PMA0 and PMA1.
	PLIB_PMP_AddressLinesA0A1Set	Sets the address lines PMA0 and PMA1 with the value specified.
	PLIB_PMP_AddressSet	Sets the current address of the PMP module to the specified address.

h) Port Configuration Functions

	Name	Description
	PLIB_PMP_AddressPortDisable	Disables the port lines specified as PMP address lines.
	PLIB_PMP_AddressPortEnable	Enables the port lines specified as PMP address lines.
	PLIB_PMP_ReadWriteStrobePortDisable	Disables the PMP module read strobe port.
	PLIB_PMP_ReadWriteStrobePortEnable	Enables the PMP module read strobe port.
	PLIB_PMP_WriteEnableStrobePortDisable	Disables the PMP module write strobe port.
	PLIB_PMP_WriteEnableStrobePortEnable	Enables the PMP module write strobe port.

i) Polarity Configuration Functions

	Name	Description
	PLIB_PMP_AddressLatchPolaritySelect	Sets the address latch strobe polarity.
	PLIB_PMP_ChipSelectXPolaritySelect	Sets the specified Chip Select polarity.
	PLIB_PMP_ReadWriteStrobePolaritySelect	Sets the polarity of the read strobe.
	PLIB_PMP_WriteEnableStrobePolaritySelect	Sets the polarity of the write enable strobe.

j) Feature Existence Functions

	Name	Description
	PLIB_PMP_ExistsAddressControl	Identifies whether the AddressControl feature exists on the PMP module.
	PLIB_PMP_ExistsAddressLatchPolarity	Identifies whether the AddressLatchPolarity feature exists on the PMP module.
	PLIB_PMP_ExistsAddressLatchStrobePortControl	Identifies whether the AddressLatchStrobePortControl feature exists on the PMP module.
	PLIB_PMP_ExistsAddressPortPinControl	Identifies whether the AddressPortPinControl feature exists on the PMP module.
	PLIB_PMP_ExistsBufferOverFlow	Identifies whether the BufferOverFlow feature exists on the PMP module.
	PLIB_PMP_ExistsBufferRead	Identifies whether the BufferRead feature exists on the PMP module.
	PLIB_PMP_ExistsBufferType	Identifies whether the BufferType feature exists on the PMP module.
	PLIB_PMP_ExistsBufferUnderFlow	Identifies whether the BufferUnderFlow feature exists on the PMP module.
	PLIB_PMP_ExistsBufferWrite	Identifies whether the BufferWrite feature exists on the PMP module.
	PLIB_PMP_ExistsBusyStatus	Identifies whether the BusyStatus feature exists on the PMP module.
	PLIB_PMP_ExistsChipSelectEnable	Identifies whether the ChipSelectEnable feature exists on the PMP module.
	PLIB_PMP_ExistsChipSelectoperation	Identifies whether the ChipSelectoperation feature exists on the PMP module.
	PLIB_PMP_ExistsChipXPolarity	Identifies whether the ChipXPolarity feature exists on the PMP module.
	PLIB_PMP_ExistsCSXActiveStatus	Identifies whether the CSXActiveStatus feature exists on the PMP module.
	PLIB_PMP_ExistsDataHoldWaitStates	Identifies whether the DataHoldWaitStates feature exists on the PMP module.
	PLIB_PMP_ExistsDataSetUpWaitStates	Identifies whether the DataSetUpWaitStates feature exists on the PMP module.
	PLIB_PMP_ExistsDataStrobeWaitStates	Identifies whether the DataStrobeWaitStates feature exists on the PMP module.
	PLIB_PMP_ExistsDataTransferSize	Identifies whether the DataTransferSize feature exists on the PMP module.
	PLIB_PMP_ExistsEnableControl	Identifies whether the EnableControl feature exists on the PMP module.
	PLIB_PMP_ExistsIncrementMode	Identifies whether the IncrementMode feature exists on the PMP module.
	PLIB_PMP_ExistsInputBufferFull	Identifies whether the InputBufferFull feature exists on the PMP module.
	PLIB_PMP_ExistsInputBufferXStatus	Identifies whether the InputBufferXStatus feature exists on the PMP module.
	PLIB_PMP_ExistsInterruptMode	Identifies whether the InterruptMode feature exists on the PMP module.
	PLIB_PMP_ExistsMasterRXTX	Identifies whether the MasterRXTX feature exists on the PMP module.
	PLIB_PMP_ExistsMUXModeSelect	Identifies whether the MUXModeSelect feature exists on the PMP module.
	PLIB_PMP_ExistsOperationMode	Identifies whether the OperationMode feature exists on the PMP module.
	PLIB_PMP_ExistsOutPutBufferEmpty	Identifies whether the OutPutBufferEmpty feature exists on the PMP module.
	PLIB_PMP_ExistsOutputBufferXStatus	Identifies whether the OutputBufferXStatus feature exists on the PMP module.

	PLIB_PMP_ExistsReadWritePolarity	Identifies whether the ReadWritePolarity feature exists on the PMP module.
	PLIB_PMP_ExistsReadWriteStrobePortControl	Identifies whether the ReadWriteStrobePortControl feature exists on the PMP module.
	PLIB_PMP_ExistsSlaveRX	Identifies whether the SlaveRX feature exists on the PMP module.
	PLIB_PMP_ExistsSlaveTX	Identifies whether the SlaveTX feature exists on the PMP module.
	PLIB_PMP_ExistsStopInIdleControl	Identifies whether the StopInIdleControl feature exists on the PMP module.
	PLIB_PMP_ExistsWriteEnablePolarity	Identifies whether the WriteEnablePolarity feature exists on the PMP module.
	PLIB_PMP_ExistsWriteEnablePortControl	Identifies whether the WriteEnablePortControl feature exists on the PMP module.
	PLIB_PMP_ExistsDualBufferControl	Identifies whether the DualBufferControl feature exists on the PMP module.
	PLIB_PMP_ExistsDualModeMasterRXTX	Identifies whether the DualModeMasterRXTX feature exists on the PMP module.
	PLIB_PMP_ExistsDualModeReadAddressControl	Identifies whether the DualModeReadAddressControl feature exists on the PMP module.
	PLIB_PMP_ExistsDualModeWriteAddressControl	Identifies whether the DualModeWriteAddressControl feature exists on the PMP module.
	PLIB_PMP_ExistsReadChipSelectEnable	Identifies whether the ReadChipSelectEnable feature exists on the PMP module.
	PLIB_PMP_ExistsWriteChipSelectEnable	Identifies whether the WriteChipSelectEnable feature exists on the PMP module.
	PLIB_PMP_ExistsStartReadControl	Identifies whether the StartReadControl feature exists on the PMP module.

k) Data Types and Constants

	Name	Description
	PMP_ACK_MODE	Defines the different mode configurations in which the PMP can be enabled.
	PMP_ADDRESS_HOLD_LATCH_WAIT_STATES	PMP hold after address latch strobe wait states configuration.
	PMP_ADDRESS_LATCH	Address Latch Strobe configuration.
	PMP_ADDRESS_LATCH_WAIT_STATES	PMP address latch strobe wait states configuration.
	PMP_ADDRESS_PORT	Defines the different address lines that are available for configuration.
	PMP_ALTERNATE_MASTER_WAIT_STATES	PMP alternate master wait states.
	PMP_CHIP_SELECT	PMP Chip Select data type.
	PMP_CHIPSELECT_FUNCTION	Defines different functions available for the Chip Select lines multiplexed with address lines.
	PMP_DATA_HOLD_STATES	PMP Data Hold after strobe wait state.
	PMP_DATA_LENGTH	Possible data lengths handled by the PMP module.
	PMP_DATA_SIZE	PMP data size.
	PMP_DATA_WAIT_STATES	PMP data setup time configuration.
	PMP_INCREMENT_MODE	PMP address incrementing configuration.
	PMP_INPUT_BUFFER_TYPE	PMP Input Buffers type.
	PMP_INTERRUPT_MODE	PMP interrupt request mode data type.
	PMP_MASTER_MODE	Defines the different mode configurations in which the PMP can be enabled.
	PMP_MODULE_ID	Possible instances of the PMP module.
	PMP_MUX_MODE	Defines the different mode configurations in which the PMP can be enabled.
	PMP_OPERATION_MODE	Defines the different mode configurations in which the PMP can be enabled.
	PMP_PMBE_PORT	Defines the available Byte Enable ports.
	PMP_POLARITY_LEVEL	Possible polarity levels for the PMP pins.
	PMP_STROBE_WAIT_STATES	PMP strobe signal wait time configuration.

Description

This section describes the Application Programming Interface (API) functions of the PMP Peripheral Library.

Refer to each section for a detailed description.

a) General Initialization Functions

PLIB_PMP_AddressIncrementModeGet Function

Gets the increment mode being used with the address of the PMP module.

File

plib_pmp.h

C

```
PMP_INCREMENT_MODE PLIB_PMP_AddressIncrementModeGet(PMP_MODULE_ID index);
```

Returns

PMP_INCREMENT_MODE - One of the possible values from PMP_INCREMENT_MODE

Description

This function gets the pins used by the PMP module. Refer to the enumeration PMP_INCREMENT_MODE for the possible settings.

Remarks

This function implements an operation of the IncrementMode feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsIncrementMode in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PMP_INCREMENT_MODE curAddressIncMode;
curAddressIncMode = PLIB_PMP_AddressIncrementModeGet( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

PMP_INCREMENT_MODE PLIB_PMP_AddressIncrementModeGet (PMP_MODULE_ID index)

PLIB_PMP_AddressIncrementModeSelect Function

Configures the increment mode being used with the address of the PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_AddressIncrementModeSelect(PMP_MODULE_ID index, PMP_INCREMENT_MODE incrementMode);
```

Returns

None.

Description

This function configures the pins used by the PMP module. Refer to the enumeration PMP_INCREMENT_MODE for the possible settings.

Remarks

This function implements an operation of the IncrementMode feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsIncrementMode in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_AddressIncrementModeSelect( PMP_ID_0, PMP_ADDRESS_INCREMENT_DECREMENT_DISABLE );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
incrementMode	One of the possible values from PMP_INCREMENT_MODE

Function

void PLIB_PMP_AddressIncrementModeSelect(PMP_MODULE_ID index,
PMP_INCREMENT_MODE incrementMode)

PLIB_PMP_AddressLatchStrobeDisable Function

Disables the specific address latch strobe.

File

plib_pmp.h

C

```
void PLIB_PMP_AddressLatchStrobeDisable(PMP_MODULE_ID index, PMP_ADDRESS_LATCH latch);
```

Returns

None.

Description

This function disables the PMP module with a specific address latch strobe depending on which strobes are not needed.

Remarks

This function implements an operation of the AddressLatchStrobePortControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressLatchStrobePortControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_AddressLatchStrobeDisable( PMP_ID_0, PMP_ADDRESS_LATCH_UPPER );
PLIB_PMP_AddressLatchStrobeDisable( PMP_ID_0, PMP_ADDRESS_LATCH_HIGH );
PLIB_PMP_AddressLatchStrobeDisable( PMP_ID_0, PMP_ADDRESS_LATCH_LOW );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
latch	Identifier for the latch to be disabled

Function

void PLIB_PMP_AddressLatchStrobeDisable (PMP_MODULE_ID index,
PMP_ADDRESS_LATCH latch)

PLIB_PMP_AddressLatchStrobeEnable Function

Enables the specific address latch strobe.

File

plib_pmp.h

C

```
void PLIB_PMP_AddressLatchStrobeEnable(PMP_MODULE_ID index, PMP_ADDRESS_LATCH latch);
```

Returns

None.

Description

This function enables the PMP module with a specific address latch strobe depending on which strobes are needed.

Remarks

This function implements an operation of the AddressLatchStrobePortControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressLatchStrobePortControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_AddressLatchStrobeEnable( PMP_ID_0, PMP_ADDRESS_LATCH_UPPER );
PLIB_PMP_AddressLatchStrobeEnable( PMP_ID_0, PMP_ADDRESS_LATCH_HIGH );
PLIB_PMP_AddressLatchStrobeEnable( PMP_ID_0, PMP_ADDRESS_LATCH_LOW );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
latch	Identifier for the latch to be enabled

Function

void PLIB_PMP_AddressLatchStrobeEnable (PMP_MODULE_ID index,
PMP_ADDRESS_LATCH latch)

PLIB_PMP_ChipSelectFunctionSelect Function

Defines the functionality of the pins intended to be used as Chip Select.

File

plib_pmp.h

C

```
void PLIB_PMP_ChipSelectFunctionSelect(PMP_MODULE_ID index, PMP_CHIPSELECT_FUNCTION chipselfunct);
```

Returns

None.

Description

This function selects the PMCS1/PMCS2 as either Chip Select or as address lines depending on the way these bits are programmed.

Remarks

This function implements an operation of the ChipSelectoperation feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsChipSelectoperation in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_ChipSelectFunctionSelect( PMP_ID_0, PMCS1_PMCS2_AS_ADDRESS_LINES );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipselfunct	One of the possible values from PMP_CHIPSELECT_FUNCTION

Function

void PLIB_PMP_ChipSelectFunctionSelect(PMP_MODULE_ID index,
PMP_CHIPSELECT_FUNCTION chipselfunct)

PLIB_PMP_ChipSelectXDisable Function

Configures the Chip Select.

File

plib_pmp.h

C

```
void PLIB_PMP_ChipSelectXDisable(PMP_MODULE_ID index, PMP_CHIP_SELECT chipSelect);
```

Returns

None.

Description

This function configures the Chip Select(s) being used by the PMP module. The specified Chip Select pin functions as the address pin.

Remarks

This function implements an operation of the ChipSelectEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsChipSelectEnable in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PMP_CHIP_SELECT chipSelect = PMP_CHIP_SELECT_ONE;
PLIB_PMP_ChipSelectXDisable( PMP_ID_0, chipSelect );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipSelect	Identifier for which Chip Select to configure

Function

void PLIB_PMP_ChipSelectXDisable(PMP_MODULE_ID index,
PMP_CHIP_SELECT chipSelect)

PLIB_PMP_ChipSelectXEnable Function

Configures the Chip Select.

File

plib_pmp.h

C

```
void PLIB_PMP_ChipSelectXEnable(PMP_MODULE_ID index, PMP_CHIP_SELECT chipSelect);
```

Returns

None.

Description

This function configures the Chip Select(s) being used by the PMP module. The specified Chip Select pin functions as chipSelect.

Remarks

This function implements an operation of the ChipSelectEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsChipSelectEnable in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PMP_CHIP_SELECT chipSelect = PMP_CHIP_SELECT_ONE;
PLIB_PMP_ChipSelectXEnable( PMP_ID_0, chipSelect );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipSelect	Identifier for which Chip Select to configure

Function

void PLIB_PMP_ChipSelectXEnable(PMP_MODULE_ID index,
PMP_CHIP_SELECT chipSelect)

PLIB_PMP_ChipSelectXIsActive Function

Gets the current status of the specified Chip Select.

File

plib_pmp.h

C

```
bool PLIB_PMP_ChipSelectXIsActive(PMP_MODULE_ID index, PMP_CHIP_SELECT chipSelect);
```

Returns

- true - Chip Select is active
- false - Chip Select is not active

Description

This function returns the current status of the specified Chip Select.

Remarks

This function implements an operation of the CSXActiveStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsCSXActiveStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PMP_CHIP_SELECT chipSelect = PMP_CHIP_SELECT_ONE;
if(PLIB_PMP_ChipSelectXIsActive( PMP_ID_0, chipSelect ))
{
  //Do something useful
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipSelect	Identifier for the Chip Select to be checked

Function

bool PLIB_PMP_ChipSelectXIsActive (PMP_MODULE_ID index,

PMP_CHIP_SELECT chipSelect)

PLIB_PMP_DataSizeSelect Function

Enables data transfer size for the PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_DataSizeSelect(PMP_MODULE_ID index, PMP_DATA_SIZE size);
```

Returns

None.

Description

This function enables 4-bit, 8-bit, or 16-bit data transfer for the PMP module.

Remarks

This function implements an operation of the DataTransferSize feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDataTransferSize in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_DataSizeSelect( PMP_ID_0, PMP_DATA_SIZE_8_BITS );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
size	Identifier for the data size to be used

Function

void PLIB_PMP_DataSizeSelect (PMP_MODULE_ID index,
PMP_DATA_SIZE size)

PLIB_PMP_Disable Function

Disables the specific PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_Disable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific PMP module.

Remarks

The default state after any reset for a PMP module is the disable state. If the PMP is disabled, all the related pins are in control of the general purpose I/O logic.

Disabling the PMP module resets the buffers to empty states. Any data characters in the buffers are lost. All error and status bits are also reset.

Disabling the PMP while the PMP is active, will abort all pending transmissions and receptions. Re-enabling the PMP will restart the module in the same configuration.

When disabled, the PMP power consumption is minimal.

This function implements an operation of the EnableControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsEnableControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_Disable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_Disable (PMP_MODULE_ID index)

PLIB_PMP_Enable Function

Enables the specific PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_Enable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific PMP module.

Remarks

This function implements an operation of the EnableControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsEnableControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_Enable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_Enable (PMP_MODULE_ID index)

PLIB_PMP_InputBufferTypeSelect Function

Selects the input buffer based on the input passed.

File

plib_pmp.h

C

```
void PLIB_PMP_InputBufferTypeSelect(PMP_MODULE_ID index, PMP_INPUT_BUFFER_TYPE inputBuffer);
```

Returns

None.

Description

This function selects the input buffer based on the input passed. Either TTL or Schmitt Trigger input buffers are selected.

Remarks

This function implements an operation of the BufferType feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsBufferType in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_InputBufferTypeSelect( PMP_ID_0, PMP_INPUT_BUFFER_TTL );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
inputBuffer	One of the possible input buffer types

Function

void PLIB_PMP_InputBufferTypeSelect (PMP_MODULE_ID index,
PMP_INPUT_BUFFER_TYPE inputBuffer)

PLIB_PMP_InterruptModeGet Function

Gets the current configured interrupt mode being used with the PMP module.

File

plib_pmp.h

C

```
PMP_INTERRUPT_MODE PLIB_PMP_InterruptModeGet(PMP_MODULE_ID index);
```

Returns

One of the possible values from PMP_INTERRUPT_MODE.

Description

This function gets the current configured interrupt mode being used with the PMP module.

Remarks

This function implements an operation of the InterruptMode feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsInterruptMode in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PMP_INTERRUPT_MODE currentIntMode;
currentIntMode = PLIB_PMP_InterruptModeGet ( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

PMP_INTERRUPT_MODE PLIB_PMP_InterruptModeGet (PMP_MODULE_ID index)

PLIB_PMP_InterruptModeSelect Function

Configures the interrupt request mode being used with the PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_InterruptModeSelect(PMP_MODULE_ID index, PMP_INTERRUPT_MODE interruptMode);
```

Returns

None.

Description

This function configures the pins used by the PMP module. Refer to the enumeration PMP_INTERRUPT_MODE for the possible settings.

Remarks

This function implements an operation of the InterruptMode feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsInterruptMode in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_InterruptModeSelect( PMP_ID_0, PMP_INTERRUPT_NONE );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
interruptMode	One of the possible values from PMP_INTERRUPT_MODE

Function

void PLIB_PMP_InterruptModeSelect(PMP_MODULE_ID index,
PMP_INTERRUPT_MODE interruptMode)

PLIB_PMP_MultiplexModeGet Function

Gets the current multiplexing mode configured between the address and data of the PMP module.

File

plib_pmp.h

C

```
PMP_MUX_MODE PLIB_PMP_MultiplexModeGet(PMP_MODULE_ID index);
```

Returns

index - Identifier for the device instance to be addressed PMP_MUX_MODE - One of the possible values from PMP_MUX_MODE

Description

This function gets the current multiplexing mode configured between the address and data of the PMP module.

Remarks

This function implements an operation of the MUXModeSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsMUXModeSelect in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PMP_MUX_MODE currentMuxMode;
currentMuxMode = PLIB_PMP_MultiplexModeGet( PMP_ID_0 );
```

Function

PMP_MUX_MODE PLIB_PMP_MultiplexModeGet(PMP_MODULE_ID index)

PLIB_PMP_MultiplexModeSelect Function

Configures the multiplexing between the address and data of the PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_MultiplexModeSelect(PMP_MODULE_ID index, PMP_MUX_MODE multiplexMode);
```

Returns

None.

Description

This function configures the pins used by the PMP module. Refer to the enumeration PMP_MUX_MODE for the possible settings.

Remarks

This function implements an operation of the MUXModeSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsMUXModeSelect in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_MultiplexModeSelect( PMP_ID_0, PMP_MUX_NONE );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
multiplexMode	One of the possible values from the PMP_MUX_MODE

Function

void PLIB_PMP_MultiplexModeSelect(PMP_MODULE_ID index,
PMP_MUX_MODE multiplexMode)

PLIB_PMP_OperationModeGet Function

Gets the current operation mode of the PMP module.

File

plib_pmp.h

C

```
PMP_OPERATION_MODE PLIB_PMP_OperationModeGet(PMP_MODULE_ID index);
```

Returns

PMP_OPERATION_MODE - One of the possible values from PMP_OPERATION_MODE

Description

This function gets the current operation mode of the PMP module.

Remarks

This function implements an operation of the OperationMode feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsOperationMode in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PMP_OPERATION_MODE curOpMode;
curOpMode = PLIB_PMP_OperationModeGet( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

PMP_OPERATION_MODE PLIB_PMP_OperationModeGet (PMP_MODULE_ID index)

PLIB_PMP_OperationModeSelect Function

Configures the operation mode of the PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_OperationModeSelect(PMP_MODULE_ID index, PMP_OPERATION_MODE operationMode);
```

Returns

None.

Description

This function configures operation mode of the PMP module. Refer to the enumeration PMP_OPERATION_MODE for the possible settings.

Remarks

This function implements an operation of the OperationMode feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsOperationMode in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_OperationModeSelect( PMP_ID_0,
                              PMP_MASTER_READ_WRITE_STROBES_MULTIPLEXED );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
operationMode	One of the possible values from PMP_OPERATION_MODE

Function

void PLIB_PMP_OperationModeSelect(PMP_MODULE_ID index,
PMP_OPERATION_MODE operationMode)

PLIB_PMP_StopInIdleDisable Function

Enables the PMP module to continue operation in Idle mode.

File

plib_pmp.h

C

```
void PLIB_PMP_StopInIdleDisable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function disables the stop in idle flag. The PMP module continues operation in Idle mode.

Remarks

By default, the PMP module will continue operation in Idle mode.

This function implements an operation of the StopInIdleControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsStopInIdleControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_StopInIdleDisable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_StopInIdleDisable (PMP_MODULE_ID index)

PLIB_PMP_StopInIdleEnable Function

Discontinues PMP module operation when the device enters Idle mode.

File

plib_pmp.h

C

```
void PLIB_PMP_StopInIdleEnable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function enables the PMP module to discontinue operation when the device enters Idle mode.

Remarks

This function implements an operation of the StopInIdleControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsStopInIdleControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_StopInIdleEnable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_StopInIdleEnable (PMP_MODULE_ID index)

PLIB_PMP_DualModeReadAddressGet Function

Gets the current read address of the PMP module.

File

plib_pmp.h

C

```
uint32_t PLIB_PMP_DualModeReadAddressGet(PMP_MODULE_ID index);
```

Returns

- readAddress - Device address from where PMP read will occur

Description

This function gets the current read address of the PMP module.

Remarks

This function implements an operation of the DualModeReadAddressControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualModeReadAddressControl in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
uint32_t readAddress;
readAddress = PLIB_PMP_DualModeReadAddressGet( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

uint32_t PLIB_PMP_DualModeReadAddressGet (PMP_MODULE_ID index)

PLIB_PMP_DualModeReadAddressSet Function

Sets the address to be written in Dual mode.

File

plib_pmp.h

C

```
void PLIB_PMP_DualModeReadAddressSet(PMP_MODULE_ID index, uint32_t readAddress);
```

Returns

None.

Description

This function sets the address to be written to the specified value in Dual mode.

Remarks

This function implements an operation of the DualModeReadAddressControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualModeReadAddressControl in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
uint8_t no_of_addressLines = 8;
PLIB_PMP_DualModeReadAddressSet( PMP_ID_0, 0xff );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
readAddress	Device address from where PMP read will happen

Function

void PLIB_PMP_DualModeReadAddressSet (PMP_MODULE_ID index,

uint32_t readAddress)

PLIB_PMP_DualModeWriteAddressGet Function

Gets the current write address of the PMP module.

File

plib_pmp.h

C

```
uint32_t PLIB_PMP_DualModeWriteAddressGet(PMP_MODULE_ID index);
```

Returns

- writeAddress - Device Write address to be set

Description

This function gets the current write address of the PMP module.

Remarks

This function implements an operation of the DualModeWriteAddressControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualModeWriteAddressControl in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
uint32_t address;
address = PLIB_PMP_DualModeWriteAddressGet( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

uint32_t PLIB_PMP_DualModeWriteAddressGet (PMP_MODULE_ID index)

PLIB_PMP_DualModeWriteAddressSet Function

Sets the address to be written in Dual mode.

File

plib_pmp.h

C

```
void PLIB_PMP_DualModeWriteAddressSet(PMP_MODULE_ID index, uint32_t writeAddress);
```

Returns

None.

Description

This function sets the address to be written to the specified value in Dual mode.

Remarks

This function implements an operation of the DualModeWriteAddressControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualModeWriteAddressControl in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
uint8_t no_of_addressLines = 8;
PLIB_PMP_DualModeWriteAddressSet( PMP_ID_0, 0xff );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
writeAddress	Device write address to be set

Function

void PLIB_PMP_DualModeWriteAddressSet (PMP_MODULE_ID index,

uint32_t writeAddress)

PLIB_PMP_DualModeMasterReceive Function

Receives the data in the Master Dual mode.

File

plib_pmp.h

C

```
uint16_t PLIB_PMP_DualModeMasterReceive(PMP_MODULE_ID index);
```

Returns

- uint16_t - Data received

Description

This function receives the data in Dual mode. The flow of data is from the slave to the master.

Remarks

This function to be used only when the PMP is acting as master. This function implements an operation of the DualModeMasterRXTX feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualModeMasterRXTX in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
uint16_t data;
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
{
    data = PLIB_PMP_DualModeMasterReceive( PMP_ID_0 );
```

```
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed.

Function

uint16_t PLIB_PMP_DualModeMasterReceive (PMP_MODULE_ID index)

PLIB_PMP_DualBufferEnable Function

Enables PMP dual Read/Write buffer.

File

plib_pmp.h

C

```
void PLIB_PMP_DualBufferEnable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function enables dual Read/Write buffers for PMP module. Once enabled, PMP uses separate registers for read and write.

- Registers used for Reads: PMRADDR and PMRDIN
- Registers used for Writes: PMRWADDR and PMDOUT

Remarks

This feature is only valid in Master mode.

This function implements an operation of the DualBufferControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualBufferControl in your application to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a master.

Example

```
PLIB_PMP_DualBufferEnable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_DualBufferEnable (PMP_MODULE_ID index)

PLIB_PMP_DualBufferDisable Function

Disables the specific PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_DualBufferDisable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific PMP module.

Remarks

This feature is only valid in Master mode.

This function implements an operation of the DualBufferControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualBufferControl in your application to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a master.

Example

```
PLIB_PMP_DualBufferDisable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_DualBufferDisable (PMP_MODULE_ID index)

PLIB_PMP_DualModeMasterSend Function

Sends the specified data in Dual Master mode.

File

plib_pmp.h

C

```
void PLIB_PMP_DualModeMasterSend(PMP_MODULE_ID index, uint16_t data);
```

Returns

None.

Description

This function sends the specified data in dual mode. The data flow is from master to slave.

Remarks

This function to be used only when the PMP is acting as master. This function implements an operation of the DualModeMasterRXTX feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualModeMasterRXTX in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
uint16_t data = 'a';
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
{
    PLIB_PMP_DualModeMasterSend( PMP_ID_0, data );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
data	Data to be transmitted

Function

void PLIB_PMP_DualModeMasterSend (PMP_MODULE_ID index,

uint16_t data)

b) Enhanced General Initialization Functions

PLIB_PMP_ReadChipSelectXDisable Function

Configures the Read Chip Select.

File

plib_pmp.h

C

```
void PLIB_PMP_ReadChipSelectXDisable(PMP_MODULE_ID index, PMP_CHIP_SELECT chipSelect);
```

Returns

None.

Description

This function configures the Read Chip Select(s) being used by the PMP module. The specified Chip Select pin functions as the address pin.

Remarks

This function implements an operation of the ReadChipSelectEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsReadChipSelectEnable in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
PMP_CHIP_SELECT chipSelect = PMP_CHIP_SELECT_ONE;
PLIB_PMP_ReadChipSelectXDisable( PMP_ID_0, chipSelect );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipSelect	Identifier for which Chip Select to configure

Function

void PLIB_PMP_ReadChipSelectXDisable(PMP_MODULE_ID index,
PMP_CHIP_SELECT chipSelect)

PLIB_PMP_ReadChipSelectXEnable Function

Configures the Read Chip Select.

File

plib_pmp.h

C

```
void PLIB_PMP_ReadChipSelectXEnable(PMP_MODULE_ID index, PMP_CHIP_SELECT chipSelect);
```

Returns

None.

Description

This function configures the Read Chip Select(s) being used by the PMP module. The specified Chip Select pin functions as chipSelect.

Remarks

This function implements an operation of the ReadChipSelectEnable feature. This feature may not be available on all devices. Please refer to the

specific device data sheet to determine availability or use PLIB_PMP_ExistsReadChipSelectEnable in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
PMP_CHIP_SELECT chipSelect = PMP_CHIP_SELECT_ONE;
PLIB_PMP_ReadChipSelectXEnable( PMP_ID_0, chipSelect );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipSelect	Identifier for which Chip Select to configure

Function

void PLIB_PMP_ReadChipSelectXEnable(PMP_MODULE_ID index,
PMP_CHIP_SELECT chipSelect)

PLIB_PMP_WriteChipSelectXDisable Function

Configures the Write Chip Select.

File

plib_pmp.h

C

```
void PLIB_PMP_WriteChipSelectXDisable(PMP_MODULE_ID index, PMP_CHIP_SELECT chipSelect);
```

Returns

None.

Description

This function configures the Write Chip Select(s) being used by the PMP module. The specified Chip Select pin functions as the address pin.

Remarks

This function implements an operation of the WriteChipSelectEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsWriteChipSelectEnable in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
PMP_CHIP_SELECT chipSelect = PMP_CHIP_SELECT_ONE;
PLIB_PMP_WriteChipSelectXDisable( PMP_ID_0, chipSelect );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipSelect	Identifier for which Chip Select to configure

Function

void PLIB_PMP_WriteChipSelectXDisable(PMP_MODULE_ID index,
PMP_CHIP_SELECT chipSelect)

PLIB_PMP_WriteChipSelectXEnable Function

Configures the Write Chip Select.

File

plib_pmp.h

C

```
void PLIB_PMP_WriteChipSelectXEnable(PMP_MODULE_ID index, PMP_CHIP_SELECT chipSelect);
```

Returns

None.

Description

This function configures the Write Chip Select(s) being used by the PMP module. The specified Chip Select pin functions as chipSelect.

Remarks

This function implements an operation of the WriteChipSelectEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsWriteChipSelectEnable in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as master. PMP Dual mode should be enabled using the API PLIB_PMP_DualBufferEnable.

Example

```
PMP_CHIP_SELECT chipSelect = PMP_CHIP_SELECT_ONE;
PLIB_PMP_WriteChipSelectXEnable( PMP_ID_0, chipSelect );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipSelect	Identifier for which Chip Select to configure

Function

void PLIB_PMP_WriteChipSelectXEnable(PMP_MODULE_ID index,
PMP_CHIP_SELECT chipSelect)

c) General Status Functions

PLIB_PMP_IsEnabled Function

Checks whether or not the PMP module is enabled.

File

plib_pmp.h

C

```
bool PLIB_PMP_IsEnabled(PMP_MODULE_ID index);
```

Returns

- true - If the PMP module is enabled
- false - if the PMP module is disabled

Description

This function checks whether or not the PMP module is enabled.

Remarks

This function implements an operation of the EnableControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsEnableControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool pmpStatus;
pmpStatus = PLIB_PMP_IsEnabled( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

bool PLIB_PMP_IsEnabled (PMP_MODULE_ID index)

PLIB_PMP_DualBufferIsEnabled Function

Checks whether or not the PMP module is enabled.

File

plib_pmp.h

C

```
bool PLIB_PMP_DualBufferIsEnabled(PMP_MODULE_ID index);
```

Returns

- true - If the PMP module is enabled
- false - if the PMP module is disabled

Description

This function checks whether or not the PMP module is enabled.

Remarks

This feature is only valid in Master mode.

This function implements an operation of the DualBufferControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDualBufferControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool pmpStatus;
pmpStatus = PLIB_PMP_DualBufferIsEnabled( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

bool PLIB_PMP_DualBufferIsEnabled (PMP_MODULE_ID index)

PLIB_PMP_PortIsBusy Function

Identifies if the (Master mode) PMP port is busy.

File

plib_pmp.h

C

```
bool PLIB_PMP_PortIsBusy(PMP_MODULE_ID index);
```

Returns

- true - If the port is busy
- false - If the port is not busy

Description

This function identifies if the PMP port is busy (in Master mode).

Remarks

Works only in Master mode. This function implements an operation of the BusyStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsBusyStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
status = PLIB_PMP_PortIsBusy( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

bool PLIB_PMP_PortIsBusy (PMP_MODULE_ID index)

PLIB_PMP_InputOverflowHasOccurred Function

Identifies if there was a receiver overflow error.

File

plib_pmp.h

C

```
bool PLIB_PMP_InputOverflowHasOccurred(PMP_MODULE_ID index);
```

Returns

- true - If the input buffer has overflowed
- false - If the input buffer has not overflowed

Description

This function identifies if there was a receiver overflow error.

Remarks

This function implements an operation of the BufferOverFlow feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsBufferOverFlow in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_PMP_InputOverflowHasOccurred( PMP_ID_0 ))
{
    PLIB_PMP_InputOverflowClear( PMP_ID_0 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

bool PLIB_PMP_InputOverflowHasOccurred (PMP_MODULE_ID index)

PLIB_PMP_OutputUnderflowHasOccurred Function

Identifies if there was an output buffer sent out with no data.

File

plib_pmp.h

C

```
bool PLIB_PMP_OutputUnderflowHasOccurred(PMP_MODULE_ID index);
```

Returns

- true - If the input buffer was empty when data was sent
- false - If the output buffer was not empty when data was sent

Description

This function identifies if there was a output buffer was sent out with no data.

Remarks

This function implements an operation of the BufferUnderFlow feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsBufferUnderFlow in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_PMP_OutputUnderflowHasOccurred( PMP_ID_0 ))
{
    PLIB_PMP_OutputUnderflowClear( PMP_ID_0 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

bool PLIB_PMP_OutputUnderflowHasOccurred (PMP_MODULE_ID index)

d) Error Status/Control Functions

PLIB_PMP_InputOverflowClear Function

Clears a PMP Overflow error.

File

plib_pmp.h

C

```
void PLIB_PMP_InputOverflowClear(PMP_MODULE_ID index);
```

Returns

None.

Description

This function clears an overflow error. Clearing the error resets the receive buffer.

Remarks

This function implements an operation of the BufferOverFlow feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsBufferOverFlow in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_PMP_InputOverflowHasOccurred( PMP_ID_0 ))
{
    PLIB_PMP_InputOverflowClear( PMP_ID_0 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_InputOverflowClear (PMP_MODULE_ID index)

PLIB_PMP_OutputUnderflowClear Function

Clears a PMP output underflow error.

File

plib_pmp.h

C

```
void PLIB_PMP_OutputUnderflowClear(PMP_MODULE_ID index);
```

Returns

None.

Description

This function clears a PMP output underflow error.

Remarks

This function implements an operation of the BufferUnderFlow feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsBufferUnderFlow in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_PMP_OutputUnderflowHasOccurred( PMP_ID_0 ))
{
    PLIB_PMP_OutputUnderflowClear( PMP_ID_0 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_OutputUnderflowClear (PMP_MODULE_ID index)

e) Data Read and Write Functions

PLIB_PMP_InputBuffersAreFull Function

Gets the state of the input buffers.

File

plib_pmp.h

C

```
bool PLIB_PMP_InputBuffersAreFull(PMP_MODULE_ID index);
```

Returns

- true - If all input buffers are full
- false - If all input buffers are not full

Description

This function gets the state of the input buffers.

Remarks

This function implements an operation of the InputBufferFull feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsInputBufferFull in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t value;
if(PLIB_PMP_InputBuffersAreFull( PMP_ID_0 ))
{
 value = PLIB_PMP_InputBufferXByteReceive( PMP_ID_0, 1 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

bool PLIB_PMP_InputBuffersAreFull (PMP_MODULE_ID index)

PLIB_PMP_InputBufferXByteReceive Function

Data to be received in Byte mode.

File

plib_pmp.h

C

```
uint8_t PLIB_PMP_InputBufferXByteReceive(PMP_MODULE_ID index, uint8_t buffer);
```

Returns

- data - Data to be received

Description

This function specifies the data to be received in Byte mode from the desired PMP module.

Remarks

This function implements an operation of the BufferRead feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsBufferRead in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t mydata;
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
{
    // get data from buffer-1
    mydata = PLIB_PMP_InputBufferXByteReceive( PMP_ID_0, 1 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
buffer	One of the possible buffers (valid values are 0 to 3)

Function

uint8_t PLIB_PMP_InputBufferXByteReceive (PMP_MODULE_ID index,
uint8_t buffer)

PLIB_PMP_InputBufferXIsFull Function

Gets the state of the identified input buffer.

File

plib_pmp.h

C

```
bool PLIB_PMP_InputBufferXIsFull(PMP_MODULE_ID index, uint8_t buffer);
```

Returns

- true - If all input buffers are full
- false - If all input buffers are not full

Description

This function gets the state of the identified input buffer.

Remarks

This function implements an operation of the InputBufferXStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsInputBufferXStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t value;
// Check the status of buffer-2
if(PLIB_PMP_InputBufferXIsFull( PMP_ID_0, 2 ))
{
   // get data from buffer 2
   value = PLIB_PMP_InputBufferXByteReceive( PMP_ID_0, 2 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
buffer	The input buffer number (valid values are 0 to 3)

Function

bool PLIB_PMP_InputBufferXIsFull (PMP_MODULE_ID index,
uint8_t buffer)

PLIB_PMP_IsDataReceived Function

Checks and returns if the data has been received in the specified buffer in Slave mode.

File

plib_pmp.h

C

```
bool PLIB_PMP_IsDataReceived(PMP_MODULE_ID index, uint8_t buffer);
```

Returns

- true - Data has been received in the specified buffer
- false - Data has not been received in the specified buffer

Description

This function checks and returns if the data has been received in the specified buffer in Slave mode.

Remarks

This function implements an operation of the InputBufferXStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsInputBufferXStatus in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module should be configured for Slave mode operation.

Example

```
int8_t data;
// Check if data is received on buffer-2
if(PLIB_PMP_IsDataReceived( PMP_ID_0, 2 ))
{
    // get data from buffer-2
    data = PLIB_PMP_InputBufferXByteReceive( PMP_ID_0, 2 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
buffer	One of the possible input buffers (valid values are 0 to 3)

Function

bool PLIB_PMP_IsDataReceived (PMP_MODULE_ID index,
uint8_t buffer)

PLIB_PMP_IsDataTransmitted Function

Checks and returns if the data has been transmitted from the specified buffer in Slave mode.

File

plib_pmp.h

C

```
bool PLIB_PMP_IsDataTransmitted(PMP_MODULE_ID index, uint8_t buffer);
```

Returns

- true - If data has been transmitted from the specified buffer

- false - If data has not been transmitted from the specified buffer

Description

This function checks and returns if data has been transmitted from the specified buffer.

Remarks

This function implements an operation of the OutputBufferXStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsOutputBufferXStatus in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module should be configured for Slave mode operation.

Example

```
uint8_t data;
if(PLIB_PMP_IsDataTransmitted( PMP_ID_0, 2 ))
{
    PLIB_PMP_OutputBufferXByteSend( PMP_ID_0, 2, data );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
buffer	One of the possible output buffers (valid range is 0 to 3)

Function

bool PLIB_PMP_IsDataTransmitted (PMP_MODULE_ID index,
uint8_t buffer)

PLIB_PMP_MasterReceive Function

Receives the data in Master mode.

File

plib_pmp.h

C

```
uint16_t PLIB_PMP_MasterReceive(PMP_MODULE_ID index);
```

Returns

uint16_t - Data received

Description

This function receives the data. The flow of data is from the slave to the master.

Remarks

This function to be used only when the PMP is acting as master. This function implements an operation of the MasterRXTX feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsMasterRXTX in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a master.

Example

```
uint16_t data;
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
{
    data = PLIB_PMP_MasterReceive( PMP_ID_0 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed.

Function

uint16_t PLIB_PMP_MasterReceive (PMP_MODULE_ID index)

PLIB_PMP_MasterSend Function

Sends the specified data in Master mode.

File

plib_pmp.h

C

```
void PLIB_PMP_MasterSend(PMP_MODULE_ID index, uint16_t data);
```

Returns

None.

Description

This function sends the specified data. The data flow is from master to slave.

Remarks

This function to be used only when the PMP is acting as master. This function implements an operation of the MasterRXTX feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsMasterRXTX in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured for Master mode.

Example

```
uint16_t data = 'a';
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
{
    PLIB_PMP_MasterSend( PMP_ID_0, data );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
data	Data to be transmitted

Function

void PLIB_PMP_MasterSend (PMP_MODULE_ID index,

uint16_t data)

PLIB_PMP_OutputBuffersAreEmpty Function

Gets the state of the output buffers.

File

plib_pmp.h

C

```
bool PLIB_PMP_OutputBuffersAreEmpty(PMP_MODULE_ID index);
```

Returns

- true - If all output buffers are empty
- false - If all output buffers are not empty

Description

This function returns the state of the output buffers.

Remarks

This function implements an operation of the OutPutBufferEmpty feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsOutPutBufferEmpty in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t value=0xEF;

if(PLIB_PMP_OutputBuffersAreEmpty( PMP_ID_0 ))
{
 PLIB_PMP_OutputBufferXByteSend( PMP_ID_0, 1, value);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

bool PLIB_PMP_OutputBuffersAreEmpty (PMP_MODULE_ID index)

PLIB_PMP_OutputBufferXByteSend Function

Data to be transmitted in Byte mode.

File

plib_pmp.h

C

```
void PLIB_PMP_OutputBufferXByteSend(PMP_MODULE_ID index, uint8_t buffer, uint8_t data);
```

Returns

None.

Description

This function specifies the data to be transmitted in Byte mode for the desired PMP module.

Remarks

This function implements an operation of the BufferWrite feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsBufferWrite in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t data = 'a';
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
{
    PLIB_PMP_OutputBufferXByteSend( PMP_ID_0, 1, data );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

buffer	One of the possible output buffers (valid range is 0 to 3)
data	Data to be transmitted

Function

void PLIB_PMP_OutputBufferXByteSend (PMP_MODULE_ID index,
uint8_t buffer,
uint8_t data)

PLIB_PMP_OutputBufferXIsEmpty Function

Gets the state of the input buffer.

File

plib_pmp.h

C

```
bool PLIB_PMP_OutputBufferXIsEmpty(PMP_MODULE_ID index, uint8_t buffer);
```

Returns

- true - If the identified output buffer is empty
- false - If the identified output buffer is not empty

Description

This function returns the state of the input buffer.

Remarks

This function implements an operation of the OutputBufferXStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsOutputBufferXStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t value = 0xEF;

if(PLIB_PMP_OutputBufferXIsEmpty( PMP_ID_0, 1 ) )
{
 PLIB_PMP_OutputBufferXByteSend( PMP_ID_0,1, value);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
buffer	Output buffer number (valid range is 0 to 3)

Function

bool PLIB_PMP_OutputBufferXIsEmpty (PMP_MODULE_ID index,
uint8_t buffer)

PLIB_PMP_SlaveReceive Function

Receives the data in Slave mode.

File

plib_pmp.h

C

```
uint16_t PLIB_PMP_SlaveReceive(PMP_MODULE_ID index);
```

Returns

- uint16_t - Data received

Description

This function receives the data. The flow of data is from the master to the slave.

Remarks

This function to be used only when the PMP is acting as slave. This function implements an operation of the SlaveRX feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsSlaveRX in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured as a slave.

Example

```
uint16_t data;
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
{
    data = PLIB_PMP_SlaveReceive( PMP_ID_0 );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed.

Function

uint16_t PLIB_PMP_SlaveReceive (PMP_MODULE_ID index)

PLIB_PMP_SlaveSend Function

Sends the specified data in Slave mode.

File

plib_pmp.h

C

```
void PLIB_PMP_SlaveSend(PMP_MODULE_ID index, uint16_t data);
```

Returns

None.

Description

This function sends the specified data. The flow of data is from the slave to the master.

Remarks

This function to be used only when the PMP is acting as slave. This function implements an operation of the SlaveTX feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsSlaveTX in your application to to automatically determine whether this feature is available.

Preconditions

The PMP module is configured for Slave mode.

Example

```
uint16_t data = 'a';
if(!PLIB_PMP_PortIsBusy( PMP_ID_0 ))
{
    PLIB_PMP_SlaveSend( PMP_ID_0, data );
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

data	Data to be transmitted

Function

void PLIB_PMP_SlaveSend (PMP_MODULE_ID index,
uint16_t data)

PLIB_PMP_ReadCycleIsStarted Function

Checks whether or not the read cycle on PMP bus is enabled.

File

plib_pmp.h

C

```
bool PLIB_PMP_ReadCycleIsStarted(PMP_MODULE_ID index);
```

Returns

- true - If the PMP Read cycle is enabled
- false - if the PMP Read cycle is not enabled

Description

This function checks whether or not the read cycle on PMP bus is enabled.

Remarks

This function implements an operation of the StartReadControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsStartReadControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool pmpReadStartStatus;
pmpReadStartStatus = PLIB_PMP_ReadCycleIsStarted( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

bool PLIB_PMP_ReadCycleIsStarted (PMP_MODULE_ID index)

PLIB_PMP_ReadCycleStart Function

Starts a read cycle on the PMP bus.

File

plib_pmp.h

C

```
void PLIB_PMP_ReadCycleStart(PMP_MODULE_ID index);
```

Returns

None.

Description

This function stars a read cycle on the bus for the selected PMP module. This bit is cleared by hardware at the end of the read cycle

Remarks

This function implements an operation of the StartReadControl feature. This feature may not be available on all devices. Please refer to the

specific device data sheet to determine availability or use PLIB_PMP_ExistsStartReadControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_ReadCycleStart( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_ReadCycleStart(PMP_MODULE_ID index)

f) Wait States Initialization Functions

PLIB_PMP_WaitStatesDataHoldSelect Function

Configures the data hold states (after data transfer) needed to be used with the PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_WaitStatesDataHoldSelect(PMP_MODULE_ID index, PMP_DATA_HOLD_STATES dataHoldState);
```

Returns

None.

Description

This function configures the number of peripheral bus clock cycles needed for wait states. Refer to the enumeration PMP_DATA_HOLD_STATES for the possible settings.

Remarks

This function implements an operation of the DataHoldWaitStates feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDataHoldWaitStates in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_WaitStatesDataHoldSelect( PMP_ID_0, PMP_DATA_HOLD_2 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
dataHoldState	One of the possible values from PMP_DATA_HOLD_STATES

Function

void PLIB_PMP_WaitStatesDataHoldSelect(PMP_MODULE_ID index,
PMP_DATA_HOLD_STATES dataHoldState)

PLIB_PMP_WaitStatesDataSetUpSelect Function

Configures the data wait states (before the data transfer) needed to be used with the PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_WaitStatesDataSetUpSelect(PMP_MODULE_ID index, PMP_DATA_WAIT_STATES dataWaitState);
```

Returns

None.

Description

This function configures the number of peripheral bus clock cycles needed for wait states. Refer to the enumeration PMP_DATA_WAIT_STATES for the possible settings.

Remarks

This function implements an operation of the DataSetUpWaitStates feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDataSetUpWaitStates in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_WaitStatesDataSetUpSelect( PMP_ID_0, PMP_DATA_WAIT_TWO );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
dataWaitState	One of the possible values from PMP_DATA_WAIT_STATES

Function

void PLIB_PMP_WaitStatesDataSetUpSelect(PMP_MODULE_ID index,
PMP_DATA_WAIT_STATES dataWaitState)

PLIB_PMP_WaitStatesStrobeSelect Function

Configures the strobe wait states (during the data transfer) needed to be used with the PMP module.

File

plib_pmp.h

C

```
void PLIB_PMP_WaitStatesStrobeSelect(PMP_MODULE_ID index, PMP_STROBE_WAIT_STATES strobeWaitState);
```

Returns

None.

Description

This function configures the number of peripheral bus clock cycles needed for wait states. Refer to the enumeration PMP_STROBE_WAIT_STATES for the possible settings.

Remarks

This function implements an operation of the DataStrobeWaitStates feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsDataStrobeWaitStates in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_WaitStatesStrobeSelect( PMP_ID_0, PMP_STROBE_WAIT_2 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
strobeWaitState	One of the possible values from PMP_STROBE_WAIT_STATES

Function

void PLIB_PMP_WaitStatesStrobeSelect(PMP_MODULE_ID index,
PMP_STROBE_WAIT_STATES strobeWaitState)

g) Address Handling Functions

PLIB_PMP_AddressGet Function

Gets the current address of the PMP module.

File

plib_pmp.h

C

```
uint32_t PLIB_PMP_AddressGet(PMP_MODULE_ID index);
```

Returns

- address - Device address to be set

Description

This function gets the current address of the PMP module.

Remarks

This function implements an operation of the AddressControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t address;
address = PLIB_PMP_AddressGet( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

uint32_t PLIB_PMP_AddressGet (PMP_MODULE_ID index)

PLIB_PMP_AddressLinesA0A1Get Function

Gets the value of the address lines PMA0 and PMA1.

File

plib_pmp.h

C

```
uint8_t PLIB_PMP_AddressLinesA0A1Get(PMP_MODULE_ID index);
```

Returns

uint8_t - The two-bit address

Description

This function gets the value of the address lines PMA0 and PMA1. This function is used in the addressable parallel slave port mode.

Remarks

This function implements an operation of the AddressControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t bufferAddress;
bufferAddress = PLIB_PMP_AddressLinesA0A1Get( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

uint8_t PLIB_PMP_AddressLinesA0A1Get (PMP_MODULE_ID index)

PLIB_PMP_AddressLinesA0A1Set Function

Sets the address lines PMA0 and PMA1 with the value specified.

File

plib_pmp.h

C

```
void PLIB_PMP_AddressLinesA0A1Set(PMP_MODULE_ID index, uint8_t address);
```

Returns

None.

Description

This function sets the address lines PMA0 and PMA1 with the value specified. This function is used in the addressable parallel slave port mode.

Remarks

This function implements an operation of the AddressControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t bufferAddress = 0x2;
PLIB_PMP_AddressLinesA0A1Set( PMP_ID_0, bufferAddress );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
address	The two-bit address

Function

void PLIB_PMP_AddressLinesA0A1Set (PMP_MODULE_ID index,

uint8_t address)

PLIB_PMP_AddressSet Function

Sets the current address of the PMP module to the specified address.

File

plib_pmp.h

C

```
void PLIB_PMP_AddressSet(PMP_MODULE_ID index, uint32_t address);
```

Returns

None.

Description

This function sets the current address of the PMP module to the specified value.

Remarks

This function implements an operation of the AddressControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t no_of_addressLines = 8;
PLIB_PMP_AddressSet( PMP_ID_0, 0xff );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
address	Device address to be set

Function

void PLIB_PMP_AddressSet (PMP_MODULE_ID index,

uint32_t address)

h) Port Configuration Functions

PLIB_PMP_AddressPortDisable Function

Disables the port lines specified as PMP address lines.

File

plib_pmp.h

C

```
void PLIB_PMP_AddressPortDisable(PMP_MODULE_ID index, PMP_ADDRESS_PORT portfunctions);
```

Returns

None.

Description

This function disables the port lines specified as PMP address lines. They function as normal I/O lines.

Remarks

This function implements an operation of the AddressPortPinControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressPortPinControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
//Example-1
PMP_ADDRESS_PORT portfunctions = PMP_PMA2_TO_PMA13_PORTS;
PLIB_PMP_AddressPortDisable( PMP_ID_0, PMP_PMA2_TO_PMA13_PORTS );

//Example-2
PLIB_PMP_AddressPortDisable( PMP_ID_0,
                             ( PMP_PMA14_PORT | PMP_PMA15_PORT ) );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
portfunctions	One of the possible values from PMP_ADDRESS_PORT

Function

void PLIB_PMP_AddressPortDisable (PMP_MODULE_ID index,
PMP_ADDRESS_PORT portfunctions)

PLIB_PMP_AddressPortEnable Function

Enables the port lines specified as PMP address lines.

File

plib_pmp.h

C

```
void PLIB_PMP_AddressPortEnable(PMP_MODULE_ID index, PMP_ADDRESS_PORT portfunctions);
```

Returns

None.

Description

This function enables the port lines specified as PMP address lines.

Remarks

This function implements an operation of the AddressPortPinControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressPortPinControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
//Example-1
PMP_ADDRESS_PORT portfunctions = PMP_PMA2_TO_PMA13_PORTS;
PLIB_PMP_AddressPortEnable( PMP_ID_0, PMP_PMA2_TO_PMA13_PORTS );

//Example-2
PLIB_PMP_AddressPortEnable( PMP_ID_0,
                            ( PMP_PMA14_PORT | PMP_PMA15_PORT ) );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
portfunctions	One of the possible values from PMP_ADDRESS_PORT

Function

void PLIB_PMP_AddressPortEnable (PMP_MODULE_ID index,

PMP_ADDRESS_PORT portfunctions)

PLIB_PMP_ReadWriteStrobePortDisable Function

Disables the PMP module read strobe port.

File

plib_pmp.h

C

```
void PLIB_PMP_ReadWriteStrobePortDisable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function disables the read strobe port of the PMP module.

Remarks

This function implements an operation of the ReadWriteStrobePortControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsReadWriteStrobePortControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_ReadWriteStrobePortDisable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_ReadWriteStrobePortDisable (PMP_MODULE_ID index)

PLIB_PMP_ReadWriteStrobePortEnable Function

Enables the PMP module read strobe port.

File

plib_pmp.h

C

```
void PLIB_PMP_ReadWriteStrobePortEnable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function enables the read strobe port of the PMP module.

Remarks

This function implements an operation of the ReadWriteStrobePortControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsReadWriteStrobePortControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_ReadWriteStrobePortEnable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_ReadWriteStrobePortEnable (PMP_MODULE_ID index)

PLIB_PMP_WriteEnableStrobePortDisable Function

Disables the PMP module write strobe port.

File

plib_pmp.h

C

```
void PLIB_PMP_WriteEnableStrobePortDisable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function disables the write strobe port of the PMP module.

Remarks

This function implements an operation of the WriteEnablePortControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsWriteEnablePortControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_WriteEnableStrobePortDisable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_WriteEnableStrobePortDisable (PMP_MODULE_ID index)

PLIB_PMP_WriteEnableStrobePortEnable Function

Enables the PMP module write strobe port.

File

plib_pmp.h

C

```
void PLIB_PMP_WriteEnableStrobePortEnable(PMP_MODULE_ID index);
```

Returns

None.

Description

This function enables the write strobe port of the PMP module.

Remarks

This function implements an operation of the WriteEnablePortControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsWriteEnablePortControl in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_WriteEnableStrobePortEnable( PMP_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed

Function

void PLIB_PMP_WriteEnableStrobePortEnable (PMP_MODULE_ID index)

i) Polarity Configuration Functions

PLIB_PMP_AddressLatchPolaritySelect Function

Sets the address latch strobe polarity.

File

plib_pmp.h

C

```
void PLIB_PMP_AddressLatchPolaritySelect(PMP_MODULE_ID index, PMP_POLARITY_LEVEL polarity);
```

Returns

None.

Description

This function sets the address latch polarity to the level specified.

Remarks

This function implements an operation of the AddressLatchPolarity feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsAddressLatchPolarity in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_AddressLatchPolaritySelect( PMP_ID_0, PMP_POLARITY_ACTIVE_HIGH );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
polarity	Possible polarity levels

Function

void PLIB_PMP_AddressLatchPolaritySelect(PMP_MODULE_ID index,
PMP_POLARITY_LEVEL polarity)

PLIB_PMP_ChipSelectXPolaritySelect Function

Sets the specified Chip Select polarity.

File

plib_pmp.h

C

```
void PLIB_PMP_ChipSelectXPolaritySelect(PMP_MODULE_ID index, PMP_CHIP_SELECT chipSelect, PMP_POLARITY_LEVEL polarity);
```

Returns

None.

Description

This function sets the specified Chip Select polarity to the level specified.

Remarks

This function implements an operation of the ChipXPolarity feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsChipXPolarity in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PMP_CHIP_SELECT chipSelect = PMP_CHIP_SELECT_ONE;
PLIB_PMP_ChipSelectXPolaritySelect( PMP_ID_0,
                                    chipSelect,
                                    PMP_POLARITY_ACTIVE_HIGH );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
chipSelect	Identifier for Chip Select
polarity	Possible polarity levels

Function

void PLIB_PMP_ChipSelectXPolaritySelect (PMP_MODULE_ID index,
PMP_CHIP_SELECT chipSelect,
PMP_POLARITY_LEVEL polarity)

PLIB_PMP_ReadWriteStrobePolaritySelect Function

Sets the polarity of the read strobe.

File

plib_pmp.h

C

```
void PLIB_PMP_ReadWriteStrobePolaritySelect(PMP_MODULE_ID index, PMP_POLARITY_LEVEL polarity);
```

Returns

None.

Description

This function sets polarity of the read strobe to the level specified.

Remarks

This function implements an operation of the ReadWritePolarity feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsReadWritePolarity in your application to to automatically determine

whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_ReadWriteStrobePolaritySelect( PMP_ID_0, PMP_POLARITY_ACTIVE_HIGH );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
polarity	Possible polarity levels

Function

void PLIB_PMP_ReadWriteStrobePolaritySelect (PMP_MODULE_ID index,
PMP_POLARITY_LEVEL polarity)

PLIB_PMP_WriteEnableStrobePolaritySelect Function

Sets the polarity of the write enable strobe.

File

plib_pmp.h

C

```
void PLIB_PMP_WriteEnableStrobePolaritySelect(PMP_MODULE_ID index, PMP_POLARITY_LEVEL polarity);
```

Returns

None.

Description

This function sets the polarity of the write enable strobe to the level specified.

Remarks

This function implements an operation of the WriteEnablePolarity feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PMP_ExistsWriteEnablePolarity in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PMP_WriteEnableStrobePolaritySelect( PMP_ID_0, PMP_POLARITY_ACTIVE_HIGH );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be addressed
polarity	Possible polarity levels

Function

void PLIB_PMP_WriteEnableStrobePolaritySelect (PMP_MODULE_ID index,
PMP_POLARITY_LEVEL polarity)

j) Feature Existence Functions

PLIB_PMP_ExistsAddressControl Function

Identifies whether the AddressControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsAddressControl(PMP_MODULE_ID index);
```

Returns

- true - The AddressControl feature is supported on the device
- false - The AddressControl feature is not supported on the device

Description

This function identifies whether the AddressControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_AddressSet
- PLIB_PMP_AddressGet
- PLIB_PMP_AddressLinesA0A1Set
- PLIB_PMP_AddressLinesA0A1Get

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsAddressControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsAddressLatchPolarity Function

Identifies whether the AddressLatchPolarity feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsAddressLatchPolarity(PMP_MODULE_ID index);
```

Returns

- true - The AddressLatchPolarity feature is supported on the device
- false - The AddressLatchPolarity feature is not supported on the device

Description

This function identifies whether the AddressLatchPolarity feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_AddressLatchPolaritySelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsAddressLatchPolarity(PMP_MODULE_ID index)

PLIB_PMP_ExistsAddressLatchStrobePortControl Function

Identifies whether the AddressLatchStrobePortControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsAddressLatchStrobePortControl(PMP_MODULE_ID index);
```

Returns

- true - The AddressLatchStrobePortControl feature is supported on the device
- false - The AddressLatchStrobePortControl feature is not supported on the device

Description

This function identifies whether the AddressLatchStrobePortControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_AddressLatchStrobeEnable
- PLIB_PMP_AddressLatchStrobeDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsAddressLatchStrobePortControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsAddressPortPinControl Function

Identifies whether the AddressPortPinControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsAddressPortPinControl(PMP_MODULE_ID index);
```

Returns

- true - The AddressPortPinControl feature is supported on the device
- false - The AddressPortPinControl feature is not supported on the device

Description

This function identifies whether the AddressPortPinControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_AddressPortEnable
- PLIB_PMP_AddressPortDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsAddressPortPinControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsBufferOverFlow Function

Identifies whether the BufferOverFlow feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsBufferOverFlow(PMP_MODULE_ID index);
```

Returns

- true - The BufferOverFlow feature is supported on the device
- false - The BufferOverFlow feature is not supported on the device

Description

This function identifies whether the BufferOverFlow feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_InputOverflowHasOccurred
- PLIB_PMP_InputOverflowClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsBufferOverFlow(PMP_MODULE_ID index)

PLIB_PMP_ExistsBufferRead Function

Identifies whether the BufferRead feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsBufferRead(PMP_MODULE_ID index);
```

Returns

- true - The BufferRead feature is supported on the device
- false - The BufferRead feature is not supported on the device

Description

This function identifies whether the BufferRead feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_InputBufferXByteReceive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsBufferRead(PMP_MODULE_ID index)

PLIB_PMP_ExistsBufferType Function

Identifies whether the BufferType feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsBufferType(PMP_MODULE_ID index);
```

Returns

- true - The BufferType feature is supported on the device
- false - The BufferType feature is not supported on the device

Description

This function identifies whether the BufferType feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_InputBufferTypeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsBufferType(PMP_MODULE_ID index)

PLIB_PMP_ExistsBufferUnderFlow Function

Identifies whether the BufferUnderFlow feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsBufferUnderFlow(PMP_MODULE_ID index);
```

Returns

- true - The BufferUnderFlow feature is supported on the device
- false - The BufferUnderFlow feature is not supported on the device

Description

This function identifies whether the BufferUnderFlow feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_OutputUnderflowHasOccurred
- PLIB_PMP_OutputUnderflowClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsBufferUnderFlow(PMP_MODULE_ID index)

PLIB_PMP_ExistsBufferWrite Function

Identifies whether the BufferWrite feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsBufferWrite(PMP_MODULE_ID index);
```

Returns

- true - The BufferWrite feature is supported on the device
- false - The BufferWrite feature is not supported on the device

Description

This function identifies whether the BufferWrite feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_OutputBufferXByteSend

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsBufferWrite(PMP_MODULE_ID index)

PLIB_PMP_ExistsBusyStatus Function

Identifies whether the BusyStatus feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsBusyStatus(PMP_MODULE_ID index);
```

Returns

- true - The BusyStatus feature is supported on the device
- false - The BusyStatus feature is not supported on the device

Description

This function identifies whether the BusyStatus feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_PortIsBusy

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsBusyStatus(PMP_MODULE_ID index)

PLIB_PMP_ExistsChipSelectEnable Function

Identifies whether the ChipSelectEnable feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsChipSelectEnable(PMP_MODULE_ID index);
```

Returns

- true - The ChipSelectEnable feature is supported on the device
- false - The ChipSelectEnable feature is not supported on the device

Description

This function identifies whether the ChipSelectEnable feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_ChipSelectXEnable
- PLIB_PMP_ChipSelectXDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsChipSelectEnable(PMP_MODULE_ID index)

PLIB_PMP_ExistsChipSelectoperation Function

Identifies whether the ChipSelectoperation feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsChipSelectoperation(PMP_MODULE_ID index);
```

Returns

- true - The ChipSelectoperation feature is supported on the device
- false - The ChipSelectoperation feature is not supported on the device

Description

This function identifies whether the ChipSelectoperation feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_ChipSelectFunctionSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsChipSelectoperation(PMP_MODULE_ID index)

PLIB_PMP_ExistsChipXPolarity Function

Identifies whether the ChipXPolarity feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsChipXPolarity(PMP_MODULE_ID index);
```

Returns

- true - The ChipXPolarity feature is supported on the device
- false - The ChipXPolarity feature is not supported on the device

Description

This function identifies whether the ChipXPolarity feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_ChipSelectXPolaritySelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsChipXPolarity(PMP_MODULE_ID index)

PLIB_PMP_ExistsCSXActiveStatus Function

Identifies whether the CSXActiveStatus feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsCSXActiveStatus(PMP_MODULE_ID index);
```

Returns

- true - The CSXActiveStatus feature is supported on the device
- false - The CSXActiveStatus feature is not supported on the device

Description

This function identifies whether the CSXActiveStatus feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_ChipSelectXIsActive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsCSXActiveStatus(PMP_MODULE_ID index)

PLIB_PMP_ExistsDataHoldWaitStates Function

Identifies whether the DataHoldWaitStates feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsDataHoldWaitStates(PMP_MODULE_ID index);
```

Returns

- true - The DataHoldWaitStates feature is supported on the device
- false - The DataHoldWaitStates feature is not supported on the device

Description

This function identifies whether the DataHoldWaitStates feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_WaitStatesDataHoldSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsDataHoldWaitStates(PMP_MODULE_ID index)

PLIB_PMP_ExistsDataSetUpWaitStates Function

Identifies whether the DataSetUpWaitStates feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsDataSetUpWaitStates(PMP_MODULE_ID index);
```

Returns

- true - The DataSetUpWaitStates feature is supported on the device
- false - The DataSetUpWaitStates feature is not supported on the device

Description

This function identifies whether the DataSetUpWaitStates feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_WaitStatesDataSetUpSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsDataSetUpWaitStates(PMP_MODULE_ID index)

PLIB_PMP_ExistsDataStrobeWaitStates Function

Identifies whether the DataStrobeWaitStates feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsDataStrobeWaitStates(PMP_MODULE_ID index);
```

Returns

- true - The DataStrobeWaitStates feature is supported on the device
- false - The DataStrobeWaitStates feature is not supported on the device

Description

This function identifies whether the DataStrobeWaitStates feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_WaitStatesStrobeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsDataStrobeWaitStates(PMP_MODULE_ID index)

PLIB_PMP_ExistsDataTransferSize Function

Identifies whether the DataTransferSize feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsDataTransferSize(PMP_MODULE_ID index);
```

Returns

- true - The DataTransferSize feature is supported on the device
- false - The DataTransferSize feature is not supported on the device

Description

This function identifies whether the DataTransferSize feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_DataSizeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsDataTransferSize(PMP_MODULE_ID index)

PLIB_PMP_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsEnableControl(PMP_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_Disable
- PLIB_PMP_Enable
- PLIB_PMP_IsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsEnableControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsIncrementMode Function

Identifies whether the IncrementMode feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsIncrementMode(PMP_MODULE_ID index);
```

Returns

- true - The IncrementMode feature is supported on the device
- false - The IncrementMode feature is not supported on the device

Description

This function identifies whether the IncrementMode feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_AddressIncrementModeSelect
- PLIB_PMP_AddressIncrementModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsIncrementMode(PMP_MODULE_ID index)

PLIB_PMP_ExistsInputBufferFull Function

Identifies whether the InputBufferFull feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsInputBufferFull(PMP_MODULE_ID index);
```

Returns

- true - The InputBufferFull feature is supported on the device
- false - The InputBufferFull feature is not supported on the device

Description

This function identifies whether the InputBufferFull feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_InputBuffersAreFull

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsInputBufferFull(PMP_MODULE_ID index)

PLIB_PMP_ExistsInputBufferXStatus Function

Identifies whether the InputBufferXStatus feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsInputBufferXStatus(PMP_MODULE_ID index);
```

Returns

- true - The InputBufferXStatus feature is supported on the device
- false - The InputBufferXStatus feature is not supported on the device

Description

This function identifies whether the InputBufferXStatus feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_InputBufferXIsFull
- PLIB_PMP_IsDataReceived

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsInputBufferXStatus(PMP_MODULE_ID index)

PLIB_PMP_ExistsInterruptMode Function

Identifies whether the InterruptMode feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsInterruptMode(PMP_MODULE_ID index);
```

Returns

- true - The InterruptMode feature is supported on the device
- false - The InterruptMode feature is not supported on the device

Description

This function identifies whether the InterruptMode feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_InterruptModeSelect
- PLIB_PMP_InterruptModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsInterruptMode(PMP_MODULE_ID index)

PLIB_PMP_ExistsMasterRXTX Function

Identifies whether the MasterRXTX feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsMasterRXTX(PMP_MODULE_ID index);
```

Returns

- true - The MasterRXTX feature is supported on the device
- false - The MasterRXTX feature is not supported on the device

Description

This function identifies whether the MasterRXTX feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_MasterSend
- PLIB_PMP_MasterReceive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsMasterRXTX(PMP_MODULE_ID index)

PLIB_PMP_ExistsMUXModeSelect Function

Identifies whether the MUXModeSelect feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsMUXModeSelect(PMP_MODULE_ID index);
```

Returns

- true - The MUXModeSelect feature is supported on the device
- false - The MUXModeSelect feature is not supported on the device

Description

This function identifies whether the MUXModeSelect feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_MultiplexModeSelect
- PLIB_PMP_MultiplexModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsMUXModeSelect(PMP_MODULE_ID index)

PLIB_PMP_ExistsOperationMode Function

Identifies whether the OperationMode feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsOperationMode(PMP_MODULE_ID index);
```

Returns

- true - The OperationMode feature is supported on the device
- false - The OperationMode feature is not supported on the device

Description

This function identifies whether the OperationMode feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_OperationModeSelect
- PLIB_PMP_OperationModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsOperationMode(PMP_MODULE_ID index)

PLIB_PMP_ExistsOutPutBufferEmpty Function

Identifies whether the OutPutBufferEmpty feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsOutPutBufferEmpty(PMP_MODULE_ID index);
```

Returns

- true - The OutPutBufferEmpty feature is supported on the device
- false - The OutPutBufferEmpty feature is not supported on the device

Description

This function identifies whether the OutPutBufferEmpty feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_OutputBuffersAreEmpty

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsOutPutBufferEmpty(PMP_MODULE_ID index)

PLIB_PMP_ExistsOutputBufferXStatus Function

Identifies whether the OutputBufferXStatus feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsOutputBufferXStatus(PMP_MODULE_ID index);
```

Returns

- true - The OutputBufferXStatus feature is supported on the device
- false - The OutputBufferXStatus feature is not supported on the device

Description

This function identifies whether the OutputBufferXStatus feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_OutputBufferXIsEmpty
- PLIB_PMP_IsDataTransmitted

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsOutputBufferXStatus(PMP_MODULE_ID index)

PLIB_PMP_ExistsReadWritePolarity Function

Identifies whether the ReadWritePolarity feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsReadWritePolarity(PMP_MODULE_ID index);
```

Returns

- true - The ReadWritePolarity feature is supported on the device
- false - The ReadWritePolarity feature is not supported on the device

Description

This function identifies whether the ReadWritePolarity feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_ReadWriteStrobePolaritySelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsReadWritePolarity(PMP_MODULE_ID index)

PLIB_PMP_ExistsReadWriteStrobePortControl Function

Identifies whether the ReadWriteStrobePortControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsReadWriteStrobePortControl(PMP_MODULE_ID index);
```

Returns

- true - The ReadWriteStrobePortControl feature is supported on the device
- false - The ReadWriteStrobePortControl feature is not supported on the device

Description

This function identifies whether the ReadWriteStrobePortControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_ReadWriteStrobePortEnable
- PLIB_PMP_ReadWriteStrobePortDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsReadWriteStrobePortControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsSlaveRX Function

Identifies whether the SlaveRX feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsSlaveRX(PMP_MODULE_ID index);
```

Returns

- true - The SlaveRX feature is supported on the device
- false - The SlaveRX feature is not supported on the device

Description

This function identifies whether the SlaveRX feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_SlaveReceive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsSlaveRX(PMP_MODULE_ID index)

PLIB_PMP_ExistsSlaveTX Function

Identifies whether the SlaveTX feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsSlaveTX(PMP_MODULE_ID index);
```

Returns

- true - The SlaveTX feature is supported on the device
- false - The SlaveTX feature is not supported on the device

Description

This function identifies whether the SlaveTX feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_SlaveSend

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsSlaveTX(PMP_MODULE_ID index)

PLIB_PMP_ExistsStopInIdleControl Function

Identifies whether the StopInIdleControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsStopInIdleControl(PMP_MODULE_ID index);
```

Returns

- true - The StopInIdleControl feature is supported on the device
- false - The StopInIdleControl feature is not supported on the device

Description

This function identifies whether the StopInIdleControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_StopInIdleEnable
- PLIB_PMP_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsStopInIdleControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsWriteEnablePolarity Function

Identifies whether the WriteEnablePolarity feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsWriteEnablePolarity(PMP_MODULE_ID index);
```

Returns

- true - The WriteEnablePolarity feature is supported on the device
- false - The WriteEnablePolarity feature is not supported on the device

Description

This function identifies whether the WriteEnablePolarity feature is available on the PMP module. When this function returns true, this function is supported on the device:

- PLIB_PMP_WriteEnableStrobePolaritySelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsWriteEnablePolarity(PMP_MODULE_ID index)

PLIB_PMP_ExistsWriteEnablePortControl Function

Identifies whether the WriteEnablePortControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsWriteEnablePortControl(PMP_MODULE_ID index);
```

Returns

- true - The WriteEnablePortControl feature is supported on the device
- false - The WriteEnablePortControl feature is not supported on the device

Description

This function identifies whether the WriteEnablePortControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_WriteEnableStrobePortEnable
- PLIB_PMP_WriteEnableStrobePortDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsWriteEnablePortControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsDualBufferControl Function

Identifies whether the DualBufferControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsDualBufferControl(PMP_MODULE_ID index);
```

Returns

- true - The DualBufferControl feature is supported on the device
- false - The DualBufferControl feature is not supported on the device

Description

This function identifies whether the DualBufferControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_DualBufferDisable
- PLIB_PMP_DualBufferEnable
- PLIB_PMP_DualBufferIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsDualBufferControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsDualModeMasterRXTX Function

Identifies whether the DualModeMasterRXTX feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsDualModeMasterRXTX(PMP_MODULE_ID index);
```

Returns

- true - The DualModeMasterRXTX feature is supported on the device
- false - The DualModeMasterRXTX feature is not supported on the device

Description

This function identifies whether the DualModeMasterRXTX feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_DualModeMasterSend
- PLIB_PMP_DualModeMasterReceive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsDualModeMasterRXTX(PMP_MODULE_ID index)

PLIB_PMP_ExistsDualModeReadAddressControl Function

Identifies whether the DualModeReadAddressControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsDualModeReadAddressControl(PMP_MODULE_ID index);
```

Returns

- true - The DualModeReadAddressControl feature is supported on the device
- false - The DualModeReadAddressControl feature is not supported on the device

Description

This function identifies whether the DualModeReadAddressControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_DualModeReadAddressSet
- PLIB_PMP_DualModeReadAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsDualModeReadAddressControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsDualModeWriteAddressControl Function

Identifies whether the DualModeWriteAddressControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsDualModeWriteAddressControl(PMP_MODULE_ID index);
```

Returns

- true - The DualModeWriteAddressControl feature is supported on the device
- false - The DualModeWriteAddressControl feature is not supported on the device

Description

This function identifies whether the DualModeWriteAddressControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_DualModeWriteAddressSet
- PLIB_PMP_DualModeWriteAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsDualModeWriteAddressControl(PMP_MODULE_ID index)

PLIB_PMP_ExistsReadChipSelectEnable Function

Identifies whether the ReadChipSelectEnable feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsReadChipSelectEnable(PMP_MODULE_ID index);
```

Returns

- true - The ReadChipSelectEnable feature is supported on the device
- false - The ReadChipSelectEnable feature is not supported on the device

Description

This function identifies whether the ReadChipSelectEnable feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_ReadChipSelectXEnable
- PLIB_PMP_ReadChipSelectXDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsReadChipSelectEnable(PMP_MODULE_ID index)

PLIB_PMP_ExistsWriteChipSelectEnable Function

Identifies whether the WriteChipSelectEnable feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsWriteChipSelectEnable(PMP_MODULE_ID index);
```

Returns

- true - The WriteChipSelectEnable feature is supported on the device
- false - The WriteChipSelectEnable feature is not supported on the device

Description

This function identifies whether the WriteChipSelectEnable feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_WriteChipSelectXEnable
- PLIB_PMP_WriteChipSelectXDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsWriteChipSelectEnable(PMP_MODULE_ID index)

PLIB_PMP_ExistsStartReadControl Function

Identifies whether the StartReadControl feature exists on the PMP module.

File

plib_pmp.h

C

```
bool PLIB_PMP_ExistsStartReadControl(PMP_MODULE_ID index);
```

Returns

- true - The StartReadControl feature is supported on the device
- false - The StartReadControl feature is not supported on the device

Description

This function identifies whether the StartReadControl feature is available on the PMP module. When this function returns true, these functions are supported on the device:

- PLIB_PMP_ReadCycleStart
- PLIB_PMP_ReadCycleIsStarted

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PMP_ExistsStartReadControl(PMP_MODULE_ID index)

k) Data Types and Constants

PMP_ACK_MODE Enumeration

Defines the different mode configurations in which the PMP can be enabled.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_USE_ACK_WITH_TIMEOUT,
  PMP_USE_ACK,
```

```
  PMP_ACK_DISABLED
} PMP_ACK_MODE;
```

Members

Members	Description
PMP_USE_ACK_WITH_TIMEOUT	Acknowledge used with a timeout
PMP_USE_ACK	Acknowledge is used
PMP_ACK_DISABLED	Acknowledge is not used

Description

PMP Acknowledge Modes

This data type defines the different configurations by which the PMP can be enabled.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_ADDRESS_HOLD_LATCH_WAIT_STATES Enumeration

PMP hold after address latch strobe wait states configuration.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_ADDRESS_HOLD_ONE_AND_ONE_QUARTER,
  PMP_ADDRESS_HOLD_ONE_QUARTER
} PMP_ADDRESS_HOLD_LATCH_WAIT_STATES;
```

Members

Members	Description
PMP_ADDRESS_HOLD_ONE_AND_ONE_QUARTER	Data Wait of 1 1/4 Peripheral Bus Clock Cycles
PMP_ADDRESS_HOLD_ONE_QUARTER	Data Wait of 1/4 Peripheral Bus Clock Cycles

Description

PMP Address Latch Strobe Wait States

This data type defines the different configurations by which the PMP holds after address latch strobe wait states can be configured. Refer to the specific device data sheet for the exact clock cycle timing.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_ADDRESS_LATCH Enumeration

Address Latch Strobe configuration.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_ADDRESS_LATCH_UPPER,
  PMP_ADDRESS_LATCH_HIGH,
  PMP_ADDRESS_LATCH_LOW
} PMP_ADDRESS_LATCH;
```

Members

Members	Description
PMP_ADDRESS_LATCH_UPPER	Address latch upper
PMP_ADDRESS_LATCH_HIGH	Address latch high
PMP_ADDRESS_LATCH_LOW	Address latch low

Description

PMP Address Latch

This data type defines the different configurations by which the PMP address latch strobes can be configured.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_ADDRESS_LATCH_WAIT_STATES Enumeration

PMP address latch strobe wait states configuration.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_ADDRESS_WAIT_THREE_AND_HALF,
  PMP_ADDRESS_WAIT_TWO_AND_HALF,
  PMP_ADDRESS_WAIT_ONE_AND_HALF,
  PMP_ADDRESS_WAIT_HALF
} PMP_ADDRESS_LATCH_WAIT_STATES;
```

Members

Members	Description
PMP_ADDRESS_WAIT_THREE_AND_HALF	Data Wait of 3 1/2 Peripheral Bus Clock Cycles
PMP_ADDRESS_WAIT_TWO_AND_HALF	Data Wait of 2 1/2 Peripheral Bus Clock Cycles
PMP_ADDRESS_WAIT_ONE_AND_HALF	Data Wait of 1 1/2 Peripheral Bus Clock Cycles
PMP_ADDRESS_WAIT_HALF	Data Wait of 1/2 Peripheral Bus Clock Cycles

Description

PMP Address Latch Strobe Wait States

This data type defines the different configurations by which the PMP address latch strobe wait states can be configured. Refer to the specific device data sheet for the exact clock cycle timing.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_ADDRESS_PORT Enumeration

Defines the different address lines that are available for configuration.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_PMA0_PORT,
  PMP_PMA1_PORT,
  PMP_PMA2_TO_PMA13_PORTS,
  PMP_PMA2_PORT,
  PMP_PMA3_PORT,
  PMP_PMA4_PORT,
  PMP_PMA5_PORT,
  PMP_PMA6_PORT,
  PMP_PMA7_PORT,
  PMP_PMA8_PORT,
  PMP_PMA9_PORT,
  PMP_PMA10_PORT,
  PMP_PMA11_PORT,
  PMP_PMA12_PORT,
  PMP_PMA13_PORT,
  PMP_PMA14_PORT,
  PMP_PMA15_PORT,
  PMP_PMA16_TO_PMA22_PORTS,
```

```
  PMP_PMA2_TO_PMA10_PORTS
} PMP_ADDRESS_PORT;
```

Members

Members	Description
PMP_PMA0_PORT	Address line 0 port (make as general purpose I/O or PMP address line)
PMP_PMA1_PORT	Address line 1 port (make as general purpose I/O or PMP address line)
PMP_PMA2_TO_PMA13_PORTS	Address line 2 to 13 ports (make as general purpose I/O or PMP address lines)
PMP_PMA2_PORT	Address line 2 port (make as general purpose I/O or PMP address line)
PMP_PMA3_PORT	Address line 3 port (make as general purpose I/O or PMP address line)
PMP_PMA4_PORT	Address line 4 port (make as general purpose I/O or PMP address line)
PMP_PMA5_PORT	Address line 5 port (make as general purpose I/O or PMP address line)
PMP_PMA6_PORT	Address line 6 port (make as general purpose I/O or PMP address line)
PMP_PMA7_PORT	Address line 7 port (make as general purpose I/O or PMP address line)
PMP_PMA8_PORT	Address line 8 port (make as general purpose I/O or PMP address line)
PMP_PMA9_PORT	Address line 9 port (make as general purpose I/O or PMP address line)
PMP_PMA10_PORT	Address line 10 port (make as general purpose I/O or PMP address line)
PMP_PMA11_PORT	Address line 11 port (make as general purpose I/O or PMP address line)
PMP_PMA12_PORT	Address line 12 port (make as general purpose I/O or PMP address line)
PMP_PMA13_PORT	Address line 13 port (make as general purpose I/O or PMP address line)
PMP_PMA14_PORT	Address line 14 port (make as general purpose I/O or PMP address line)
PMP_PMA15_PORT	Address line 15 port (make as general purpose I/O or PMP address line)
PMP_PMA16_TO_PMA22_PORTS	Address line 16 to 22 ports (make as general purpose I/O or PMP address lines)
PMP_PMA2_TO_PMA10_PORTS	Address line 2 to 10 ports (make as general purpose I/O or PMP address lines)

Description

PMP Address Port Pins

This data type defines the different address that can be configured by the PMP module. The user application can make each pin as a general purpose I/O or part of PMP functionality.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h). These enumerator values can be passed in a bitwise ORed fashion to select multiple ports at a time.

PMP_ALTERNATE_MASTER_WAIT_STATES Enumeration

PMP alternate master wait states.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_ALTERNATE_MASTER_WAIT_10,
  PMP_ALTERNATE_MASTER_WAIT_9,
  PMP_ALTERNATE_MASTER_WAIT_8,
  PMP_ALTERNATE_MASTER_WAIT_7,
  PMP_ALTERNATE_MASTER_WAIT_6,
  PMP_ALTERNATE_MASTER_WAIT_5,
  PMP_ALTERNATE_MASTER_WAIT_4,
  PMP_ALTERNATE_MASTER_WAIT_3
} PMP_ALTERNATE_MASTER_WAIT_STATES;
```

Members

Members	Description
PMP_ALTERNATE_MASTER_WAIT_10	Wait of 10 Alternate Master Cycles
PMP_ALTERNATE_MASTER_WAIT_9	Wait of 9 Alternate Master Cycles
PMP_ALTERNATE_MASTER_WAIT_8	Wait of 8 Alternate Master Cycles
PMP_ALTERNATE_MASTER_WAIT_7	Wait of 7 Alternate Master Cycles
PMP_ALTERNATE_MASTER_WAIT_6	Wait of 6 Alternate Master Cycles

PMP_ALTERNATE_MASTER_WAIT_5	Wait of 5 Alternate Master Cycles
PMP_ALTERNATE_MASTER_WAIT_4	Wait of 4 Alternate Master Cycles
PMP_ALTERNATE_MASTER_WAIT_3	Wait of 3 Alternate Master Cycles

Description

PMP Alternate Master Wait States

This data type defines the different configurations by which the PMP alternate master wait states can be configured.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_CHIP_SELECT Enumeration

PMP Chip Select data type.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_CHIP_SELECT_ONE,
  PMP_CHIP_SELECT_TWO
} PMP_CHIP_SELECT;
```

Members

Members	Description
PMP_CHIP_SELECT_ONE	Chip Select One
PMP_CHIP_SELECT_TWO	Chip Select Two

Description

PMP Chip Select

This data type defines the different Chip Select lines of the PMP module.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_CHIPSELECT_FUNCTION Enumeration

Defines different functions available for the Chip Select lines multiplexed with address lines.

File

plib_pmp_help.h

C

```
typedef enum {
  PMCS1_AS_CHIP_SELECT,
  PMCS1_AS_ADDRESS_LINE,
  PMCS1_PMCS2_AS_ADDRESS_LINES,
  PMCS1_AS_ADDRESS_LINE_PMCS2_AS_CHIP_SELECT,
  PMCS1_AND_PMCS2_AS_CHIP_SELECT
} PMP_CHIPSELECT_FUNCTION;
```

Members

Members	Description
PMCS1_AS_CHIP_SELECT	CS1 used as Chip Select
PMCS1_AS_ADDRESS_LINE	CS1 used as address line
PMCS1_PMCS2_AS_ADDRESS_LINES	CS1 and CS2 used as address lines
PMCS1_AS_ADDRESS_LINE_PMCS2_AS_CHIP_SELECT	CS1 used as address line and CS2 as Chip Select
PMCS1_AND_PMCS2_AS_CHIP_SELECT	Both CS1 and CS2 used as Chip Selects

Description

PMP Chip Select pin functions

This data type defines different functions of Chip Select pins.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_DATA_HOLD_STATES Enumeration

PMP Data Hold after strobe wait state.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_DATA_HOLD_FOUR,
  PMP_DATA_HOLD_THREE,
  PMP_DATA_HOLD_TWO,
  PMP_DATA_HOLD_ONE
} PMP_DATA_HOLD_STATES;
```

Members

Members	Description
PMP_DATA_HOLD_FOUR	Data Hold of 4 Peripheral Bus Clock Cycles
PMP_DATA_HOLD_THREE	Data Hold of 3 Peripheral Bus Clock Cycles
PMP_DATA_HOLD_TWO	Data Hold of 2 Peripheral Bus Clock Cycles
PMP_DATA_HOLD_ONE	Data Hold of 1 Peripheral Bus Clock Cycles

Description

PMP Data Hold after strobe wait state

This data type defines the different data Hold after strobe wait states.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_DATA_LENGTH Enumeration

Possible data lengths handled by the PMP module.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_DATA_8_BITS,
  PMP_DATA_16_BITS,
  PMP_DATA_32_BITS
} PMP_DATA_LENGTH;
```

Members

Members	Description
PMP_DATA_8_BITS	8-bit data length
PMP_DATA_16_BITS	16-bit data length
PMP_DATA_32_BITS	32-bit data length

Description

PMP data length

This data type defines the possible data lengths handled by the PMP module.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_DATA_SIZE Enumeration

PMP data size.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_DATA_SIZE_8_BITS = 0x0,
  PMP_DATA_SIZE_16_BITS = 0x1
} PMP_DATA_SIZE;
```

Members

Members	Description
PMP_DATA_SIZE_8_BITS = 0x0	Data length of 8-bits
PMP_DATA_SIZE_16_BITS = 0x1	Data length of 16-bits

Description

PMP DATA Size

This data type defines the different configurations for the data lengths handled by the PMP module.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_DATA_WAIT_STATES Enumeration

PMP data setup time configuration.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_DATA_WAIT_FOUR,
  PMP_DATA_WAIT_THREE,
  PMP_DATA_WAIT_TWO,
  PMP_DATA_WAIT_ONE
} PMP_DATA_WAIT_STATES;
```

Members

Members	Description
PMP_DATA_WAIT_FOUR	Data Wait of 4 Peripheral Bus Clock Cycles
PMP_DATA_WAIT_THREE	Data Wait of 3 Peripheral Bus Clock Cycles
PMP_DATA_WAIT_TWO	Data Wait of 2 Peripheral Bus Clock Cycles
PMP_DATA_WAIT_ONE	Data Wait of 1 Peripheral Bus Clock Cycles

Description

PMP Data setup to read/write/address phase wait state configuration

This data type defines the different wait state configurations for setup to read/write/address phase.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_INCREMENT_MODE Enumeration

PMP address incrementing configuration.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_BUFFERS_AUTO_INCREMENT,
  PMP_ADDRESS_AUTO_DECREMENT,
  PMP_ADDRESS_AUTO_INCREMENT,
  PMP_ADDRESS_INCREMENT_DECREMENT_DISABLE
} PMP_INCREMENT_MODE;
```

Members

Members	Description
PMP_BUFFERS_AUTO_INCREMENT	Read and write buffers auto-increment
PMP_ADDRESS_AUTO_DECREMENT	Decrement PMP Address by one every read/write cycle
PMP_ADDRESS_AUTO_INCREMENT	Increment PMP Address by one every read/write cycle
PMP_ADDRESS_INCREMENT_DECREMENT_DISABLE	PMP Address does not change

Description

PMP Increment Modes

This data type defines the different configurations by which the PMP address incrementing can be configured.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_INPUT_BUFFER_TYPE Enumeration

PMP Input Buffers type.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_INPUT_BUFFER_TTL,
  PMP_INPUT_BUFFER_SCHMITT
} PMP_INPUT_BUFFER_TYPE;
```

Members

Members	Description
PMP_INPUT_BUFFER_TTL	TTL input buffer
PMP_INPUT_BUFFER_SCHMITT	Schmitt trigger input buffer

Description

PMP Input Buffers type

This data type defines the input buffer types.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_INTERRUPT_MODE Enumeration

PMP interrupt request mode data type.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_INTERRUPT_BUFFER_3_IS_ACCESSED,
  PMP_INTERRUPT_EVERY_RW_CYCLE,
```

```
  PMP_INTERRUPT_NONE
} PMP_INTERRUPT_MODE;
```

Members

Members	Description
PMP_INTERRUPT_BUFFER_3_IS_ACCESSED	Interrupt generated when Read/Write Buffer 3 is read/written
PMP_INTERRUPT_EVERY_RW_CYCLE	Interrupt Occurs Every Read/Write Cycle
PMP_INTERRUPT_NONE	No interrupt generated

Description

PMP Interrupt Mode

This data type defines the different configurations by which the PMP can be configured for interrupt requests.

Remarks

None.

PMP_MASTER_MODE Enumeration

Defines the different mode configurations in which the PMP can be enabled.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_ALTERNATE_MASTER_DIRECT,
  PMP_ALTERNATE_MASTER,
  PMP_CPU_MASTER
} PMP_MASTER_MODE;
```

Members

Members	Description
PMP_ALTERNATE_MASTER_DIRECT	Alternate Master has PMP control with Direct I/O access
PMP_ALTERNATE_MASTER	Alternate Master has PMP control
PMP_CPU_MASTER	CPU has PMP control

Description

PMP Master Modes

This data type defines the different configurations by which the PMP can be enabled.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_MODULE_ID Enumeration

Possible instances of the PMP module.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_ID_0
} PMP_MODULE_ID;
```

Members

Members	Description
PMP_ID_0	first instance of the PMP

Description

PMP module ID

This data type defines the possible instances of the PMP module.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_MUX_MODE Enumeration

Defines the different mode configurations in which the PMP can be enabled.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_MUX_ADDRESS_PHASES_3,
  PMP_MUX_ADDRESS_PHASES_2,
  PMP_MUX_ADDRESS_PHASES_1,
  PMP_MUX_LINES_16_ADDRESS_16_DATA,
  PMP_MUX_LINES_16_ADDRESS_8_DATA,
  PMP_MUX_LINES_8_ADDRESS_8_DATA,
  PMP_MUX_NONE
} PMP_MUX_MODE;
```

Members

Members	Description
PMP_MUX_ADDRESS_PHASES_3	Lower address bits are multiplexed with data bits using 3 address phase
PMP_MUX_ADDRESS_PHASES_2	Lower address bits are multiplexed with data bits using 2 address phases
PMP_MUX_ADDRESS_PHASES_1	Lower address bits are multiplexed with data bits using 1 address phase
PMP_MUX_LINES_16_ADDRESS_16_DATA	16 address lines are multiplexed on 16 data lines
PMP_MUX_LINES_16_ADDRESS_8_DATA	16 address lines multiplexed on 8 data lines
PMP_MUX_LINES_8_ADDRESS_8_DATA	8 bits of address is multiplexed on 8 data lines
PMP_MUX_NONE	No multiplexing of address and data lines

Description

PMP Multiplex Modes

This data type defines the different configurations by which the PMP can be enabled.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_OPERATION_MODE Enumeration

Defines the different mode configurations in which the PMP can be enabled.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_MASTER_READ_WRITE_STROBES_MULTIPLEXED,
  PMP_MASTER_READ_WRITE_STROBES_INDEPENDENT,
  PMP_BUFFERED_SLAVE,
  PMP_ENHANCED_SLAVE,
  PMP_LEGACY_SLAVE
} PMP_OPERATION_MODE;
```

Members

Members	Description
PMP_MASTER_READ_WRITE_STROBES_MULTIPLEXED	Master mode 1, the read and the write strobes share a single line. The enable strobe is used to decode the info sent on read/write strobe line
PMP_MASTER_READ_WRITE_STROBES_INDEPENDENT	Master mode 2, the read and write strobes are on independent lines
PMP_BUFFERED_SLAVE	Buffered Slave mode
PMP_ENHANCED_SLAVE	Enhanced Slave mode

PMP_LEGACY_SLAVE	Legacy Parallel Slave mode

Description

PMP Operation Modes

This data type defines the different configurations by which the PMP can be enabled.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_PMBE_PORT Enumeration

Defines the available Byte Enable ports.

File

plib_pmp_help.h

C

```
typedef enum {
  PMBE_0,
  PMBE_1
} PMP_PMBE_PORT;
```

Members

Members	Description
PMBE_0	Byte Enable Port-0
PMBE_1	Byte Enable Port-1

Description

PMP Byte Enable port.

This data type defines the available Byte Enable ports.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PMP_POLARITY_LEVEL Enumeration

Possible polarity levels for the PMP pins.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_POLARITY_ACTIVE_HIGH,
  PMP_POLARITY_ACTIVE_LOW
} PMP_POLARITY_LEVEL;
```

Members

Members	Description
PMP_POLARITY_ACTIVE_HIGH	Active high polarity
PMP_POLARITY_ACTIVE_LOW	Active low polarity

Description

PMP Pins Polarity

This data type defines the possible polarity levels for the PMP pins.

Remarks

None.

PMP_STROBE_WAIT_STATES Enumeration

PMP strobe signal wait time configuration.

File

plib_pmp_help.h

C

```
typedef enum {
  PMP_STROBE_WAIT_FIFTEEN,
  PMP_STROBE_WAIT_FOURTEEN,
  PMP_STROBE_WAIT_THIRTEEN,
  PMP_STROBE_WAIT_TWELVE,
  PMP_STROBE_WAIT_ELEVEN,
  PMP_STROBE_WAIT_TEN,
  PMP_STROBE_WAIT_NINE,
  PMP_STROBE_WAIT_EIGHT,
  PMP_STROBE_WAIT_SEVEN,
  PMP_STROBE_WAIT_SIX,
  PMP_STROBE_WAIT_FIVE,
  PMP_STROBE_WAIT_FOUR,
  PMP_STROBE_WAIT_THREE,
  PMP_STROBE_WAIT_TWO,
  PMP_STROBE_WAIT_ONE,
  PMP_STROBE_WAIT_NONE
} PMP_STROBE_WAIT_STATES;
```

Members

Members	Description
PMP_STROBE_WAIT_FIFTEEN	Strobe Wait of 15 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_FOURTEEN	Strobe Wait of 14 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_THIRTEEN	Strobe Wait of 13 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_TWELVE	Strobe Wait of 12 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_ELEVEN	Strobe Wait of 11 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_TEN	Strobe Wait of 10 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_NINE	Strobe Wait of 9 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_EIGHT	Strobe Wait of 8 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_SEVEN	Strobe Wait of 7 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_SIX	Strobe Wait of 6 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_FIVE	Strobe Wait of 5 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_FOUR	Strobe Wait of 4 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_THREE	Strobe Wait of 3 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_TWO	Strobe Wait of 2 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_ONE	Strobe Wait of 1 Peripheral Bus Clock Cycles
PMP_STROBE_WAIT_NONE	No wait states

Description

PMP Read to Byte enable strobe configuration

This data type defines the different configurations by which the PMP strobe wait signal time can be configured.

Remarks

This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

Functions

	Name	Description
	PLIB_PMP_AddressGet	Gets the current address of the PMP module.
	PLIB_PMP_AddressIncrementModeGet	Gets the increment mode being used with the address of the PMP module.
	PLIB_PMP_AddressIncrementModeSelect	Configures the increment mode being used with the address of the PMP module.
	PLIB_PMP_AddressLatchPolaritySelect	Sets the address latch strobe polarity.
	PLIB_PMP_AddressLatchStrobeDisable	Disables the specific address latch strobe.
	PLIB_PMP_AddressLatchStrobeEnable	Enables the specific address latch strobe.
	PLIB_PMP_AddressLinesA0A1Get	Gets the value of the address lines PMA0 and PMA1.
	PLIB_PMP_AddressLinesA0A1Set	Sets the address lines PMA0 and PMA1 with the value specified.
	PLIB_PMP_AddressPortDisable	Disables the port lines specified as PMP address lines.
	PLIB_PMP_AddressPortEnable	Enables the port lines specified as PMP address lines.
	PLIB_PMP_AddressSet	Sets the current address of the PMP module to the specified address.
	PLIB_PMP_ChipSelectFunctionSelect	Defines the functionality of the pins intended to be used as Chip Select.
	PLIB_PMP_ChipSelectXDisable	Configures the Chip Select.
	PLIB_PMP_ChipSelectXEnable	Configures the Chip Select.
	PLIB_PMP_ChipSelectXIsActive	Gets the current status of the specified Chip Select.
	PLIB_PMP_ChipSelectXPolaritySelect	Sets the specified Chip Select polarity.
	PLIB_PMP_DataSizeSelect	Enables data transfer size for the PMP module.
	PLIB_PMP_Disable	Disables the specific PMP module.
	PLIB_PMP_DualBufferDisable	Disables the specific PMP module.
	PLIB_PMP_DualBufferEnable	Enables PMP dual Read/Write buffer.
	PLIB_PMP_DualBufferIsEnabled	Checks whether or not the PMP module is enabled.
	PLIB_PMP_DualModeMasterReceive	Receives the data in the Master Dual mode.
	PLIB_PMP_DualModeMasterSend	Sends the specified data in Dual Master mode.
	PLIB_PMP_DualModeReadAddressGet	Gets the current read address of the PMP module.
	PLIB_PMP_DualModeReadAddressSet	Sets the address to be written in Dual mode.
	PLIB_PMP_DualModeWriteAddressGet	Gets the current write address of the PMP module.
	PLIB_PMP_DualModeWriteAddressSet	Sets the address to be written in Dual mode.
	PLIB_PMP_Enable	Enables the specific PMP module.
	PLIB_PMP_ExistsAddressControl	Identifies whether the AddressControl feature exists on the PMP module.
	PLIB_PMP_ExistsAddressLatchPolarity	Identifies whether the AddressLatchPolarity feature exists on the PMP module.
	PLIB_PMP_ExistsAddressLatchStrobePortControl	Identifies whether the AddressLatchStrobePortControl feature exists on the PMP module.
	PLIB_PMP_ExistsAddressPortPinControl	Identifies whether the AddressPortPinControl feature exists on the PMP module.
	PLIB_PMP_ExistsBufferOverFlow	Identifies whether the BufferOverFlow feature exists on the PMP module.
	PLIB_PMP_ExistsBufferRead	Identifies whether the BufferRead feature exists on the PMP module.
	PLIB_PMP_ExistsBufferType	Identifies whether the BufferType feature exists on the PMP module.
	PLIB_PMP_ExistsBufferUnderFlow	Identifies whether the BufferUnderFlow feature exists on the PMP module.
	PLIB_PMP_ExistsBufferWrite	Identifies whether the BufferWrite feature exists on the PMP module.
	PLIB_PMP_ExistsBusyStatus	Identifies whether the BusyStatus feature exists on the PMP module.
	PLIB_PMP_ExistsChipSelectEnable	Identifies whether the ChipSelectEnable feature exists on the PMP module.
	PLIB_PMP_ExistsChipSelectoperation	Identifies whether the ChipSelectoperation feature exists on the PMP module.
	PLIB_PMP_ExistsChipXPolarity	Identifies whether the ChipXPolarity feature exists on the PMP module.
	PLIB_PMP_ExistsCSXActiveStatus	Identifies whether the CSXActiveStatus feature exists on the PMP module.
	PLIB_PMP_ExistsDataHoldWaitStates	Identifies whether the DataHoldWaitStates feature exists on the PMP module.
	PLIB_PMP_ExistsDataSetUpWaitStates	Identifies whether the DataSetUpWaitStates feature exists on the PMP module.

	PLIB_PMP_ExistsDataStrobeWaitStates	Identifies whether the DataStrobeWaitStates feature exists on the PMP module.
	PLIB_PMP_ExistsDataTransferSize	Identifies whether the DataTransferSize feature exists on the PMP module.
	PLIB_PMP_ExistsDualBufferControl	Identifies whether the DualBufferControl feature exists on the PMP module.
	PLIB_PMP_ExistsDualModeMasterRXTX	Identifies whether the DualModeMasterRXTX feature exists on the PMP module.
	PLIB_PMP_ExistsDualModeReadAddressControl	Identifies whether the DualModeReadAddressControl feature exists on the PMP module.
	PLIB_PMP_ExistsDualModeWriteAddressControl	Identifies whether the DualModeWriteAddressControl feature exists on the PMP module.
	PLIB_PMP_ExistsEnableControl	Identifies whether the EnableControl feature exists on the PMP module.
	PLIB_PMP_ExistsIncrementMode	Identifies whether the IncrementMode feature exists on the PMP module.
	PLIB_PMP_ExistsInputBufferFull	Identifies whether the InputBufferFull feature exists on the PMP module.
	PLIB_PMP_ExistsInputBufferXStatus	Identifies whether the InputBufferXStatus feature exists on the PMP module.
	PLIB_PMP_ExistsInterruptMode	Identifies whether the InterruptMode feature exists on the PMP module.
	PLIB_PMP_ExistsMasterRXTX	Identifies whether the MasterRXTX feature exists on the PMP module.
	PLIB_PMP_ExistsMUXModeSelect	Identifies whether the MUXModeSelect feature exists on the PMP module.
	PLIB_PMP_ExistsOperationMode	Identifies whether the OperationMode feature exists on the PMP module.
	PLIB_PMP_ExistsOutPutBufferEmpty	Identifies whether the OutPutBufferEmpty feature exists on the PMP module.
	PLIB_PMP_ExistsOutputBufferXStatus	Identifies whether the OutputBufferXStatus feature exists on the PMP module.
	PLIB_PMP_ExistsReadChipSelectEnable	Identifies whether the ReadChipSelectEnable feature exists on the PMP module.
	PLIB_PMP_ExistsReadWritePolarity	Identifies whether the ReadWritePolarity feature exists on the PMP module.
	PLIB_PMP_ExistsReadWriteStrobePortControl	Identifies whether the ReadWriteStrobePortControl feature exists on the PMP module.
	PLIB_PMP_ExistsSlaveRX	Identifies whether the SlaveRX feature exists on the PMP module.
	PLIB_PMP_ExistsSlaveTX	Identifies whether the SlaveTX feature exists on the PMP module.
	PLIB_PMP_ExistsStartReadControl	Identifies whether the StartReadControl feature exists on the PMP module.
	PLIB_PMP_ExistsStopInIdleControl	Identifies whether the StopInIdleControl feature exists on the PMP module.
	PLIB_PMP_ExistsWriteChipSelectEnable	Identifies whether the WriteChipSelectEnable feature exists on the PMP module.
	PLIB_PMP_ExistsWriteEnablePolarity	Identifies whether the WriteEnablePolarity feature exists on the PMP module.
	PLIB_PMP_ExistsWriteEnablePortControl	Identifies whether the WriteEnablePortControl feature exists on the PMP module.
	PLIB_PMP_InputBuffersAreFull	Gets the state of the input buffers.
	PLIB_PMP_InputBufferTypeSelect	Selects the input buffer based on the input passed.
	PLIB_PMP_InputBufferXByteReceive	Data to be received in Byte mode.
	PLIB_PMP_InputBufferXIsFull	Gets the state of the identified input buffer.
	PLIB_PMP_InputOverflowClear	Clears a PMP Overflow error.
	PLIB_PMP_InputOverflowHasOccurred	Identifies if there was a receiver overflow error.
	PLIB_PMP_InterruptModeGet	Gets the current configured interrupt mode being used with the PMP module.
	PLIB_PMP_InterruptModeSelect	Configures the interrupt request mode being used with the PMP module.
	PLIB_PMP_IsDataReceived	Checks and returns if the data has been received in the specified buffer in Slave mode.
	PLIB_PMP_IsDataTransmitted	Checks and returns if the data has been transmitted from the specified buffer in Slave mode.
	PLIB_PMP_IsEnabled	Checks whether or not the PMP module is enabled.
	PLIB_PMP_MasterReceive	Receives the data in Master mode.
	PLIB_PMP_MasterSend	Sends the specified data in Master mode.
	PLIB_PMP_MultiplexModeGet	Gets the current multiplexing mode configured between the address and data of the PMP module.
	PLIB_PMP_MultiplexModeSelect	Configures the multiplexing between the address and data of the PMP module.
	PLIB_PMP_OperationModeGet	Gets the current operation mode of the PMP module.
	PLIB_PMP_OperationModeSelect	Configures the operation mode of the PMP module.
	PLIB_PMP_OutputBuffersAreEmpty	Gets the state of the output buffers.
	PLIB_PMP_OutputBufferXByteSend	Data to be transmitted in Byte mode.
	PLIB_PMP_OutputBufferXIsEmpty	Gets the state of the input buffer.
	PLIB_PMP_OutputUnderflowClear	Clears a PMP output underflow error.

	PLIB_PMP_OutputUnderflowHasOccurred	Identifies if there was an output buffer sent out with no data.
	PLIB_PMP_PortIsBusy	Identifies if the (Master mode) PMP port is busy.
	PLIB_PMP_ReadChipSelectXDisable	Configures the Read Chip Select.
	PLIB_PMP_ReadChipSelectXEnable	Configures the Read Chip Select.
	PLIB_PMP_ReadCycleIsStarted	Checks whether or not the read cycle on PMP bus is enabled.
	PLIB_PMP_ReadCycleStart	Starts a read cycle on the PMP bus.
	PLIB_PMP_ReadWriteStrobePolaritySelect	Sets the polarity of the read strobe.
	PLIB_PMP_ReadWriteStrobePortDisable	Disables the PMP module read strobe port.
	PLIB_PMP_ReadWriteStrobePortEnable	Enables the PMP module read strobe port.
	PLIB_PMP_SlaveReceive	Receives the data in Slave mode.
	PLIB_PMP_SlaveSend	Sends the specified data in Slave mode.
	PLIB_PMP_StopInIdleDisable	Enables the PMP module to continue operation in Idle mode.
	PLIB_PMP_StopInIdleEnable	Discontinues PMP module operation when the device enters Idle mode.
	PLIB_PMP_WaitStatesDataHoldSelect	Configures the data hold states (after data transfer) needed to be used with the PMP module.
	PLIB_PMP_WaitStatesDataSetUpSelect	Configures the data wait states (before the data transfer) needed to be used with the PMP module.
	PLIB_PMP_WaitStatesStrobeSelect	Configures the strobe wait states (during the data transfer) needed to be used with the PMP module.
	PLIB_PMP_WriteChipSelectXDisable	Configures the Write Chip Select.
	PLIB_PMP_WriteChipSelectXEnable	Configures the Write Chip Select.
	PLIB_PMP_WriteEnableStrobePolaritySelect	Sets the polarity of the write enable strobe.
	PLIB_PMP_WriteEnableStrobePortDisable	Disables the PMP module write strobe port.
	PLIB_PMP_WriteEnableStrobePortEnable	Enables the PMP module write strobe port.

Description

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the PMP Peripheral Library.

Enumerations

	Name	Description
	PMP_ACK_MODE	Defines the different mode configurations in which the PMP can be enabled.
	PMP_ADDRESS_HOLD_LATCH_WAIT_STATES	PMP hold after address latch strobe wait states configuration.
	PMP_ADDRESS_LATCH	Address Latch Strobe configuration.
	PMP_ADDRESS_LATCH_WAIT_STATES	PMP address latch strobe wait states configuration.
	PMP_ADDRESS_PORT	Defines the different address lines that are available for configuration.
	PMP_ALTERNATE_MASTER_WAIT_STATES	PMP alternate master wait states.
	PMP_CHIP_SELECT	PMP Chip Select data type.
	PMP_CHIPSELECT_FUNCTION	Defines different functions available for the Chip Select lines multiplexed with address lines.
	PMP_DATA_HOLD_STATES	PMP Data Hold after strobe wait state.
	PMP_DATA_LENGTH	Possible data lengths handled by the PMP module.
	PMP_DATA_SIZE	PMP data size.
	PMP_DATA_WAIT_STATES	PMP data setup time configuration.
	PMP_INCREMENT_MODE	PMP address incrementing configuration.
	PMP_INPUT_BUFFER_TYPE	PMP Input Buffers type.
	PMP_INTERRUPT_MODE	PMP interrupt request mode data type.

	PMP_MASTER_MODE	Defines the different mode configurations in which the PMP can be enabled.
	PMP_MODULE_ID	Possible instances of the PMP module.
	PMP_MUX_MODE	Defines the different mode configurations in which the PMP can be enabled.
	PMP_OPERATION_MODE	Defines the different mode configurations in which the PMP can be enabled.
	PMP_PMBE_PORT	Defines the available Byte Enable ports.
	PMP_POLARITY_LEVEL	Possible polarity levels for the PMP pins.
	PMP_STROBE_WAIT_STATES	PMP strobe signal wait time configuration.

Description

PMP/EPMP Peripheral Library Help Header

This header file contains the data types and constants that make up the interface to the PMP Peripheral Library.

Prefetch Cache Peripheral Library

This section describes the Prefetch Cache Peripheral Library.

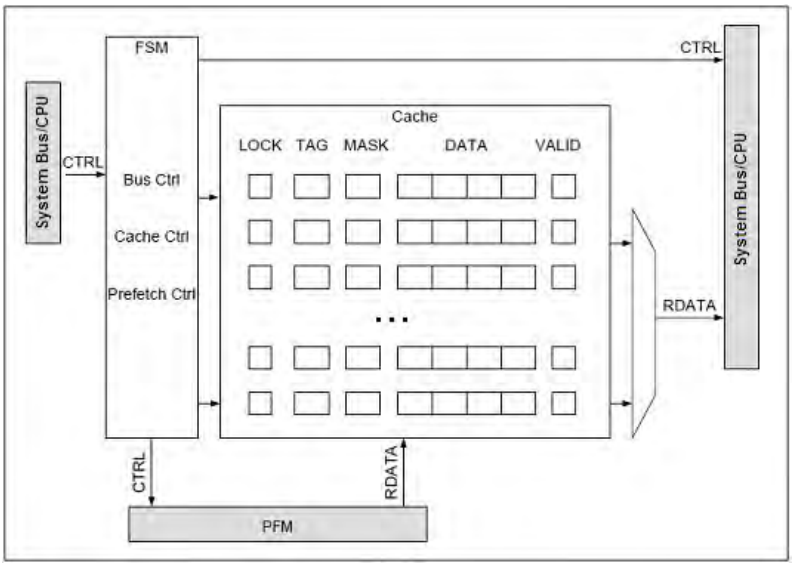
Introduction

This library provides a low-level abstraction of the Prefetch Cache module on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

The Prefetch Cache module increases system performance for most applications by:

- Predictive prefetching of instructions ahead of the current program counter, hiding the access time of the Flash memory
- Instruction and data caching



The program Flash memory (PFM) contains a Prefetch module and a number of cache lines, each containing four words. Some of the cache lines may be allocated to data or peripherals. Each cache line has an associated tag. The tag contains the address of the data in the cache line, and a number of status bits. The number of cache lines and number and type of status bits may vary between devices. Refer to your specific device data sheet for details.

Using the Library

This topic describes the basic architecture of the Prefetch Cache Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_pcache.h`

The interface to the Prefetch Cache Peripheral Library is defined in the `plib_pcache.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Prefetch Cache Peripheral Library must include `peripheral.h`.

Library File:

The Prefetch Cache Peripheral Library is part of the processor-specific peripheral library archive (`.a`) file installed with the compiler. Libraries in this archive are automatically available to the linker (in the default search path) for any project built using the Microchip compiler.

Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

Hardware Abstraction Model

This library provides a low-level abstraction of the Prefetch Cache module on Microchip family microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

Hardware Abstraction Model

The Prefetch Cache module is a performance enhancing module included in some microcontrollers. When running at high clock rates, wait states must be inserted into program Flash memory (PFM) read transactions to meet the access time of the PFM. Wait states can be hidden to the core

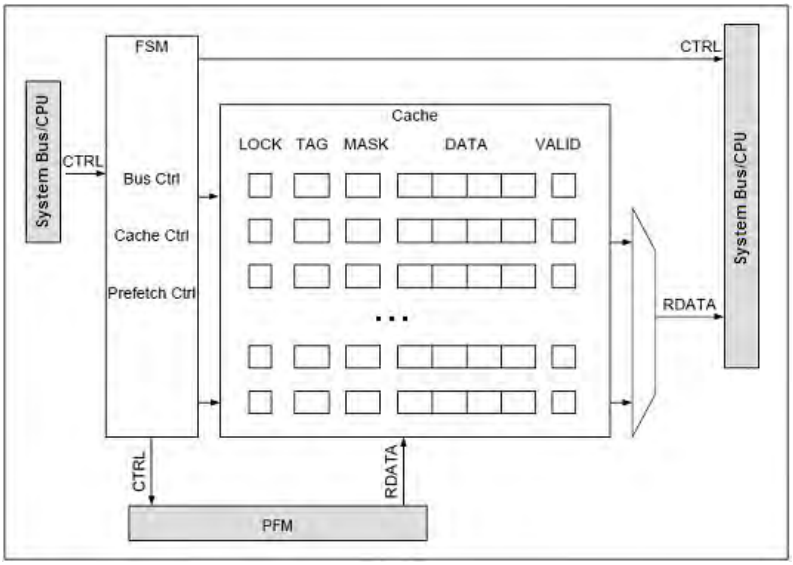
by prefetching and storing instructions in a temporary holding area that the CPU can access quickly.

There are two main functions that the Prefetch Cache module performs: Caching instructions when they are accessed, and prefetching instructions from the PFM before they are needed.

The cache holds a subset of the cacheable memory in temporary holding spaces known as cache lines. Each cache line has a tag describing what it is currently holding, and the address where it is mapped. Normally, the cache lines just hold a copy of what is currently in memory to make data available to the CPU without wait states.

CPU-requested data may or may not be in the cache. A cache-miss occurs if the CPU requests cacheable data that is not in the cache. In this case, a read is performed to the PFM at the correct address, the data is supplied to the cache and to the CPU. A cache-hit occurs if the cache contains the data that the CPU requests. In the case of a cache-hit, data is supplied to the CPU without wait states.

The second main function of the Prefetch Cache module is to prefetch CPU instructions. The module calculates the address of the next cache line and performs a read of the PFM to get the next cache line. This line is placed into a prefetch cache buffer in anticipation of executing straight-line code.



Cache Control

This library provides a set of functions to control the behavior of the overall Cache Module. Those functions include:

- Setting or reading the number of clock wait cycles
- Setting or reading the number of cache lines allocated to data
- Controlling which cache lines are invalidated on a PFM write cycle

Cache Line Operations

This library provides a set of functions to read, write and control the behavior of individual Cache Lines. Operations on individual Cache Lines are performed using a two-step process:

1. Select the individual cache line with PLIB_PCACHE_CacheLineSelect.
2. Perform the required cache line operation using any of the routines in the Cache Line Operations section. The operations available are:
   - Set the cache line to data or instruction type
   - Mark the cache line as valid or invalid
   - Lock or unlock the cache line
   - Read or write the Flash type (boot or program) associated with the cache line
   - Read or write the address associated with the cache line
   - Read or write the mask field to force a match between the cache line and multiple physical addresses
   - Read or write any individual word in the cache line data array

Once the operation is performed, the cache line remains selected until PLIB_PCACHE_CacheLineDeselect is performed. Only one cache line can be selected at a time.

Cache Status

The cache maintains a count of hits and misses for profiling purposes. The cache hit counter increments each time the processor issues an instruction fetch or load that hits the prefetch cache from a cacheable region. Similarly, the cache miss counter increments each time the processor issues an instruction fetch or load that misses the prefetch cache from a cacheable region. Accesses to non-cacheable regions do not affect the counters. These values can be read or written using the Cache Status routines.

The cache uses a Least Recently Used (LRU) algorithm to replace cache lines on a miss. The specific algorithm may vary between devices. In some devices, the state of the LRU algorithm encoding bits can be read with PLIB_PCACHE_LeastRecentlyUsedStateRead.

Prefetch Control

Predictive prefetch is controlled by the Prefetch Control routines. Devices with no L1 CPU cache can prefetch from cacheable or non-cacheable regions or both. Devices with L1 CPU cache can prefetch from any address, CPU instructions or CPU instructions and data. Predictive prefetch

can be disabled for either type of device.

Prefetch Status

The Prefetch Cache module maintains a count of prefetch aborts for profiling purposes. The prefetch abort counter is incremented each time a prefetch is aborted due to a non-sequential instruction fetch, load or store. This value can be read or written using the Prefetch Status routines.

Flash ECC

On some devices, the Flash ECC module has the ability to detect single and double bit errors on PFM reads. When a single bit error is detected, the error is corrected and the Single Error Correction (SEC) counter is decremented. When the SEC counter reaches zero, an interrupt is generated to the CPU. The user has the ability to enable or disable the SEC interrupt. It is disabled by default. The user may set the SEC counter value at any time. The maximum counter value may be device-specific and is defined for each processor by the PLIB_PCACHE_MAX_SEC_COUNT constant.

When a double bit error is detected, the device will set the DED status to true and generate a bus exception to the initiator.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Prefetch Cache module.

Library Interface Section	Description
Cache Control Functions	Provides Cache Control interface routines.
Cache Line Functions	Provides Cache Line interface routines.
Cache Status Functions	Provides Cache Status interface routines.
Prefetch Control Functions	Provides Prefetch Control interface routines.
Prefetch Status Functions	Provides Prefetch Status interface routines.
Flash ECC Functions	Provides Flash ECC interface routines.
Feature Existence Functions	Provides interface routines that determine whether or not certain features are available.

How the Library Works

Provides information on how the library works.

Description

This library can be used to optimize the performance of the processor while executing out of cacheable program Flash memory. This is done by implementing the following:

- Instruction caching
- Data caching
- Cache line control
- Predictive prefetching
- ECC detection

Arrays

The cache consists of two arrays: tag and data. The data array contains a number of lines of program instructions or data words. The word size is the same as the processor data width.

The tag array contains a number of corresponding fields, each containing:

- Mask – address mask value
- Tag – tag address to match against
- Valid – indicates whether the data in the cache line is valid or not
- Lock – indicates the line is locked to hold its contents
- Type – instruction, data or peripheral

Note: Not all Tag fields are available on all devices. The number of cache lines may vary between devices. Refer to the specific device data sheet for details.

Example Cache Line

Operations

This library allows the programmer to perform various operations on the cache tag and data arrays:

- Enable/Disable
- Set the Wait state
- Read, write, lock, invalidate

Note: Not all operations are available on all devices. Refer to the specific device data sheet for details.

Cache Control Operations

Cache Wait States

When operating at high clock rates, the Prefetch Cache module must insert wait states into Program Flash Memory (PFM) read operations to meet PFM access time requirements. One Wait state is equivalent to one clock cycle delay. At reset, the Prefetch Cache Module is set to the maximum number of wait states for the device. The PFM read time can be optimized for the device by selecting the minimum number of wait states for the clock rate used. The number of wait states for a given clock frequency may vary between devices.

Note: Refer to the specific device data sheet for details on how to calculate the optimum number of wait states for your device.

Example: Setting the Number of PFM wait states based on the System Clock

This example assumes one wait state for every 20 MHz of system clock.

```
if (sysclk < 20000000)
{
 PLIB_PCACHE_WaitStateSet(0);
}
else if (sysclk < 40000000)
{
 PLIB_PCACHE_WaitStateSet(1);
}
...
```

Data Caching

Some Prefetch Cache modules allow the user to allocate cache lines to data. This is to provide improved CPU access to constant data stored in PFM. By default, data caching is disabled. The Prefetch Cache Peripheral Library allows the user to set the number of cache lines allocated to data. The number of lines available may vary among devices. The available settings are provided by the device-dependent PLIB_PCACHE_DATA_ENABLE enumeration.

Example: Allocating two Cache Lines to Data

```
PLIB_PCACHE_DataCacheEnableSet(PLIB_PCACHE_DATA_2LINE);
```

Cache Line Invalidating on PFM Write

It is not possible to execute out of cache while programming the PFM. The PFM controller stalls the cache during the programming sequence. Therefore, user code that initiates a programming sequence should not be located in a cacheable address region.

During program operation, the Prefetch Cache is flushed by invalidating some or all of the cache lines. To invalidate all of the cache lines on a PFM write operation, the function PLIB_PCACHE_InvalidateOnPFMProgramAll should be called prior to the PFM write. This will invalidate and unlock every cache line during the write operation. The cache tags and masks are also cleared for all lines.

If PLIB_PCACHE_InvalidateOnPFMProgramUnlocked is called before the PFM write, only lines that are not locked will be forced invalid.

By default, only unlocked cache lines are invalidated during a PFM write.

Cache Line Operations

Performing a cache line operation is a two-step process. Before calling a Cache Line operation function, the cache line must be selected and write-enabled. Once selected and write-enabled, any number of cache line operations may be performed on the selected line until the line is cleared or a different line is selected and write-enabled.

Cache lines are selected and write-enabled using PLIB_PCACHE_CacheLineSelect. Cache lines are write-disabled using PLIB_PCACHE_CacheLineDeselect.

The following example shows operations on two different cache lines. The code comments describe each operation.

Example: Cache Line Operations

```
uint32_t cacheLine[4] = {0x01234567, 0x12345678, 0x23456789, 0x34567890};

//Select Cache Line 4
PLIB_PCACHE_CacheLineSelect(4);

//Invalidate Cache Line 4
```

```
PLIB_PCACHE_CacheLineInvalid();

//Select Cache Line 6
PLIB_PCACHE_CacheLineSelect(6);

//Set Cache Line 6 to Data Type
PLIB_PCACHE_CacheLineData();

//Write Data to Cache Line 6
for (i=0; i<PLIB_PCACHE_NUM_WORDS_PER_LINE; i++)
{
    PLIB_PCACHE_WordWrite(i, cacheLine[i]);
}

//Lock Cache Line 6
PLIB_PCACHE_CacheLineLock();

//Disable Writes to Cache Line 6
PLIB_PCACHE_CacheLineDeselect();
```

Cache Status Operations

Cache Statistics Counters

It is often useful to gather statistics related to cache utilization for performance or profiling reasons. Some devices with a Prefetch Cache module maintain cache hit and miss counters for this purpose. This library provides routines to read and write the cache hit and miss counters.

The cache hit counter increments each time the processor issues an instruction fetch or load that hits the prefetch cache from a cacheable region. Non-cacheable accesses do not modify this value. This value can be read with PLIB_PCACHE_CacheHitRead.

Similarly, the cache miss counter increments each time the processor issues an instruction fetch or load that misses the prefetch cache from a cacheable region. This value can be read with PLIB_PCACHE_CacheMissRead.

Cache Replacement State

The Prefetch Cache module uses a pseudo-Least Recently Used (LRU) algorithm to replace cache lines. The specific algorithm may vary among devices.

Note: Refer to the specific device data sheet for details on a specific device.

Some devices maintain the state of the LRU algorithm for use by software. The state of the LRU algorithm can be read with PLIB_PCACHE_LeastRecentlyUsedStateRead.

Prefetch Control Operations

The Prefetch Cache module is configured differently for different CPU configurations. For devices with a CPU L1 cache, the Prefetch Cache module holds one line of CPU instructions, one line of CPU data, and two lines of peripheral data. For devices without a CPU L1 cache, the Prefetch Cache module holds up to 16 lines of instructions and up to four lines of data. Control of either configuration is done using the PLIB_PCACHE_PrefetchEnableSet function.

Note: Refer to the specific device data sheet for the Prefetch Cache module configuration for a specific device.

For the CPU L1 configuration, the Prefetch Cache module can be configured to enable any address, CPU instructions and data, or CPU instructions only. For devices without a CPU L1 cache, predictive prefetch can be enabled for cacheable regions, uncacheable regions, or both. In either configuration, predictive prefetch may be disabled entirely.

The PLIB_PCACHE_PrefetchEnableSet and PLIB_PCACHE_PrefetchEnableGet functions take or return the enumerated value PLIB_PCACHE_PREFETCH_ENABLE. This enumeration will be defined differently for different CPU configurations.

Example: Enable Prefetch for Non-Cacheable Regions Only (no L1 configuration)

```
PLIB_PCACHE_PrefetchEnableSet(PLIB_PCACHE_PREFETCH_ENABLE_NONCACHED_REGIONS);
```

Example: Enable Prefetch for CPU Instructions and CPU Data (L1 configuration)

```
PLIB_PCACHE_PrefetchEnableSet(PLIB_PCACHE_PREFETCH_ENABLE_CPU_INST_DATA);
```

Prefetch Status Operations

Prefetch Abort Statistics Counter

Much like the cache hit/miss counters, the Prefetch Abort module maintains a prefetch abort counter. This counter is incremented each time an automatic prefetch is aborted due to a non-sequential instruction fetch, load or store. This value can be read using the PLIB_PCACHE_PrefetchAbortRead function.

Flash ECC Operations

The Prefetch Cache module may handle and report information about two error types: ECC Double-bit Error Detected (DED) and ECC Single-bit Error Corrected (SEC).

A read from the Flash memory that results in a program Flash memory ECC DED causes the Prefetch Cache module to return a bus exception to the initiator. An ECC DED will also set the DED status bit. The state of the DED status bit may be read using the PLIB_PCACHE_FlashDEDStatusGet function.

A single-bit error read from the Flash memory is not a critical error, and as such is reported as an interrupt. The user has the option to enable or disable the SEC interrupt, and to set the number of SEC events that must occur before an SEC interrupt is generated. An SEC interrupt is generated when all of the following conditions are met:

- The Flash SEC counter is zero
- The Flash SEC interrupt is enabled
- An SEC event occurs

The Flash SEC counter is decremented once each time an SEC event occurs, and holds at zero. When a Flash SEC interrupt is triggered, the Flash SEC status bit is set. Once an SEC interrupt occurs, the Flash SEC status must be cleared by software and the Flash SEC counter must be reloaded by software.

Example: Set Flash SEC to Interrupt after three SEC events

```
PLIB_PCACHE_FlashSECStatusClear();
PLIB_PCACHE_FlashSECCountSet(3);
PLIB_PCACHE_FlashSECIntEnable();
```

It is possible to generate an SEC interrupt for testing purposes by enabling the Flash SEC interrupt and setting the Flash SEC status while the Flash SEC counter is zero.

Example: Generate an SEC Interrupt

```
PLIB_PCACHE_FlashSECStatusClear();
PLIB_PCACHE_FlashSECCountSet(0);
PLIB_PCACHE_FlashSECIntEnable();
PLIB_PCACHE_FlashSECStatusSet();
```

Configuring the Library

The library is configured for the supported Prefetch Cache module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) Cache Control Functions

	Name	Description
	PLIB_PCACHE_DataCacheEnableGet	Gets the data cache enable bits.
	PLIB_PCACHE_DataCacheEnableSet	Sets the data cache enable bits.
	PLIB_PCACHE_InvalidateOnPFMProgramAll	Sets Prefetch Cache to invalidate all data and instruction lines on a PFM program cycle.
	PLIB_PCACHE_InvalidateOnPFMProgramUnlocked	Sets Prefetch Cache to invalidate all unlocked data and instruction lines on a PFM program cycle.
	PLIB_PCACHE_WaitStateGet	Gets the Prefetch Cache access time.
	PLIB_PCACHE_WaitStateSet	Sets the Prefetch Cache access time.

b) Cache Line Functions

	Name	Description
	PLIB_PCACHE_CacheLineAddrGet	Gets the TAG address in the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineAddrSet	Sets the TAG address in the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineData	Sets cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect to data type.
	PLIB_PCACHE_CacheLineDeselect	Disables write access to the cache line specified by cache_line.
	PLIB_PCACHE_CacheLineFlashTypeBoot	Set the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect as residing in Boot Flash.
	PLIB_PCACHE_CacheLineFlashTypeInst	Set the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect as residing in Instruction Flash.

	PLIB_PCACHE_CacheLineFlashTypeIsInst	Returns true if the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect shows the line is residing in Instruction Flash.
	PLIB_PCACHE_CacheLineInst	Sets cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect to instruction type.
	PLIB_PCACHE_CacheLineInvalid	Invalidates cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineIsInst	Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is set to instruction type.
	PLIB_PCACHE_CacheLineIsLocked	Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is locked.
	PLIB_PCACHE_CacheLineIsValid	Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is valid.
	PLIB_PCACHE_CacheLineLock	Locks cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineMaskGet	Returns the current state of the cache tag mask for the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineMaskSet	Sets the cache tag mask to force a match on set bits on the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineSelect	Enables write access to the cache line specified by cache_line.
	PLIB_PCACHE_CacheLineUnlock	Unlocks cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineValid	Validates cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_WordRead	Reads the word specified by word from cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_WordWrite	Writes the word (specified by word parameter) with data (specified by data parameter) to cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

c) Cache Status Functions

	Name	Description
	PLIB_PCACHE_CacheHitRead	Reads the number of cache hits.
	PLIB_PCACHE_CacheHitWrite	Sets the number of cache hits.
	PLIB_PCACHE_CacheMissRead	Reads the number of cache misses.
	PLIB_PCACHE_CacheMissWrite	Sets the number of cache misses.
	PLIB_PCACHE_LeastRecentlyUsedStateRead	Reads the state of the cache Least Recently Used (LRU) encoding bits.

d) Prefetch Control Functions

	Name	Description
	PLIB_PCACHE_PrefetchEnableGet	Gets the predictive Prefetch state for the Prefetch Cache module.
	PLIB_PCACHE_PrefetchEnableSet	Sets the predictive Prefetch state for the Prefetch Cache module.

e) Prefetch Status Functions

	Name	Description
	PLIB_PCACHE_PrefetchAbortRead	Reads the number of prefetch aborts.
	PLIB_PCACHE_PrefetchAbortWrite	Sets the number of prefetch aborts.

f) Flash ECC Functions

	Name	Description
	PLIB_PCACHE_FlashDEDStatusClear	Clears a bus exception caused by a double-bit error.
	PLIB_PCACHE_FlashDEDStatusGet	Determines if a bus exception was caused by a double-bit error.
	PLIB_PCACHE_FlashSECCountGet	Returns the current value of the Flash SEC counter.
	PLIB_PCACHE_FlashSECCountSet	Sets the number of single-bit error corrections that must occur before the SEC status is set to true.
	PLIB_PCACHE_FlashSECIntDisable	Disables an interrupt on SEC.
	PLIB_PCACHE_FlashSECIntEnable	Enables an interrupt on SEC.
	PLIB_PCACHE_FlashSECStatusClear	Sets the single-bit error corrected status to false.
	PLIB_PCACHE_FlashSECStatusGet	Determines if a SEC event triggered a Prefetch Cache interrupt.
	PLIB_PCACHE_FlashSECStatusSet	Sets the single-bit error corrected status to true.

g) Feature Existence Functions

	Name	Description
	PLIB_PCACHE_ExistsCacheHit	Identifies that the CacheHit feature exists on the Prefetch Cache module.

	PLIB_PCACHE_ExistsCacheLine	Identifies that the CacheLineSelect feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineAddr	Identifies that the CacheLineAddr feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineFlashType	Identifies that the CacheLineFlashType feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineLock	Identifies that the CacheLineLock feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineMask	Identifies that the CacheLineMask feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineType	Identifies that the CacheLineType feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineValid	Identifies that the CacheLineValid feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheMiss	Identifies that the CacheMiss feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsDataCacheEnable	Identifies that the DataCacheEnable feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsFlashDEDStatus	Identifies that the FlashDEDStatus feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsFlashSECCount	Identifies that the FlashSECCount feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsFlashSECInt	Identifies that the FlashSECInt feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsFlashSECStatus	Identifies that the FlashSECStatus feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsInvalidateOnPFMProgram	Identifies that the InvalidateOnPFMProgram feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsLeastRecentlyUsedState	Identifies that the LeastRecentlyUsedState feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsPrefetchAbort	Identifies that the PrefetchAbort feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsPrefetchEnable	Identifies that the PrefetchEnable feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsWaitState	Identifies that the WaitState feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsWord	Identifies that the Word feature exists on the Prefetch Cache module.

h) Data Types and Constants

	Name	Description
	PLIB_PCACHE_MAX_SEC_COUNT	Defines the maximum value for single bit error counter.
	PLIB_PCACHE_NUM_LINES	Defines the number of available Prefetch Cache Lines.
	PLIB_PCACHE_NUM_WORDS_PER_LINE	Defines the number of Words per Prefetch Cache Line.
	PCACHE_MODULE_ID	Lists the possible Module IDs for the Prefetch Cache.
	PLIB_PCACHE_DATA_ENABLE	Lists the possible predictive prefetch states for the Prefetch Cache.
	PLIB_PCACHE_PREFETCH_ENABLE	Lists the possible predictive prefetch states for the Prefetch Cache.

Description

This section describes the Application Programming Interface (API) functions of the Prefetch Cache Peripheral Library.

Refer to each section for a detailed description.

a) Cache Control Functions

PLIB_PCACHE_DataCacheEnableGet Function

Gets the data cache enable bits.

File

plib_pcache.h

C

```
PLIB_PCACHE_DATA_ENABLE PLIB_PCACHE_DataCacheEnableGet(PCACHE_MODULE_ID index);
```

Returns

PLIB_PCACHE_DATA_ENABLE

Description

This function gets the data cache enable bits.

Remarks

At reset, data caching is disabled, and this function will return PLIB_PCACHE_DATA_DISABLE.

This function implements an operation of the DataCacheEnable feature. This feature may not be available on all devices. Please refer to the

specific device data sheet to determine availability or use PLIB_RTCC_ExistsDataCacheEnable in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_DATA_ENABLE dcache_en;
dcache_en = PLIB_PCACHE_DataCacheEnableGet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

PLIB_PCACHE_DATA_ENABLE PLIB_PCACHE_DataCacheEnableGet(PCACHE_MODULE_ID index)

PLIB_PCACHE_DataCacheEnableSet Function

Sets the data cache enable bits.

File

plib_pcache.h

C

```
void PLIB_PCACHE_DataCacheEnableSet(PCACHE_MODULE_ID index, PLIB_PCACHE_DATA_ENABLE dcache_en);
```

Returns

None.

Description

This function sets the data cache enable bits.

Remarks

Data caching is disabled at reset.

This function implements an operation of the DataCacheEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsDataCacheEnable in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_DataCacheEnableSet(PCACHE_ID_0, PLIB_PCACHE_DATA_4LINE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
dcache_en	PLIB_PCACHE_DATA_ENABLE

Function

void PLIB_PCACHE_DataCacheEnableSet(PCACHE_MODULE_ID index,
PLIB_PCACHE_DATA_ENABLE dcache_en)

PLIB_PCACHE_InvalidateOnPFMProgramAll Function

Sets Prefetch Cache to invalidate all data and instruction lines on a PFM program cycle.

File

plib_pcache.h

C

```
void PLIB_PCACHE_InvalidateOnPFMProgramAll(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function sets the Prefetch Cache to invalidate all data and instruction lines on a PFM program cycle.

Remarks

This function implements an operation of the InvalidateOnPFMProgram feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsInvalidateOnPFMProgram in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_InvalidateOnPFMProgramAll(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_InvalidateOnPFMProgramAll(PCACHE_MODULE_ID index)

PLIB_PCACHE_InvalidateOnPFMProgramUnlocked Function

Sets Prefetch Cache to invalidate all unlocked data and instruction lines on a PFM program cycle.

File

plib_pcache.h

C

```
void PLIB_PCACHE_InvalidateOnPFMProgramUnlocked(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function sets the Prefetch Cache to invalidate all unlocked data and instruction lines on a PFM program cycle.

Remarks

This is the default state at reset.

This function implements an operation of the InvalidateOnPFMProgram feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsInvalidateOnPFMProgram in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_InvalidateOnPFMProgramUnlocked(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_InvalidateOnPFMProgramUnlocked(PCACHE_MODULE_ID index)

PLIB_PCACHE_WaitStateGet Function

Gets the Prefetch Cache access time.

File

plib_pcache.h

C

```
uint32_t PLIB_PCACHE_WaitStateGet(PCACHE_MODULE_ID index);
```

Returns

Number of clock cycles.

Description

This function gets the Prefetch Cache access time in terms of SYSCLK wait. states.

Remarks

At reset, this value is set to seven wait states.

This function implements an operation of the WaitState feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsWaitState in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t wait;
wait = PLIB_PCACHE_WaitStateGet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

uint32_t PLIB_PCACHE_WaitStateGet(PCACHE_MODULE_ID index)

PLIB_PCACHE_WaitStateSet Function

Sets the Prefetch Cache access time.

File

plib_pcache.h

C

```
void PLIB_PCACHE_WaitStateSet(PCACHE_MODULE_ID index, uint32_t clocks);
```

Returns

None.

Description

This function sets the Prefetch Cache access time in terms of SYSCLK wait. states.

Remarks

At reset, this value is set to seven wait states.

This function implements an operation of the WaitState feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsWaitState in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_WaitStateSet(PCACHE_ID_0, 0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
clocks	Identifies the wait state in terms of number of SYSCLK cycles

Function

void PLIB_PCACHE_WaitStateSet(PCACHE_MODULE_ID index, uint32_t clocks)

b) Cache Line Functions

PLIB_PCACHE_CacheLineAddrGet Function

Gets the TAG address in the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
uint32_t PLIB_PCACHE_CacheLineAddrGet(PCACHE_MODULE_ID index);
```

Returns

The address in the cache line TAG register.

Description

This function gets the TAG address in the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the CacheLineAddr feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineAddr in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t addr;
addr = PLIB_PCACHE_CacheLineAddrGet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

uint32_t PLIB_PCACHE_CacheLineAddrGet(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineAddrSet Function

Sets the TAG address in the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineAddrSet(PCACHE_MODULE_ID index, uint32_t addr);
```

Returns

None.

Description

This function Sets the TAG address in the cache line previously write- enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the CacheLineAddr feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineAddr in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t addr = 0x1FC01234;
PLIB_PCACHE_CacheLineAddrSet(PCACHE_ID_0, addr);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
addr	Address to program into the cache line TAG register

Function

void PLIB_PCACHE_CacheLineAddrSet(PCACHE_MODULE_ID index, uint32_t addr)

PLIB_PCACHE_CacheLineData Function

Sets cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect to data type.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineData(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function sets the cache line previously enabled by PLIB_PCACHE_CacheLineSelect to data type.

Remarks

This function implements an operation of the CacheLineType feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineType in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineData(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_CacheLineData(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineDeselect Function

Disables write access to the cache line specified by cache_line.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineDeselect(PCACHE_MODULE_ID index, uint32_t cache_line);
```

Returns

None.

Description

This function disables write access to the cache line specified by cache_line.

Remarks

This function implements an operation of the CacheLineSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineSelect in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineDeselect(PCACHE_ID_0, 0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
cache_line	Specifies the cache line to disable write access

Function

void PLIB_PCACHE_CacheLineDeselect(PCACHE_MODULE_ID index,
uint32_t cache_line)

PLIB_PCACHE_CacheLineFlashTypeBoot Function

Set the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect as residing in Boot Flash.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineFlashTypeBoot(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function sets the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect as residing in Boot Flash.

Remarks

This function implements an operation of the CacheLineFlashType feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineFlashType in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineFlashTypeBoot(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_CacheLineFlashTypeBoot(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineFlashTypeInst Function

Set the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect as residing in Instruction Flash.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineFlashTypeInst(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function sets the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect as residing in Instruction Flash.

Remarks

This function implements an operation of the CacheLineFlashType feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineFlashType in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineFlashTypeInst(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_CacheLineFlashTypeInst(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineFlashTypeIsInst Function

Returns true if the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect shows the line is residing in Instruction Flash.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_CacheLineFlashTypeIsInst(PCACHE_MODULE_ID index);
```

Returns

- true - The cache line resides in Instruction Flash
- false - The cache line resides in Boot Flash

Description

This function returns true if the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect shows the line is residing

in Instruction Flash.

Remarks

This function implements an operation of the CacheLineFlashType feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineFlashType in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool LineFlashType;
LineFlashType = PLIB_PCACHE_CacheLineFlashTypeIsInst(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_PCACHE_CacheLineFlashTypeIsInst(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineInst Function

Sets cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect to instruction type.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineInst(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function sets the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect to instruction type.

Remarks

This function implements an operation of the CacheLineType feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineType in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineInst(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_CacheLineInst(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineInvalid Function

Invalidates cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineInvalid(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function invalidates the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the CacheLineValid feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineValid in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineInvalid(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_CacheLineInvalid(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineIsInst Function

Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is set to instruction type.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_CacheLineIsInst(PCACHE_MODULE_ID index);
```

Returns

- true - The cache line is instruction
- false - The cache line is data

Description

This function returns true if the cache line previously enabled by PLIB_PCACHE_CacheLineSelect is set to instruction type.

Remarks

This function implements an operation of the CacheLineType feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineType in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool CacheLineType;
CacheLineType = PLIB_PCACHE_CacheLineIsInst(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

bool PLIB_PCACHE_CacheLineIsInst(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineIsLocked Function

Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is locked.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_CacheLineIsLocked(PCACHE_MODULE_ID index);
```

Returns

- true - The cache line is locked
- false - The cache line is unlocked

Description

This function returns true if the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is locked.

Remarks

This function implements an operation of the CacheLineLock feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineLock in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool CacheLineLocked;
CacheLineLocked = PLIB_PCACHE_CacheLineIsLocked(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_PCACHE_CacheLineIsLocked(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineIsValid Function

Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is valid.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_CacheLineIsValid(PCACHE_MODULE_ID index);
```

Returns

- true - The cache line is valid
- false - The cache line is invalid

Description

This function returns true if the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is valid.

Remarks

This function implements an operation of the CacheLineValid feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineValid in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool CacheLineValid;
CacheLineValid = PLIB_PCACHE_CacheLineIsValid(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_PCACHE_CacheLineIsValid(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineLock Function

Locks cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineLock(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function locks the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the CacheLineLock feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineLock in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineLock(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_CacheLineLock(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineMaskGet Function

Returns the current state of the cache tag mask for the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
uint32_t PLIB_PCACHE_CacheLineMaskGet(PCACHE_MODULE_ID index);
```

Returns

- Address mask - Bits set to '1' will force a match (valid bits: <15:5>).

Description

This function returns the current state of the cache tag mask for the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the CacheLineMask feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineMask in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t mask;
mask = PLIB_PCACHE_CacheLineMaskGet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

uint32_t PLIB_PCACHE_CacheLineMaskGet(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineMaskSet Function

Sets the cache tag mask to force a match on set bits on the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineMaskSet(PCACHE_MODULE_ID index, uint32_t mask);
```

Returns

None.

Description

This function sets the cache tag mask to force a match on set bits on the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the CacheLineMask feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineMask in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t mask = 0x0C0;
PLIB_PCACHE_CacheLineMaskSet(PCACHE_ID_0, mask);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mask	Address mask (bits set to '1' will force a match; valid bits: <15:5>)

Function

void PLIB_PCACHE_CacheLineMaskSet(PCACHE_MODULE_ID index, uint32_t mask)

PLIB_PCACHE_CacheLineSelect Function

Enables write access to the cache line specified by cache_line.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineSelect(PCACHE_MODULE_ID index, uint32_t cache_line);
```

Returns

None.

Description

This function enables write access to the cache line specified by cache_line.

Remarks

At reset, all cache lines are read-only.

This function implements an operation of the CacheLineSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineSelect in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineSelect(PCACHE_ID_0, 0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
cache_line	Specifies the cache line to enable write access

Function

void PLIB_PCACHE_CacheLineSelect(PCACHE_MODULE_ID index,

uint32_t cache_line)

PLIB_PCACHE_CacheLineUnlock Function

Unlocks cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineUnlock(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function unlocks the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the CacheLineLock feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineLock in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineUnlock(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_CacheLineUnlock(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheLineValid Function

Validates cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheLineValid(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function validates the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the CacheLineValid feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheLineValid in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheLineValid(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_CacheLineValid(PCACHE_MODULE_ID index)

PLIB_PCACHE_WordRead Function

Reads the word specified by word from cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
uint32_t PLIB_PCACHE_WordRead(PCACHE_MODULE_ID index, uint32_t word);
```

Returns

A 32-bit unsigned word from the cache data array.

Description

This function reads the word specified by word from the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the Word feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsWord in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t word;
word = PLIB_PCACHE_WordRead(PCACHE_ID_0, 0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read
word	Location of the word in the data array to be read

Function

uint32_t PLIB_PCACHE_WordRead(PCACHE_MODULE_ID index, uint32_t word)

PLIB_PCACHE_WordWrite Function

Writes the word (specified by word parameter) with data (specified by data parameter) to cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

File

plib_pcache.h

C

```
void PLIB_PCACHE_WordWrite(PCACHE_MODULE_ID index, uint32_t word, uint32_t data);
```

Returns

None.

Description

This function writes the word (specified by word parameter) with data (specified by data parameter) to the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Remarks

This function implements an operation of the Word feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsWord in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t word = 0;
uint32_t data = 0xDEADBEEF;
PLIB_PCACHE_WordWrite(PCACHE_ID_0, word, data);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be written.
word	Location of the word in the data array to be written
data	32-bit unsigned word to write to cache data array

Function

void PLIB_PCACHE_WordWrite(PCACHE_MODULE_ID index, uint32_t word,

uint32_t data)

c) Cache Status Functions

PLIB_PCACHE_CacheHitRead Function

Reads the number of cache hits.

File

plib_pcache.h

C

```
uint32_t PLIB_PCACHE_CacheHitRead(PCACHE_MODULE_ID index);
```

Returns

The number of cache hits.

Description

This function reads and returns the number of cache hits.

Remarks

This function implements an operation of the CacheHit feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheHit in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t cache_hits;
cache_hits = PLIB_PCACHE_CacheHitRead(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

uint32_t PLIB_PCACHE_CacheHitRead(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheHitWrite Function

Sets the number of cache hits.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheHitWrite(PCACHE_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

This function sets the number of cache hits.

Remarks

This function implements an operation of the CacheHit feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheHit in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheHitWrite(PCACHE_ID_0, 0xF00);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be written
data	Number of cache hits to write

Function

void PLIB_PCACHE_CacheHitWrite(PCACHE_MODULE_ID index, uint32_t data)

PLIB_PCACHE_CacheMissRead Function

Reads the number of cache misses.

File

plib_pcache.h

C

```
uint32_t PLIB_PCACHE_CacheMissRead(PCACHE_MODULE_ID index);
```

Returns

The number of cache misses.

Description

This function reads and returns the number of cache misses.

Remarks

This function implements an operation of the CacheMiss feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCacheMiss in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t cache_misses;
cache_misses = PLIB_PCACHE_CacheMissRead(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read.

Function

uint32_t PLIB_PCACHE_CacheMissRead(PCACHE_MODULE_ID index)

PLIB_PCACHE_CacheMissWrite Function

Sets the number of cache misses.

File

plib_pcache.h

C

```
void PLIB_PCACHE_CacheMissWrite(PCACHE_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

This function sets the number of cache misses.

Remarks

This function implements an operation of the CacheMiss feature. This feature may not be available on all devices. Please refer to the specific

device data sheet to determine availability or use PLIB_RTCC_ExistsCacheMiss in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_CacheMissWrite(PCACHE_ID_0, 0xF00);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be written
data	Number of cache misses to write

Function

void PLIB_PCACHE_CacheMissWrite(PCACHE_MODULE_ID index, uint32_t data)

PLIB_PCACHE_LeastRecentlyUsedStateRead Function

Reads the state of the cache Least Recently Used (LRU) encoding bits.

File

plib_pcache.h

C

```
uint32_t PLIB_PCACHE_LeastRecentlyUsedStateRead(PCACHE_MODULE_ID index);
```

Returns

The state of the LRU encoding bits represented as a 25-bit unsigned integer.

Description

This function reads the state of the cache LRU encoding bits.

Remarks

This function implements an operation of the LeastRecentlyUsedState feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsLeastRecentlyUsedState in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t lru_state;
lru_state = PLIB_PCACHE_LeastRecentlyUsedStateRead(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read.

Function

uint32_t PLIB_PCACHE_LeastRecentlyUsedStateRead(PCACHE_MODULE_ID index)

d) Prefetch Control Functions

PLIB_PCACHE_PrefetchEnableGet Function

Gets the predictive Prefetch state for the Prefetch Cache module.

File

plib_pcache.h

C

```
PLIB_PCACHE_PREFETCH_ENABLE PLIB_PCACHE_PrefetchEnableGet(PCACHE_MODULE_ID index);
```

Returns

PLIB_PCACHE_PREFETCH_ENABLE

Description

This function gets the predictive Prefetch state for the Prefetch Cache module.

Remarks

At reset, the Prefetch Cache module is disabled and this function will return PLIB_PCACHE_DISABLE.

This function implements an operation of the PrefetchEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsPrefetchEnable in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_PREFETCH_ENABLE region;
region = PLIB_PCACHE_PrefetchEnableGet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

PLIB_PCACHE_PREFETCH_ENABLE PLIB_PCACHE_PrefetchEnableGet(PCACHE_MODULE_ID index)

PLIB_PCACHE_PrefetchEnableSet Function

Sets the predictive Prefetch state for the Prefetch Cache module.

File

plib_pcache.h

C

```
void PLIB_PCACHE_PrefetchEnableSet(PCACHE_MODULE_ID index, PLIB_PCACHE_PREFETCH_ENABLE region);
```

Returns

None.

Description

This function sets the predictive Prefetch state for the Prefetch Cache module.

Remarks

At reset, the Prefetch Cache module is disabled.

This function implements an operation of the PrefetchEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsPrefetchEnable in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_PrefetchEnableSet(PCACHE_ID_0,
                              PLIB_PCACHE_PREFETCH_ENABLE_ALL);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

region	PLIB_PCACHE_PREFETCH_ENABLE

Function

void PLIB_PCACHE_PrefetchEnableSet(PCACHE_MODULE_ID index,
PLIB_PCACHE_PREFETCH_ENABLE region)

e) Prefetch Status Functions

PLIB_PCACHE_PrefetchAbortRead Function

Reads the number of prefetch aborts.

File

plib_pcache.h

C

```
uint32_t PLIB_PCACHE_PrefetchAbortRead(PCACHE_MODULE_ID index);
```

Returns

The number of prefetch aborts.

Description

This function reads and returns the number of prefetch aborts.

Remarks

This function implements an operation of the PrefetchAbort feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsPrefetchAbort in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t pfabt;
pfabt = PLIB_PCACHE_PrefetchAbortRead(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

uint32_t PLIB_PCACHE_PrefetchAbortRead(PCACHE_MODULE_ID index)

PLIB_PCACHE_PrefetchAbortWrite Function

Sets the number of prefetch aborts.

File

plib_pcache.h

C

```
void PLIB_PCACHE_PrefetchAbortWrite(PCACHE_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

This function Sets the number of prefetch aborts.

Remarks

This function implements an operation of the PrefetchAbort feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsPrefetchAbort in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_PrefetchAbortWrite(PCACHE_ID_0, 0xF00);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be written
data	Number of prefetch aborts

Function

void PLIB_PCACHE_PrefetchAbortWrite(PCACHE_MODULE_ID index, uint32_t data)

f) Flash ECC Functions

PLIB_PCACHE_FlashDEDStatusClear Function

Clears a bus exception caused by a double-bit error.

File

plib_pcache.h

C

```
void PLIB_PCACHE_FlashDEDStatusClear(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function clears a bus exception caused by a double-bit error.

Remarks

The DED status is set by hardware.

This function implements an operation of the FlashDEDStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashDEDStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_FlashDEDStatusClear(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be cleared

Function

void PLIB_PCACHE_FlashDEDStatusClear(PCACHE_MODULE_ID index)

PLIB_PCACHE_FlashDEDStatusGet Function

Determines if a bus exception was caused by a double-bit error.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_FlashDEDStatusGet(PCACHE_MODULE_ID index);
```

Returns

- true - A double-bit error was detected
- false - A double-bit error was not detected

Description

This function determines if a bus exception was caused by a double-bit error.

Remarks

The Double-bit Error Detected (DED) status is set by hardware.

This function implements an operation of the FlashDEDStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashDEDStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool dedStatus;
dedStatus = PLIB_PCACHE_FlashDEDStatusGet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

bool PLIB_PCACHE_FlashDEDStatusGet(PCACHE_MODULE_ID index)

PLIB_PCACHE_FlashSECCountGet Function

Returns the current value of the Flash SEC counter.

File

plib_pcache.h

C

```
uint8_t PLIB_PCACHE_FlashSECCountGet(PCACHE_MODULE_ID index);
```

Returns

- count - Number of SEC events to occur before the SEC status is set to true

Description

This function returns the current value of the Flash SEC counter.

Remarks

This function implements an operation of the FlashSECCount feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashSECCount in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t count;
count = PLIB_PCACHE_FlashSECCountGet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

uint8_t PLIB_PCACHE_FlashSECCountGet(PCACHE_MODULE_ID index)

PLIB_PCACHE_FlashSECCountSet Function

Sets the number of single-bit error corrections that must occur before the SEC status is set to true.

File

plib_pcache.h

C

```
void PLIB_PCACHE_FlashSECCountSet(PCACHE_MODULE_ID index, uint8_t count);
```

Returns

None.

Description

This function sets the number of single-bit error corrections that must occur before the SEC status is set to true.

Remarks

This function implements an operation of the FlashSECCount feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashSECCount in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_FlashSECCountSet(PCACHE_ID_0, 255);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
count	Number of SEC events to occur before SEC status is set to true

Function

void PLIB_PCACHE_FlashSECCountSet(PCACHE_MODULE_ID index, uint8_t count)

PLIB_PCACHE_FlashSECIntDisable Function

Disables an interrupt on SEC.

File

plib_pcache.h

C

```
void PLIB_PCACHE_FlashSECIntDisable(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function disables an interrupt on SEC.

Remarks

At reset the SEC interrupt is disabled.

This function implements an operation of the FlashSECInt feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashSECInt in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_FlashSECIntDisable(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be disabled

Function

void PLIB_PCACHE_FlashSECIntDisable(PCACHE_MODULE_ID index)

PLIB_PCACHE_FlashSECIntEnable Function

Enables an interrupt on SEC.

File

plib_pcache.h

C

```
void PLIB_PCACHE_FlashSECIntEnable(PCACHE_MODULE_ID index);
```

Returns

None

Description

This function enables an interrupt on SEC.

Remarks

At reset the SEC interrupt is disabled.

This function implements an operation of the FlashSECInt feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashSECInt in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_FlashSECIntEnable(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be enabled

Function

void PLIB_PCACHE_FlashSECIntEnable(PCACHE_MODULE_ID index)

PLIB_PCACHE_FlashSECStatusClear Function

Sets the single-bit error corrected status to false.

File

plib_pcache.h

C

```
void PLIB_PCACHE_FlashSECStatusClear(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function sets the single-bit error corrected status to false.

Remarks

The SEC status must be cleared in response to a Prefetch Cache SEC interrupt.

This function implements an operation of the FlashSECStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashSECStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_FlashSECStatusClear(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be cleared

Function

void PLIB_PCACHE_FlashSECStatusClear(PCACHE_MODULE_ID index)

PLIB_PCACHE_FlashSECStatusGet Function

Determines if a SEC event triggered a Prefetch Cache interrupt.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_FlashSECStatusGet(PCACHE_MODULE_ID index);
```

Returns

- true - A single-bit error was corrected
- false - A double-bit error was not corrected

Description

This function determines if a SEC event triggered a Prefetch Cache interrupt.

Remarks

The SEC bit is set when a single-bit error is corrected and the SEC counter is zero. If the Flash SEC interrupt is enabled, an error event is reported to the CPU by a Prefetch Cache interrupt event.

This function implements an operation of the FlashSECStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashSECStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool secStatus;
secStatus = PLIB_PCACHE_FlashSECStatusGet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be read

Function

bool PLIB_PCACHE_FlashSECStatusGet(PCACHE_MODULE_ID index)

PLIB_PCACHE_FlashSECStatusSet Function

Sets the single-bit error corrected status to true.

File

plib_pcache.h

C

```
void PLIB_PCACHE_FlashSECStatusSet(PCACHE_MODULE_ID index);
```

Returns

None.

Description

This function sets the single-bit error corrected status to true.

Remarks

This function is provided for code testing and debug purposes. Setting the SEC status while the SEC count is zero and the SEC interrupt is enabled will trigger a Prefetch Cache interrupt to the CPU.

This function implements an operation of the FlashSECStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsFlashSECStatus in your application to to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PCACHE_FlashSECStatusSet(PCACHE_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PCACHE_FlashSECStatusSet(PCACHE_MODULE_ID index)

g) Feature Existence Functions

PLIB_PCACHE_ExistsCacheHit Function

Identifies that the CacheHit feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheHit(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheHit feature is supported on the device
- false - The CacheHit feature is not supported on the device

Description

This interface identifies that the CacheHit feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheHitRead

- PLIB_PCACHE_CacheHitWrite

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheHit(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsCacheLine Function

Identifies that the CacheLineSelect feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheLine(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheLineSelect feature is supported on the device
- false - The CacheLineSelect feature is not supported on the device

Description

This interface identifies that the CacheLineSelect feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheLineSelect
- PLIB_PCACHE_CacheLineDeselect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheLine(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsCacheLineAddr Function

Identifies that the CacheLineAddr feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheLineAddr(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheLineAddr feature is supported on the device
- false - The CacheLineAddr feature is not supported on the device

Description

This interface identifies that the CacheLineAddr feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheLineAddrSet
- PLIB_PCACHE_CacheLineAddrGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheLineAddr(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsCacheLineFlashType Function

Identifies that the CacheLineFlashType feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheLineFlashType(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheLineFlashType feature is supported on the device
- false - The CacheLineFlashType feature is not supported on the device

Description

This interface identifies that the CacheLineFlashType feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheLineFlashTypeBoot
- PLIB_PCACHE_CacheLineFlashTypeInst
- PLIB_PCACHE_CacheLineFlashTypeIsInst

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheLineFlashType(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsCacheLineLock Function

Identifies that the CacheLineLock feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheLineLock(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheLineLock feature is supported on the device
- false - The CacheLineLock feature is not supported on the device

Description

This interface identifies that the CacheLineLock feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheLineLock
- PLIB_PCACHE_CacheLineUnlock
- PLIB_PCACHE_CacheLineIsLocked

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheLineLock(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsCacheLineMask Function

Identifies that the CacheLineMask feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheLineMask(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheLineMask feature is supported on the device
- false - The CacheLineMask feature is not supported on the device

Description

This interface identifies that the CacheLineMask feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheLineMaskSet
- PLIB_PCACHE_CacheLineMaskGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheLineMask(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsCacheLineType Function

Identifies that the CacheLineType feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheLineType(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheLineType feature is supported on the device
- false - The CacheLineType feature is not supported on the device

Description

This interface identifies that the CacheLineType feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheLineData
- PLIB_PCACHE_CacheLineInst
- PLIB_PCACHE_CacheLineIsInst

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheLineType(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsCacheLineValid Function

Identifies that the CacheLineValid feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheLineValid(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheLineValid feature is supported on the device
- false - The CacheLineValid feature is not supported on the device

Description

This interface identifies that the CacheLineValid feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheLineValid
- PLIB_PCACHE_CacheLineInvalid
- PLIB_PCACHE_CacheLineIsValid

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheLineValid(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsCacheMiss Function

Identifies that the CacheMiss feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsCacheMiss(PCACHE_MODULE_ID index);
```

Returns

- true - The CacheMiss feature is supported on the device
- false - The CacheMiss feature is not supported on the device

Description

This interface identifies that the CacheMiss feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_CacheMissRead
- PLIB_PCACHE_CacheMissWrite

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsCacheMiss(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsDataCacheEnable Function

Identifies that the DataCacheEnable feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsDataCacheEnable(PCACHE_MODULE_ID index);
```

Returns

- true - The DataCacheEnable feature is supported on the device
- false - The DataCacheEnable feature is not supported on the device

Description

This interface identifies that the DataCacheEnable feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_DataCacheEnableSet
- PLIB_PCACHE_DataCacheEnableGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsDataCacheEnable(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsFlashDEDStatus Function

Identifies that the FlashDEDStatus feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsFlashDEDStatus(PCACHE_MODULE_ID index);
```

Returns

- true - The FlashDEDStatus feature is supported on the device
- false - The FlashDEDStatus feature is not supported on the device

Description

This interface identifies that the FlashDEDStatus feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_FlashDEDStatusGet
- PLIB_PCACHE_FlashDEDStatusClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsFlashDEDStatus(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsFlashSECCount Function

Identifies that the FlashSECCount feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsFlashSECCount(PCACHE_MODULE_ID index);
```

Returns

- true - The FlashSECCount feature is supported on the device
- false - The FlashSECCount feature is not supported on the device

Description

This interface identifies that the FlashSECCount feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_FlashSECCountSet
- PLIB_PCACHE_FlashSECCountGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsFlashSECCount(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsFlashSECInt Function

Identifies that the FlashSECInt feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsFlashSECInt(PCACHE_MODULE_ID index);
```

Returns

- true - The FlashSECInt feature is supported on the device
- false - The FlashSECInt feature is not supported on the device

Description

This interface identifies that the FlashSECInt feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_FlashSECIntEnable
- PLIB_PCACHE_FlashSECIntDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsFlashSECInt(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsFlashSECStatus Function

Identifies that the FlashSECStatus feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsFlashSECStatus(PCACHE_MODULE_ID index);
```

Returns

- true - The FlashSECStatus feature is supported on the device
- false - The FlashSECStatus feature is not supported on the device

Description

This interface identifies that the FlashSECStatus feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_FlashSECStatusGet
- PLIB_PCACHE_FlashSECStatusSet
- PLIB_PCACHE_FlashSECStatusClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsFlashSECStatus(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsInvalidateOnPFMProgram Function

Identifies that the InvalidateOnPFMProgram feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsInvalidateOnPFMProgram(PCACHE_MODULE_ID index);
```

Returns

- true - The InvalidateOnPFMProgram feature is supported on the device
- false - The InvalidateOnPFMProgram feature is not supported on the device

Description

This interface identifies that the InvalidateOnPFMProgram feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_InvalidateOnPFMProgramAll
- PLIB_PCACHE_InvalidateOnPFMProgramUnlocked

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsInvalidateOnPFMProgram(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsLeastRecentlyUsedState Function

Identifies that the LeastRecentlyUsedState feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsLeastRecentlyUsedState(PCACHE_MODULE_ID index);
```

Returns

- true - The LeastRecentlyUsedState feature is supported on the device
- false - The LeastRecentlyUsedState feature is not supported on the device

Description

This interface identifies that the LeastRecentlyUsedState feature is available on the Prefetch Cache module. When this interface returns true, this function is supported on the device:

- PLIB_PCACHE_LeastRecentlyUsedStateRead

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsLeastRecentlyUsedState(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsPrefetchAbort Function

Identifies that the PrefetchAbort feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsPrefetchAbort(PCACHE_MODULE_ID index);
```

Returns

- true - The PrefetchAbort feature is supported on the device
- false - The PrefetchAbort feature is not supported on the device

Description

This interface identifies that the PrefetchAbort feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_PrefetchAbortRead
- PLIB_PCACHE_PrefetchAbortWrite

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsPrefetchAbort(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsPrefetchEnable Function

Identifies that the PrefetchEnable feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsPrefetchEnable(PCACHE_MODULE_ID index);
```

Returns

- true - The PrefetchEnable feature is supported on the device
- false - The PrefetchEnable feature is not supported on the device

Description

This interface identifies that the PrefetchEnable feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_PrefetchEnableSet
- PLIB_PCACHE_PrefetchEnableGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsPrefetchEnable(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsWaitState Function

Identifies that the WaitState feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsWaitState(PCACHE_MODULE_ID index);
```

Returns

- true - The WaitState feature is supported on the device
- false - The WaitState feature is not supported on the device

Description

This interface identifies that the WaitState feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_WaitStateSet
- PLIB_PCACHE_WaitStateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsWaitState(PCACHE_MODULE_ID index)

PLIB_PCACHE_ExistsWord Function

Identifies that the Word feature exists on the Prefetch Cache module.

File

plib_pcache.h

C

```
bool PLIB_PCACHE_ExistsWord(PCACHE_MODULE_ID index);
```

Returns

- true - The Word feature is supported on the device
- false - The Word feature is not supported on the device

Description

This interface identifies that the Word feature is available on the Prefetch Cache module. When this interface returns true, these functions are supported on the device:

- PLIB_PCACHE_WordRead
- PLIB_PCACHE_WordWrite

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PCACHE_ExistsWord(PCACHE_MODULE_ID index)

h) Data Types and Constants

PLIB_PCACHE_MAX_SEC_COUNT Macro

Defines the maximum value for single bit error counter.

File

help_plib_pcache.h

C

```
#define PLIB_PCACHE_MAX_SEC_COUNT 255
```

Description

Maximum Value for Single Bit Error Counter

This definition specifies the maximum value for single bit error counter.

Remarks

The actual maximum value of the SEC counter is processor specific and is defined in the processor-specific header files (see processor.h).

PLIB_PCACHE_NUM_LINES Macro

Defines the number of available Prefetch Cache Lines.

File

help_plib_pcache.h

C

```
#define PLIB_PCACHE_NUM_LINES
```

Description

Number of Cache Lines

This definition specifies the number of Prefetch Cache Lines available.

Remarks

The actual number of cache lines is processor specific and is defined in the processor-specific header files (see processor.h).

PLIB_PCACHE_NUM_WORDS_PER_LINE Macro

Defines the number of Words per Prefetch Cache Line.

File

help_plib_pcache.h

C

```
#define PLIB_PCACHE_NUM_WORDS_PER_LINE
```

Description

Number of Words per Cache Line

This definition specifies the number of Words per Prefetch Cache Line.

Remarks

The actual number of words per cache line is processor specific and is defined in the processor-specific header files (see processor.h).

PCACHE_MODULE_ID Enumeration

Lists the possible Module IDs for the Prefetch Cache.

File

help_plib_pcache.h

C

```
typedef enum {
  PCACHE_ID_1,
  PCACHE_NUMBER_OF_MODULES
} PCACHE_MODULE_ID;
```

Description

Module ID

This enumeration lists the possible Module IDs for the Prefetch Cache.

Remarks

Refer to the data sheet to get the correct number of modules defined for the desired device.

PLIB_PCACHE_DATA_ENABLE Enumeration

Lists the possible predictive prefetch states for the Prefetch Cache.

File

help_plib_pcache.h

C

```
typedef enum {
  PLIB_PCACHE_DATA_DISABLE,
  PLIB_PCACHE_DATA_1LINE,
  PLIB_PCACHE_DATA_2LINE,
  PLIB_PCACHE_DATA_4LINE
} PLIB_PCACHE_DATA_ENABLE;
```

Members

Members	Description
PLIB_PCACHE_DATA_DISABLE	Disable data caching
PLIB_PCACHE_DATA_1LINE	Enable data caching with a size of 1 Line
PLIB_PCACHE_DATA_2LINE	Enable data caching with a size of 2 Lines
PLIB_PCACHE_DATA_4LINE	Enable data caching with a size of 4 Lines

Description

Data Cache Enable

This enumeration lists the possible predictive prefetch states for the Prefetch Cache.

Remarks

Not all settings are available for all devices. See the device-specific data sheet for details. This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

PLIB_PCACHE_PREFETCH_ENABLE Enumeration

Lists the possible predictive prefetch states for the Prefetch Cache.

File

help_plib_pcache.h

C

```
typedef enum {
  PLIB_PCACHE_PREFETCH_DISABLE,
  PLIB_PCACHE_PREFETCH_ENABLE_CACHED_REGIONS,
  PLIB_PCACHE_PREFETCH_ENABLE_CPU_INST,
  PLIB_PCACHE_PREFETCH_ENABLE_NONCACHED_REGIONS,
  PLIB_PCACHE_PREFETCH_ENABLE_CPU_INST_DATA,
  PLIB_PCACHE_PREFETCH_ENABLE_ALL
} PLIB_PCACHE_PREFETCH_ENABLE;
```

Members

Members	Description
PLIB_PCACHE_PREFETCH_DISABLE	Disable predictive prefetch enable
PLIB_PCACHE_PREFETCH_ENABLE_CACHED_REGIONS	Enable predictive prefetch cache for cacheable regions only
PLIB_PCACHE_PREFETCH_ENABLE_CPU_INST	Enable predictive prefetch cache for cacheable regions only
PLIB_PCACHE_PREFETCH_ENABLE_NONCACHED_REGIONS	Enable predictive prefetch cache for non-cacheable regions only
PLIB_PCACHE_PREFETCH_ENABLE_CPU_INST_DATA	Enable predictive prefetch cache for non-cacheable regions only
PLIB_PCACHE_PREFETCH_ENABLE_ALL	Enable predictive prefetch cache for cacheable and non-cacheable regions

Description

Predictive Prefetch Cache Enable Bits

This enumeration lists the possible predictive prefetch states for the Prefetch Cache.

Remarks

Not all settings are available for all devices. See the device-specific data sheet for details. This enumeration is processor specific and is defined in the processor-specific header files (see processor.h).

Files

Files

Name	Description
plib_pcache.h	Defines the Prefetch Cache Peripheral Library Interface
help_plib_pcache.h	This file is used for documentation purposes

Description

This section lists the source and header files used by the library.

plib_pcache.h

Defines the Prefetch Cache Peripheral Library Interface

Functions

	Name	Description
	PLIB_PCACHE_CacheHitRead	Reads the number of cache hits.
	PLIB_PCACHE_CacheHitWrite	Sets the number of cache hits.
	PLIB_PCACHE_CacheLineAddrGet	Gets the TAG address in the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineAddrSet	Sets the TAG address in the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineData	Sets cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect to data type.
	PLIB_PCACHE_CacheLineDeselect	Disables write access to the cache line specified by cache_line.
	PLIB_PCACHE_CacheLineFlashTypeBoot	Set the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect as residing in Boot Flash.
	PLIB_PCACHE_CacheLineFlashTypeInst	Set the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect as residing in Instruction Flash.
	PLIB_PCACHE_CacheLineFlashTypeIsInst	Returns true if the cache line tag for the line previously write-enabled by PLIB_PCACHE_CacheLineSelect shows the line is residing in Instruction Flash.
	PLIB_PCACHE_CacheLineInst	Sets cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect to instruction type.
	PLIB_PCACHE_CacheLineInvalid	Invalidates cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineIsInst	Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is set to instruction type.
	PLIB_PCACHE_CacheLineIsLocked	Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is locked.
	PLIB_PCACHE_CacheLineIsValid	Returns true if cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect is valid.
	PLIB_PCACHE_CacheLineLock	Locks cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineMaskGet	Returns the current state of the cache tag mask for the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineMaskSet	Sets the cache tag mask to force a match on set bits on the cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineSelect	Enables write access to the cache line specified by cache_line.
	PLIB_PCACHE_CacheLineUnlock	Unlocks cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheLineValid	Validates cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.
	PLIB_PCACHE_CacheMissRead	Reads the number of cache misses.
	PLIB_PCACHE_CacheMissWrite	Sets the number of cache misses.

	PLIB_PCACHE_DataCacheEnableGet	Gets the data cache enable bits.
	PLIB_PCACHE_DataCacheEnableSet	Sets the data cache enable bits.
	PLIB_PCACHE_ExistsCacheHit	Identifies that the CacheHit feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLine	Identifies that the CacheLineSelect feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineAddr	Identifies that the CacheLineAddr feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineFlashType	Identifies that the CacheLineFlashType feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineLock	Identifies that the CacheLineLock feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineMask	Identifies that the CacheLineMask feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineType	Identifies that the CacheLineType feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheLineValid	Identifies that the CacheLineValid feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsCacheMiss	Identifies that the CacheMiss feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsDataCacheEnable	Identifies that the DataCacheEnable feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsFlashDEDStatus	Identifies that the FlashDEDStatus feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsFlashSECCount	Identifies that the FlashSECCount feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsFlashSECInt	Identifies that the FlashSECInt feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsFlashSECStatus	Identifies that the FlashSECStatus feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsInvalidateOnPFMProgram	Identifies that the InvalidateOnPFMProgram feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsLeastRecentlyUsedState	Identifies that the LeastRecentlyUsedState feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsPrefetchAbort	Identifies that the PrefetchAbort feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsPrefetchEnable	Identifies that the PrefetchEnable feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsWaitState	Identifies that the WaitState feature exists on the Prefetch Cache module.
	PLIB_PCACHE_ExistsWord	Identifies that the Word feature exists on the Prefetch Cache module.
	PLIB_PCACHE_FlashDEDStatusClear	Clears a bus exception caused by a double-bit error.
	PLIB_PCACHE_FlashDEDStatusGet	Determines if a bus exception was caused by a double-bit error.
	PLIB_PCACHE_FlashSECCountGet	Returns the current value of the Flash SEC counter.
	PLIB_PCACHE_FlashSECCountSet	Sets the number of single-bit error corrections that must occur before the SEC status is set to true.
	PLIB_PCACHE_FlashSECIntDisable	Disables an interrupt on SEC.
	PLIB_PCACHE_FlashSECIntEnable	Enables an interrupt on SEC.
	PLIB_PCACHE_FlashSECStatusClear	Sets the single-bit error corrected status to false.
	PLIB_PCACHE_FlashSECStatusGet	Determines if a SEC event triggered a Prefetch Cache interrupt.
	PLIB_PCACHE_FlashSECStatusSet	Sets the single-bit error corrected status to true.
	PLIB_PCACHE_InvalidateOnPFMProgramAll	Sets Prefetch Cache to invalidate all data and instruction lines on a PFM program cycle.
	PLIB_PCACHE_InvalidateOnPFMProgramUnlocked	Sets Prefetch Cache to invalidate all unlocked data and instruction lines on a PFM program cycle.
	PLIB_PCACHE_LeastRecentlyUsedStateRead	Reads the state of the cache Least Recently Used (LRU) encoding bits.
	PLIB_PCACHE_PrefetchAbortRead	Reads the number of prefetch aborts.
	PLIB_PCACHE_PrefetchAbortWrite	Sets the number of prefetch aborts.
	PLIB_PCACHE_PrefetchEnableGet	Gets the predictive Prefetch state for the Prefetch Cache module.
	PLIB_PCACHE_PrefetchEnableSet	Sets the predictive Prefetch state for the Prefetch Cache module.
	PLIB_PCACHE_WaitStateGet	Gets the Prefetch Cache access time.
	PLIB_PCACHE_WaitStateSet	Sets the Prefetch Cache access time.
	PLIB_PCACHE_WordRead	Reads the word specified by word from cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

	PLIB_PCACHE_WordWrite	Writes the word (specified by word parameter) with data (specified by data parameter) to cache line previously write-enabled by PLIB_PCACHE_CacheLineSelect.

Description

Prefetch Cache Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Prefetch Cache Peripheral Library for Microchip microcontrollers. The definitions in this file are for the Prefetch Cache module.

File Name

plib_pcache.h

Company

Microchip Technology Inc.

help_plib_pcache.h

Enumerations

	Name	Description
	PCACHE_MODULE_ID	Lists the possible Module IDs for the Prefetch Cache.
	PLIB_PCACHE_DATA_ENABLE	Lists the possible predictive prefetch states for the Prefetch Cache.
	PLIB_PCACHE_PREFETCH_ENABLE	Lists the possible predictive prefetch states for the Prefetch Cache.

Macros

	Name	Description
	PLIB_PCACHE_MAX_SEC_COUNT	Defines the maximum value for single bit error counter.
	PLIB_PCACHE_NUM_LINES	Defines the number of available Prefetch Cache Lines.
	PLIB_PCACHE_NUM_WORDS_PER_LINE	Defines the number of Words per Prefetch Cache Line.

Description

This file is used for documentation purposes

Ports Peripheral Library

This section describes the Ports Peripheral Library.

Introduction

This library provides a low-level abstraction of the I/O Ports module on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

The general purpose I/O pins can be considered the simplest of peripherals. These I/O pins allow the microcontroller to monitor and control other devices. To add flexibility and functionality to a device, some pins are multiplexed with alternate function(s). These functions depend on which peripheral features are on the device. In general, when a peripheral is functioning, that pin may not be used as a general purpose I/O pin.

A major challenge in general purpose devices is providing the largest possible set of peripheral features while minimizing the conflict of features on I/O pins. The Peripheral Pin Select (PPS) feature simplifies this challenge by enabling the user's peripheral set selection and their placement on a wide range of I/O pins. By increasing the pin out options available on a particular device, users can better tailor the microcontroller to their entire application. The PPS feature operates over a fixed subset of digital I/O pins. Users may independently map the input and/or output of any one of many digital peripherals to any one of these I/O pins. PPS is performed in software and generally does not require the device to be reprogrammed. Hardware safeguards are included that prevent accidental or spurious changes to the peripheral mapping once it has been established.

Note: Peripheral Pin Select is not available on all devices. Please refer to the specific device data sheet to determine availability of this feature.

Following are some of the key features of the I/O Ports module:

- Individual output pin/port open-drain control
- Individual input pin/port pull-up/down control
- Monitor select inputs and generate interrupt on mismatch condition (Change Notification)
- Operation during Sleep and Idle modes
- Port line analog/digital selection
- Port slew rate control
- PPS peripheral function remapping

Using the Library

This topic describes the basic architecture of the Ports Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_ports.h`

The interface to the Ports Peripheral Library is defined in the `plib_ports.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Ports Peripheral Library must include `peripheral.h`.

Library File:

The Ports Peripheral Library is part of the processor-specific peripheral library installed with the compiler. This library is automatically available (in the default search path) for any project built using the Microchip compilers.

Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

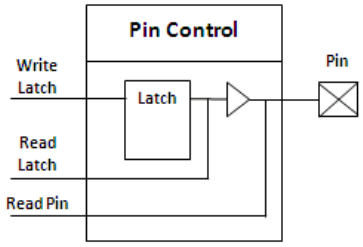
Hardware Abstraction Model

This topic provides detailed information for general purpose I/O and pin mapping.

Description

General Purpose I/O

All port pins have three controls directly associated with their operation as digital I/O. The data direction control determines whether the pin is an input or an output. All port pins are defined as inputs after a Reset. Writes to a port are latched and, if programmed as an output, driven by a buffer to the pin. The value of pin can be read directly from an input buffer, (after it has been synchronized to the clock), regardless of whether the pin direction has been selected as input or output. Additionally, the value being driven by the latch before the output buffer, can also be read.



Internal pull-up resistors are available on selected port pins to eliminate the need to use external pull-up resistors. These pull-ups can be controlled by this library. The open-drain feature allows the generation of outputs higher than VDD on any desired digital-only pins by using external pull-up resistors.

Note: For detailed specifications on the maximum allowed open-drain voltage, refer to the **"Electrical Characteristics"** chapter in the specific device data sheet.

The input change notification feature of the I/O ports allows the microcontrollers to generate interrupt requests to the processor in response to a change of state on selected input pins. This feature is capable of detecting input change of states even in Sleep mode, when the clocks are disabled.

The alternate pin function selections are used to steer specific peripheral input and output functions between different pins.

The output slew rate of some port pins are programmable to select either the standard transition rate or a reduced transition rate of 'x' times the standard to minimize EMI.

Peripheral Pin Select

In addition to general purpose IO control, this library also provides a low-level abstraction of the PPS module on Microchip microcontrollers with a convenient C language interface.

Available Pins

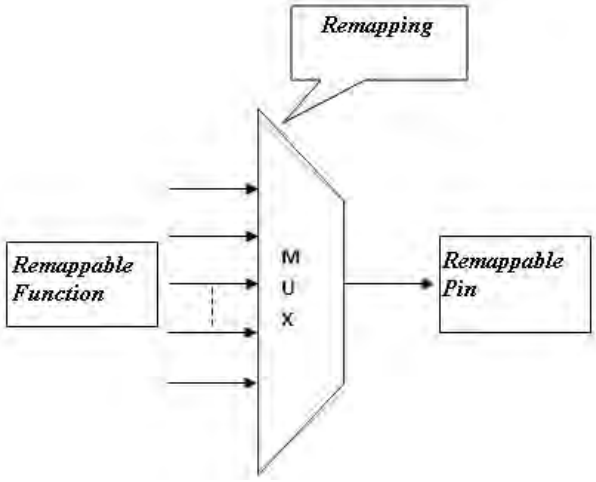
The number of available pins is dependent on the particular device and its pin count. Pins that support the PPS feature include the designation 'RPn' or 'RPIn' in their full pin designation, where 'RP' designates a remappable peripheral and 'n' is the remappable pin number. RP is used to designate pins that support both remappable input and output functions, while RPI indicates pins that only support remappable input functions.

Available Peripherals

The peripherals managed by PPS are all digital-only peripherals. These include general serial communications (UART and SPI), general purpose timer clock inputs, timer-related peripherals (Input Capture and Output Compare), comparator digital output, interrupt-on-change inputs, etc.

In comparison, some digital-only peripheral modules are never included in the peripheral pin select feature. This is because the peripheral's function requires special I/O circuitry on a specific port and cannot be easily connected to multiple pins. These modules include I2C, among others. A similar requirement excludes all modules with analog inputs, such as the Analog-to-Digital Converter (ADC).

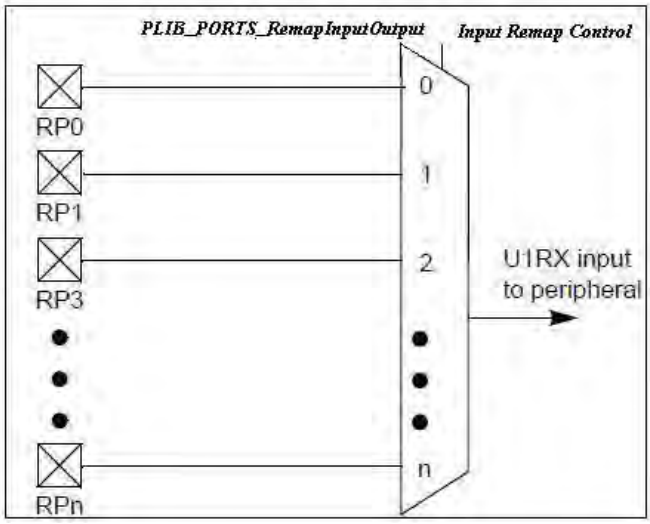
If multiple peripherals are enabled on the same pin(s), there is an internal priority that decides which function is mapped to the pin. When a remappable peripheral is active on a given I/O pin, it takes priority over all other digital I/O and digital communication peripherals associated with the pin. Priority is given regardless of the type of peripheral that is mapped. Remappable peripherals never take priority over any analog functions associated with the pin. In other words, If an analog function is enabled on the pin, the PPS input will be disabled.



Input Mapping

The inputs of the peripheral pin select options are mapped on the basis of the peripheral.

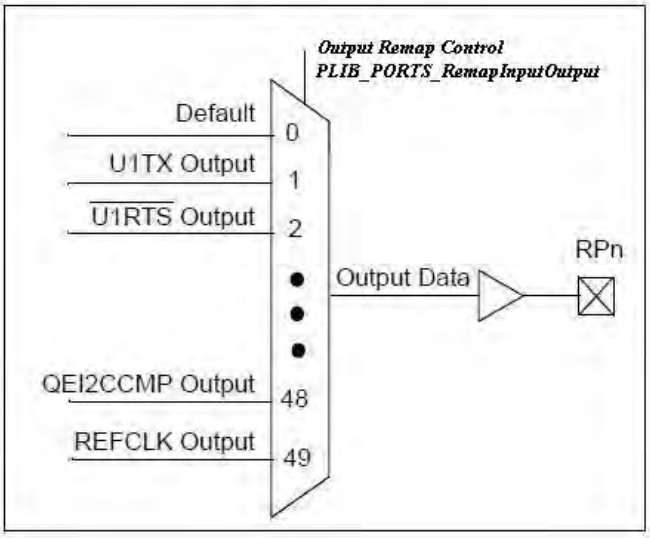
Remappable Input Example for USART 1 Receive



Output Mapping

In contrast to inputs, the outputs of the peripheral pin select options are mapped on the basis of the pin. In this case, a control associated with a particular pin dictates the peripheral output to be mapped.

Multiplexing of Remappable Output for RPn



Mapping Limitations

The control schema of the peripheral select pins is not limited to a small range of fixed peripheral configurations. There are no mutual-exclusion or hardware-enforced lockouts between any of the peripheral mapping SFRs. Literally any combination of peripheral mappings across any or all of the RPn pins is possible. This includes both many-to-one and one-to-many mappings of peripheral inputs and outputs to pins. While such mappings may be technically possible from a configuration point of view, they may not be supportable from an electrical point of view and may cause damage to the part.

Notes:

1. For detailed specifications on the mapping limitations, refer to the **"I/O Ports"** chapter in the specific device data sheet.
2. Regrading pin priorities, the priority of the pins are assigned from left to right, left being the highest priority and the right most being the least priority.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Ports module.

Library Interface Section	Description
Port Functions	Port access read/write/toggle/clear interfaces with 8-/16-/32-bit widths based on the selected device.
Port Pin Functions	Port bit/pin read/write/toggle/clear interfaces.
Change Notification Functions	Port change notification.
Peripheral Pin Select Functions	Interface routines for mapping the digital input/output to a specific the PPS remappable input/output pin.
Feature Existence Functions	Determine whether certain features exist.

How the Library Works

How the Library Works

The following topics discuss the processes involved while using a Ports module:

- Ports Control
- Ports Function Remap
- Ports Change Notification
- Special Considerations

Ports Control

Port Functions Usage:

- Port Read - Ports can be read at byte/word level using PLIB_PORTS_Read, and at the bit/pin level using PLIB_PORTS_PinGet
- Port Write - Ports can be written to at byte/word level using PLIB_PORTS_Write and at the bit/pin level using PLIB_PORTS_PinWrite. The function PLIB_PORTS_PinSet can be used to set a specific bit/pin of a port. A mask-based PORTx write can be accomplished using the function PLIB_PORTS_Set with the appropriate mask as a parameter along with the value.
- Port Clear - Ports can be cleared at byte/word level using PLIB_PORTS_Clear with appropriate mask as a parameter and at the bit/pin level using PLIB_PORTS_PinClear
- Port Direction - The ports read direction can be set at byte/word level using PLIB_PORTS_DirectionInputSet and at the bit/pin level using PLIB_PORTS_PinDirectionInputSet. Similarly, the ports write direction can be set at the byte/word level using PLIB_PORTS_DirectionOutputSet and at the bit/pin level using PLIB_PORTS_PinDirectionOutputSet. The direction information can be read using PLIB_PORTS_DirectionGet.
- Port Toggle - Ports can be toggled at the byte/word level using PLIB_PORTS_Toggle with the appropriate mask as a parameter and at the bit/pin level using PLIB_PORTS_PinToggle
- Port Open Drain - Ports can be enabled for open-drain functionality at the byte/word level using the interface PLIB_PORTS_OpenDrainEnable and at the bit/pin level using PLIB_PORTS_PinOpenDrainEnable. Similarly, the ports can be disabled for open-drain functionality at the byte/word level using PLIB_PORTS_OpenDrainDisable and at the bit/pin level using PLIB_PORTS_PinOpenDrainDisable.

Example:

```
// PORT Direction setting for output
   PLIB_PORTS_DirectionOutputSet(MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_MASK)0xFFFF);

// Writing a value into a PORT
   PLIB_PORTS_Write(MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_TYPE)0x1234);

// PORT Direction setting for input
   PLIB_PORTS_DirectionInputSet(MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_MASK)0xFFFF);

// Reading back the previously written value
   PORTS_DATA_TYPE readData = PLIB_PORTS_Read(MY_PORTS_INSTANCE, MY_CHANNEL);

// Clearing the PORT
   PLIB_PORTS_Clear(MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_MASK)0x00FF);

// Writing the value based on the mask, only 0x34 gets written to the PORT
   PLIB_PORTS_Set(MY_PORTS_INSTANCE, MY_CHANNEL, 0x1234, (PORTS_DATA_MASK)0x00FF);

// Toggling a PORT
   PLIB_PORTS_Toggle(MY_PORTS_INSTANCE, MY_CHANNEL, (PORTS_DATA_MASK)0x00FF);
```

Ports Function Remap

Using the PPS Feature:

1. Ensure that any fixed digital peripherals on the pins to be used are disabled.
2. Ensure that pins with analog functionality are set to Digital mode.
3. Enable writing to the Input/Output control register using PLIB_DEVCON_SystemUnlock and PLIB_DEVCON_DeviceRegistersUnlock.
4. Remap the input and/or output pins using the internal PPS module. This can be achieved with the functions PLIB_PORTS_RemapInput and PLIB_PORTS_RemapOutput with the respective parameters defined in the processor specific headers.
5. Lock the Input/Output control register using PLIB_DEVCON_SystemUnlock and PLIB_DEVCON_DeviceRegistersUnlock.
6. Configure and enable newly mapped PPS peripherals.

Example:

```
// System Unlock
PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);
// Unlock PPS registers
PLIB_DEVCON_DeviceRegistersUnlock(DEVCON_ID_0, DEVCON_PPS_REGISTERS);

// Remapping input function 'Input Capture 1' to the Remappable pin 'RPD2'
PLIB_PORTS_RemapInput(PORTS_ID_0, INPUT_FUNC_IC1, INPUT_PIN_RPD2 );

// Remapping output function 'UART3 Transmit' to the Remappable pin 'RPA14'
PLIB_PORTS_RemapOutput(PORTS_ID_0, OUTPUT_FUNC_U3TX, OUTPUT_PIN_RPA14);

// Lock PPS registers
PLIB_DEVCON_DeviceRegistersLock(DEVCON_ID_0, DEVCON_PPS_REGISTERS);
```

Note: For more information, refer to the **"I/O Ports"** chapter in the specific device data sheet or the family reference manual section specified in that chapter.

Ports Change Notification

Change Notification Feature Usage

1. Ensure that the change notify pin is configured as a digital input by setting the associated bit in the direction register using the PLIB_PORTS_PinDirectionInputSet or PLIB_PORTS_DirectionInputSet functions.

2. Select the desired change notification pin using PLIB_PORTS_PinChangeNoticeEnable.

3. Turn on the weak pull-up devices (if desired) for the selected change notification pins using PLIB_PORTS_ChangeNoticePullUpEnable (weak pull-ups can be disabled using PLIB_PORTS_ChangeNoticePullUpDisable).

4. Clear the selected change notification interrupt flag.

5. Select the desired interrupt priority for change notification pin.

6. Enable change notification interrupts.

7. Change notification can be disabled after the successful usage using PLIB_PORTS_PinChangeNoticeDisable. Certain microcontrollers support the global control over the change notification feature using the following functions: PLIB_PORTS_ChangeNoticeEnable and PLIB_PORTS_ChangeNoticeDisable. If there are any requirements to control the pull-downs, the following two functions could be used: PLIB_PORTS_ChangeNoticePullDownPerPortEnable and PLIB_PORTS_ChangeNoticePullDownPerPortDisable.

Change Notification Operation in Sleep and Idle Modes

The change notification feature continues to operate during Sleep or Idle mode. Its operation can be enabled or disabled using PLIB_PORTS_ChangeNoticeInIdleEnable or PLIB_PORTS_ChangeNoticeInIdleDisable. If one of the enabled change notification pins changes states, the respective status bit will be set, which can be monitored using PLIB_PORTS_ChangeNoticePerPortHasOccurred.

Example:

```
// Enabling the global change notification
PLIB_PORTS_ChangeNoticeEnable(MY_PORTS_INSTANCE);
// Enabling weak pull-ups for the change notification PIN 10
PLIB_PORTS_ChangeNoticePullUpEnable(MY_PORTS_INSTANCE, PORTS_CHANGE_NOTICE_PIN_10);
// Enabling change notification on PIN 10
PLIB_PORTS_PinChangeNoticeEnable(MY_PORTS_INSTANCE, PORTS_CHANGE_NOTICE_PIN_10);
```

Note: For more information, refer to the **"I/O Ports"** chapter in the specific device data sheet or the related family reference manual section specified in that chapter.

Special Considerations

Considerations on Ports Usage

When reading a port register, all pins configured as analog input channels will read as cleared.

Pins configured as digital inputs will not operate correctly with analog peripherals. Analog levels on any pin that is defined as a digital input may cause the input buffer of analog peripherals to consume current that exceeds the device specifications.

Pull-ups and pull-downs on change notification pins should always be disabled when the port pin is configured as a digital output.

One instruction cycle is required between a port direction change or port write operation and a read operation of the same port. Typically, this instruction would be a NOP.

Considerations for PPS

The ability to control PPS options introduces several considerations into application design that could be overlooked. This is particularly true for several common peripherals that are available only as remappable peripherals.

The main consideration is that the peripheral pin selects are not available on default pins in the device's default (i.e., Reset) state, all PPS inputs are tied to VSS and all PPS outputs are disconnected. This condition requires the user to initialize the device with the proper peripheral configuration before any other application code is executed. For application safety, however, it is best to lock the configuration after writing to the PPS control.

The assignment of a peripheral signal to a particular pin does not automatically perform any other configuration of the pin's I/O circuitry. In theory, this means adding a pin-selectable output to a pin may mean inadvertently driving an existing peripheral input when the output is driven. Users must be familiar with the behavior of other fixed peripherals that share a remappable pin and know when to enable or disable them. To be safe, fixed digital peripherals that share the same pin should be disabled when not in use. In addition, configuring a remappable pin for a specific peripheral does not automatically turn on that feature. The peripheral must be specifically configured for operation and enabled, as if it were tied to a fixed pin. Where this occurs in the application code (immediately following a device Reset and peripheral configuration or inside the main application routine) depends on the peripheral and its use in the application.

A final consideration is that PPS functions neither override analog inputs, nor reconfigure pins with analog functions for digital I/O. If a pin is configured as an analog input on a device Reset, it must be explicitly reconfigured as a digital I/O when used with PPS.

Note: For more information, refer to the **"I/O Ports"** chapter in the specific device data sheet or the family reference manual section specified in that chapter.

Configuring the Library

The library is configured for the supported Ports module when the supported processor is chosen in the MPLAB X IDE.

Library Interface

a) Port Pin Functions

	Name	Description
	PLIB_PORTS_PinClear	Clears the selected digital pin/latch.
	PLIB_PORTS_PinDirectionInputSet	Makes the selected pin direction input
	PLIB_PORTS_PinDirectionOutputSet	Makes the selected pin direction output
	PLIB_PORTS_PinGet	Reads/Gets data from the selected digital pin.
	PLIB_PORTS_PinModeSelect	Enables the selected pin as analog or digital.
	PLIB_PORTS_PinSet	Sets the selected digital pin/latch.
	PLIB_PORTS_PinToggle	Toggles the selected digital pin/latch.
	PLIB_PORTS_PinWrite	Writes the selected digital pin/latch.
	PLIB_PORTS_PinModePerPortSelect	Enables the selected port pin as analog or digital.
	PLIB_PORTS_PinGetLatched	Reads/Gets data from the selected latch.
	PLIB_PORTS_PinChangeNoticeEdgeHasOccurred	Check Change Notice edge status.
	PLIB_PORTS_PinChangeNoticeEdgeIsEnabled	Check if Change Notice edge is enabled or not.
	PLIB_PORTS_PinSlewRateGet	Gets the slew rate for selected port pin.
	PLIB_PORTS_PinOpenDrainDisable	Disables the open drain functionality for the selected pin.
	PLIB_PORTS_PinOpenDrainEnable	Enables the open drain functionality for the selected pin.

b) Port Functions

	Name	Description
	PLIB_PORTS_Clear	Clears the selected digital port/latch bits.

	PLIB_PORTS_DirectionGet	Reads the direction of the selected digital port.
	PLIB_PORTS_DirectionInputSet	Makes the selected pins direction input.
	PLIB_PORTS_DirectionOutputSet	Makes the selected pins direction output.
	PLIB_PORTS_Read	Reads the selected digital port.
	PLIB_PORTS_Set	Sets the selected bits of the port.
	PLIB_PORTS_Toggle	Toggles the selected digital port/latch.
	PLIB_PORTS_Write	Writes the selected digital port/latch.
	PLIB_PORTS_OpenDrainDisable	Disables the open drain functionality for the selected port.
	PLIB_PORTS_OpenDrainEnable	Enables the open drain functionality for the selected port pins.
	PLIB_PORTS_ReadLatched	Reads and returns data from the selected Latch.
	PLIB_PORTS_ChannelModeSelect	Enables the selected channel pins as analog or digital.
	PLIB_PORTS_ChannelSlewRateSelect	Selects the slew rate for selected channel pins.

c) Peripheral Pin Select Functions

	Name	Description
	PLIB_PORTS_RemapInput	Input function remapping.
	PLIB_PORTS_RemapOutput	Output function remapping.

d) Change Notification Functions

	Name	Description
	PLIB_PORTS_ChangeNoticeDisable	Global Change Notice disable.
	PLIB_PORTS_ChangeNoticeEnable	Global Change Notice enable.
	PLIB_PORTS_ChangeNoticeInIdleDisable	CPU Idle halts the Change Notice operation.
	PLIB_PORTS_ChangeNoticeInIdleEnable	CPU Idle mode does not affect Change Notice operation.
	PLIB_PORTS_ChangeNoticeInIdlePerPortDisable	Change Notification halts in Idle mode for selected channel.
	PLIB_PORTS_ChangeNoticeInIdlePerPortEnable	Allows CN to be working in Idle mode for selected channel.
	PLIB_PORTS_ChangeNoticePerPortHasOccured	This is function PLIB_PORTS_ChangeNoticePerPortHasOccured.
	PLIB_PORTS_ChangeNoticePerPortTurnOff	Disables the change notification for selected port.
	PLIB_PORTS_ChangeNoticePerPortTurnOn	Enables the change notification for selected port.
	PLIB_PORTS_ChangeNoticePullDownPerPortDisable	Disables the pull-down for selected Change Notice pins.
	PLIB_PORTS_ChangeNoticePullDownPerPortEnable	Enables the pull-down for selected Change Notice pins.
	PLIB_PORTS_ChangeNoticePullUpDisable	Disable pull-up on input change.
	PLIB_PORTS_ChangeNoticePullUpEnable	Enable pull-up on input change.
	PLIB_PORTS_ChangeNoticePullUpPerPortDisable	Disables weak pull-up for the selected pin.
	PLIB_PORTS_ChangeNoticePullUpPerPortEnable	Enables the pull-up for selected Change Notice pins.
	PLIB_PORTS_PinChangeNoticeDisable	Port pin Change Notice disable.
	PLIB_PORTS_PinChangeNoticeEnable	Port pin Change Notice interrupt enable.
	PLIB_PORTS_PinChangeNoticePerPortDisable	Disables CN interrupt for the selected pin.
	PLIB_PORTS_PinChangeNoticePerPortEnable	Enables CN interrupt for the selected pin.
	PLIB_PORTS_ChangeNoticePerPortHasOccurred	checks the status of change on the pin
	PLIB_PORTS_ChannelChangeNoticeDisable	Disables CN interrupt for the selected pins of a channel.
	PLIB_PORTS_ChannelChangeNoticeEnable	Enables CN interrupt for the selected pins of a channel.
	PLIB_PORTS_ChannelChangeNoticePullDownDisable	Disables Change Notice pull-down for the selected channel pins.
	PLIB_PORTS_ChannelChangeNoticePullDownEnable	Enables Change Notice pull-down for the selected channel pins.
	PLIB_PORTS_ChannelChangeNoticePullUpDisable	Disables Change Notice pull-up for the selected channel pins.
	PLIB_PORTS_ChannelChangeNoticePullUpEnable	Enables Change Notice pull-up for the selected channel pins.
	PLIB_PORTS_ChannelChangeNoticeEdgeDisable	Disables selected type of edge for selected CN pins.
	PLIB_PORTS_ChannelChangeNoticeEdgeEnable	Enables selected type of edge for selected CN pins.
	PLIB_PORTS_ChannelChangeNoticeMethodGet	Gets the Change Notice style for the selected port channel.
	PLIB_PORTS_ChannelChangeNoticeMethodSelect	Selects the Change Notice style for selected port channel.
	PLIB_PORTS_AnPinsModeSelect	Enables the selected AN pins as analog or digital.
	PLIB_PORTS_CnPinsDisable	Disables CN interrupt for the selected pins of a channel.
	PLIB_PORTS_CnPinsEnable	Enables CN interrupt for the selected pins of a channel.
	PLIB_PORTS_CnPinsPullUpDisable	Disables Change Notice pull-up for the selected channel pins.
	PLIB_PORTS_CnPinsPullUpEnable	Enables Change Notice pull-up for the selected channel pins.

e) Feature Existence Functions

	Name	Description
	PLIB_PORTS_ExistsChangeNotice	Identifies whether the ChangeNotice feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticeInIdle	Identifies whether the ChangeNoticeInIdle feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePerPortInIdle	Identifies whether the ChangeNoticeInIdlePerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePerPortStatus	Identifies whether the ChangeNoticePerPortStatus feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePerPortTurnOn	Identifies whether the ChangeNoticePerPortTurnOn feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePullDownPerPort	Identifies whether the ChangeNoticePullDownPerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePullUp	Identifies whether the ChangeNoticePullup feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePullUpPerPort	Identifies whether the ChangeNoticePullUpPerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsPinChangeNotice	Identifies whether the PinChangeNotice feature exists on the Ports module.
	PLIB_PORTS_ExistsPinChangeNoticePerPort	Identifies whether the PinChangeNoticePerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsPinMode	Identifies whether the PinMode feature exists on the Ports module.
	PLIB_PORTS_ExistsPinModePerPort	Identifies whether the PinModePerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsPortsDirection	Identifies whether the PortsDirection feature exists on the Ports module.
	PLIB_PORTS_ExistsPortsOpenDrain	Identifies whether the PortsOpenDrain feature exists on the Ports module.
	PLIB_PORTS_ExistsPortsRead	Identifies whether the PortsRead feature exists on the Ports module.
	PLIB_PORTS_ExistsPortsWrite	Identifies whether the PortsWrite feature exists on the Ports module.
	PLIB_PORTS_ExistsRemapInput	Identifies whether the RemapInput feature exists on the Ports module.
	PLIB_PORTS_ExistsRemapOutput	Identifies whether the RemapOutput feature exists on the Ports module.
	PLIB_PORTS_ExistsLatchRead	Identifies whether the LatchRead feature exists on the Ports module.
	PLIB_PORTS_ExistsAnPinsMode	Identifies whether the AnPinsMode feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticeEdgeControl	Identifies whether the ChangeNoticeEdgeControl feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticeEdgeStatus	Identifies whether the ChangeNoticeEdgeStatus feature exists on the Ports module.
	PLIB_PORTS_ExistsChannelChangeNoticeMethod	Identifies whether the ChannelChangeNoticeMethod feature exists on the Ports module.
	PLIB_PORTS_ExistsSlewRateControl	Identifies whether the SlewRateControl feature exists on the Ports module.

f) Data Types and Constants

	Name	Description
	PORTS_ANALOG_PIN	Data type defining the different analog input pins.
	PORTS_BIT_POS	Lists the constants that hold different PORTS bit positions.
	PORTS_CHANGE_NOTICE_PIN	Data type defining the different Change Notification (CN) pins enumerations.
	PORTS_CHANNEL	Identifies the available Ports channels.
	PORTS_DATA_MASK	Data type defining the Ports data mask
	PORTS_DATA_TYPE	Data type defining the Ports data type.
	PORTS_MODULE_ID	Identifies the available Ports modules.
	PORTS_PIN_MODE	Identifies the available pin modes.
	PORTS_REMAP_FUNCTION	Data type defining the different remap function enumerations.
	PORTS_REMAP_INPUT_FUNCTION	Data type defining the different remap input function enumerations.
	PORTS_REMAP_INPUT_PIN	Data type defining the different Ports I/O input pins enumerations.
	PORTS_REMAP_OUTPUT_FUNCTION	Data type defining the different remap output function enumerations.
	PORTS_REMAP_OUTPUT_PIN	Data type defining the different Ports I/O output pins enumerations.
	PORTS_REMAP_PIN	Data type defining the different remappable input/output enumerations.
	PORTS_AN_PIN	Data type defining the different analog input pins.
	PORTS_CN_PIN	Data type defining the different Change Notification (CN) pins enumerations.
	PORTS_CHANGE_NOTICE_EDGE	Data type defining the different edge type for change notification.
	PORTS_CHANGE_NOTICE_METHOD	Data type defining the different method of ports pin change notification.

	PORTS_PIN_SLEW_RATE	Data type defining the different slew rates for port pins.

Description

This section describes the Application Programming Interface (API) functions of the Ports Peripheral Library.

Refer to each section for a detailed description.

a) Port Pin Functions

PLIB_PORTS_PinClear Function

Clears the selected digital pin/latch.

File

plib_ports.h

C

```
void PLIB_PORTS_PinClear(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function clears the selected digital pin/latch.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsWrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Clears port pin RC4
PLIB_PORTS_PinClear(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void PLIB_PORTS_PinClear(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

PLIB_PORTS_PinDirectionInputSet Function

Makes the selected pin direction input

File

plib_ports.h

C

```
void PLIB_PORTS_PinDirectionInputSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function makes the selected pin direction as input

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsDirection in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// make pin RC4 as input
PLIB_PORTS_PinDirectionInputSet(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS direction that has to be made input

Function

void PLIB_PORTS_PinDirectionInputSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

PLIB_PORTS_PinDirectionOutputSet Function

Makes the selected pin direction output

File

plib_ports.h

C

```
void PLIB_PORTS_PinDirectionOutputSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function makes the selected pin direction as output

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsDirection in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// make pin RC4 as output
PLIB_PORTS_PinDirectionOutputSet(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS direction that has to be made output

Function

void PLIB_PORTS_PinDirectionOutputSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

PLIB_PORTS_PinGet Function

Reads/Gets data from the selected digital pin.

File

plib_ports.h

C

```
bool PLIB_PORTS_PinGet(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

Port pin read data.

Description

This function reads/gets data from the selected digital PORT i/o pin. This function should be used to read the live data at the pin.

Remarks

For reading the Latched data, PLIB_PORTS_PinGetLatched function should be used.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsRead in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// read port pin RC4
bool bitStatus = PLIB_PORTS_PinGet(PORTS_ID_0, PORT_CHANNEL_C,
                                                PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

bool PLIB_PORTS_PinGet(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

PLIB_PORTS_PinModeSelect Function

Enables the selected pin as analog or digital.

File

plib_ports.h

C

```
void PLIB_PORTS_PinModeSelect(PORTS_MODULE_ID index, PORTS_ANALOG_PIN pin, PORTS_PIN_MODE mode);
```

Returns

None.

Description

This function enables the selected pin as analog or digital.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPinMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Make AN0 pin as Analog
PLIB_PORTS_PinModeSelect(PORTS_ID_0, PORTS_ANALOG_PIN_0, PORTS_PIN_MODE_ANALOG);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pin	Possible values of PORTS_ANALOG_PIN
mode	Possible values of PORTS_PIN_MODE

Function

void PLIB_PORTS_PinModeSelect(PORTS_MODULE_ID index,
PORTS_ANALOG_PIN pin,
PORTS_PIN_MODE mode);

PLIB_PORTS_PinSet Function

Sets the selected digital pin/latch.

File

plib_ports.h

C

```
void PLIB_PORTS_PinSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function sets the selected digital pin/latch.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsWrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Sets port pin RC4
PLIB_PORTS_PinSet(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void PLIB_PORTS_PinSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

PLIB_PORTS_PinToggle Function

Toggles the selected digital pin/latch.

File

plib_ports.h

C

```
void PLIB_PORTS_PinToggle(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function toggles the selected digital pin/latch.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsWrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Toggles port pin RC4
PLIB_PORTS_PinToggle(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void PLIB_PORTS_PinToggle(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

PLIB_PORTS_PinWrite Function

Writes the selected digital pin/latch.

File

plib_ports.h

C

```
void PLIB_PORTS_PinWrite(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos, bool value);
```

Returns

None.

Description

This function writes to the selected digital pin/latch.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsWrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// write 'one' in port RC4
PLIB_PORTS_PinWrite(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_4, 1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS
value	Value to be written to the specific pin/latch
true	sets the bit, false - clears the bit

Function

void PLIB_PORTS_PinWrite(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos,
bool value)

PLIB_PORTS_PinModePerPortSelect Function

Enables the selected port pin as analog or digital.

File

plib_ports.h

C

```
void PLIB_PORTS_PinModePerPortSelect(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos,
PORTS_PIN_MODE mode);
```

Returns

None.

Description

This function enables the selected port pin as analog or digital.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_PinModeSelect function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPinModePerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Make RC5 pin Analog
PLIB_PORTS_PinModePerPortSelect(PORTS_ID_0, PORT_CHANNEL_C,
                                PORTS_BIT_POS_5, PORTS_PIN_MODE_ANALOG);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	Position in the PORT pins
mode	Possible values of PORTS_PIN_MODE

Function

void PLIB_PORTS_PinModePerPortSelect(PORTS_MODULE_ID index,
PORTS_CHANNEL channel, PORTS_BIT_POS bitPos,
PORTS_PIN_MODE mode);

PLIB_PORTS_PinGetLatched Function

Reads/Gets data from the selected latch.

File

plib_ports.h

C

```
bool PLIB_PORTS_PinGetLatched(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

Latch read data.

Description

This function reads/gets data from the selected PORTx Data Latch, not from the port I/O pins.

Remarks

For reading the Live data from the i/o pin, PLIB_PORTS_PinGet function should be used.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsLatchRead in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// read latch RC4
bool bitStatus = PLIB_PORTS_PinGetLatched(PORTS_ID_0, PORT_CHANNEL_C,
                                                      PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

bool PLIB_PORTS_PinGetLatched(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

PLIB_PORTS_PinChangeNoticeEdgeHasOccurred Function

Check Change Notice edge status.

File

plib_ports.h

C

```
bool PLIB_PORTS_PinChangeNoticeEdgeHasOccurred(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS
bitPos);
```

Returns

- true - Change Notice edge transition has occurred
- false - Change Notice edge transition has not occurred

Description

This function checks whether or no a Change Notice edge transition has occurred on the selected port pin.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeEdgeStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Check if Change Notice edge transition has occurred for pin RC1.
if (PLIB_PORTS_PinChangeNoticeEdgeHasOccurred(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_1))
{
```

```
    // do something
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	One of the possible values of PORTS_BIT_POS

Function

bool PLIB_PORTS_PinChangeNoticeEdgeHasOccurred

```
(
    PORTS_MODULE_ID index,
    PORTS_CHANNEL channel,
    PORTS_BIT_POS bitPos
);
```

PLIB_PORTS_PinChangeNoticeEdgeIsEnabled Function

Check if Change Notice edge is enabled or not.

File

plib_ports.h

C

```
bool PLIB_PORTS_PinChangeNoticeEdgeIsEnabled(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS
bitPos, PORTS_CHANGE_NOTICE_EDGE cnEdgeType);
```

Returns

- true - Selected type of Change Notice Edge is enabled.
- false - Selected type of Change Notice Edge is not enabled.

Description

This function checks if selected type of Change Notice edge is enabled on a particular port pin or not.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeEdgeControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Check if Change Notice at rising edge is enabled or not for pin RC1.
if (PLIB_PORTS_PinChangeNoticeEdgeIsEnabled(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_1,
PORTS_CHANGE_NOTICE_EDGE_RISING))
{
    // do something
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	One of the possible values of PORTS_BIT_POS.
cnEdgeType	Type of the edge which has to be checked.

Function

bool PLIB_PORTS_PinChangeNoticeEdgeIsEnabled

```
(
    PORTS_MODULE_ID index,
```

```
    PORTS_CHANNEL channel,
    PORTS_BIT_POS bitPos,
    PORTS_CHANGE_NOTICE_EDGE  cnEdgeType
);
```

PLIB_PORTS_PinSlewRateGet Function

Gets the slew rate for selected port pin.

File

plib_ports.h

C

```
PORTS_PIN_SLEW_RATE PLIB_PORTS_PinSlewRateGet(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS
bitPos);
```

Returns

One of the possible values of PORTS_PIN_SLEW_RATE.

Description

This function gets the slew rate of selected port pin.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsSlewRateControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PORTS_PIN_SLEW_RATE slewRate;

// Get the slew rate of pin RC1
slewRate = PLIB_PORTS_PinSlewRateGet(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	One of the possible values of PORTS_BIT_POS.

Function

```
PORTS_PIN_SLEW_RATE PLIB_PORTS_PinSlewRateGet
(
    PORTS_MODULE_ID  index,
    PORTS_CHANNEL channel,
    PORTS_BIT_POS bitPos
);
```

PLIB_PORTS_PinOpenDrainDisable Function

Disables the open drain functionality for the selected pin.

File

plib_ports.h

C

```
void PLIB_PORTS_PinOpenDrainDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function disables the open drain functionality for the selected pin.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsOpenDrain in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable open drain for pin RC4
PLIB_PORTS_PinOpenDrainDisable(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	One of the possible values of PORTS_BIT_POS.

Function

void PLIB_PORTS_PinOpenDrainDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

PLIB_PORTS_PinOpenDrainEnable Function

Enables the open drain functionality for the selected pin.

File

plib_ports.h

C

```
void PLIB_PORTS_PinOpenDrainEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function enables the open drain functionality for the selected pin.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsOpenDrain in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable open drain for pin RC4
PLIB_PORTS_PinOpenDrainEnable(PORTS_ID_0, PORT_CHANNEL_C, PORTS_BIT_POS_4);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
bitPos	Possible values of PORTS_BIT_POS

Function

void PLIB_PORTS_PinOpenDrainEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos)

b) Port Functions

PLIB_PORTS_Clear Function

Clears the selected digital port/latch bits.

File

plib_ports.h

C

```
void PLIB_PORTS_Clear(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK clearMask);
```

Returns

None.

Description

This function clears the selected digital port/latch bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsWrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Clears the three least significant Port C bits
PLIB_PORTS_Clear(PORTS_ID_0, PORT_CHANNEL_C, 0x0007);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
clearMask	Identifies the bits to be cleared

Function

void PLIB_PORTS_Clear(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK clearMask)

PLIB_PORTS_DirectionGet Function

Reads the direction of the selected digital port.

File

plib_ports.h

C

```
PORTS_DATA_MASK PLIB_PORTS_DirectionGet(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

Direction of the selected port of type PORTS_DATA_MASK

Description

This function reads the direction of the selected digital port.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsDirection in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Reads the direction of Port C pins
PORTS_DATA_MASK readDir = PLIB_PORTS_DirectionGet(PORTS_ID_0, PORT_CHANNEL_C);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.

Function

PORTS_DATA_MASK PLIB_PORTS_DirectionGet(PORTS_MODULE_ID index, PORTS_CHANNEL channel)

PLIB_PORTS_DirectionInputSet Function

Makes the selected pins direction input.

File

plib_ports.h

C

```
void PLIB_PORTS_DirectionInputSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function makes the selected pins direction input.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsDirection in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Make RC0, RC1 and RC2 pins as Input
PLIB_PORTS_DirectionInputSet(PORTS_ID_0, PORT_CHANNEL_C, 0x0007);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
mask	Identifies the pins direction that has to be made input

Function

void PLIB_PORTS_DirectionInputSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask)

PLIB_PORTS_DirectionOutputSet Function

Makes the selected pins direction output.

File

plib_ports.h

C

```
void PLIB_PORTS_DirectionOutputSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function makes the selected pins direction output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsDirection in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Make RC0, RC1 and RC2 pins as Output
PLIB_PORTS_DirectionOutputSet(PORTS_ID_0, PORT_CHANNEL_C, 0x0007);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
mask	Identifies the pins direction that has to be made output

Function

void PLIB_PORTS_DirectionOutputSet(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask)

PLIB_PORTS_Read Function

Reads the selected digital port.

File

plib_ports.h

C

```
PORTS_DATA_TYPE PLIB_PORTS_Read(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

data on a port with width PORTS_DATA_TYPE

Description

This function reads from the selected digital port.

Remarks

For reading the Latched data, PLIB_PORTS_ReadLatched function should be used.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsRead in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Read PORT C
PORTS_DATA_TYPE readData = PLIB_PORTS_Read(PORTS_ID_0, PORT_CHANNEL_C);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.

Function

PORTS_DATA_TYPE PLIB_PORTS_Read(PORTS_MODULE_ID index, PORTS_CHANNEL channel)

PLIB_PORTS_Set Function

Sets the selected bits of the port.

File

plib_ports.h

C

```
void PLIB_PORTS_Set(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_TYPE value, PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function performs an 'AND' operation on the value and mask parameters, and then sets the bits in the port channel that were set by the result of the 'AND' operation.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsWrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// MY_VALUE - 0x1234
PORTS_DATA_MASK myMask = (PORTS_DATA_MASK)0x00FF;

// Set the PORT C bit positions 2,4 and 5 (0x0034 = b0000 0000 0011 0100)
PLIB_PORTS_Set(MY_PORTS_INSTANCE, PORT_CHANNEL_C, MY_VALUE, myMask);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
value	Consists of information about which port bit has to be set and which not
mask	Identifies the bits which could be intended for setting

Function

void PLIB_PORTS_Set(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_TYPE value,
PORTS_DATA_MASK mask)

PLIB_PORTS_Toggle Function

Toggles the selected digital port/latch.

File

plib_ports.h

C

```
void PLIB_PORTS_Toggle(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK toggleMask);
```

Returns

None.

Description

This function toggles the selected digital port/latch.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsWrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Toggles the three least significant Port C bits
PLIB_PORTS_Toggle(PORTS_ID_0, PORT_CHANNEL_C, 0x0007);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
toggleMask	Identifies the bits to be toggled

Function

void PLIB_PORTS_Toggle(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK toggleMask)

PLIB_PORTS_Write Function

Writes the selected digital port/latch.

File

plib_ports.h

C

```
void PLIB_PORTS_Write(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_TYPE value);
```

Returns

None.

Description

This function writes to the selected digital port/latch.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsWrite in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Write 0x12 into PORT C
PLIB_PORTS_Write(PORTS_ID_0, PORT_CHANNEL_C, 0x12);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

channel	Identifier for the Ports channel A, B, C, etc.
value	Value to be written into a port of width PORTS_DATA_TYPE

Function

void PLIB_PORTS_Write(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_TYPE value)

PLIB_PORTS_OpenDrainDisable Function

Disables the open drain functionality for the selected port.

File

plib_ports.h

C

```
void PLIB_PORTS_OpenDrainDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function disables the open drain functionality for the selected port.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsOpenDrain in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable Open Drain for RC0, RC1 and RC2 pins
PLIB_PORTS_OpenDrainDisable(PORTS_ID_0, PORT_CHANNEL_C, 0x0007);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
mask	Identifies the pins for the open drain to be disabled

Function

void PLIB_PORTS_OpenDrainDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask)

PLIB_PORTS_OpenDrainEnable Function

Enables the open drain functionality for the selected port pins.

File

plib_ports.h

C

```
void PLIB_PORTS_OpenDrainEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function enables the open drain functionality for the selected port pins.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPortsOpenDrain in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable Open Drain for RC0, RC1 and RC2 pins
PLIB_PORTS_OpenDrainEnable(PORTS_ID_0, PORT_CHANNEL_C, 0x0007);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.
mask	Identifies the pins for the open drain to be enabled

Function

void PLIB_PORTS_OpenDrainEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask)

PLIB_PORTS_ReadLatched Function

Reads and returns data from the selected Latch.

File

plib_ports.h

C

```
PORTS_DATA_TYPE PLIB_PORTS_ReadLatched(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

Latch read data.

Description

This function reads and returns the data from the selected Latch.

Remarks

For reading the Live data, PLIB_PORTS_Read function should be used.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsLatchRead in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Read latch C
PORTS_DATA_TYPE bitStatus = PLIB_PORTS_ReadLatched(PORTS_ID_0, PORT_CHANNEL_C);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Identifier for the Ports channel A, B, C, etc.

Function

PORTS_DATA_TYPE PLIB_PORTS_ReadLatched
(
PORTS_MODULE_ID index,
PORTS_CHANNEL channel
)

PLIB_PORTS_ChannelModeSelect Function

Enables the selected channel pins as analog or digital.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelModeSelect(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK modeMask,
PORTS_PIN_MODE mode);
```

Returns

None.

Description

This function enables the selected channel pins as analog or digital.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_AnPinsModeSelect function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPinModePerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Make pins RC5, RC8 and RC13 Analog
PLIB_PORTS_ChannelModeSelect(PORTS_ID_0, PORT_CHANNEL_C, 0x2120, PORTS_PIN_MODE_ANALOG);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
modeMask	Identifies the pins whose mode has to be modified. Modes of the pins whose corresponding bit is '1' get modified, mode of the other pins remains the same.
mode	Possible values of PORTS_PIN_MODE (Analog or Digital)

Function

void PLIB_PORTS_ChannelModeSelect

(

PORTS_MODULE_ID index,

PORTS_CHANNEL channel,

PORTS_DATA_MASK modeMask,

PORTS_PIN_MODE mode

);

PLIB_PORTS_ChannelSlewRateSelect Function

Selects the slew rate for selected channel pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelSlewRateSelect(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK
channelMask, PORTS_PIN_SLEW_RATE slewRate);
```

Returns

None.

Description

This function selects the slew rate for selected channel pins.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsSlewRateControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Make slew rate of pins RC5, RC8 and RC13 slowest
PLIB_PORTS_ChannelSlewRateSelect(PORTS_ID_0,
                                 PORT_CHANNEL_C,
                                 0x2120,
                                 PORTS_PIN_SLEW_RATE_SLOWEST);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
channelMask	Identifies the pins for which slew rate has to be modified. Slew rate of the pins which corresponding bit is "1" get modified, slew rate of the other pins remains the same.
slewRate	One of the possible values of PORTS_PIN_SLEW_RATE.

Function

void PLIB_PORTS_ChannelSlewRateSelect

(

PORTS_MODULE_ID index,

PORTS_CHANNEL channel,

PORTS_DATA_MASK channelMask,

PORTS_PIN_SLEW_RATE slewRate

);

c) Peripheral Pin Select Functions

PLIB_PORTS_RemapInput Function

Input function remapping.

File

plib_ports.h

C

```
void PLIB_PORTS_RemapInput(PORTS_MODULE_ID index, PORTS_REMAP_INPUT_FUNCTION inputFunction,
PORTS_REMAP_INPUT_PIN remapInputPin);
```

Returns

None.

Description

This function controls the Input function remapping. It allows user to map any of the input functionality on any of the remappable input pin.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsRemapInputOutput in your application to determine whether this feature is available.

Preconditions

IOLOCK bit of configuration register should be clear to allow any remapping. PLIB_DEVCON_DeviceRegistersUnlock function can be used for that purpose. Refer DEVCON PLIB (or System Service) and the specific device data sheet to find more information.

Example

```
// System Unlock
PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);
// Unlock PPS registers
PLIB_DEVCON_DeviceRegistersUnlock(DEVCON_ID_0, DEVCON_PPS_REGISTERS);
// Remapping input function 'Input Capture 1' to the Remappable pin 'RPD2'
PLIB_PORTS_RemapInput(PORTS_ID_0, INPUT_FUNC_IC1, INPUT_PIN_RPD2 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
inputFunction	One of the possible values of PORTS_REMAP_INPUT_FUNCTION
remapInputPin	One of the possible values of PORTS_REMAP_INPUT_PIN

Function

void PLIB_PORTS_RemapInput(PORTS_MODULE_ID index,
PORTS_REMAP_INPUT_FUNCTION inputFunction,
PORTS_REMAP_INPUT_PIN remapInputPin);

PLIB_PORTS_RemapOutput Function

Output function remapping.

File

plib_ports.h

C

```
void PLIB_PORTS_RemapOutput(PORTS_MODULE_ID index, PORTS_REMAP_OUTPUT_FUNCTION outputFunction,
PORTS_REMAP_OUTPUT_PIN remapOutputPin);
```

Returns

None.

Description

This function controls the Output function remapping. it allows user to map any of the output functionality on any of the remappable output pin.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsRemapInputOutput in your application to determine whether this feature is available.

Preconditions

IOLOCK bit of configuration register should be clear to allow any remapping. PLIB_DEVCON_DeviceRegistersUnlock function can be used for that purpose. Refer DEVCON PLIB (or System Service) and the specific device data sheet to find more information.

Example

```
// System Unlock
PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);
// Unlock PPS registers
PLIB_DEVCON_DeviceRegistersUnlock(DEVCON_ID_0, DEVCON_PPS_REGISTERS);
// Remapping output function 'UART3 Transmit' to the Remappable pin 'RPA14'
PLIB_PORTS_RemapOutput(PORTS_ID_0, OUTPUT_FUNC_U3TX, OUTPUT_PIN_RPA14);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
outputFunction	One of the possible values of PORTS_REMAP_OUTPUT_FUNCTION
remapOutputPin	One of the possible values of PORTS_REMAP_OUTPUT_PIN

Function

void PLIB_PORTS_RemapOutput(PORTS_MODULE_ID index,
PORTS_REMAP_OUTPUT_FUNCTION outputFunction,
PORTS_REMAP_OUTPUT_PIN remapOutputPin);

d) Change Notification Functions

PLIB_PORTS_ChangeNoticeDisable Function

Global Change Notice disable.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticeDisable(PORTS_MODULE_ID index);
```

Returns

None.

Description

This function disables the global Change Notice feature.

Remarks

This function is only available in devices without PPS. For PPS devices, use the PLIB_PORTS_ChangeNoticePerPortTurnOff function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNotice in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable Change Notification
PLIB_PORTS_ChangeNoticeDisable(PORTS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PORTS_ChangeNoticeDisable(PORTS_MODULE_ID index)

PLIB_PORTS_ChangeNoticeEnable Function

Global Change Notice enable.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticeEnable(PORTS_MODULE_ID index);
```

Returns

None.

Description

This function enables the global Change Notice feature.

Remarks

This function is only available in devices without PPS. For PPS devices, use the PLIB_PORTS_ChangeNoticePerPortTurnOn function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNotice in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable Change Notification
PLIB_PORTS_ChangeNoticeEnable(PORTS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PORTS_ChangeNoticeEnable(PORTS_MODULE_ID index)

PLIB_PORTS_ChangeNoticeInIdleDisable Function

CPU Idle halts the Change Notice operation.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticeInIdleDisable(PORTS_MODULE_ID index);
```

Returns

None.

Description

This function halts the Change Notice operation when the CPU enters Idle mode.

Remarks

This function is only available in devices without PPS. For PPS devices, use the PLIB_PORTS_ChangeNoticeInIdlePerPortDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Halts the Change notification operation when CPU enters Idle mode
PLIB_PORTS_ChangeNoticeInIdleDisable(PORTS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PORTS_ChangeNoticeInIdleDisable(PORTS_MODULE_ID index)

PLIB_PORTS_ChangeNoticeInIdleEnable Function

CPU Idle mode does not affect Change Notice operation.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticeInIdleEnable(PORTS_MODULE_ID index);
```

Returns

None.

Description

This function makes sure that Change Notice feature continues working in Idle mode.

Remarks

This function is only available in devices without PPS. For PPS devices, use the PLIB_PORTS_ChangeNoticeInIdlePerPortEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Change notification feature will be working even when CPU goes to
// Idle mode
PLIB_PORTS_ChangeNoticeInIdleEnable(PORTS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_PORTS_ChangeNoticeInIdleEnable(PORTS_MODULE_ID index)

PLIB_PORTS_ChangeNoticeInIdlePerPortDisable Function

Change Notification halts in Idle mode for selected channel.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticeInIdlePerPortDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

None.

Description

This function makes sure that change notification feature halts in Idle mode for the selected channel.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_ChangeNoticeInIdleDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePerPortInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Change notification halts in Idle mode for Port C
PLIB_PORTS_ChangeNoticeInIdlePerPortDisable(PORTS_ID_0, PORT_CHANNEL_C);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel

Function

void PLIB_PORTS_ChangeNoticeInIdlePerPortDisable(PORTS_MODULE_ID index,
PORTS_CHANNEL channel);

PLIB_PORTS_ChangeNoticeInIdlePerPortEnable Function

Allows CN to be working in Idle mode for selected channel.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticeInIdlePerPortEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

None.

Description

This function makes sure that change notification feature keeps working in Idle mode for the selected channel.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_ChangeNoticeInIdleEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePerPortInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Change notification continues working in Idle mode for Port C
PLIB_PORTS_ChangeNoticeInIdlePerPortEnable(PORTS_ID_0, PORT_CHANNEL_C);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel

Function

void PLIB_PORTS_ChangeNoticeInIdlePerPortEnable (PORTS_MODULE_ID index,
PORTS_CHANNEL channel);

PLIB_PORTS_ChangeNoticePerPortHasOccured Function

File

plib_ports.h

C

```
bool PLIB_PORTS_ChangeNoticePerPortHasOccured(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);
```

Description

This is function PLIB_PORTS_ChangeNoticePerPortHasOccured.

PLIB_PORTS_ChangeNoticePerPortTurnOff Function

Disables the change notification for selected port.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticePerPortTurnOff(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

None.

Description

This function disables the change notification for selected port.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_ChangeNoticeDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePerPortTurnOn in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable Change notification for Port C
PLIB_PORTS_ChangeNoticePerPortTurnOff(PORTS_ID_0, PORT_CHANNEL_C);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel

Function

void PLIB_PORTS_ChangeNoticePerPortTurnOff(PORTS_MODULE_ID index,
PORTS_CHANNEL channel);

PLIB_PORTS_ChangeNoticePerPortTurnOn Function

Enables the change notification for selected port.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticePerPortTurnOn(PORTS_MODULE_ID index, PORTS_CHANNEL channel);
```

Returns

None.

Description

This function enables the change notification for selected port.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_ChangeNoticeEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePerPortTurnOn in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable Change notification for Port C
PLIB_PORTS_ChangeNoticePerPortTurnOn(PORTS_ID_0, PORT_CHANNEL_C);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel

Function

void PLIB_PORTS_ChangeNoticePerPortTurnOn (PORTS_MODULE_ID index,
PORTS_CHANNEL channel);

PLIB_PORTS_ChangeNoticePullDownPerPortDisable Function

Disables the pull-down for selected Change Notice pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticePullDownPerPortDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function disables the pull-down for selected Change Notice pins.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullDownPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable pull-down for RC5 pin
PLIB_PORTS_ChangeNoticePullDownPerPortDisable(PORTS_ID_0, PORT_CHANNEL_C,
                                                PORTS_BIT_POS_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	Position in the PORT pins

Function

void PLIB_PORTS_ChangeNoticePullDownPerPortDisable(PORTS_MODULE_ID index,
PORTS_CHANNEL channel, PORTS_BIT_POS bitPos)

PLIB_PORTS_ChangeNoticePullDownPerPortEnable Function

Enables the pull-down for selected Change Notice pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticePullDownPerPortEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function enables the pull-down for selected Change Notice pins.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullDownPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable pull-down for RC5 pin
PLIB_PORTS_ChangeNoticePullDownPerPortEnable(PORTS_ID_0, PORT_CHANNEL_C,
                                                        PORTS_BIT_POS_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	Position in the PORT pins

Function

void PLIB_PORTS_ChangeNoticePullDownPerPortEnable(PORTS_MODULE_ID index,
PORTS_CHANNEL channel, PORTS_BIT_POS bitPos)

PLIB_PORTS_ChangeNoticePullUpDisable Function

Disable pull-up on input change.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticePullUpDisable(PORTS_MODULE_ID index, PORTS_CHANGE_NOTICE_PIN pinNum);
```

Returns

None.

Description

This function disables pull-up on selected input change notification pin.

Remarks

This function is only available in devices without PPS. For PPS devices, use the PLIB_PORTS_ChangeNoticePullUpPerPortDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullUp in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable pull-up on pin CN13
PLIB_PORTS_ChangeNoticePullUpDisable(PORTS_ID_0, CN13);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

pinNum	Possible values of PORTS_CHANGE_NOTICE_PIN

Function

void PLIB_PORTS_ChangeNoticePullUpDisable(PORTS_MODULE_ID index,
PORTS_CHANGE_NOTICE_PIN pinNum)

PLIB_PORTS_ChangeNoticePullUpEnable Function

Enable pull-up on input change.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticePullUpEnable(PORTS_MODULE_ID index, PORTS_CHANGE_NOTICE_PIN pinNum);
```

Returns

None.

Description

This function enables pull-up on selected input change notification pin

Remarks

This function is only available in devices without PPS. For PPS devices, use the PLIB_PORTS_ChangeNoticePullUpPerPortEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullUp in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable pull-up on pin CN13
PLIB_PORTS_ChangeNoticePullUpEnable(PORTS_ID_0, CN13);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pinNum	Possible values of PORTS_CHANGE_NOTICE_PIN

Function

void PLIB_PORTS_ChangeNoticePullUpEnable(PORTS_MODULE_ID index,
PORTS_CHANGE_NOTICE_PIN pinNum)

PLIB_PORTS_ChangeNoticePullUpPerPortDisable Function

Disables weak pull-up for the selected pin.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticePullUpPerPortDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_BIT_POS bitPos);
```

Returns

None.

Description

This function disables weak pull-up for the selected port pin.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_ChangeNoticePullUpDisable function.

Pull-ups on change notification pins should always be disabled when the port pin is configured as a digital output.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullUpPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable pull-up for RC5 pin
PLIB_PORTS_ChangeNoticePullUpPerPortDisable(PORTS_ID_0, PORT_CHANNEL_C,
                                                        PORTS_BIT_POS_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	Position in the PORT pins

Function

void PLIB_PORTS_ChangeNoticePullUpPerPortDisable(PORTS_MODULE_ID index,
PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);

PLIB_PORTS_ChangeNoticePullUpPerPortEnable Function

Enables the pull-up for selected Change Notice pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChangeNoticePullUpPerPortEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS
bitPos);
```

Returns

None.

Description

This function enables the pull-up for selected Change Notice pins.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_ChangeNoticePullUpEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullUpPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable pull-up for RC5 pin
PLIB_PORTS_ChangeNoticePullUpPerPortEnable(PORTS_ID_0, PORT_CHANNEL_C,
                                                        PORTS_BIT_POS_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	Position in the PORT pins

Function

void PLIB_PORTS_ChangeNoticePullUpPerPortEnable (PORTS_MODULE_ID index,
PORTS_CHANNEL channel, PORTS_BIT_POS bitPos)

PLIB_PORTS_PinChangeNoticeDisable Function

Port pin Change Notice disable.

File

plib_ports.h

C

```
void PLIB_PORTS_PinChangeNoticeDisable(PORTS_MODULE_ID index, PORTS_CHANGE_NOTICE_PIN pinNum);
```

Returns

None.

Description

This function disables the port pin Change Notice feature.

Remarks

This function is only available in devices without PPS. For PPS devices, use the PLIB_PORTS_PinChangeNoticePerPortDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPinChangeNotice in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable Change Notice interrupt for pin CN13
PLIB_PORTS_PinChangeNoticeDisable(PORTS_ID_0, CN13);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pinNum	Possible values of PORTS_CHANGE_NOTICE_PIN

Function

void PLIB_PORTS_PinChangeNoticeDisable(PORTS_MODULE_ID index,
PORTS_CHANGE_NOTICE_PIN pinNum)

PLIB_PORTS_PinChangeNoticeEnable Function

Port pin Change Notice interrupt enable.

File

plib_ports.h

C

```
void PLIB_PORTS_PinChangeNoticeEnable(PORTS_MODULE_ID index, PORTS_CHANGE_NOTICE_PIN pinNum);
```

Returns

None.

Description

This function enables the port pin Change Notice feature.

Remarks

This function is only available in devices without PPS. For PPS devices, use the PLIB_PORTS_PinChangeNoticePerPortEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use

PLIB_PORTS_ExistsPinChangeNotice in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable Change Notice interrupt for pin CN13
PLIB_PORTS_PinChangeNoticeEnable(PORTS_ID_0, CN13);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pinNum	Possible values of PORTS_CHANGE_NOTICE_PIN

Function

void PLIB_PORTS_PinChangeNoticeEnable(PORTS_MODULE_ID index,
PORTS_CHANGE_NOTICE_PIN pinNum)

PLIB_PORTS_PinChangeNoticePerPortDisable Function

Disables CN interrupt for the selected pin.

File

plib_ports.h

C

```
void PLIB_PORTS_PinChangeNoticePerPortDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS
bitPos);
```

Returns

None.

Description

This function disables Change Notice interrupt for the selected port pin.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_PinChangeNoticeDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeIntPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable CN interrupt for RC5 pin
PLIB_PORTS_PinChangeNoticePerPortDisable(PORTS_ID_0, PORT_CHANNEL_C,
                                                    PORTS_BIT_POS_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	Position in the PORT pins

Function

void PLIB_PORTS_PinChangeNoticePerPortDisable(PORTS_MODULE_ID index,
PORTS_CHANNEL channel, PORTS_BIT_POS bitPos)

PLIB_PORTS_PinChangeNoticePerPortEnable Function

Enables CN interrupt for the selected pin.

File

plib_ports.h

C

```
void PLIB_PORTS_PinChangeNoticePerPortEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS
bitPos);
```

Returns

None.

Description

This function enables Change Notice interrupt for the selected port pin.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_PinChangeNoticeEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeIntPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable CN interrupt for RC5 pin
PLIB_PORTS_PinChangeNoticePerPortEnable(PORTS_ID_0, PORT_CHANNEL_C,
                                                    PORTS_BIT_POS_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	Position in the PORT pins

Function

void PLIB_PORTS_PinChangeNoticePerPortEnable (PORTS_MODULE_ID index,
PORTS_CHANNEL channel, PORTS_BIT_POS bitPos)

PLIB_PORTS_ChangeNoticePerPortHasOccurred Function

checks the status of change on the pin

File

plib_ports.h

C

```
bool PLIB_PORTS_ChangeNoticePerPortHasOccurred(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_BIT_POS
bitPos);
```

Returns

None.

Description

This function checks if the change has occurred on the given pin or not.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePerPortStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_PORTS_ChangeNoticePerPortHasOccurred( PORTS_ID_0,
                                PORT_CHANNEL_C, PORTS_BIT_POS_4 ) == True)
{
 //do something
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
bitPos	Position in the PORT pins

Function

bool PLIB_PORTS_ChangeNoticePerPortHasOccurred (PORTS_MODULE_ID index,
PORTS_CHANNEL channel, PORTS_BIT_POS bitPos);

PLIB_PORTS_ChannelChangeNoticeDisable Function

Disables CN interrupt for the selected pins of a channel.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticeDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK
mask);
```

Returns

None.

Description

This function Disables Change Notice interrupt for the selected port pins of a channel.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_CnPinsDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeIntPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable CN interrupt for RC5, RC8 and RC13 pins
PLIB_PORTS_ChannelChangeNoticeDisable(PORTS_ID_0, PORT_CHANNEL_C, 0x2120);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
mask	Identifies the pins for which change notification is to be disabled

Function

void PLIB_PORTS_ChannelChangeNoticeDisable
(
PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_DATA_MASK mask
);

PLIB_PORTS_ChannelChangeNoticeEnable Function

Enables CN interrupt for the selected pins of a channel.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticeEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK
mask);
```

Returns

None.

Description

This function enables Change Notice interrupt for the selected port pins of a channel.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_CnPinsEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeIntPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable CN interrupt for RC5, RC8 and RC13 pins
PLIB_PORTS_ChannelChangeNoticeEnable(PORTS_ID_0, PORT_CHANNEL_C, 0x2120);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
mask	Identifies the pins for which change notification is to be enabled

Function

void PLIB_PORTS_ChannelChangeNoticeEnable

(

PORTS_MODULE_ID index,

PORTS_CHANNEL channel,

PORTS_DATA_MASK mask

);

PLIB_PORTS_ChannelChangeNoticePullDownDisable Function

Disables Change Notice pull-down for the selected channel pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticePullDownDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function Disables the Change Notice pull-down for the selected channel pins.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullDownPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable pull-down for RC5, RC8 and RC13 pins
PLIB_PORTS_ChannelChangeNoticePullDownDisable(PORTS_ID_0, PORT_CHANNEL_C,
                                                0x2120);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
mask	Identifies the pins for the pull-down to be disabled

Function

void PLIB_PORTS_ChannelChangeNoticePullDownDisable

(

PORTS_MODULE_ID index,

PORTS_CHANNEL channel,

PORTS_DATA_MASK mask

);

PLIB_PORTS_ChannelChangeNoticePullDownEnable Function

Enables Change Notice pull-down for the selected channel pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticePullDownEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function enables the Change Notice pull-down for the selected channel pins.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullDownPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable pull-down for RC5, RC8 and RC13 pins
PLIB_PORTS_ChannelChangeNoticePullDownEnable(PORTS_ID_0, PORT_CHANNEL_C,
                                                0x2120);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
mask	Identifies the pins for the pull-down to be enabled

Function

void PLIB_PORTS_ChannelChangeNoticePullDownEnable
(
PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_DATA_MASK mask
);

PLIB_PORTS_ChannelChangeNoticePullUpDisable Function

Disables Change Notice pull-up for the selected channel pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticePullUpDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function Disables the Change Notice pull-up for the selected channel pins.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_CnPinsPullUpDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullUpPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable pull-up for RC5, RC8 and RC13 pins
PLIB_PORTS_ChannelChangeNoticePullUpDisable(PORTS_ID_0, PORT_CHANNEL_C,
                                                        0x2120);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
mask	Identifies the pins of the pull-up to be disabled

Function

void PLIB_PORTS_ChannelChangeNoticePullUpDisable
(
PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_DATA_MASK mask
);

PLIB_PORTS_ChannelChangeNoticePullUpEnable Function

Enables Change Notice pull-up for the selected channel pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticePullUpEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK mask);
```

Returns

None.

Description

This function enables the Change Notice pull-up for the selected channel pins.

Remarks

This function is only available in devices with PPS. For Non-PPS devices, use the PLIB_PORTS_CnPinsPullUpEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullUpPerPort in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable pull-up for RC5, RC8 and RC13 pins
PLIB_PORTS_ChannelChangeNoticePullUpEnable(PORTS_ID_0, PORT_CHANNEL_C,
                                                       0x2120);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
mask	Identifies the pins of the pull-up to be enabled

Function

void PLIB_PORTS_ChannelChangeNoticePullUpEnable

(

PORTS_MODULE_ID index,

PORTS_CHANNEL channel,

PORTS_DATA_MASK mask

);

PLIB_PORTS_ChannelChangeNoticeEdgeDisable Function

Disables selected type of edge for selected CN pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticeEdgeDisable(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_DATA_MASK edgeRisingMask, PORTS_DATA_MASK edgeFallingMask);
```

Returns

None.

Description

This function Disables selected type of edge (falling or rising) for selected CN pins of a port channel.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeEdgeControl in your application to determine whether this feature is available.

Preconditions

Change Notice method should be selected as "PORTS_CHANGE_NOTICE_METHOD_EDGE_DETECT" using PLIB_PORTS_ChannelChangeNoticeMethodSelect before using this function.

Example

```
// Disable Change Notice at rising edge for RC1 pin and at falling edge for
// RC1 & RC5 pins.
PLIB_PORTS_ChannelChangeNoticeEdgeDisable(PORTS_ID_0, PORT_CHANNEL_C, 0x0002, 0x0022);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
edgeRisingMask	Identifies the pins for which Change Notice has to be enabled for rising edge. Change notice interrupt at rising edge is enabled for the pins which corresponding bit is '1', for the other pins it remains the same.
edgeFallingMask	Identifies the pins for which Change Notice has to be enabled for falling edge. Change notice interrupt at falling edge is enabled for the pins which corresponding bit is '1', for the other pins it remains the same.

Function

void PLIB_PORTS_ChannelChangeNoticeEdgeDisable

(

PORTS_MODULE_ID index,

PORTS_CHANNEL channel,

PORTS_DATA_MASK edgeRisingMask,

PORTS_DATA_MASK edgeFallingMask

);

PLIB_PORTS_ChannelChangeNoticeEdgeEnable Function

Enables selected type of edge for selected CN pins.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticeEdgeEnable(PORTS_MODULE_ID index, PORTS_CHANNEL channel, PORTS_DATA_MASK
edgeRisingMask, PORTS_DATA_MASK edgeFallingMask);
```

Returns

None.

Description

This function Enables selected type of edge (falling or rising) for selected CN pins of a port channel.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticeEdgeControl in your application to determine whether this feature is available.

Preconditions

Change Notice method should be selected as "PORTS_CHANGE_NOTICE_METHOD_EDGE_DETECT" using PLIB_PORTS_ChannelChangeNoticeMethodSelect before using this function.

Example

```
// Enable Change Notice at rising edge for RC1 pin and at falling edge for
// RC1 & RC5 pins.
PLIB_PORTS_ChannelChangeNoticeEdgeEnable(PORTS_ID_0, PORT_CHANNEL_C, 0x0002, 0x0022);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel

edgeRisingMask	Identifies the pins for which Change Notice has to be enabled for rising edge. Change Notice interrupt at rising edge is enabled for the pins which corresponding bit is '1', for the other pins it remains the same.
edgeFallingMask	Identifies the pins for which Change Notice has to be enabled for falling edge. Change Notice interrupt at falling edge is enabled for the pins which corresponding bit is '1', for the other pins it remains the same.

Function

void PLIB_PORTS_ChannelChangeNoticeEdgeEnable
(
PORTS_MODULE_ID index,
PORTS_CHANNEL channel,
PORTS_DATA_MASK edgeRisingMask,
PORTS_DATA_MASK edgeFallingMask
);

PLIB_PORTS_ChannelChangeNoticeMethodGet Function

Gets the Change Notice style for the selected port channel.

File

plib_ports.h

C

```
PORTS_CHANGE_NOTICE_METHOD PLIB_PORTS_ChannelChangeNoticeMethodGet(PORTS_MODULE_ID index, PORTS_CHANNEL
channel);
```

Returns

One of the possible values of PORTS_CHANGE_NOTICE_METHOD.

Description

This function gets the Change Notice style (or method) for the selected port channel.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChannelChangeNoticeMethod in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PORTS_CHANGE_NOTICE_METHOD changeNoticeMethod;
changeNoticeMethod = PLIB_PORTS_ChannelChangeNoticeMethodGet(PORTS_ID_0,
PORT_CHANNEL_C);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel

Function

PORTS_CHANGE_NOTICE_METHOD PLIB_PORTS_ChannelChangeNoticeMethodGet
(
PORTS_MODULE_ID index,
PORTS_CHANNEL channel
);

PLIB_PORTS_ChannelChangeNoticeMethodSelect Function

Selects the Change Notice style for selected port channel.

File

plib_ports.h

C

```
void PLIB_PORTS_ChannelChangeNoticeMethodSelect(PORTS_MODULE_ID index, PORTS_CHANNEL channel,
PORTS_CHANGE_NOTICE_METHOD changeNoticeMethod);
```

Returns

None.

Description

This function selects the Change Notice style (or method) for selected port channel. It allows user to select whether the Change Notice detection will happen based on edge transition or level transition on all the CN pins of a particular channel.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChannelChangeNoticeMethod in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_PORTS_ChannelChangeNoticeMethodSelect(PORTS_ID_0, PORT_CHANNEL_C,
                                           PORTS_CHANGE_NOTICE_METHOD_EDGE_DETECT);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
channel	Port pin channel
changeNoticeMethod	One of the possible values of PORTS_CHANGE_NOTICE_METHOD.

Function

void PLIB_PORTS_ChannelChangeNoticeMethodSelect

(

PORTS_MODULE_ID index,

PORTS_CHANNEL channel,

PORTS_CHANGE_NOTICE_METHOD changeNoticeMethod

);

PLIB_PORTS_AnPinsModeSelect Function

Enables the selected AN pins as analog or digital.

File

plib_ports.h

C

```
void PLIB_PORTS_AnPinsModeSelect(PORTS_MODULE_ID index, PORTS_AN_PIN anPins, PORTS_PIN_MODE mode);
```

Returns

None.

Description

This function enables the selected AN pins as analog or digital.

Remarks

This function is only available in devices without PPS feature. For PPS devices, use the PLIB_PORTS_ChannelModeSelect function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsAnPinsMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Make pins AN5, AN8 and AN13 Analog
PLIB_PORTS_AnPinsModeSelect(PORTS_ID_0, PORTS_AN_PIN_5 |
                            PORTS_AN_PIN_8 |
                            PORTS_AN_PIN_13,
                            PORTS_PIN_MODE_ANALOG);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
anPins	AN pins whose mode is to be changed. Multiple AN pins can be ORed.
mode	Possible values of PORTS_PIN_MODE (Analog or Digital)

Function

void PLIB_PORTS_AnPinsModeSelect

(

PORTS_MODULE_ID index,

PORTS_AN_PIN anPins,

PORTS_PIN_MODE mode

);

PLIB_PORTS_CnPinsDisable Function

Disables CN interrupt for the selected pins of a channel.

File

plib_ports.h

C

```
void PLIB_PORTS_CnPinsDisable(PORTS_MODULE_ID index, PORTS_CN_PIN cnPins);
```

Returns

None.

Description

This function Disables Change Notice interrupt for the selected port pins of a channel.

Remarks

This function is only available in devices without PPS feature. For PPS devices, use the PLIB_PORTS_ChannelChangeNoticeDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPinChangeNotice in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable CN interrupt for CN5, CN8 and CN13 pins
PLIB_PORTS_CnPinsDisable(PORTS_ID_0,
                         CHANGE_NOTICE_PIN_5 |
                         CHANGE_NOTICE_PIN_8 |
                         CHANGE_NOTICE_PIN_13);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
cnPins	CN pins to be disabled. Multiple CN pins can be ORed.

Function

void PLIB_PORTS_CnPinsDisable
(
PORTS_MODULE_ID index,
PORTS_CN_PIN cnPins
);

PLIB_PORTS_CnPinsEnable Function

Enables CN interrupt for the selected pins of a channel.

File

plib_ports.h

C

```
void PLIB_PORTS_CnPinsEnable(PORTS_MODULE_ID index, PORTS_CN_PIN cnPins);
```

Returns

None.

Description

This function enables Change Notice interrupt for the selected port pins of a channel.

Remarks

This function is only available in devices without PPS feature. For PPS devices, use the PLIB_PORTS_ChannelChangeNoticeEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsPinChangeNotice in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable CN interrupt for CN5, CN8 and CN13 pins
PLIB_PORTS_CnPinsEnable(PORTS_ID_0,
                        CHANGE_NOTICE_PIN_5 |
                        CHANGE_NOTICE_PIN_8 |
                        CHANGE_NOTICE_PIN_13);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
cnPins	CN pins to be enabled. Multiple CN pins can be ORed.

Function

void PLIB_PORTS_CnPinsEnable
(
PORTS_MODULE_ID index,
PORTS_CN_PIN cnPins
);

PLIB_PORTS_CnPinsPullUpDisable Function

Disables Change Notice pull-up for the selected channel pins.

File

plib_ports.h

C

```
void PLIB_PORTS_CnPinsPullUpDisable(PORTS_MODULE_ID index, PORTS_CN_PIN cnPins);
```

Returns

None.

Description

This function Disables the Change Notice pull-up for the selected channel pins.

Remarks

This function is only available in devices without PPS feature. For PPS devices, use the PLIB_PORTS_ChannelChangeNoticePullUpDisable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullUp in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Disable pull-up for CN5, CN8 and CN13 pins
PLIB_PORTS_CnPinsPullUpDisable(PORTS_ID_0,
                               CHANGE_NOTICE_PIN_5 |
                               CHANGE_NOTICE_PIN_8 |
                               CHANGE_NOTICE_PIN_13);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
cnPins	CN pins whose pull-up is to be disabled. Multiple CN pins can be ORed.

Function

void PLIB_PORTS_CnPinsPullUpDisable

(

PORTS_MODULE_ID index,

PORTS_CN_PIN cnPins

);

PLIB_PORTS_CnPinsPullUpEnable Function

Enables Change Notice pull-up for the selected channel pins.

File

plib_ports.h

C

```
void PLIB_PORTS_CnPinsPullUpEnable(PORTS_MODULE_ID index, PORTS_CN_PIN cnPins);
```

Returns

None.

Description

This function enables the Change Notice pull-up for the selected channel pins.

Remarks

This function is only available in devices without PPS feature. For PPS devices, use the PLIB_PORTS_ChannelChangeNoticePullUpEnable function.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_PORTS_ExistsChangeNoticePullUp in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Enable pull-up for CN5, CN8 and CN13 pins
```

```
PLIB_PORTS_CnPinsPullUpEnable(PORTS_ID_0, CHANGE_NOTICE_PIN_5 |
                                          CHANGE_NOTICE_PIN_8 |
                                          CHANGE_NOTICE_PIN_13);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
cnPins	CN pins whose pull-up is to be enabled. Multiple CN pins can be ORed.

Function

void PLIB_PORTS_CnPinsPullUpEnable
(
PORTS_MODULE_ID index,
PORTS_CN_PIN cnPins
);

e) Feature Existence Functions

PLIB_PORTS_ExistsChangeNotice Function

Identifies whether the ChangeNotice feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNotice(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNotice feature is supported on the device
- false - The ChangeNotice feature is not supported on the device

Description

This function identifies whether the ChangeNotice feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChangeNoticeEnable
- PLIB_PORTS_ChangeNoticeDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNotice(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticeInIdle Function

Identifies whether the ChangeNoticeInIdle feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticeInIdle(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticeInIdle feature is supported on the device
- false - The ChangeNoticeInIdle feature is not supported on the device

Description

This function identifies whether the ChangeNoticeInIdle feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChangeNoticeInIdleEnable
- PLIB_PORTS_ChangeNoticeInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticeInIdle(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticePerPortInIdle Function

Identifies whether the ChangeNoticeInIdlePerPort feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticePerPortInIdle(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticeInIdlePerPort feature is supported on the device
- false - The ChangeNoticeInIdlePerPort feature is not supported on the device

Description

This function identifies whether the ChangeNoticeInIdlePerPort feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChangeNoticeInIdlePerPortEnable
- PLIB_PORTS_ChangeNoticeInIdlePerPortDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticePerPortInIdle(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticePerPortStatus Function

Identifies whether the ChangeNoticePerPortStatus feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticePerPortStatus(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticePerPortStatus feature is supported on the device
- false - The ChangeNoticePerPortStatus feature is not supported on the device

Description

This function identifies whether the ChangeNoticePerPortStatus feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChangeNoticePerPortHasOccured
- PLIB_PORTS_ChangeNoticePerPortHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticePerPortStatus(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticePerPortTurnOn Function

Identifies whether the ChangeNoticePerPortTurnOn feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticePerPortTurnOn(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticePerPortTurnOn feature is supported on the device
- false - The ChangeNoticePerPortTurnOn feature is not supported on the device

Description

This function identifies whether the ChangeNoticePerPortTurnOn feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChangeNoticePerPortTurnOn
- PLIB_PORTS_ChangeNoticePerPortTurnOff

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticePerPortTurnOn(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticePullDownPerPort Function

Identifies whether the ChangeNoticePullDownPerPort feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticePullDownPerPort(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticePullDownPerPort feature is supported on the device
- false - The ChangeNoticePullDownPerPort feature is not supported on the device

Description

This function identifies whether the ChangeNoticePullDownPerPort feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChangeNoticePullDownPerPortEnable
- PLIB_PORTS_ChangeNoticePullDownPerPortDisable
- PLIB_PORTS_ChannelChangeNoticePullDownEnable
- PLIB_PORTS_ChannelChangeNoticePullDownDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticePullDownPerPort(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticePullUp Function

Identifies whether the ChangeNoticePullup feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticePullUp(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticePullup feature is supported on the device
- false - The ChangeNoticePullup feature is not supported on the device

Description

This function identifies whether the ChangeNoticePullup feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChangeNoticePullUpEnable

- PLIB_PORTS_ChangeNoticePullUpDisable
- PLIB_PORTS_CnPinsPullUpEnable
- PLIB_PORTS_CnPinsPullUpDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticePullUp(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticePullUpPerPort Function

Identifies whether the ChangeNoticePullUpPerPort feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticePullUpPerPort(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticePullUpPerPort feature is supported on the device
- false - The ChangeNoticePullUpPerPort feature is not supported on the device

Description

This function identifies whether the ChangeNoticePullUpPerPort feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChangeNoticePullUpPerPortEnable
- PLIB_PORTS_ChangeNoticePullUpPerPortDisable
- PLIB_PORTS_ChannelChangeNoticePullUpEnable
- PLIB_PORTS_ChannelChangeNoticePullUpDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticePullUpPerPort(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsPinChangeNotice Function

Identifies whether the PinChangeNotice feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsPinChangeNotice(PORTS_MODULE_ID index);
```

Returns

- true - The PinChangeNotice feature is supported on the device
- false - The PinChangeNotice feature is not supported on the device

Description

This function identifies whether the PinChangeNotice feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_PinChangeNoticeEnable
- PLIB_PORTS_PinChangeNoticeDisable
- PLIB_PORTS_CnPinsEnable
- PLIB_PORTS_CnPinsDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsPinChangeNotice(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsPinChangeNoticePerPort Function

Identifies whether the PinChangeNoticePerPort feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsPinChangeNoticePerPort(PORTS_MODULE_ID index);
```

Returns

- true - The PinChangeNoticePerPort feature is supported on the device
- false - The PinChangeNoticePerPort feature is not supported on the device

Description

This function identifies whether the PinChangeNoticePerPort feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_PinChangeNoticePerPortEnable
- PLIB_PORTS_PinChangeNoticePerPortDisable
- PLIB_PORTS_ChannelChangeNoticeEnable
- PLIB_PORTS_ChannelChangeNoticeDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsPinChangeNoticePerPort(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsPinMode Function

Identifies whether the PinMode feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsPinMode(PORTS_MODULE_ID index);
```

Returns

- true - The PinMode feature is supported on the device
- false - The PinMode feature is not supported on the device

Description

This function identifies whether the PinMode (Analog Pin or Digital Pin) feature is available on the Ports module. When this function returns true, this function is supported on the device:

- PLIB_PORTS_PinModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsPinMode(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsPinModePerPort Function

Identifies whether the PinModePerPort feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsPinModePerPort(PORTS_MODULE_ID index);
```

Returns

- true - The PinModePerPort feature is supported on the device
- false - The PinModePerPort feature is not supported on the device

Description

This function identifies whether the PinModePerPort (Analog Pin or Digital Pin) feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_PinModePerPortSelect
- PLIB_PORTS_ChannelModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsPinModePerPort(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsPortsDirection Function

Identifies whether the PortsDirection feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsPortsDirection(PORTS_MODULE_ID index);
```

Returns

- true - The PortsDirection feature is supported on the device
- false - The PortsDirection feature is not supported on the device

Description

This function identifies whether the PortsDirection feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_PinDirectionInputSet
- PLIB_PORTS_PinDirectionOutputSet
- PLIB_PORTS_DirectionInputSet
- PLIB_PORTS_DirectionOutputSet
- PLIB_PORTS_DirectionGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsPortsDirection(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsPortsOpenDrain Function

Identifies whether the PortsOpenDrain feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsPortsOpenDrain(PORTS_MODULE_ID index);
```

Returns

- true - The PortsOpenDrain feature is supported on the device
- false - The PortsOpenDrain feature is not supported on the device

Description

This function identifies whether the PortsOpenDrain feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_PinOpenDrainEnable
- PLIB_PORTS_PinOpenDrainDisable
- PLIB_PORTS_OpenDrainEnable
- PLIB_PORTS_OpenDrainDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsPortsOpenDrain(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsPortsRead Function

Identifies whether the PortsRead feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsPortsRead(PORTS_MODULE_ID index);
```

Returns

- true - The PortsRead feature is supported on the device
- false - The PortsRead feature is not supported on the device

Description

This function identifies whether the PortsRead feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_PinGet
- PLIB_PORTS_Read

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsPortsRead(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsPortsWrite Function

Identifies whether the PortsWrite feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsPortsWrite(PORTS_MODULE_ID index);
```

Returns

- true - The PortsWrite feature is supported on the device
- false - The PortsWrite feature is not supported on the device

Description

This function identifies whether the PortsWrite feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_PinWrite
- PLIB_PORTS_PinSet
- PLIB_PORTS_PinClear
- PLIB_PORTS_PinToggle
- PLIB_PORTS_Write
- PLIB_PORTS_Set
- PLIB_PORTS_Toggle
- PLIB_PORTS_Clear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsPortsWrite(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsRemapInput Function

Identifies whether the RemapInput feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsRemapInput(PORTS_MODULE_ID index);
```

Returns

- true - The RemapInput feature is supported on the device
- false - The RemapInput feature is not supported on the device

Description

This function identifies whether the RemapInput feature is available on the Ports module. When this function returns true, this function is supported on the device:

- PLIB_PORTS_RemapInput

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsRemapInput(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsRemapOutput Function

Identifies whether the RemapOutput feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsRemapOutput(PORTS_MODULE_ID index);
```

Returns

- true - The RemapOutput feature is supported on the device
- false - The RemapOutput feature is not supported on the device

Description

This function identifies whether the RemapOutput feature is available on the Ports module. When this function returns true, this function is supported on the device:

- PLIB_PORTS_RemapOutput

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsRemapOutput(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsLatchRead Function

Identifies whether the LatchRead feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsLatchRead(PORTS_MODULE_ID index);
```

Returns

- true - The LatchRead feature is supported on the device
- false - The LatchRead feature is not supported on the device

Description

This function identifies whether the LatchRead feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_PinGetLatched
- PLIB_PORTS_ReadLatched

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsLatchRead(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsAnPinsMode Function

Identifies whether the AnPinsMode feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsAnPinsMode(PORTS_MODULE_ID index);
```

Returns

- true - The AnPinsMode feature is supported on the device
- false - The AnPinsMode feature is not supported on the device

Description

This function identifies whether the AnPinsMode feature is available on the Ports module. When this function returns true, this function is supported on the device:

- PLIB_PORTS_AnPinsModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsAnPinsMode(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticeEdgeControl Function

Identifies whether the ChangeNoticeEdgeControl feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticeEdgeControl(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticeEdgeControl feature is supported on the device
- false - The ChangeNoticeEdgeControl feature is not supported on the device

Description

This function identifies whether the ChangeNoticeEdgeControl feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChannelChangeNoticeEdgeEnable
- PLIB_PORTS_ChannelChangeNoticeEdgeDisable
- PLIB_PORTS_PinChangeNoticeEdgeIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticeEdgeControl(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChangeNoticeEdgeStatus Function

Identifies whether the ChangeNoticeEdgeStatus feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChangeNoticeEdgeStatus(PORTS_MODULE_ID index);
```

Returns

- true - The ChangeNoticeEdgeStatus feature is supported on the device
- false - The ChangeNoticeEdgeStatus feature is not supported on the device

Description

This function identifies whether the ChangeNoticeEdgeStatus feature is available on the Ports module. When this function returns true, this function is supported on the device:

- PLIB_PORTS_PinChangeNoticeEdgeHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChangeNoticeEdgeStatus(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsChannelChangeNoticeMethod Function

Identifies whether the ChannelChangeNoticeMethod feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsChannelChangeNoticeMethod(PORTS_MODULE_ID index);
```

Returns

- true - The ChannelChangeNoticeMethod feature is supported on the device
- false - The ChannelChangeNoticeMethod feature is not supported on the device

Description

This function identifies whether the ChannelChangeNoticeMethod feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChannelChangeNoticeMethodSelect
- PLIB_PORTS_ChannelChangeNoticeMethodGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsChannelChangeNoticeMethod(PORTS_MODULE_ID index)

PLIB_PORTS_ExistsSlewRateControl Function

Identifies whether the SlewRateControl feature exists on the Ports module.

File

plib_ports.h

C

```
bool PLIB_PORTS_ExistsSlewRateControl(PORTS_MODULE_ID index);
```

Returns

- true - The SlewRateControl feature is supported on the device
- false - The SlewRateControl feature is not supported on the device

Description

This function identifies whether the SlewRateControl feature is available on the Ports module. When this function returns true, these functions are supported on the device:

- PLIB_PORTS_ChannelSlewRateSelect
- PLIB_PORTS_PinSlewRateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_PORTS_ExistsSlewRateControl(PORTS_MODULE_ID index)

f) Data Types and Constants

PORTS_ANALOG_PIN Enumeration

Data type defining the different analog input pins.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_ANALOG_PIN_0,
  PORTS_ANALOG_PIN_1,
  PORTS_ANALOG_PIN_2,

PORTS_ANALOG_PIN_47	Analog Input Pin 47
PORTS_ANALOG_PIN_48	Analog Input Pin 48
PORTS_ANALOG_PIN_49	Analog Input Pin 49

Description

PORTS Analog input pins

This data type defines the different analog input pins.

Remarks

Values of these AN Pin enums are different from the other similar enumerators by name PORTS_AN_PIN.

These are the superset enumerations provided for documentation, not all constants are available on all devices.

PORTS_BIT_POS Enumeration

Lists the constants that hold different PORTS bit positions.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_BIT_POS_0,
  PORTS_BIT_POS_1,
  PORTS_BIT_POS_2,
  PORTS_BIT_POS_3,
  PORTS_BIT_POS_4,
  PORTS_BIT_POS_5,
  PORTS_BIT_POS_6,
  PORTS_BIT_POS_7,
  PORTS_BIT_POS_8,
  PORTS_BIT_POS_9,
  PORTS_BIT_POS_10,
  PORTS_BIT_POS_11,
  PORTS_BIT_POS_12,
  PORTS_BIT_POS_13,
  PORTS_BIT_POS_14,
  PORTS_BIT_POS_15
} PORTS_BIT_POS;
```

Members

Members	Description
PORTS_BIT_POS_0	PORT bit position 0
PORTS_BIT_POS_1	PORT bit position 1
PORTS_BIT_POS_2	PORT bit position 2
PORTS_BIT_POS_3	PORT bit position 3
PORTS_BIT_POS_4	PORT bit position 4
PORTS_BIT_POS_5	PORT bit position 5
PORTS_BIT_POS_6	PORT bit position 6

PORTS_BIT_POS_11	PORT bit position 11
PORTS_BIT_POS_12	PORT bit position 12
PORTS_BIT_POS_13	PORT bit position 13
PORTS_BIT_POS_14	PORT bit position 14
PORTS_BIT_POS_15	PORT bit position 15

Description

PORTS bit positions

Lists the constants that hold different PORTS bit positions.

Remarks

These are the superset enumerations provided for documentation, not all constants are available on all devices.

PORTS_CHANGE_NOTICE_PIN Enumeration

Data type defining the different Change Notification (CN) pins enumerations.

File

help_plib_ports.h

C

```
typedef enum {
  CN0,
  CN1,
  CN2,
  CN3,
  CN4,
  CN5,
  CN6,
  CN7,
```

```
  CN8,
  CN9,
  CN10,
  CN11,
  CN12,
  CN13,
  CN14,
  CN15,
  CN16,
  CN17,
  CN18,
  CN19,
  CN20,
  CN21
} PORTS_CHANGE_NOTICE_PIN;
```

Members

Members	Description
CN0	Change Notification Pin 0
CN1	Change Notification Pin 1
CN2	Change Notification Pin 2
CN3	Change Notification Pin 3
CN4	Change Notification Pin 4
CN5	Change Notification Pin 5
CN6	Change Notification Pin 6
CN7	Change Notification Pin 7
CN8	Change Notification Pin 8
CN9	Change Notification Pin 9
CN10	Change Notification Pin 10
CN11	Change Notification Pin 11
CN12	Change Notification Pin 12
CN13	Change Notification Pin 13
CN14	Change Notification Pin 14
CN15	Change Notification Pin 15
CN16	Change Notification Pin 16
CN17	Change Notification Pin 17
CN18	Change Notification Pin 18
CN19	Change Notification Pin 19
CN20	Change Notification Pin 20
CN21	Change Notification Pin 21

Description

Change Notification Pins enumeration

This data type defines the different CN pins enumerations.

Remarks

Values of these CN Pin enums are different from the other similar enumerators by name PORTS_CN_PIN. These are the superset enumerations provided for documentation, not all constants are available on all devices.

PORTS_CHANNEL Enumeration

Identifies the available Ports channels.

File

help_plib_ports.h

C

```
typedef enum {
  PORT_CHANNEL_A,
  PORT_CHANNEL_B,
  PORT_CHANNEL_C,
  PORT_CHANNEL_D,
```

```
    PORT_CHANNEL_E,
    PORT_CHANNEL_F,
    PORT_CHANNEL_G,
    PORT_CHANNEL_H,
    PORT_CHANNEL_J,
    PORT_CHANNEL_K
} PORTS_CHANNEL;
```

Members

Members	Description
PORT_CHANNEL_A	Port A
PORT_CHANNEL_B	Port B
PORT_CHANNEL_C	Port C
PORT_CHANNEL_D	Port D
PORT_CHANNEL_E	Port E
PORT_CHANNEL_F	Port F
PORT_CHANNEL_G	Port G
PORT_CHANNEL_H	Port H
PORT_CHANNEL_J	Port J
PORT_CHANNEL_K	Port K

Description

PORT Channel ID

This enumeration identifies the available Ports channels.

Remarks

The caller should not rely on the specific numbers assigned to any of these values as they may change from one processor to the next.

Not all modules are available on all devices. Refer to the specific device data sheet to determine which modules are supported. The numbers used in the enumeration values will match the numbers given in the data sheet.

PORTS_DATA_MASK Type

Data type defining the Ports data mask

File

plib_ports.h

C

```
typedef uint16_t PORTS_DATA_MASK;
```

Description

Ports data mask definition

This data type defines the Ports data mask

Remarks

None.

PORTS_DATA_TYPE Type

Data type defining the Ports data type.

File

plib_ports.h

C

```
typedef uint32_t PORTS_DATA_TYPE;
```

Description

Ports data type definition

This data type defines the Ports data type.

Remarks

None.

PORTS_MODULE_ID Enumeration

Identifies the available Ports modules.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_ID_0,
  PORT_NUMBER_OF_MODULES
} PORTS_MODULE_ID;
```

Members

Members	Description
PORT_NUMBER_OF_MODULES	Max number of Instances

Description

PORT Module ID

This enumeration identifies the available Ports modules.

Remarks

Not all modules are available on all devices. Refer to the specific device data sheet to determine which modules are supported. The numbers used in the enumeration values will match the numbers given in the data sheet.

PORTS_PIN_MODE Enumeration

Identifies the available pin modes.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_PIN_MODE_ANALOG,
  PORTS_PIN_MODE_DIGITAL
} PORTS_PIN_MODE;
```

Members

Members	Description
PORTS_PIN_MODE_ANALOG	Port Pin is in Analog Mode
PORTS_PIN_MODE_DIGITAL	Port pin is in Digital Mode

Description

PORTs Pin Mode

This enumeration identifies the available pin modes.

Remarks

Not all modules are available on all devices. Refer to the specific device data sheet to determine which modules are supported.

PORTS_REMAP_FUNCTION Enumeration

Data type defining the different remap function enumerations.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_REMAP_FUNCTION_EXT_INT1,
  PORTS_REMAP_FUNCTION_EXT_INT2,
  PORTS_REMAP_FUNCTION_EXT_INT3,
  PORTS_REMAP_FUNCTION_EXT_INT4,
  PORTS_REMAP_FUNCTION_IC1,

PORTS_REMAP_FUNCTION_OC5	Output Function Name - Output Compare 5
PORTS_REMAP_FUNCTION_OC6	Output Function Name - Output Compare 6
PORTS_REMAP_FUNCTION_OC7	Output Function Name - Output Compare 7
PORTS_REMAP_FUNCTION_OC8	Output Function Name - Output Compare 8
PORTS_REMAP_FUNCTION_U3TX	Output Function Name - UART3 Transmit
PORTS_REMAP_FUNCTION_U3RTS	Output Function Name - UART3 Request To Send
PORTS_REMAP_FUNCTION_U4TX	Output Function Name - UART4 Transmit
PORTS_REMAP_FUNCTION_U4RTS	Output Function Name - UART4 Request To Send
PORTS_REMAP_FUNCTION_SDO3	Output Function Name - SPI3 Data Output
PORTS_REMAP_FUNCTION_SCK3OUT	Output Function Name - SPI3 Clock Output
PORTS_REMAP_FUNCTION_SS3OUT	Output Function Name - SPI3 Slave Select Output
PORTS_REMAP_FUNCTION_OC9	Output Function Name - Output Compare 9
PORTS_REMAP_FUNCTION_C3OUT	Output Function Name - Comparator 3 Output
PORTS_REMAP_FUNCTION_REFCLKO	Output Function Name - Reference Clock Output

Description

Remap Function Enumeration

This data type defines the different remap function enumerations.

Remarks

These are the superset enumerations provided for documentation, not all constants are available on all devices.

PORTS_REMAP_INPUT_FUNCTION Enumeration

Data type defining the different remap input function enumerations.

File

help_plib_ports.h

C

```
typedef enum {

Description

Remappable Input/Output Enumeration

This data type defines the different remappable input/output enumerations.

Remarks

These are the super set enumerations provided for documentation, not all constants are available on all devices.

PORTS_AN_PIN Enumeration

Data type defining the different analog input pins.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_AN_PIN_0,
  PORTS_AN_PIN_1,
  PORTS_AN_PIN_2,
  PORTS_AN_PIN_3,
  PORTS_AN_PIN_4,
  PORTS_AN_PIN_5,
  PORTS_AN_PIN_6,
  PORTS_AN_PIN_7,
  PORTS_AN_PIN_8,
  PORTS_AN_PIN_9,
  PORTS_AN_PIN_10,
  PORTS_AN_PIN_11,
  PORTS_AN_PIN_12,
  PORTS_AN_PIN_13,
  PORTS_AN_PIN_14,
  PORTS_AN_PIN_15,
```

```
  PORTS_AN_PIN_ALL
} PORTS_AN_PIN;
```

Members

Members	Description
PORTS_AN_PIN_0	AN Pin 0
PORTS_AN_PIN_1	AN Pin 1
PORTS_AN_PIN_2	AN Pin 2

CHANGE_NOTICE_PIN_ALL	All the Change Notice Pins

Description

Change Notice Pins enumeration

This data type defines the different CN pins enumerations.

Remarks

Values of these CN Pin enums are different from the other similar enumerators by name PORTS_CHANGE_NOTICE_PIN. These are the superset enumerations provided for documentation, not all constants are available on all devices.

PORTS_CHANGE_NOTICE_EDGE Enumeration

Data type defining the different edge type for change notification.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_CHANGE_NOTICE_EDGE_RISING = 0,
  PORTS_CHANGE_NOTICE_EDGE_FALLING = 1
} PORTS_CHANGE_NOTICE_EDGE;
```

Members

Members	Description
PORTS_CHANGE_NOTICE_EDGE_RISING = 0	Change Notification on rising edge
PORTS_CHANGE_NOTICE_EDGE_FALLING = 1	Change Notification on falling edge

Description

PORTS Change Notice Edge Type

This data type defines the different edge type for change notification.

Remarks

These are the superset enumerations provided for documentation, not all constants are available on all devices.

PORTS_CHANGE_NOTICE_METHOD Enumeration

Data type defining the different method of ports pin change notification.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_CHANGE_NOTICE_METHOD_SAMPLED = 0,
  PORTS_CHANGE_NOTICE_METHOD_EDGE_DETECT = 1
} PORTS_CHANGE_NOTICE_METHOD;
```

Members

Members	Description
PORTS_CHANGE_NOTICE_METHOD_SAMPLED = 0	Change notification happens when there is level transition
PORTS_CHANGE_NOTICE_METHOD_EDGE_DETECT = 1	Change notification happens when there is edge transition

Description

PORTS Pin Change Notice Method

This data type defines the different method of ports pin change notification.

Remarks

These are the superset enumerations provided for documentation, not all constants are available on all devices.

PORTS_PIN_SLEW_RATE Enumeration

Data type defining the different slew rates for port pins.

File

help_plib_ports.h

C

```
typedef enum {
  PORTS_PIN_SLEW_RATE_FASTEST = 0x00,
  PORTS_PIN_SLEW_RATE_FAST = 0x01,
  PORTS_PIN_SLEW_RATE_SLOW = 0x02,
  PORTS_PIN_SLEW_RATE_SLOWEST = 0x03
} PORTS_PIN_SLEW_RATE;
```

Members

Members	Description
PORTS_PIN_SLEW_RATE_FASTEST = 0x00	Slew rate fastest
PORTS_PIN_SLEW_RATE_FAST = 0x01	Slew rate fast
PORTS_PIN_SLEW_RATE_SLOW = 0x02	Slew rate slow
PORTS_PIN_SLEW_RATE_SLOWEST = 0x03	Slew rate slowest

Description

PORTS Pin Slew Rate

This data type defines the different slew rates for port pins.

Remarks

These are the superset enumerations provided for documentation, not all constants are available on all devices.

Functions

	Name	Description
	PLIB_PORTS_AnPinsModeSelect	Enables the selected AN pins as analog or digital.
	PLIB_PORTS_ChangeNoticeDisable	Global Change Notice disable.
	PLIB_PORTS_ChangeNoticeEnable	Global Change Notice enable.
	PLIB_PORTS_ChangeNoticeInIdleDisable	CPU Idle halts the Change Notice operation.
	PLIB_PORTS_ChangeNoticeInIdleEnable	CPU Idle mode does not affect Change Notice operation.
	PLIB_PORTS_ChangeNoticeInIdlePerPortDisable	Change Notification halts in Idle mode for selected channel.
	PLIB_PORTS_ChangeNoticeInIdlePerPortEnable	Allows CN to be working in Idle mode for selected channel.
	PLIB_PORTS_ChangeNoticePerPortHasOccured	This is function PLIB_PORTS_ChangeNoticePerPortHasOccured.
	PLIB_PORTS_ChangeNoticePerPortHasOccurred	checks the status of change on the pin
	PLIB_PORTS_ChangeNoticePerPortTurnOff	Disables the change notification for selected port.
	PLIB_PORTS_ChangeNoticePerPortTurnOn	Enables the change notification for selected port.
	PLIB_PORTS_ChangeNoticePullDownPerPortDisable	Disables the pull-down for selected Change Notice pins.
	PLIB_PORTS_ChangeNoticePullDownPerPortEnable	Enables the pull-down for selected Change Notice pins.
	PLIB_PORTS_ChangeNoticePullUpDisable	Disable pull-up on input change.
	PLIB_PORTS_ChangeNoticePullUpEnable	Enable pull-up on input change.
	PLIB_PORTS_ChangeNoticePullUpPerPortDisable	Disables weak pull-up for the selected pin.
	PLIB_PORTS_ChangeNoticePullUpPerPortEnable	Enables the pull-up for selected Change Notice pins.
	PLIB_PORTS_ChannelChangeNoticeDisable	Disables CN interrupt for the selected pins of a channel.
	PLIB_PORTS_ChannelChangeNoticeEdgeDisable	Disables selected type of edge for selected CN pins.
	PLIB_PORTS_ChannelChangeNoticeEdgeEnable	Enables selected type of edge for selected CN pins.
	PLIB_PORTS_ChannelChangeNoticeEnable	Enables CN interrupt for the selected pins of a channel.
	PLIB_PORTS_ChannelChangeNoticeMethodGet	Gets the Change Notice style for the selected port channel.
	PLIB_PORTS_ChannelChangeNoticeMethodSelect	Selects the Change Notice style for selected port channel.
	PLIB_PORTS_ChannelChangeNoticePullDownDisable	Disables Change Notice pull-down for the selected channel pins.
	PLIB_PORTS_ChannelChangeNoticePullDownEnable	Enables Change Notice pull-down for the selected channel pins.
	PLIB_PORTS_ChannelChangeNoticePullUpDisable	Disables Change Notice pull-up for the selected channel pins.
	PLIB_PORTS_ChannelChangeNoticePullUpEnable	Enables Change Notice pull-up for the selected channel pins.
	PLIB_PORTS_ChannelModeSelect	Enables the selected channel pins as analog or digital.
	PLIB_PORTS_ChannelSlewRateSelect	Selects the slew rate for selected channel pins.
	PLIB_PORTS_Clear	Clears the selected digital port/latch bits.
	PLIB_PORTS_CnPinsDisable	Disables CN interrupt for the selected pins of a channel.
	PLIB_PORTS_CnPinsEnable	Enables CN interrupt for the selected pins of a channel.
	PLIB_PORTS_CnPinsPullUpDisable	Disables Change Notice pull-up for the selected channel pins.
	PLIB_PORTS_CnPinsPullUpEnable	Enables Change Notice pull-up for the selected channel pins.
	PLIB_PORTS_DirectionGet	Reads the direction of the selected digital port.
	PLIB_PORTS_DirectionInputSet	Makes the selected pins direction input.
	PLIB_PORTS_DirectionOutputSet	Makes the selected pins direction output.
	PLIB_PORTS_ExistsAnPinsMode	Identifies whether the AnPinsMode feature exists on the Ports module.

	PLIB_PORTS_ExistsChangeNotice	Identifies whether the ChangeNotice feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticeEdgeControl	Identifies whether the ChangeNoticeEdgeControl feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticeEdgeStatus	Identifies whether the ChangeNoticeEdgeStatus feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticeInIdle	Identifies whether the ChangeNoticeInIdle feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePerPortInIdle	Identifies whether the ChangeNoticeInIdlePerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePerPortStatus	Identifies whether the ChangeNoticePerPortStatus feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePerPortTurnOn	Identifies whether the ChangeNoticePerPortTurnOn feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePullDownPerPort	Identifies whether the ChangeNoticePullDownPerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePullUp	Identifies whether the ChangeNoticePullup feature exists on the Ports module.
	PLIB_PORTS_ExistsChangeNoticePullUpPerPort	Identifies whether the ChangeNoticePullUpPerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsChannelChangeNoticeMethod	Identifies whether the ChannelChangeNoticeMethod feature exists on the Ports module.
	PLIB_PORTS_ExistsLatchRead	Identifies whether the LatchRead feature exists on the Ports module.
	PLIB_PORTS_ExistsPinChangeNotice	Identifies whether the PinChangeNotice feature exists on the Ports module.
	PLIB_PORTS_ExistsPinChangeNoticePerPort	Identifies whether the PinChangeNoticePerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsPinMode	Identifies whether the PinMode feature exists on the Ports module.
	PLIB_PORTS_ExistsPinModePerPort	Identifies whether the PinModePerPort feature exists on the Ports module.
	PLIB_PORTS_ExistsPortsDirection	Identifies whether the PortsDirection feature exists on the Ports module.
	PLIB_PORTS_ExistsPortsOpenDrain	Identifies whether the PortsOpenDrain feature exists on the Ports module.
	PLIB_PORTS_ExistsPortsRead	Identifies whether the PortsRead feature exists on the Ports module.
	PLIB_PORTS_ExistsPortsWrite	Identifies whether the PortsWrite feature exists on the Ports module.
	PLIB_PORTS_ExistsRemapInput	Identifies whether the RemapInput feature exists on the Ports module.
	PLIB_PORTS_ExistsRemapOutput	Identifies whether the RemapOutput feature exists on the Ports module.
	PLIB_PORTS_ExistsSlewRateControl	Identifies whether the SlewRateControl feature exists on the Ports module.
	PLIB_PORTS_OpenDrainDisable	Disables the open drain functionality for the selected port.
	PLIB_PORTS_OpenDrainEnable	Enables the open drain functionality for the selected port pins.
	PLIB_PORTS_PinChangeNoticeDisable	Port pin Change Notice disable.
	PLIB_PORTS_PinChangeNoticeEdgeHasOccurred	Check Change Notice edge status.
	PLIB_PORTS_PinChangeNoticeEdgeIsEnabled	Check if Change Notice edge is enabled or not.
	PLIB_PORTS_PinChangeNoticeEnable	Port pin Change Notice interrupt enable.
	PLIB_PORTS_PinChangeNoticePerPortDisable	Disables CN interrupt for the selected pin.
	PLIB_PORTS_PinChangeNoticePerPortEnable	Enables CN interrupt for the selected pin.
	PLIB_PORTS_PinClear	Clears the selected digital pin/latch.
	PLIB_PORTS_PinDirectionInputSet	Makes the selected pin direction input
	PLIB_PORTS_PinDirectionOutputSet	Makes the selected pin direction output
	PLIB_PORTS_PinGet	Reads/Gets data from the selected digital pin.
	PLIB_PORTS_PinGetLatched	Reads/Gets data from the selected latch.
	PLIB_PORTS_PinModePerPortSelect	Enables the selected port pin as analog or digital.
	PLIB_PORTS_PinModeSelect	Enables the selected pin as analog or digital.
	PLIB_PORTS_PinOpenDrainDisable	Disables the open drain functionality for the selected pin.
	PLIB_PORTS_PinOpenDrainEnable	Enables the open drain functionality for the selected pin.
	PLIB_PORTS_PinSet	Sets the selected digital pin/latch.
	PLIB_PORTS_PinSlewRateGet	Gets the slew rate for selected port pin.
	PLIB_PORTS_PinToggle	Toggles the selected digital pin/latch.
	PLIB_PORTS_PinWrite	Writes the selected digital pin/latch.
	PLIB_PORTS_Read	Reads the selected digital port.
	PLIB_PORTS_ReadLatched	Reads and returns data from the selected Latch.
	PLIB_PORTS_RemapInput	Input function remapping.

	PLIB_PORTS_RemapOutput	Output function remapping.
	PLIB_PORTS_Set	Sets the selected bits of the port.
	PLIB_PORTS_Toggle	Toggles the selected digital port/latch.
	PLIB_PORTS_Write	Writes the selected digital port/latch.

Types

	Name	Description
	PORTS_DATA_MASK	Data type defining the Ports data mask
	PORTS_DATA_TYPE	Data type defining the Ports data type.

Description

Ports Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Ports Peripheral Library for all families of Microchip microcontrollers. The definitions in this file are common to the Ports peripheral.

Enumerations

	Name	Description
	PORTS_AN_PIN	Data type defining the different analog input pins.
	PORTS_ANALOG_PIN	Data type defining the different analog input pins.
	PORTS_BIT_POS	Lists the constants that hold different PORTS bit positions.
	PORTS_CHANGE_NOTICE_EDGE	Data type defining the different edge type for change notification.
	PORTS_CHANGE_NOTICE_METHOD	Data type defining the different method of ports pin change notification.
	PORTS_CHANGE_NOTICE_PIN	Data type defining the different Change Notification (CN) pins enumerations.
	PORTS_CHANNEL	Identifies the available Ports channels.
	PORTS_CN_PIN	Data type defining the different Change Notification (CN) pins enumerations.
	PORTS_MODULE_ID	Identifies the available Ports modules.
	PORTS_PIN_MODE	Identifies the available pin modes.
	PORTS_PIN_SLEW_RATE	Data type defining the different slew rates for port pins.
	PORTS_REMAP_FUNCTION	Data type defining the different remap function enumerations.
	PORTS_REMAP_INPUT_FUNCTION	Data type defining the different remap input function enumerations.
	PORTS_REMAP_INPUT_PIN	Data type defining the different Ports I/O input pins enumerations.
	PORTS_REMAP_OUTPUT_FUNCTION	Data type defining the different remap output function enumerations.
	PORTS_REMAP_OUTPUT_PIN	Data type defining the different Ports I/O output pins enumerations.
	PORTS_REMAP_PIN	Data type defining the different remappable input/output enumerations.

Description

This is file help_plib_ports.h.

Power Peripheral Library

This section describes the Power Peripheral Library.

Introduction

This library provides a low-level abstraction of the Power Controller modules on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

The Power Controller is a key component of a microcontroller. Power control features allow the user to obtain the balance of power consumption and performance that is best suited to their application.

The features provided in this library discuss specific software commands that are used dynamically to place the device in low-power (i.e., power-saving) modes, which disable power and clocking of selected features. When implementing a system to achieve the lowest possible power consumption while maintain the needed performance, the oscillator configuration and clocking of all peripherals must also be considered. Oscillator configuration and peripheral clocking are addressed in the Oscillator Peripheral Library. In addition, each peripheral may have its own low-power mode settings that are controlled by the library of that peripheral. The user is advised to refer to the libraries of the peripherals used for their particular application.

Key features present on a power controller include (a microcontroller can support one or more of these power features):

- **Power Source Configuration**: Provides the ability to enable and disable a source that may regulate the power consumption in the device
- **Power Status Flags:** Indicate the status of the particular power feature in the device

Note: Not all devices support all of the features discussed in this section. Please refer to specific device data sheet to determine the supported features for your device.

Using the Library

This topic describes the basic architecture of the Power Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_power.h`

The interface to the Power Peripheral Library is defined in the `plib_power.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Power Peripheral Library must include `peripheral.h`.

Peripheral Module IDs

Peripheral libraries are indexed to allow a single library to control any number of instances of a peripheral in a single microcontroller. To support this, the first parameter to each operation in a peripheral library is the module instance ID. The module instance ID is defined by an enumeration that is defined in the processor-specific header files (included by the library's interface header). Not all microcontrollers will have all instances of the module listed in this enumeration. Please refer to the specific data sheet to determine availability.

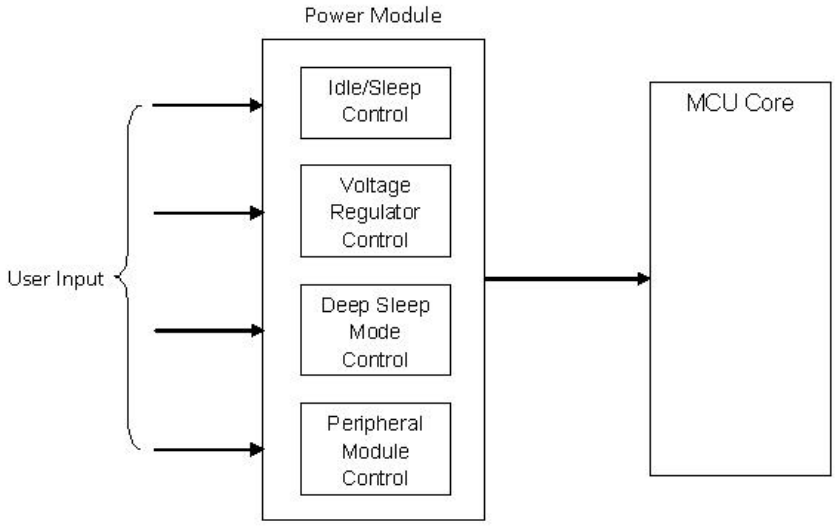
Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

Hardware Abstraction Model

This library provides a low-level abstraction of the Power Controller module on Microchip microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

Hardware Abstraction Block Diagram



This section discusses the various power-saving features implemented in hardware. Combinations of these methods can be used to selectively tailor an application's power consumption, while still maintaining critical or timing-sensitive application features.

Note: Not all devices support all of the features discussed in this section. Please refer to specific device data sheet to determine the supported features for your device.

Instruction-based Power-Saving Modes

In addition to full-power operation, otherwise known as Run mode, PIC microcontrollers also provide other instruction-based power-saving modes. By powering down to different modes, different functional areas of the microcontroller allow progressive reductions of operating and idle power consumption. In addition, these modes can be tailored for more power reduction, but at a trade-off of some operating features.

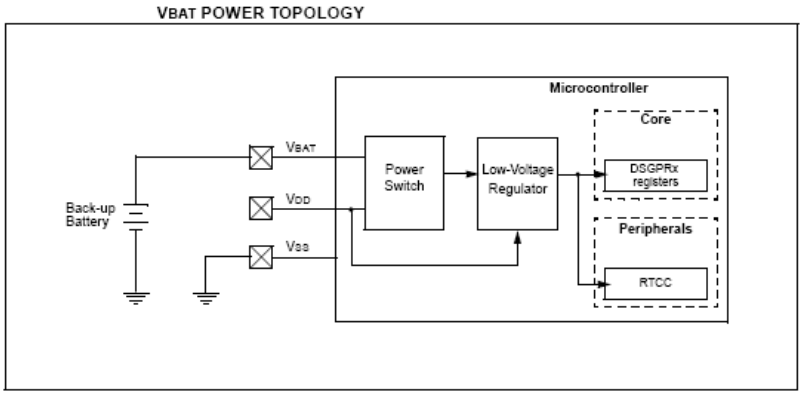
- **Idle Mode:** In Idle mode, the CPU is halted, but the System Clock (SYSCLK) source is still enabled. This allows peripherals to continue to operate when the CPU is halted. Peripherals can be individually configured to halt when entering Idle mode by setting their respective SIDL bit. Latency when exiting Idle mode is very low due to the CPU oscillator source remaining active.
- **Sleep Mode:** The CPU, SYSCLK source and any peripherals that operate on the system clock source are disabled
- **Deep Sleep Mode:** The CPU SYSCLK source, and all the peripherals, with the exception of the Real-Time Clock and Calendar (RTCC) and the Deep Sleep Watchdog Timer (DSWDT), are disabled. This is the lowest power mode for the device. The power to RAM and Flash is also disabled. Deep Sleep mode represents the lowest power mode available without removing power from the application.

The instruction-based power-saving modes are exited as a result of several different hardware triggers. When the device exits one of these three operating modes, it is said to 'wake-up'.

Hardware-based Power-Saving Mode

VBAT mode is a hardware-based power-saving mode that maintains only the most critical operations when a power loss occurs on VDD. The mode does this by powering the systems from a back-up power source connected to the VBAT pin. In this mode, the RTCC can run even when there is no power on VDD.

VBAT mode is entered whenever power is removed from VDD. An on-chip power switch detects the power loss from VDD and connects the VBAT pin to the low-voltage regulator. Entering VBAT mode requires that a power source, distinct from the main VDD power source, be available on the VBAT pin and that VDD be completely removed from the VDD pin(s). Removing VDD can be either unintentional, as in a power failure, or as part of a deliberate power reduction strategy.



Note: Not all devices support all of the features discussed in this section. Please refer to specific device data sheet to determine the supported features for your device.

Selective Peripheral Power Control

Sleep and Idle modes allow users to substantially reduce power consumption by slowing or stopping the CPU clock. Even so, peripheral modules may still remain clocked, and thus, consume some amount of power. There may be cases where the application needs what these modes do not provide: the ability to allocate limited power resources to the CPU while eliminating power consumption from the peripherals. PIC microcontrollers address this requirement by allowing peripheral modules to be selectively enabled or disabled, reducing or eliminating their power consumption.

In addition to the selective peripheral power control implemented as part of this library, devices will also include power saving features that are implemented in their specific libraries. These features include the ability to stop (shutdown) automatically when entering idle mode. On some peripherals the ability to continue operation in Sleep mode is available. Always review the libraries for the peripherals used by your application for specific and unique features that will help minimize power consumption.

Disabling Peripheral Modules

Most of the peripheral modules in the PIC microcontroller family architecture can be selectively disabled, reducing or essentially eliminating their power consumption during all operating modes.

All peripheral modules (except for I/O ports) also have a Control bit that can disable their functionality. These bits, known as the Peripheral Module Disable (PMD) bits, are generically named: 'xxMD'. These bits are located in the PMDx Special Function Registers (SFRs). In contrast to the module enable bits, the xxMD bit must be set to a '1' to disable the module.

While the PMD and module enable bits both disable a peripheral's functionality, the PMD bit completely shuts down the peripheral, effectively powering down all circuits and removing all clock sources. This has the additional effect of making any of the module's control and buffer registers, mapped in the SFR space, unavailable for operations. In other words, when the PMD bit is used to disable a module, the peripheral ceases to exist until the PMD bit is cleared.

The PMD bit is most useful in highly power-sensitive applications, where even tiny savings in power consumption can determine the ability of an application to function. In these cases, the bits can be set before the main body of the application to remove those peripherals that will not be needed.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Power Controller module.

Library Interface Section	Description
Initialization Functions	This section provides a set of functions for configuring the Power-Saving features and enabling or disabling the particular power feature.
Status Functions	This section provides a function to read the status of a particular power feature.
HLVD Functions	This section provides High/Low-Voltage Detect functions.
Deep Sleep Functions	This section provides Deep Sleep mode functions.
Feature Existence Functions	This section provides functions that can be used to determine available features.

Note: The interface provided is a superset of all power functionality available on the device. Refer to the **"Power-Saving Features"** chapter in the specific device data sheet for availability.

How the Library Works

Provides information on how the library works.

Description

Usage of this library is partitioned into two major sections.

Initialization

The steps that are required to initialize the Power Controller module vary for different microcontrollers. Refer to the specific device data sheet to determine the correct initialization sequence. The following information provides a general overview.

Power Source Setup

- A module can be disabled for the microcontroller to be able to save power. Use the function PLIB_POWER_ModuleDisable to disable the particular module. POWER_MODULE_DISABLE provides a list of possible modules sources.
- On most microcontrollers, the voltage regulator can be controlled during Sleep mode. It can be enabled (turned on) using PLIB_POWER_VoltageRegulatorEnable and disabled (turned off) using PLIB_POWER_VoltageRegulatorDisable.

- On some microcontrollers, Deep Sleep mode is enabled using PLIB_POWER_DeepSleepModeEnable. The Deep Sleep mode is disabled using PLIB_POWER_DeepSleepModeDisable.

Power Status

Status of the particular power feature indicates the previous status of that feature. This feature can be used to determine whether the device was in Sleep or Idle mode before waking up. It also allows software to clear the previous status of the device.

Configuring the Library

The library is configured for the supported Power Controller modules when the processor is chosen in the MPLAB X IDE.

Library Interface

a) Initialization Functions

	Name	Description
	PLIB_POWER_DeepSleepModeDisable	Disables Deep Sleep mode.
	PLIB_POWER_DeepSleepModeEnable	Enables Deep Sleep mode.
	PLIB_POWER_PeripheralModuleDisable	Disable the power supply for the module selected in the source.
	PLIB_POWER_PeripheralModuleEnable	Enable the power supply for the module selected in the source.
	PLIB_POWER_PeripheralModuleIsEnabled	Checks to see whether or not the selected peripheral is enabled.
	PLIB_POWER_VoltageRegulatorDisable	Disables the voltage regulator during Sleep mode.
	PLIB_POWER_VoltageRegulatorEnable	Enable the voltage regulator during Sleep mode.
	PLIB_POWER_DeepSleepGPRsRetentionDisable	Disables the General Purpose Registers retention.
	PLIB_POWER_DeepSleepGPRsRetentionEnable	Enables the General Purpose Registers retention.
	PLIB_POWER_DeepSleepModeIsEnabled	Returns the enable/disable status of Deep Sleep mode.
	PLIB_POWER_DeepSleepModuleDisable	Disables the module in Deep Sleep mode.
	PLIB_POWER_DeepSleepModuleEnable	Enables the module in Deep Sleep mode.
	PLIB_POWER_DeepSleepPortPinsStateRelease	Releases I/O pins upon wake-up from Deep Sleep mode.
	PLIB_POWER_DeepSleepPortPinsStateRetain	Enables the I/O pins to retain their previous states upon wake-up from Deep Sleep mode.
	PLIB_POWER_DeepSleepWakeupEventDisable	Disables wake-up from Deep Sleep mode by the selected event.
	PLIB_POWER_DeepSleepWakeupEventEnable	Enables wake-up from the Deep Sleep mode by the selected event.

b) Status Functions

	Name	Description
	PLIB_POWER_ClearIdleStatus	Clears the Idle mode status of the device.
	PLIB_POWER_ClearSleepStatus	Clear the Sleep mode status bit of the device.
	PLIB_POWER_DeviceWasInIdleMode	Returns the Idle mode status of the device.
	PLIB_POWER_DeviceWasInSleepMode	Returns the Sleep mode status of the device.
	PLIB_POWER_HighVoltageOnVDD1V8HasOccurred	Returns the DDR2 High Voltage Detection status of the device.
	PLIB_POWER_VoltageRegulatorIsEnabled	Provides the status of the voltage regulator during Sleep mode.
	PLIB_POWER_DeepSleepStatusClear	Clears the Deep Sleep mode status bit of the device.
	PLIB_POWER_DeepSleepEventStatusClear	Clear any events that occurred during Deep Sleep mode.
	PLIB_POWER_DeepSleepEventStatusGet	Returns the events that occurred during Deep Sleep mode.
	PLIB_POWER_DeepSleepModeHasOccurred	Returns the Deep Sleep mode status of the device.

c) HLVD Functions

	Name	Description
	PLIB_POWER_HLVDBandGapVoltageIsStable	Returns the status of Band Gap voltage.
	PLIB_POWER_HLVDDisable	Disables High/Low-Voltage Detection on VDD.
	PLIB_POWER_HLVDEnable	Enables High/Low-Voltage Detection (HLVD) on VDD.
	PLIB_POWER_HLVDIsEnabled	Returns the enable/disable status of High/Low-Voltage Detection on VDD.
	PLIB_POWER_HLVDLimitSelect	Selects the HLVD limit.
	PLIB_POWER_HLVDModeSelect	Selects the Voltage Detection mode.
	PLIB_POWER_HLVDStatusGet	Returns the HLVD event status.
	PLIB_POWER_HLVDStopInIdleDisable	Continues HLVD operation when the device enters Idle mode.

	PLIB_POWER_HLVDStopInIdleEnable	Discontinues HLVD operation when the device enters Idle mode.
	PLIB_POWER_HLVDStopInIdleIsEnabled	Returns the Stop in Idle mode status of the HLVD operation.

d) Deep Sleep Functions

	Name	Description
	PLIB_POWER_DeepSleepGPRRead	Reads 32-bit data from the Deep Sleep General Purpose Register.
	PLIB_POWER_DeepSleepGPRWrite	Writes 32-bit data into the Deep Sleep General Purpose Register.

e) Feature Existence Functions

	Name	Description
	PLIB_POWER_ExistsDeepSleepMode	Identifies whether the DeepSleepModeControl feature exists on the Power module.
	PLIB_POWER_ExistsIdleStatus	Identifies whether the IdleStatus feature exists on the Power module.
	PLIB_POWER_ExistsPeripheralModuleControl	Identifies whether the PeripheralModuleControl feature exists on the Power module.
	PLIB_POWER_ExistsSleepStatus	Identifies whether the SleepStatus feature exists on the Power module.
	PLIB_POWER_ExistsVoltageRegulatorControl	Identifies whether the VoltageRegulatorControl feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepEventStatus	Identifies whether the DeepSleepEventStatus feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepGPROperation	Identifies whether the DeepSleepGPROperation feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepGPRsRetentionControl	Identifies whether the DeepSleepGPRsRetentionControl feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepModuleControl	Identifies whether the DeepSleepModuleControl feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepPortPinsStateControl	Identifies whether the DeepSleepPortPinsStateControl feature exists on the Power module.
	PLIB_POWER_ExistsHighVoltageOnVDD1V8	Identifies whether the HighVoltageOnVDD1V8 feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepModeOccurrence	Identifies whether the DeepSleepModeOccurrence feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepWakeupEventControl	Identifies whether the DeepSleepWakeupEventControl feature exists on the Power module.
	PLIB_POWER_ExistsHLVDBandGapVoltageStability	Identifies whether the HLVDBandGapVoltageStability feature exists on the Power module.
	PLIB_POWER_ExistsHLVDEnableControl	Identifies whether the HLVDEnableControl feature exists on the Power module.
	PLIB_POWER_ExistsHLVDLimitSelection	Identifies whether the HLVDLimitSelection feature exists on the Power module.
	PLIB_POWER_ExistsHLVDModeControl	Identifies whether the HLVDModeControl feature exists on the Power module.
	PLIB_POWER_ExistsHLVDStatus	Identifies whether the HLVDStatus feature exists on the Power module.
	PLIB_POWER_ExistsHLVDStopInIdleControl	Identifies whether the HLVDStopInIdleControl feature exists on the Power module.

f) Data Types and Constants

	Name	Description
	DEEP_SLEEP_EVENT	Lists the events that occurred during Deep Sleep mode.
	DEEP_SLEEP_GPR	Lists the Deep Sleep General Purpose Registers (GPRs).
	DEEP_SLEEP_MODULE	Lists the modules that can be enabled/disabled during Deep Sleep mode.
	DEEP_SLEEP_WAKE_UP_EVENT	Lists the events that can be used to wake the device from Deep Sleep mode.
	POWER_MODULE	List of the modules whose power can be controlled.
	POWER_MODULE_ID	Identifies the supported Power modules.
	HLVD_LIMIT	Lists the voltage limits for the HLVD module.
	HLVD_MODE	Lists the modes for the High/Low Voltage Detection (HLVD) module.

Description

This section describes the Application Programming Interface (API) functions of the Power Peripheral Library.

Refer to each section for a detailed description.

a) Initialization Functions

PLIB_POWER_DeepSleepModeDisable Function

Disables Deep Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepModeDisable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function disables Deep Sleep mode. Deep Sleep mode is intended to provide the lowest levels of power consumption available without requiring the use of external switches to completely remove all power from the device.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepModeDisable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_DeepSleepModeDisable (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepModeEnable Function

Enables Deep Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepModeEnable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function enables Deep Sleep mode. Deep Sleep mode is intended to provide the lowest levels of power consumption available without requiring the use of external switches to completely remove all power from the device.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepModeEnable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_DeepSleepModeEnable (POWER_MODULE_ID index)

PLIB_POWER_PeripheralModuleDisable Function

Disable the power supply for the module selected in the source.

File

plib_power.h

C

```
void PLIB_POWER_PeripheralModuleDisable(POWER_MODULE_ID index, POWER_MODULE source);
```

Returns

None.

Description

This function completely shuts down the selected peripheral, effectively powering down all circuits and removing all clock sources. This has the additional affect of making any of the module's control and buffer registers, which are mapped in the SFR space, unavailable for operations.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsPeripheralModuleControl in your application to determine whether this feature is available.

Disabling a peripheral module while it's ON bit is set, may result in undefined behavior. The ON bit for the associated peripheral module must be cleared prior to disable a module via this API.

Preconditions

The PMDLOCK bit of the Configuration register should be cleared using the function PLIB_DEVCON_DeviceRegistersUnlock (this function allows changes in the PMD registers). Refer to the Device Control (DEVCON) Peripheral Library Help (or System Service) and the specific device data sheet for more information.

Example

```
// System Unlock
PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);
// Unlock PMD registers
PLIB_DEVCON_DeviceRegistersUnlock(DEVCON_ID_0, DEVCON_PMD_REGISTERS);
// Disable ADC module
PLIB_POWER_PeripheralModuleDisable (POWER_ID_0, POWER_MODULE_ADC);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
source	Select the module to be disabled from POWER_MODULE enum

Function

void PLIB_POWER_PeripheralModuleDisable (POWER_MODULE_ID index, POWER_MODULE source)

PLIB_POWER_PeripheralModuleEnable Function

Enable the power supply for the module selected in the source.

File

plib_power.h

C

```
void PLIB_POWER_PeripheralModuleEnable(POWER_MODULE_ID index, POWER_MODULE source);
```

Returns

None.

Description

This function enables the power supply for the selected module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsPeripheralModuleControl in your application to determine whether this feature is available.

Preconditions

The PMDLOCK bit of the Configuration register should be cleared using the function PLIB_DEVCON_DeviceRegistersUnlock (this function allows changes in the PMD registers). Refer to the Device Control (DEVCON) Peripheral Library Help (or System Service) and the specific device data sheet for more information.

Example

```
// System Unlock
PLIB_DEVCON_SystemUnlock(DEVCON_ID_0);
// Unlock PMD registers
PLIB_DEVCON_DeviceRegistersUnlock(DEVCON_ID_0, DEVCON_PMD_REGISTERS);
// Enable ADC module
PLIB_POWER_PeripheralModuleEnable (POWER_ID_0, POWER_MODULE_ADC);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
source	Select the module to be enabled from POWER_MODULE enum

Function

void PLIB_POWER_PeripheralModuleEnable (POWER_MODULE_ID index, POWER_MODULE source)

PLIB_POWER_PeripheralModuleIsEnabled Function

Checks to see whether or not the selected peripheral is enabled.

File

plib_power.h

C

```
bool PLIB_POWER_PeripheralModuleIsEnabled(POWER_MODULE_ID index, POWER_MODULE source);
```

Returns

- true - Power of the selected peripheral is enabled
- false - Power of the selected peripheral is disabled

Description

This function checks to see whether or not the selected peripheral is enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsPeripheralModuleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_POWER_PeripheralModuleIsEnabled ( POWER_MODULE_0, POWER_MODULE_ADC ))
{
```

```
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
source	Select the module to be enabled from the POWER_MODULE enum

Function

bool PLIB_POWER_PeripheralModuleIsEnabled (POWER_MODULE_ID index, POWER_MODULE source)

PLIB_POWER_VoltageRegulatorDisable Function

Disables the voltage regulator during Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_VoltageRegulatorDisable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function disables the voltage regulator during Sleep mode for the selected device.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsVoltageRegulatorControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_VoltageRegulatorDisable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_VoltageRegulatorDisable (POWER_MODULE_ID index)

PLIB_POWER_VoltageRegulatorEnable Function

Enable the voltage regulator during Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_VoltageRegulatorEnable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function enables the voltage regulator during Sleep mode for the selected device.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsVoltageRegulatorControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_VoltageRegulatorEnable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_VoltageRegulatorEnable (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepGPRsRetentionDisable Function

Disables the General Purpose Registers retention.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepGPRsRetentionDisable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function disables the Deep Sleep General Purpose Registers to retain their values when the device enters Deep Sleep/VBAT mode, which means the power to DEEP_SLEEP_GPR_1 to DEEP_SLEEP_GPR_32 will be dismissed. Power to DEEP_SLEEP_GPR_0 will be retained by default.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepGPRsRetentionControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepGPRsRetentionDisable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_DeepSleepGPRsRetentionDisable (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepGPRsRetentionEnable Function

Enables the General Purpose Registers retention.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepGPRsRetentionEnable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function enables the Deep Sleep General Purpose Registers to retain their values when the device enters Deep Sleep/VBAT mode, which means the power to DEEP_SLEEP_GPR_1 to DEEP_SLEEP_GPR_32 will be maintained. Power to DEEP_SLEEP_GPR_0 will be retained by default.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepGPRsRetentionControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepGPRsRetentionEnable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_DeepSleepGPRsRetentionEnable (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepModeIsEnabled Function

Returns the enable/disable status of Deep Sleep mode.

File

plib_power.h

C

```
bool PLIB_POWER_DeepSleepModeIsEnabled(POWER_MODULE_ID index);
```

Returns

- true - Deep Sleep mode is enabled
- false - Deep Sleep mode is not enabled

Description

This function returns whether or not Deep Sleep mode is enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_DeepSleepModeIsEnabled(POWER_ID_0))
{
    //Enter Deep Sleep by executing Sleep mode.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_DeepSleepModeIsEnabled (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepModuleDisable Function

Disables the module in Deep Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepModuleDisable(POWER_MODULE_ID index, DEEP_SLEEP_MODULE module);
```

Returns

None.

Description

This function disables the selected module in Deep Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepModuleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepModuleDisable(POWER_ID_0 , DEEP_SLEEP_MODULE_RTCC);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
module	Possible module from DEEP_SLEEP_MODULE

Function

void PLIB_POWER_DeepSleepModuleDisable(POWER_MODULE_ID index, DEEP_SLEEP_MODULE module)

PLIB_POWER_DeepSleepModuleEnable Function

Enables the module in Deep Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepModuleEnable(POWER_MODULE_ID index, DEEP_SLEEP_MODULE module);
```

Returns

None.

Description

This function enables the selected module in Deep Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepModuleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepModuleEnable(POWER_ID_0 , DEEP_SLEEP_MODULE_RTCC);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
module	Possible module from DEEP_SLEEP_MODULE

Function

void PLIB_POWER_DeepSleepModuleEnable(POWER_MODULE_ID index, DEEP_SLEEP_MODULE module)

PLIB_POWER_DeepSleepPortPinsStateRelease Function

Releases I/O pins upon wake-up from Deep Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepPortPinsStateRelease(POWER_MODULE_ID index);
```

Returns

None.

Description

This function releases the I/O pins upon wake-up from Deep Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepPortPinsStateControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepPortPinsStateRelease(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_DeepSleepPortPinsStateRelease (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepPortPinsStateRetain Function

Enables the I/O pins to retain their previous states upon wake-up from Deep Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepPortPinsStateRetain(POWER_MODULE_ID index);
```

Returns

None.

Description

This function enables the I/O pins to retain their previous states upon wake-up from Deep Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepPortPinsStateControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepPortPinsStateRetain(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_DeepSleepPortPinsStateRetain (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepWakeupEventDisable Function

Disables wake-up from Deep Sleep mode by the selected event.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepWakeupEventDisable(POWER_MODULE_ID index, DEEP_SLEEP_WAKE_UP_EVENT event);
```

Returns

None.

Description

This function disables wake-up from Deep Sleep mode by the selected event.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepWakeupEventControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepWakeupEventDisable(POWER_ID_0 , DEEP_SLEEP_WAKE_UP_EVENT_RTCC);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
event	Possible event from DEEP_SLEEP_WAKE_UP_EVENT

Function

void PLIB_POWER_DeepSleepWakeupEventDisable(POWER_MODULE_ID index, DEEP_SLEEP_WAKE_UP_EVENT event)

PLIB_POWER_DeepSleepWakeupEventEnable Function

Enables wake-up from the Deep Sleep mode by the selected event.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepWakeupEventEnable(POWER_MODULE_ID index, DEEP_SLEEP_WAKE_UP_EVENT event);
```

Returns

None.

Description

This function enables wake-up from the Deep Sleep mode by the selected event.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepWakeupEventControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_DeepSleepWakeupEventEnable(POWER_ID_0 , DEEP_SLEEP_WAKE_UP_EVENT_RTCC);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
event	Possible event from DEEP_SLEEP_WAKE_UP_EVENT

Function

void PLIB_POWER_DeepSleepWakeupEventEnable(POWER_MODULE_ID index, DEEP_SLEEP_WAKE_UP_EVENT event)

b) Status Functions

PLIB_POWER_ClearIdleStatus Function

Clears the Idle mode status of the device.

File

plib_power.h

C

```
void PLIB_POWER_ClearIdleStatus(POWER_MODULE_ID index);
```

Returns

None.

Description

This function clears the Idle status bit of the device if it was previously in Idle mode. However, it does not mean that it wakes the device from Idle.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsIdleStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_DeviceWasInIdleMode(POWER_ID_0))
{
    PLIB_POWER_ClearIdleStatus (POWER_ID_0);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_ClearIdleStatus (POWER_MODULE_ID index)

PLIB_POWER_ClearSleepStatus Function

Clear the Sleep mode status bit of the device.

File

plib_power.h

C

```
void PLIB_POWER_ClearSleepStatus(POWER_MODULE_ID index);
```

Returns

None.

Description

This function clears the Sleep status bit of the device if it was previously in Sleep mode. However, it does not mean that it wakes the device from sleep.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsSleepStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_DeviceWasInSleepMode(POWER_ID_0))
{
    PLIB_POWER_ClearSleepStatus (POWER_ID_0);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_ClearSleepStatus (POWER_MODULE_ID index)

PLIB_POWER_DeviceWasInIdleMode Function

Returns the Idle mode status of the device.

File

plib_power.h

C

```
bool PLIB_POWER_DeviceWasInIdleMode(POWER_MODULE_ID index);
```

Returns

- true - The device was in Idle mode before waking up
- false - The device was not in Idle mode

Description

This function returns the Idle mode status of the device. It indicates whether or not the device was in Idle mode before waking up.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsIdleStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_DeviceWasInIdleMode(POWER_ID_0))
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_DeviceWasInIdleMode (POWER_MODULE_ID index)

PLIB_POWER_DeviceWasInSleepMode Function

Returns the Sleep mode status of the device.

File

plib_power.h

C

```
bool PLIB_POWER_DeviceWasInSleepMode(POWER_MODULE_ID index);
```

Returns

- true - The device was in Sleep mode before waking up
- false - The device was not in Sleep mode

Description

This function returns the Sleep mode status of the device. It indicates whether or not the device was in Sleep mode before waking up.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsSleepStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_DeviceWasInSleepMode(POWER_ID_0))
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_DeviceWasInSleepMode (POWER_MODULE_ID index)

PLIB_POWER_HighVoltageOnVDD1V8HasOccurred Function

Returns the DDR2 High Voltage Detection status of the device.

File

plib_power.h

C

```
bool PLIB_POWER_HighVoltageOnVDD1V8HasOccurred(POWER_MODULE_ID index);
```

Returns

- true - A high-voltage condition on the VDD1V8 voltage has occurred
- false - A high-voltage condition on the VDD1V8 voltage has not occurred

Description

This function returns the DDR2 High Voltage Detection status of the device.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHighVoltageOnVDD1V8 in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_HighVoltageOnVDD1V8HasOccurred(POWER_ID_0))
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_HighVoltageOnVDD1V8HasOccurred (POWER_MODULE_ID index)

PLIB_POWER_VoltageRegulatorIsEnabled Function

Provides the status of the voltage regulator during Sleep mode.

File

plib_power.h

C

```
bool PLIB_POWER_VoltageRegulatorIsEnabled(POWER_MODULE_ID index);
```

Returns

- true - The voltage regulator will be enabled in Sleep mode
- false - The voltage regulator will be disabled in Sleep mode

Description

This function provides the status of the voltage regulator during Sleep mode for the selected device.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsVoltageRegulatorControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_POWER_VoltageRegulatorIsEnabled(POWER_ID_0))
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_VoltageRegulatorIsEnabled (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepStatusClear Function

Clears the Deep Sleep mode status bit of the device.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepStatusClear(POWER_MODULE_ID index);
```

Returns

None.

Description

This function clears the Deep Sleep status bit of the device if it was previously in Deep Sleep mode. However, it does not mean that it wakes the device from Deep Sleep.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepModeOccurrence in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_DeepSleepModeHasOccurred(POWER_ID_0))
{
    PLIB_POWER_DeepSleepStatusClear (POWER_ID_0);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_DeepSleepStatusClear (POWER_MODULE_ID index)

PLIB_POWER_DeepSleepEventStatusClear Function

Clear any events that occurred during Deep Sleep mode.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepEventStatusClear(POWER_MODULE_ID index, DEEP_SLEEP_EVENT event);
```

Returns

None.

Description

This function accept the events to clear that occurred during Deep Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepEventStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if((PLIB_POWER_DeepSleepEventStatusGet(POWER_ID_0)& DEEP_SLEEP_EVENT_BOR) != 0)
{
    PLIB_POWER_DeepSleepEventStatusClear(POWER_ID_0, DEEP_SLEEP_EVENT_BOR);
    //BOR event occurred in Deep Sleep Mode
    //Therefore, take appropriate action

}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
event	The event that occurred during the Deep Sleep

Function

void PLIB_POWER_DeepSleepEventStatusClear(POWER_MODULE_ID index , DEEP_SLEEP_EVENT event)

PLIB_POWER_DeepSleepEventStatusGet Function

Returns the events that occurred during Deep Sleep mode.

File

plib_power.h

C

```
DEEP_SLEEP_EVENT PLIB_POWER_DeepSleepEventStatusGet(POWER_MODULE_ID index);
```

Returns

DEEP_SLEEP_EVENT - The Event that has occurred during Deep Sleep

Description

This function returns the events that occurred during Deep Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepEventStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if((PLIB_POWER_DeepSleepEventStatusGet(POWER_ID_0)&
(DEEP_SLEEP_EVENT_RTCC_ALARM|DEEP_SLEEP_EVENT_BOR) != 0)
{
    //BOR or RTCC alarm event occurred in Deep Sleep Mode
    //Therefore, take appropriate action
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

DEEP_SLEEP_EVENT PLIB_POWER_DeepSleepEventStatusGet(POWER_MODULE_ID index)

PLIB_POWER_DeepSleepModeHasOccurred Function

Returns the Deep Sleep mode status of the device.

File

plib_power.h

C

```
bool PLIB_POWER_DeepSleepModeHasOccurred(POWER_MODULE_ID index);
```

Returns

- true - The device was in Deep Sleep mode before waking up
- false - The device was not in Deep Sleep mode

Description

This function returns whether or not the device was in Deep Sleep mode before waking up.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepModeOccurrence in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_DeepSleepModeHasOccurred(POWER_ID_0))
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_DeepSleepModeHasOccurred (POWER_MODULE_ID index)

c) HLVD Functions

PLIB_POWER_HLVDBandGapVoltageIsStable Function

Returns the status of Band Gap voltage.

File

plib_power.h

C

```
bool PLIB_POWER_HLVDBandGapVoltageIsStable(POWER_MODULE_ID index);
```

Returns

- true - Band Gap Voltage is stable
- false - Band Gap Voltage is unstable

Description

This function returns whether the Band Gap Voltage is stable or not.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDBandGapVoltageStability in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool BGStatus;
BGStatus = PLIB_POWER_HLVDBandGapVoltageIsStable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_HLVDBandGapVoltageIsStable (POWER_MODULE_ID index)

PLIB_POWER_HLVDDisable Function

Disables High/Low-Voltage Detection on VDD.

File

plib_power.h

C

```
void PLIB_POWER_HLVDDisable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function disables the HLVD module. The HLVD module is used to detect high/low-voltage conditions on VDD.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_HLVDDisable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_HLVDDisable (POWER_MODULE_ID index)

PLIB_POWER_HLVDEnable Function

Enables High/Low-Voltage Detection (HLVD) on VDD.

File

plib_power.h

C

```
void PLIB_POWER_HLVDEnable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function enables the High/Low-Voltage Detection (HLVD) module. The HLVD module is used to detect high/low-voltage conditions on VDD.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDEnableControl in your application to determine whether this feature is available.

Preconditions

Select Low-Voltage or High-Voltage Detection mode by calling PLIB_POWER_HLVDModeSelect.

Example

```
PLIB_POWER_HLVDEnable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_HLVDEnable (POWER_MODULE_ID index)

PLIB_POWER_HLVDIsEnabled Function

Returns the enable/disable status of High/Low-Voltage Detection on VDD.

File

plib_power.h

C

```
bool PLIB_POWER_HLVDIsEnabled(POWER_MODULE_ID index);
```

Returns

- true - HLVD on VDD is enabled
- false - HLVD on VDD is not enabled

Description

This function returns whether or not High/Low-Voltage Detection on VDD is enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_HLVDIsEnabled(POWER_ID_0))
{
    // HLVD is enabled.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_HLVDIsEnabled (POWER_MODULE_ID index)

PLIB_POWER_HLVDLimitSelect Function

Selects the HLVD limit.

File

plib_power.h

C

```
void PLIB_POWER_HLVDLimitSelect(POWER_MODULE_ID index, HLVD_LIMIT limit);
```

Returns

None.

Description

This function selects voltage limit for HLVD on VDD.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDLimitSelection in your application to determine whether this feature is available.

Preconditions

The HLVD module should be disabled by calling PLIB_POWER_HLVDDisable.

Example

```
PLIB_POWER_HLVDLimitSelect( POWER_ID_0, HLVD_LIMIT_ANALOG_INPUT_ON_HLVDIN );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
limit	Voltage limit for HLVD on VDD

Function

void PLIB_POWER_HLVDLimitSelect (POWER_MODULE_ID index, HLVD_LIMIT limit)

PLIB_POWER_HLVDModeSelect Function

Selects the Voltage Detection mode.

File

plib_power.h

C

```
void PLIB_POWER_HLVDModeSelect(POWER_MODULE_ID index, HLVD_MODE mode);
```

Returns

None.

Description

This function selects either the High-Voltage or Low-Voltage Detection mode.

In High-Voltage Detection (HVD) mode, an event occurs when the voltage equals or exceeds the voltage limit.

In Low-Voltage Detection (LVD) mode, an event occurs when the voltage equals or falls below the voltage limit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDModeControl in your application to determine whether this feature is available.

Preconditions

The HLVD module should be disabled by calling PLIB_POWER_HLVDDisable.

Example

```
PLIB_POWER_HLVDModeSelect( POWER_ID_0, HLVD_MODE_HIGH_VOLTAGE_DETECTION );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	Voltage Detection mode, either HVD or LVD

Function

void PLIB_POWER_HLVDModeSelect (POWER_MODULE_ID index, HLVD_MODE mode)

PLIB_POWER_HLVDStatusGet Function

Returns the HLVD event status.

File

plib_power.h

C

```
bool PLIB_POWER_HLVDStatusGet(POWER_MODULE_ID index);
```

Returns

- true - HLVD event interrupt is active
- false - HLVD event interrupt is not active

Description

This function returns the HLVD event interrupt status.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if(PLIB_POWER_HLVDStatusGet(POWER_ID_0))
{
    //HLVD event has occurred.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_HLVDStatusGet(POWER_MODULE_ID index)

PLIB_POWER_HLVDStopInIdleDisable Function

Continues HLVD operation when the device enters Idle mode.

File

plib_power.h

C

```
void PLIB_POWER_HLVDStopInIdleDisable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function continues HLVD operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDStopInIdleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_HLVDStopInIdleDisable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_HLVDStopInIdleDisable(POWER_MODULE_ID index)

PLIB_POWER_HLVDStopInIdleEnable Function

Discontinues HLVD operation when the device enters Idle mode.

File

plib_power.h

C

```
void PLIB_POWER_HLVDStopInIdleEnable(POWER_MODULE_ID index);
```

Returns

None.

Description

This function discontinues HLVD operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDStopInIdleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_POWER_HLVDStopInIdleEnable(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_POWER_HLVDStopInIdleEnable(POWER_MODULE_ID index)

PLIB_POWER_HLVDStopInIdleIsEnabled Function

Returns the Stop in Idle mode status of the HLVD operation.

File

plib_power.h

C

```
bool PLIB_POWER_HLVDStopInIdleIsEnabled(POWER_MODULE_ID index);
```

Returns

- true - HLVD discontinues operation when the device enters Idle mode
- false - HLVD continues operation when the device enters Idle mode

Description

This function returns whether HLVD continues or discontinues operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsHLVDStopInIdleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
bool sidl_status;
sidl_status = PLIB_POWER_HLVDStopInIdleIsEnabled(POWER_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_POWER_HLVDStopInIdleIsEnabled(POWER_MODULE_ID index)

d) Deep Sleep Functions

PLIB_POWER_DeepSleepGPRRead Function

Reads 32-bit data from the Deep Sleep General Purpose Register.

File

plib_power.h

C

```
uint32_t PLIB_POWER_DeepSleepGPRRead(POWER_MODULE_ID index, DEEP_SLEEP_GPR gpr);
```

Returns

32-bit data from the selected Deep Sleep General Purpose Register.

Description

This function reads 32-bit value from the Deep Sleep General Purpose Register. User can store content in these registers (any application critical content) before entering the Deep Sleep/VBAT modes and read them upon exit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepGPROperation in your application to determine whether this feature is available.

Preconditions

The content of the DEEP_SLEEP_GPR_0 register is retained even in the Deep Sleep and VBAT modes, but the DEEP_SLEEP_GPR_1 through DEEP_SLEEP_GPR_32 registers are disabled by default in Deep Sleep and VBAT modes. They can be enabled with PLIB_POWER_DeepSleepGPRsRetentionEnable.

Example

```
uint32_t data;
//Enable power to DEEP_SLEEP_GPR_1 through DEEP_SLEEP_GPR_32 in Deep Sleep
PLIB_POWER_DeepSleepGPRsRetentionEnable(POWER_ID_0);

//Write 32-bit data into the DEEP_SLEEP_GPR_1
PLIB_POWER_DeepSleepGPRWrite(POWER_ID_0, DEEP_SLEEP_GPR_1, 0x1234);

//Enter the Deep Sleep mode and Exit
//Now read the data from DEEP_SLEEP_GPR_1
data = PLIB_POWER_DeepSleepGPRRead(POWER_ID_0, DEEP_SLEEP_GPR_1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
gpr	The available Deep Sleep General Purpose Register

Function

uint32_t PLIB_POWER_DeepSleepGPRRead(POWER_MODULE_ID index, DEEP_SLEEP_GPR gpr)

PLIB_POWER_DeepSleepGPRWrite Function

Writes 32-bit data into the Deep Sleep General Purpose Register.

File

plib_power.h

C

```
void PLIB_POWER_DeepSleepGPRWrite(POWER_MODULE_ID index, DEEP_SLEEP_GPR gpr, uint32_t data);
```

Returns

None.

Description

This function accepts a 32-bit value to write into the Deep Sleep General Purpose Register. User can store content in these registers (any application critical content) before entering the Deep Sleep/VBAT modes and read them upon exit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_POWER_ExistsDeepSleepGPROperation in your application to determine whether this feature is available.

Preconditions

The content of the DEEP_SLEEP_GPR_0 register is retained even in the Deep Sleep and VBAT modes, but the DEEP_SLEEP_GPR_1 through DEEP_SLEEP_GPR_32 registers are disabled by default in Deep Sleep and VBAT modes. They can be enabled with PLIB_POWER_DeepSleepGPRsRetentionEnable.

Example

```
uint32_t data;
//Enable power to DEEP_SLEEP_GPR_1 through DEEP_SLEEP_GPR_32 in Deep Sleep
PLIB_POWER_DeepSleepGPRsRetentionEnable(POWER_ID_0);

//Write 32-bit data into the DEEP_SLEEP_GPR_1
PLIB_POWER_DeepSleepGPRWrite(POWER_ID_0, DEEP_SLEEP_GPR_1, 0x1234);

//Enter the Deep Sleep mode and Exit
//Now read the data from DEEP_SLEEP_GPR_1
data = PLIB_POWER_DeepSleepGPRRead(POWER_ID_0, DEEP_SLEEP_GPR_1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
gpr	The available Deep Sleep General Purpose Register
data	32-bit data to write into the Deep Sleep General Purpose Register

Function

void PLIB_POWER_DeepSleepGPRWrite(POWER_MODULE_ID index, DEEP_SLEEP_GPR gpr, uint32_t data)

e) Feature Existence Functions

PLIB_POWER_ExistsDeepSleepMode Function

Identifies whether the DeepSleepModeControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsDeepSleepMode(POWER_MODULE_ID index);
```

Returns

- true - The DeepSleepModeControl feature is supported on the device
- false - The DeepSleepModeControl feature is not supported on the device

Description

This function identifies whether the DeepSleepModeControl feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_DeepSleepModeEnable
- PLIB_POWER_DeepSleepModeDisable
- PLIB_POWER_DeepSleepModeIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsDeepSleepMode(POWER_MODULE_ID index)

PLIB_POWER_ExistsIdleStatus Function

Identifies whether the IdleStatus feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsIdleStatus(POWER_MODULE_ID index);
```

Returns

- true - The IdleStatus feature is supported on the device
- false - The IdleStatus feature is not supported on the device

Description

This function identifies whether the IdleStatus feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_DeviceWasInIdleMode
- PLIB_POWER_ClearIdleStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsIdleStatus(POWER_MODULE_ID index)

PLIB_POWER_ExistsPeripheralModuleControl Function

Identifies whether the PeripheralModuleControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsPeripheralModuleControl(POWER_MODULE_ID index);
```

Returns

- true - The PeripheralModuleControl feature is supported on the device
- false - The PeripheralModuleControl feature is not supported on the device

Description

This function identifies whether the PeripheralModuleControl feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_PeripheralModuleDisable
- PLIB_POWER_PeripheralModuleEnable
- PLIB_POWER_PeripheralModuleIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsPeripheralModuleControl(POWER_MODULE_ID index)

PLIB_POWER_ExistsSleepStatus Function

Identifies whether the SleepStatus feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsSleepStatus(POWER_MODULE_ID index);
```

Returns

- true - The SleepStatus feature is supported on the device
- false - The SleepStatus feature is not supported on the device

Description

This function identifies whether the SleepStatus feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_DeviceWasInSleepMode
- PLIB_POWER_ClearSleepStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsSleepStatus(POWER_MODULE_ID index)

PLIB_POWER_ExistsVoltageRegulatorControl Function

Identifies whether the VoltageRegulatorControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsVoltageRegulatorControl(POWER_MODULE_ID index);
```

Returns

- true - The VoltageRegulatorControl feature is supported on the device
- false - The VoltageRegulatorControl feature is not supported on the device

Description

This function identifies whether the VoltageRegulatorControl feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_VoltageRegulatorEnable
- PLIB_POWER_VoltageRegulatorDisable
- PLIB_POWER_VoltageRegulatorIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsVoltageRegulatorControl(POWER_MODULE_ID index)

PLIB_POWER_ExistsDeepSleepEventStatus Function

Identifies whether the DeepSleepEventStatus feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsDeepSleepEventStatus(POWER_MODULE_ID index);
```

Returns

- true - The DeepSleepEventStatus feature is supported on the device
- false - The DeepSleepEventStatus feature is not supported on the device

Description

This function identifies whether the DeepSleepEventStatus feature is available on the Power module. When this function returns true, these

functions are supported on the device:

- PLIB_POWER_DeepSleepEventStatusGet
- PLIB_POWER_DeepSleepEventStatusClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsDeepSleepEventStatus(POWER_MODULE_ID index)

PLIB_POWER_ExistsDeepSleepGPROperation Function

Identifies whether the DeepSleepGPROperation feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsDeepSleepGPROperation(POWER_MODULE_ID index);
```

Returns

- true - The DeepSleepGPROperation feature is supported on the device
- false - The DeepSleepGPROperation feature is not supported on the device

Description

This function identifies whether the DeepSleepGPROperation feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_DeepSleepGPRWrite
- PLIB_POWER_DeepSleepGPRRead

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsDeepSleepGPROperation(POWER_MODULE_ID index)

PLIB_POWER_ExistsDeepSleepGPRsRetentionControl Function

Identifies whether the DeepSleepGPRsRetentionControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsDeepSleepGPRsRetentionControl(POWER_MODULE_ID index);
```

Returns

- true - The DeepSleepGPRsRetentionControl feature is supported on the device
- false - The DeepSleepGPRsRetentionControl feature is not supported on the device

Description

This function identifies whether the DeepSleepGPRsRetentionControl feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_DeepSleepGPRsRetentionEnable
- PLIB_POWER_DeepSleepGPRsRetentionDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsDeepSleepGPRsRetentionControl(POWER_MODULE_ID index)

PLIB_POWER_ExistsDeepSleepModuleControl Function

Identifies whether the DeepSleepModuleControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsDeepSleepModuleControl(POWER_MODULE_ID index);
```

Returns

- true - The DeepSleepModuleControl feature is supported on the device
- false - The DeepSleepModuleControl feature is not supported on the device

Description

This function identifies whether the DeepSleepModuleControl feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_DeepSleepModuleEnable
- PLIB_POWER_DeepSleepModuleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsDeepSleepModuleControl(POWER_MODULE_ID index)

PLIB_POWER_ExistsDeepSleepPortPinsStateControl Function

Identifies whether the DeepSleepPortPinsStateControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsDeepSleepPortPinsStateControl(POWER_MODULE_ID index);
```

Returns

- true - The DeepSleepPortPinsStateControl feature is supported on the device
- false - The DeepSleepPortPinsStateControl feature is not supported on the device

Description

This function identifies whether the DeepSleepPortPinsStateControl feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_DeepSleepPortPinsStateRetain
- PLIB_POWER_DeepSleepPortPinsStateRelease

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsDeepSleepPortPinsStateControl(POWER_MODULE_ID index)

PLIB_POWER_ExistsHighVoltageOnVDD1V8 Function

Identifies whether the HighVoltageOnVDD1V8 feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsHighVoltageOnVDD1V8(POWER_MODULE_ID index);
```

Returns

- true - The HighVoltageOnVDD1V8 feature is supported on the device
- false - The HighVoltageOnVDD1V8 feature is not supported on the device

Description

This function identifies whether the HighVoltageOnVDD1V8 feature is available on the Power module. When this function returns true, this function is supported on the device:

- PLIB_POWER_HighVoltageOnVDD1V8HasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsHighVoltageOnVDD1V8(POWER_MODULE_ID index)

PLIB_POWER_ExistsDeepSleepModeOccurrence Function

Identifies whether the DeepSleepModeOccurrence feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsDeepSleepModeOccurrence(POWER_MODULE_ID index);
```

Returns

- true - The DeepSleepModeOccurrence feature is supported on the device
- false - The DeepSleepModeOccurrence feature is not supported on the device

Description

This function identifies whether the DeepSleepModeOccurrence feature is available on the Power module. When this function returns true, this function is supported on the device:

- PLIB_POWER_DeepSleepModeHasOccurred
- PLIB_POWER_DeepSleepStatusClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsDeepSleepModeOccurrence(POWER_MODULE_ID index)

PLIB_POWER_ExistsDeepSleepWakeupEventControl Function

Identifies whether the DeepSleepWakeupEventControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsDeepSleepWakeupEventControl(POWER_MODULE_ID index);
```

Returns

- true - The DeepSleepWakeupEventControl feature is supported on the device
- false - The DeepSleepWakeupEventControl feature is not supported on the device

Description

This function identifies whether the DeepSleepWakeupEventControl feature is available on the Power module. When this function returns true, these functions are supported on the device:

- PLIB_POWER_DeepSleepWakeupEventEnable
- PLIB_POWER_DeepSleepWakeupEventDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsDeepSleepWakeupEventControl(POWER_MODULE_ID index)

PLIB_POWER_ExistsHLVDBandGapVoltageStability Function

Identifies whether the HLVDBandGapVoltageStability feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsHLVDBandGapVoltageStability(POWER_MODULE_ID index);
```

Returns

- true - The HLVDBandGapVoltageStability feature is supported on the device
- false - The HLVDBandGapVoltageStability feature is not supported on the device

Description

This function identifies whether the HLVDBandGapVoltageStability feature is available on the Power module. When this function returns true, this function is supported on the device:

- PLIB_POWER_HLVDBandGapVoltageIsStable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsHLVDBandGapVoltageStability(POWER_MODULE_ID index)

PLIB_POWER_ExistsHLVDEnableControl Function

Identifies whether the HLVDEnableControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsHLVDEnableControl(POWER_MODULE_ID index);
```

Returns

- true - The HLVDEnableControl feature is supported on the device
- false - The HLVDEnableControl feature is not supported on the device

Description

This function identifies whether the HLVDEnableControl feature is available on the Power module. When this function returns true, this function is supported on the device:

- PLIB_POWER_HLVDEnable
- PLIB_POWER_HLVDDisable
- PLIB_POWER_HLVDIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsHLVDEnableControl(POWER_MODULE_ID index)

PLIB_POWER_ExistsHLVDLimitSelection Function

Identifies whether the HLVDLimitSelection feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsHLVDLimitSelection(POWER_MODULE_ID index);
```

Returns

- true - The HLVDLimitSelection feature is supported on the device
- false - The HLVDLimitSelection feature is not supported on the device

Description

This function identifies whether the HLVDLimitSelection feature is available on the Power module. When this function returns true, this function is supported on the device:

- PLIB_POWER_HLVDLimitSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsHLVDLimitSelection(POWER_MODULE_ID index)

PLIB_POWER_ExistsHLVDModeControl Function

Identifies whether the HLVDModeControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsHLVDModeControl(POWER_MODULE_ID index);
```

Returns

- true - The HLVDModeControl feature is supported on the device
- false - The HLVDModeControl feature is not supported on the device

Description

This function identifies whether the HLVDModeControl feature is available on the Power module. When this function returns true, this function is supported on the device:

- PLIB_POWER_HLVDModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsHLVDModeControl(POWER_MODULE_ID index)

PLIB_POWER_ExistsHLVDStatus Function

Identifies whether the HLVDStatus feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsHLVDStatus(POWER_MODULE_ID index);
```

Returns

- true - The HLVDStatus feature is supported on the device
- false - The HLVDStatus feature is not supported on the device

Description

This function identifies whether the HLVDStatus feature is available on the Power module. When this function returns true, this function is supported on the device:

- PLIB_POWER_HLVDStatusGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsHLVDStatus(POWER_MODULE_ID index)

PLIB_POWER_ExistsHLVDStopInIdleControl Function

Identifies whether the HLVDStopInIdleControl feature exists on the Power module.

File

plib_power.h

C

```
bool PLIB_POWER_ExistsHLVDStopInIdleControl(POWER_MODULE_ID index);
```

Returns

- true - The HLVDStopInIdleControl feature is supported on the device
- false - The HLVDStopInIdleControl feature is not supported on the device

Description

This function identifies whether the HLVDStopInIdleControl feature is available on the Power module. When this function returns true, this function is supported on the device:

- PLIB_POWER_HLVDStopInIdleEnable
- PLIB_POWER_HLVDStopInIdleDisable
- PLIB_POWER_HLVDStopInIdleIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_POWER_ExistsHLVDStopInIdleControl(POWER_MODULE_ID index)

f) Data Types and Constants

DEEP_SLEEP_EVENT Enumeration

Lists the events that occurred during Deep Sleep mode.

File

help_plib_power.h

C

```
typedef enum {
  DEEP_SLEEP_EVENT_BOR,
  DEEP_SLEEP_EVENT_RTCC_ALARM,
  DEEP_SLEEP_EVENT_EXTERNAL_INTERRUPT,
  DEEP_SLEEP_EVENT_FAULT_DETECTION,
  DEEP_SLEEP_EVENT_WDT_TIMEOUT,
  DEEP_SLEEP_EVENT_MCLR
} DEEP_SLEEP_EVENT;
```

Members

Members	Description
DEEP_SLEEP_EVENT_BOR	BOR event has occurred during Deep Sleep
DEEP_SLEEP_EVENT_RTCC_ALARM	RTCC alarm has occurred during Deep Sleep
DEEP_SLEEP_EVENT_EXTERNAL_INTERRUPT	Interrupt-On-Change on pin INT0 has occurred during Deep Sleep
DEEP_SLEEP_EVENT_FAULT_DETECTION	Fault has occurred during Deep Sleep and some Deep Sleep configuration settings may have been corrupted
DEEP_SLEEP_EVENT_WDT_TIMEOUT	DSWDT time-out has occurred during Deep Sleep
DEEP_SLEEP_EVENT_MCLR	Master Clear (MCLR) has occurred during Deep Sleep

Description

Deep Sleep events

This enumeration lists the events that occurred during Deep Sleep mode.

Remarks

Not all events exist on all devices. Please refer to the specific device data sheet for availability.

DEEP_SLEEP_GPR Enumeration

Lists the Deep Sleep General Purpose Registers (GPRs).

File

help_plib_power.h

C

```
typedef enum {
  DEEP_SLEEP_GPR_0,
  DEEP_SLEEP_GPR_1,
  DEEP_SLEEP_GPR_2,
  DEEP_SLEEP_GPR_3,
  DEEP_SLEEP_GPR_4,
  DEEP_SLEEP_GPR_5,
  DEEP_SLEEP_GPR_6,
  DEEP_SLEEP_GPR_7,
  DEEP_SLEEP_GPR_8,
  DEEP_SLEEP_GPR_9,
  DEEP_SLEEP_GPR_10,
  DEEP_SLEEP_GPR_11,
  DEEP_SLEEP_GPR_12,

  DEEP_SLEEP_GPR_25,
  DEEP_SLEEP_GPR_26,
  DEEP_SLEEP_GPR_27,
  DEEP_SLEEP_GPR_28,
  DEEP_SLEEP_GPR_29,
  DEEP_SLEEP_GPR_30,
  DEEP_SLEEP_GPR_31,
  DEEP_SLEEP_GPR_32
} DEEP_SLEEP_GPR;
```

Members

Members	Description
DEEP_SLEEP_GPR_0	Deep Sleep General Purpose Register 0. This will be active in Deep Sleep by default.
DEEP_SLEEP_GPR_1	Deep Sleep General Purpose Register 1.
DEEP_SLEEP_GPR_2	Deep Sleep General Purpose Register 2.
DEEP_SLEEP_GPR_3	Deep Sleep General Purpose Register 3.
DEEP_SLEEP_GPR_4	Deep Sleep General Purpose Register 4.
DEEP_SLEEP_GPR_5	Deep Sleep General Purpose Register 5.
DEEP_SLEEP_GPR_6	Deep Sleep General Purpose Register 6.
DEEP_SLEEP_GPR_7	Deep Sleep General Purpose Register 7.
DEEP_SLEEP_GPR_8	Deep Sleep General Purpose Register 8.
DEEP_SLEEP_GPR_9	Deep Sleep General Purpose Register 9.
DEEP_SLEEP_GPR_10	Deep Sleep General Purpose Register 10.
DEEP_SLEEP_GPR_11	Deep Sleep General Purpose Register 11.
DEEP_SLEEP_GPR_12	Deep Sleep General Purpose Register 12.
DEEP_SLEEP_GPR_13	Deep Sleep General Purpose Register 13.
DEEP_SLEEP_GPR_14	Deep Sleep General Purpose Register 14.
DEEP_SLEEP_GPR_15	Deep Sleep General Purpose Register 15.
DEEP_SLEEP_GPR_16	Deep Sleep General Purpose Register 16.
DEEP_SLEEP_GPR_17	Deep Sleep General Purpose Register 17.

DEEP_SLEEP_GPR_18	Deep Sleep General Purpose Register 18.
DEEP_SLEEP_GPR_19	Deep Sleep General Purpose Register 19.
DEEP_SLEEP_GPR_20	Deep Sleep General Purpose Register 20.
DEEP_SLEEP_GPR_21	Deep Sleep General Purpose Register 21.
DEEP_SLEEP_GPR_22	Deep Sleep General Purpose Register 22.
DEEP_SLEEP_GPR_23	Deep Sleep General Purpose Register 23.
DEEP_SLEEP_GPR_24	Deep Sleep General Purpose Register 24.
DEEP_SLEEP_GPR_25	Deep Sleep General Purpose Register 25.
DEEP_SLEEP_GPR_26	Deep Sleep General Purpose Register 26.
DEEP_SLEEP_GPR_27	Deep Sleep General Purpose Register 27.
DEEP_SLEEP_GPR_28	Deep Sleep General Purpose Register 28.
DEEP_SLEEP_GPR_29	Deep Sleep General Purpose Register 29.
DEEP_SLEEP_GPR_30	Deep Sleep General Purpose Register 30.
DEEP_SLEEP_GPR_31	Deep Sleep General Purpose Register 31.
DEEP_SLEEP_GPR_32	Deep Sleep General Purpose Register 32.

Description

Deep Sleep General Purpose Register set.

This enumeration lists the Deep Sleep General Purpose Registers. These registers can be used to save some application critical content while entering into Deep Sleep mode and can be read upon exit.

Remarks

Not all GPRs exist on all devices. Please refer to the specific device data sheet for availability.

DEEP_SLEEP_MODULE Enumeration

Lists the modules that can be enabled/disabled during Deep Sleep mode.

File

help_plib_power.h

C

```
typedef enum {
  DEEP_SLEEP_MODULE_RTCC
} DEEP_SLEEP_MODULE;
```

Members

Members	Description
DEEP_SLEEP_MODULE_RTCC	RTCC module

Description

Deep Sleep Module

This enumeration lists the modules that can be enabled/disabled during Deep Sleep mode.

Remarks

Not all modules exist on all devices. Please refer to the specific device data sheet for availability.

DEEP_SLEEP_WAKE_UP_EVENT Enumeration

Lists the events that can be used to wake the device from Deep Sleep mode.

File

help_plib_power.h

C

```
typedef enum {
  DEEP_SLEEP_WAKE_UP_EVENT_RTCC,
  DEEP_SLEEP_WAKE_UP_EVENT_EXTERNAL_INTERRUPT
} DEEP_SLEEP_WAKE_UP_EVENT;
```

Members

Members	Description
DEEP_SLEEP_WAKE_UP_EVENT_RTCC	Deep Sleep wake-up by RTCC alarm event
DEEP_SLEEP_WAKE_UP_EVENT_EXTERNAL_INTERRUPT	Deep Sleep wake-up by Interrupt-On-Change (IOC) on INT0 pin

Description

Deep Sleep Wake-up events

This enumeration lists the events that can be used to wake the device from Deep Sleep mode.

Remarks

Not all events exist on all devices. Please refer to the specific device data sheet for availability.

POWER_MODULE Enumeration

List of the modules whose power can be controlled.

File

help_plib_power.h

C

```
typedef enum {
  POWER_MODULE_ADC1,
  POWER_MODULE_CTMU,
  POWER_MODULE_CVR,

POWER_MODULE_DMA	Data Memory Access module
POWER_MODULE_RANDOM_NUM_GENERATOR	Random Number Generator module
POWER_MODULE_DDR2	DDR2 module
POWER_MODULE_CRYPTO	Cryptographic module

Description

POWER module enumeration

This enumeration lists the modules whose power can be controlled by the Peripheral Module Disable (PMD) Registers.

Remarks

Not all modules exist on all devices. Please refer to the specific device data sheet for availability.

POWER_MODULE_ID Enumeration

Identifies the supported Power modules.

File

help_plib_power.h

C

```
typedef enum {
```

```
  POWER_ID_0,
  POWER_NUMBER_OF_MODULES
} POWER_MODULE_ID;
```

Members

Members	Description
POWER_ID_0	POWER Module ID
POWER_NUMBER_OF_MODULES	Number of available POWER modules.

Description

Power Module ID

This enumeration identifies the Power modules that are available on the microcontroller. This is the superset of all of the possible instances that might be available on a Microchip microcontroller.

Remarks

The caller should not rely on the specific numbers assigned to any of these values, as they may change from one processor to the next.

Not all modules are available on all microcontrollers. Refer to the "Power-Saving Features" chapter in the specific device data sheet to determine which modules are supported. The numbers used in the enumeration values will match the numbers provided in the data sheet.

HLVD_LIMIT Enumeration

Lists the voltage limits for the HLVD module.

File

help_plib_power.h

C

```
typedef enum {
  HLVD_LIMIT_TRIP_POINT_4,
  HLVD_LIMIT_TRIP_POINT_5,
  HLVD_LIMIT_TRIP_POINT_6,
  HLVD_LIMIT_TRIP_POINT_7,
  HLVD_LIMIT_TRIP_POINT_8,
  HLVD_LIMIT_TRIP_POINT_9,
  HLVD_LIMIT_TRIP_POINT_10,
  HLVD_LIMIT_TRIP_POINT_11,
  HLVD_LIMIT_TRIP_POINT_12,
  HLVD_LIMIT_TRIP_POINT_13,
  HLVD_LIMIT_TRIP_POINT_14,
  HLVD_LIMIT_ANALOG_INPUT_ON_HLVDIN
} HLVD_LIMIT;
```

Members

Members	Description
HLVD_LIMIT_TRIP_POINT_4	Voltage limit is trip point 4
HLVD_LIMIT_TRIP_POINT_5	Voltage limit is trip point 5
HLVD_LIMIT_TRIP_POINT_6	Voltage limit is trip point 6
HLVD_LIMIT_TRIP_POINT_7	Voltage limit is trip point 7
HLVD_LIMIT_TRIP_POINT_8	Voltage limit is trip point 8
HLVD_LIMIT_TRIP_POINT_9	Voltage limit is trip point 9
HLVD_LIMIT_TRIP_POINT_10	Voltage limit is trip point 10
HLVD_LIMIT_TRIP_POINT_11	Voltage limit is trip point 11
HLVD_LIMIT_TRIP_POINT_12	Voltage limit is trip point 12
HLVD_LIMIT_TRIP_POINT_13	Voltage limit is trip point 13
HLVD_LIMIT_TRIP_POINT_14	Voltage limit is trip point 14
HLVD_LIMIT_ANALOG_INPUT_ON_HLVDIN	Voltage limit is external analog voltage on the pin HLVDIN

Description

High/Low-Voltage Detection limits

This enumeration lists the voltage limits that can be used as reference to High/Low-Voltage Detection on VDD.

Refer to the â€œElectrical Characteristicsâ€• chapter of the specific device data sheet for the actual trip points (i.e., voltages).

Remarks

Not all voltage limits exist on all devices. Please refer to the specific device data sheet for availability.

HLVD_MODE Enumeration

Lists the modes for the High/Low Voltage Detection (HLVD) module.

File

help_plib_power.h

C

```
typedef enum {
  HLVD_MODE_LOW_VOLTAGE_DETECTION,
  HLVD_MODE_HIGH_VOLTAGE_DETECTION
} HLVD_MODE;
```

Members

Members	Description
HLVD_MODE_LOW_VOLTAGE_DETECTION	In Low-Voltage Detection (LVD) mode, an event occurs when the voltage equals or falls below the voltage limit.
HLVD_MODE_HIGH_VOLTAGE_DETECTION	In High-Voltage Detection (HVD) mode, an event occurs when the voltage equals or exceeds the voltage limit.

Description

High/Low-Voltage Detection modes

This enumeration lists the modes those can be used for High/Low Voltage Detection on VDD.

Remarks

None.

Files

Files

Name	Description
plib_power.h	Defines the Power Peripheral Library interface.
help_plib_power.h	This is file help_plib_power.h.

Description

This section lists the source and header files used by the library.

plib_power.h

Defines the Power Peripheral Library interface.

Functions

	Name	Description
	PLIB_POWER_ClearIdleStatus	Clears the Idle mode status of the device.
	PLIB_POWER_ClearSleepStatus	Clear the Sleep mode status bit of the device.
	PLIB_POWER_DeepSleepEventStatusClear	Clear any events that occurred during Deep Sleep mode.
	PLIB_POWER_DeepSleepEventStatusGet	Returns the events that occurred during Deep Sleep mode.
	PLIB_POWER_DeepSleepGPRRead	Reads 32-bit data from the Deep Sleep General Purpose Register.
	PLIB_POWER_DeepSleepGPRsRetentionDisable	Disables the General Purpose Registers retention.
	PLIB_POWER_DeepSleepGPRsRetentionEnable	Enables the General Purpose Registers retention.
	PLIB_POWER_DeepSleepGPRWrite	Writes 32-bit data into the Deep Sleep General Purpose Register.
	PLIB_POWER_DeepSleepModeDisable	Disables Deep Sleep mode.
	PLIB_POWER_DeepSleepModeEnable	Enables Deep Sleep mode.
	PLIB_POWER_DeepSleepModeHasOccurred	Returns the Deep Sleep mode status of the device.
	PLIB_POWER_DeepSleepModeIsEnabled	Returns the enable/disable status of Deep Sleep mode.

	PLIB_POWER_DeepSleepModuleDisable	Disables the module in Deep Sleep mode.
	PLIB_POWER_DeepSleepModuleEnable	Enables the module in Deep Sleep mode.
	PLIB_POWER_DeepSleepPortPinsStateRelease	Releases I/O pins upon wake-up from Deep Sleep mode.
	PLIB_POWER_DeepSleepPortPinsStateRetain	Enables the I/O pins to retain their previous states upon wake-up from Deep Sleep mode.
	PLIB_POWER_DeepSleepStatusClear	Clears the Deep Sleep mode status bit of the device.
	PLIB_POWER_DeepSleepWakeupEventDisable	Disables wake-up from Deep Sleep mode by the selected event.
	PLIB_POWER_DeepSleepWakeupEventEnable	Enables wake-up from the Deep Sleep mode by the selected event.
	PLIB_POWER_DeviceWasInIdleMode	Returns the Idle mode status of the device.
	PLIB_POWER_DeviceWasInSleepMode	Returns the Sleep mode status of the device.
	PLIB_POWER_ExistsDeepSleepEventStatus	Identifies whether the DeepSleepEventStatus feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepGPROperation	Identifies whether the DeepSleepGPROperation feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepGPRsRetentionControl	Identifies whether the DeepSleepGPRsRetentionControl feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepMode	Identifies whether the DeepSleepModeControl feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepModeOccurrence	Identifies whether the DeepSleepModeOccurrence feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepModuleControl	Identifies whether the DeepSleepModuleControl feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepPortPinsStateControl	Identifies whether the DeepSleepPortPinsStateControl feature exists on the Power module.
	PLIB_POWER_ExistsDeepSleepWakeupEventControl	Identifies whether the DeepSleepWakeupEventControl feature exists on the Power module.
	PLIB_POWER_ExistsHighVoltageOnVDD1V8	Identifies whether the HighVoltageOnVDD1V8 feature exists on the Power module.
	PLIB_POWER_ExistsHLVDBandGapVoltageStability	Identifies whether the HLVDBandGapVoltageStability feature exists on the Power module.
	PLIB_POWER_ExistsHLVDEnableControl	Identifies whether the HLVDEnableControl feature exists on the Power module.
	PLIB_POWER_ExistsHLVDLimitSelection	Identifies whether the HLVDLimitSelection feature exists on the Power module.
	PLIB_POWER_ExistsHLVDModeControl	Identifies whether the HLVDModeControl feature exists on the Power module.
	PLIB_POWER_ExistsHLVDStatus	Identifies whether the HLVDStatus feature exists on the Power module.
	PLIB_POWER_ExistsHLVDStopInIdleControl	Identifies whether the HLVDStopInIdleControl feature exists on the Power module.
	PLIB_POWER_ExistsIdleStatus	Identifies whether the IdleStatus feature exists on the Power module.
	PLIB_POWER_ExistsPeripheralModuleControl	Identifies whether the PeripheralModuleControl feature exists on the Power module.
	PLIB_POWER_ExistsSleepStatus	Identifies whether the SleepStatus feature exists on the Power module.
	PLIB_POWER_ExistsVoltageRegulatorControl	Identifies whether the VoltageRegulatorControl feature exists on the Power module.
	PLIB_POWER_HighVoltageOnVDD1V8HasOccurred	Returns the DDR2 High Voltage Detection status of the device.
	PLIB_POWER_HLVDBandGapVoltageIsStable	Returns the status of Band Gap voltage.
	PLIB_POWER_HLVDDisable	Disables High/Low-Voltage Detection on VDD.
	PLIB_POWER_HLVDEnable	Enables High/Low-Voltage Detection (HLVD) on VDD.
	PLIB_POWER_HLVDIsEnabled	Returns the enable/disable status of High/Low-Voltage Detection on VDD.
	PLIB_POWER_HLVDLimitSelect	Selects the HLVD limit.
	PLIB_POWER_HLVDModeSelect	Selects the Voltage Detection mode.
	PLIB_POWER_HLVDStatusGet	Returns the HLVD event status.
	PLIB_POWER_HLVDStopInIdleDisable	Continues HLVD operation when the device enters Idle mode.
	PLIB_POWER_HLVDStopInIdleEnable	Discontinues HLVD operation when the device enters Idle mode.
	PLIB_POWER_HLVDStopInIdleIsEnabled	Returns the Stop in Idle mode status of the HLVD operation.
	PLIB_POWER_PeripheralModuleDisable	Disable the power supply for the module selected in the source.
	PLIB_POWER_PeripheralModuleEnable	Enable the power supply for the module selected in the source.
	PLIB_POWER_PeripheralModuleIsEnabled	Checks to see whether or not the selected peripheral is enabled.

	PLIB_POWER_VoltageRegulatorDisable	Disables the voltage regulator during Sleep mode.
	PLIB_POWER_VoltageRegulatorEnable	Enable the voltage regulator during Sleep mode.
	PLIB_POWER_VoltageRegulatorIsEnabled	Provides the status of the voltage regulator during Sleep mode.

Description

Power Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Power Peripheral Library for Microchip microcontrollers. The definitions in this file are for the Power Controller module.

File Name

plib_power.h

Company

Microchip Technology Inc.

Enumerations

	Name	Description
	DEEP_SLEEP_EVENT	Lists the events that occurred during Deep Sleep mode.
	DEEP_SLEEP_GPR	Lists the Deep Sleep General Purpose Registers (GPRs).
	DEEP_SLEEP_MODULE	Lists the modules that can be enabled/disabled during Deep Sleep mode.
	DEEP_SLEEP_WAKE_UP_EVENT	Lists the events that can be used to wake the device from Deep Sleep mode.
	HLVD_LIMIT	Lists the voltage limits for the HLVD module.
	HLVD_MODE	Lists the modes for the High/Low Voltage Detection (HLVD) module.
	POWER_MODULE	List of the modules whose power can be controlled.
	POWER_MODULE_ID	Identifies the supported Power modules.

Description

This is file help_plib_power.h.

Reset Peripheral Library

This section describes the Reset Peripheral Library.

Introduction

This library provides a low-level abstraction of the Reset Controller modules on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

The Reset Controller is a key component of a microcontroller. The Reset Controller gives the reset status of the device at any point of time.

The following are the key features present on a Reset Controller:

- **Reset Source Configuration**: Provides the ability to enable and disable a source that may reset the device
- **Reset Status:** Identifies the source of a reset and clears it

A microcontroller can support one or more of the previously described reset modes.

Note: Please refer to the **"Resets"** chapter in the specific device data sheet to determine the exact set of supported features.

Using the Library

This topic describes the basic architecture of the Reset Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_reset.h`

The interface to the Reset Peripheral Library is defined in the `plib_reset.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Reset Peripheral Library must include `peripheral.h`.

Peripheral Module IDs

Peripheral libraries are indexed to allow a single library to control any number of instances of a peripheral in a single microcontroller. To support this, the first parameter to each operation in a peripheral library is the module instance ID. The module instance ID is defined by an enumeration that is defined in the processor-specific header files (included by the library's interface header). Not all microcontrollers will have all instances of the module listed in this enumeration. Please refer to the **"Resets"** chapter in the specific device data sheet for availability.

Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

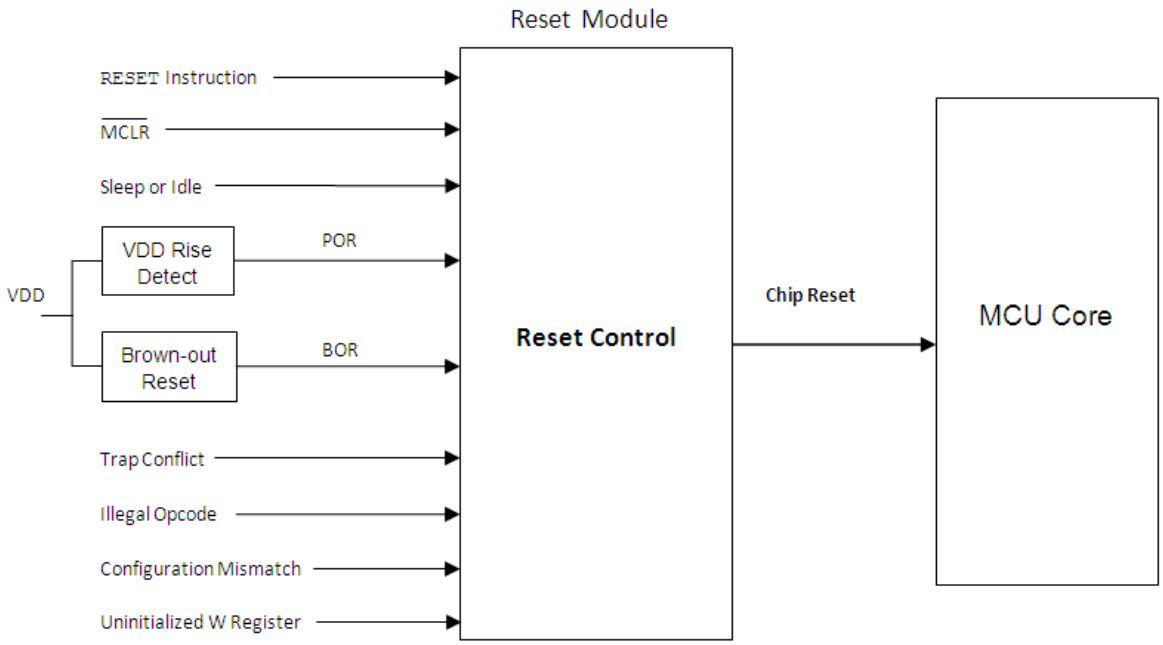
Hardware Abstraction Model

This library provides a low-level abstraction of the Reset Controller module on Microchip PIC microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

The following figure illustrates the hardware abstraction model for the Reset Peripheral Library.

Hardware Abstraction Model



The **Reset Controller** receives requests from multiple **Reset Sources**. The **Reset Controller** controls the overall operation of the reset controller.

Source Enable Configuration enables or disables a particular source of reset. Some of the reset sources such as Traps are not controlled by the users, whereas others can be user controlled.

Note: Not all features are available on all devices. Refer to the **"Resets"** chapter in the specific device data sheet for availability.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Reset Controller module.

Library Interface Section	Description
Initialization Functions	This section provides a set of functions for configuring and enabling a reset.
Status Functions	This section provides a function to read the status of a particular reset.
NMI Events Functions	This section provides functions for NMI events.
Feature Existence Functions	This section provides functions that determine whether certain features exist.

Note: Please refer to the **"Resets"** chapter in the specific device data sheet to determine the exact set of supported features.

How the Library Works

Initialization

The steps that are required to initialize the Reset Controller module vary for different microcontrollers. Refer to the **"Resets"** chapter in the specific device data sheet for the correct initialization sequence. The following information provides a general overview.

Description

Reset Source Setup

Some reset sources need to be enabled for it to be able to Reset the device. Use the function PLIB_RESET_SoftwareResetEnable to enable the reset source.

Reset Status

The status of the reset indicates which source generated the reset. The status of the reset source can be obtained using the function PLIB_RESET_ReasonGet. The reason for the reset can be cleared using the function PLIB_RESET_ReasonClear.

Configuring the Library

The library is configured for the supported Reset Controller modules when the processor is chosen in the MPLAB X IDE.

Library Interface

a) Initialization Functions

	Name	Description
	PLIB_RESET_SoftwareResetEnable	Enables the software reset.

b) Status Functions

	Name	Description
	PLIB_RESET_ReasonClear	Clears the RCON register.
	PLIB_RESET_ReasonGet	Returns the reason for a reset.
	PLIB_RESET_ConfigRegReadErrorGet	Gets the Configuration register read error.
	PLIB_RESET_WdtTimeOutHasOccurredInSleep	Returns the state of the device when WDT time-out occurred

c) NMI Events Functions

	Name	Description
	PLIB_RESET_NmiCounterValueGet	Gets the NMI counter value.
	PLIB_RESET_NmiCounterValueSet	Sets the NMI counter.
	PLIB_RESET_NmiEventClear	Clears the NMI event
	PLIB_RESET_NmiEventTrigger	Triggers the NMI event.
	PLIB_RESET_NmiReasonGet	Returns the reason for the Non-Maskable Interrupt (NMI).

d) Feature Existence Functions

	Name	Description
	PLIB_RESET_ExistsResetReasonStatus	Identifies whether the ResetReasonStatus feature exists on the Reset module.
	PLIB_RESET_ExistsSoftwareResetTrigger	Identifies whether the SoftwareResetTrigger feature exists on the Reset module.
	PLIB_RESET_ExistsConfigRegReadError	Identifies whether the ConfigRegReadError feature exists on the Reset module.
	PLIB_RESET_ExistsNmiControl	Identifies whether the NmiControl feature exists on the Reset module.
	PLIB_RESET_ExistsNmiCounter	Identifies whether the NmiCounter feature exists on the Reset module.
	PLIB_RESET_ExistsWdtoInSleep	Identifies whether the WdtoInSleep feature exists on the Reset module.

e) Data Types and Constants

	Name	Description
	RESET_MODULE_ID	Identifies the supported Reset modules.
	RESET_REASON	Lists the reset sources.
	RESET_CONFIG_REG_READ_ERROR	Lists the Configuration register read errors.
	RESET_NMI_COUNT_TYPE	Defines NMI counter data type
	RESET_NMI_REASON	Lists the NMI reasons.

Description

This section describes the Application Programming Interface (API) functions of the Reset Peripheral Library.

Refer to each section for a detailed description.

a) Initialization Functions

PLIB_RESET_SoftwareResetEnable Function

Enables the software reset.

File

plib_reset.h

C

```
void PLIB_RESET_SoftwareResetEnable(RESET_MODULE_ID index);
```

Returns

None.

Description

This function triggers a software reset.

Remarks

This function implements an operation of the SoftwareResetTrigger feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsSoftwareResetTrigger function in your application to determine whether this feature is available.

Preconditions

The system unlock sequence must be performed before calling PLIB_RESET_SoftwareResetEnable.

Example

```
//Call system service to unlock the system
PLIB_RESET_SoftwareResetEnable( RESET_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RESET_SoftwareResetEnable (RESET_MODULE_ID index)

b) Status Functions

PLIB_RESET_ReasonClear Function

Clears the RCON register.

File

plib_reset.h

C

```
void PLIB_RESET_ReasonClear(RESET_MODULE_ID index, RESET_REASON reason);
```

Returns

None

Description

This function clears the particular reset bit in the RCON register. Multiple reasons for a reset can be ORed together and given as an input parameter to clear them simultaneously.

Remarks

This function implements an operation of the ResetReasonStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsResetReasonStatus function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RESET_ReasonClear( RESET_ID_0, RESET_REASON_MCLR | RESET_REASON_POWERON );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
reason	Select the reset type from enum RESET_REASON

Function

void PLIB_RESET_ReasonClear(RESET_MODULE_ID index, RESET_REASON reason)

PLIB_RESET_ReasonGet Function

Returns the reason for a reset.

File

plib_reset.h

C

```
RESET_REASON PLIB_RESET_ReasonGet(RESET_MODULE_ID index);
```

Returns

RESET_REASON - Type of reset (when there is more than one reason for a reset, this function will logically OR (bitwise) the reasons and return the value.

Description

This function returns the reason a reset has occurred for the selected device.

Remarks

This function implements an operation of the ResetReasonStatus feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsResetReasonStatus function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
RESET_REASON type;

type = PLIB_RESET_ReasonGet ( RESET_ID_0 );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

RESET_REASON PLIB_RESET_ReasonGet (RESET_MODULE_ID index)

PLIB_RESET_ConfigRegReadErrorGet Function

Gets the Configuration register read error.

File

plib_reset.h

C

```
RESET_CONFIG_REG_READ_ERROR PLIB_RESET_ConfigRegReadErrorGet(RESET_MODULE_ID index);
```

Returns

RESET_CONFIG_REG_READ_ERROR - Type of Configuration Register Read Error

Description

This function returns the Configuration register read error, if any, after the reset.

Remarks

This function implements an operation of the ConfigRegReadError feature. This feature may not be available on all devices. Refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsConfigRegReadError function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_RESET_ConfigRegReadErrorGet( RESET_ID_0 )== PRIMARY_CONFIG_REG_READ_ERROR )
{
    //Do Something
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

RESET_CONFIG_REG_READ_ERROR PLIB_RESET_ConfigRegReadErrorGet(RESET_MODULE_ID index);

PLIB_RESET_WdtTimeOutHasOccurredInSleep Function

Returns the state of the device when WDT time-out occurred

File

plib_reset.h

C

```
bool PLIB_RESET_WdtTimeOutHasOccurredInSleep(RESET_MODULE_ID index);
```

Returns

- true - The device was in Sleep mode when a WDT time-out occurred
- false - The device was not in Sleep mode when a WDT time-out occurred

Description

This function returns whether or not the the device was in Sleep mode when a WDT time-out event occurred.

Remarks

This function implements an operation of the WdtoInSleep feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsWdtoInSleep function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_RESET_WdtTimeOutHasOccurredInSleep( RESET_ID_0 ))
{
    //Do Something
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_RESET_WdtTimeOutHasOccurredInSleep (RESET_MODULE_ID index)

c) NMI Events Functions

PLIB_RESET_NmiCounterValueGet Function

Gets the NMI counter value.

File

plib_reset.h

C

```
RESET_NMI_COUNT_TYPE PLIB_RESET_NmiCounterValueGet(RESET_MODULE_ID index);
```

Returns

nmi_count - NMI counter value

Description

This function returns the NMI Reset counter value.

Remarks

This function implements an operation of the NmiCounter feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsNmiCounter function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
RESET_NMI_COUNT_TYPE nmi_count;
nmi_count = PLIB_RESET_NmiCounterValueGet( RESET_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

RESET_NMI_COUNT_TYPE PLIB_RESET_NmiCounterValueGet (RESET_MODULE_ID index)

PLIB_RESET_NmiCounterValueSet Function

Sets the NMI counter.

File

plib_reset.h

C

```
void PLIB_RESET_NmiCounterValueSet(RESET_MODULE_ID index, RESET_NMI_COUNT_TYPE nmi_count);
```

Returns

None.

Description

This function sets the NMI counter to be expired for a WDT or DMT reset.

Remarks

NMI counter value range may vary between devices. Please refer to the specific device data sheet. This function implements an operation of the NmiCounter feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsNmiCounter function in your application to determine whether this feature is available.

Preconditions

The system unlock sequence must be performed before calling PLIB_RESET_NmiCounterValueSet

Example

```
//Call system service to unlock the system
PLIB_RESET_NmiCounterValueSet( RESET_ID_0,  0x54);
//Call system service to lock the system
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
nmi_count	NMI counter value

Function

void PLIB_RESET_NmiCounterValueSet (RESET_MODULE_ID index, RESET_NMI_COUNT_TYPE nmi_count)

PLIB_RESET_NmiEventClear Function

Clears the NMI event

File

plib_reset.h

C

```
void PLIB_RESET_NmiEventClear(RESET_MODULE_ID index, RESET_NMI_REASON nmi_reason);
```

Returns

None

Description

This function clears the NMI event. If a WDTO or DMTO NMI event is cleared before the NMI counter reaches zero, no device Reset is asserted.

Remarks

This function implements an operation of the NmiControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsNmiControl function in your application to determine whether this feature is available.

Preconditions

The system unlock sequence must be performed before calling PLIB_RESET_NmiEventTrigger.

Example

```
//Call system service to unlock the system
PLIB_RESET_NmiEventClear( RESET_ID_0, SOFTWARE_NMI );
//Call system service to lock the system
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
nmi_reason	Sets of reasons that can cause a NMI

Function

void PLIB_RESET_NmiEventClear (RESET_MODULE_ID index, RESET_NMI_REASON nmi_reason)

PLIB_RESET_NmiEventTrigger Function

Triggers the NMI event.

File

plib_reset.h

C

```
void PLIB_RESET_NmiEventTrigger(RESET_MODULE_ID index, RESET_NMI_REASON nmi_reason);
```

Returns

None

Description

This function triggers the NMI. In case of a Deadman Timer (DMT) or Watchdog Timer (WDT) NMI event, it will also trigger the NMI counter to start the countdown.

Remarks

This function implements an operation of the NmiControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsNmiControl function in your application to determine whether this feature is available.

Preconditions

The system unlock sequence must be performed before calling PLIB_RESET_NmiEventTrigger.

Example

```
//Call system service to unlock the system
PLIB_RESET_NmiEventTrigger( RESET_ID_0, SOFTWARE_NMI );
//Call system service to lock the system
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
nmi_reason	Sets of reasons which can cause NMI

Function

void PLIB_RESET_NmiEventTrigger (RESET_MODULE_ID index, RESET_NMI_REASON nmi_reason)

PLIB_RESET_NmiReasonGet Function

Returns the reason for the Non-Maskable Interrupt (NMI).

File

plib_reset.h

C

```
RESET_NMI_REASON PLIB_RESET_NmiReasonGet(RESET_MODULE_ID index);
```

Returns

RESET_NMI_REASON - Sets of reasons that can cause a NMI.

Description

This function returns the reason that caused the NMI.

Remarks

This function implements an operation of the NmiControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or include the PLIB_RESET_ExistsNmiControl function in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_RESET_NmiReasonGet( RESET_ID_0 )== WDTO_NMI )
{
    //Do Something
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

RESET_NMI_REASON PLIB_RESET_NmiReasonGet (RESET_MODULE_ID index)

d) Feature Existence Functions

PLIB_RESET_ExistsResetReasonStatus Function

Identifies whether the ResetReasonStatus feature exists on the Reset module.

File

plib_reset.h

C

```
bool PLIB_RESET_ExistsResetReasonStatus(RESET_MODULE_ID index);
```

Returns

- true - The ResetReasonStatus feature is supported on the device
- false - The ResetReasonStatus feature is not supported on the device

Description

This function identifies whether the ResetReasonStatus feature is available on the Reset module. When this function returns true, these functions are supported on the device:

- PLIB_RESET_ReasonGet
- PLIB_RESET_ReasonClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RESET_ExistsResetReasonStatus(RESET_MODULE_ID index)

PLIB_RESET_ExistsSoftwareResetTrigger Function

Identifies whether the SoftwareResetTrigger feature exists on the Reset module.

File

plib_reset.h

C

```
bool PLIB_RESET_ExistsSoftwareResetTrigger(RESET_MODULE_ID index);
```

Returns

- true - The SoftwareResetTrigger feature is supported on the device
- false - The SoftwareResetTrigger feature is not supported on the device

Description

This function identifies whether the SoftwareResetTrigger feature is available on the Reset module. When this function returns true, this function is supported on the device:

- PLIB_RESET_SoftwareResetEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RESET_ExistsSoftwareResetTrigger(RESET_MODULE_ID index)

PLIB_RESET_ExistsConfigRegReadError Function

Identifies whether the ConfigRegReadError feature exists on the Reset module.

File

plib_reset.h

C

```
bool PLIB_RESET_ExistsConfigRegReadError(RESET_MODULE_ID index);
```

Returns

- true - The ConfigRegReadError feature is supported on the device
- false - The ConfigRegReadError feature is not supported on the device

Description

This function identifies whether the ConfigRegReadError feature is available on the Reset module. When this function returns true, this function is supported on the device:

- PLIB_RESET_ConfigRegReadErrorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RESET_ExistsConfigRegReadError(RESET_MODULE_ID index)

PLIB_RESET_ExistsNmiControl Function

Identifies whether the NmiControl feature exists on the Reset module.

File

plib_reset.h

C

```
bool PLIB_RESET_ExistsNmiControl(RESET_MODULE_ID index);
```

Returns

- true - The NmiControl feature is supported on the device
- false - The NmiControl feature is not supported on the device

Description

This function identifies whether the NmiControl feature is available on the Reset module. When this function returns true, these functions are supported on the device:

- PLIB_RESET_NmiReasonGet

- PLIB_RESET_NmiEventTrigger
- PLIB_RESET_NmiEventClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RESET_ExistsNmiControl(RESET_MODULE_ID index)

PLIB_RESET_ExistsNmiCounter Function

Identifies whether the NmiCounter feature exists on the Reset module.

File

plib_reset.h

C

```
bool PLIB_RESET_ExistsNmiCounter(RESET_MODULE_ID index);
```

Returns

- true - The NmiCounter feature is supported on the device
- false - The NmiCounter feature is not supported on the device

Description

This function identifies whether the NmiCounter feature is available on the Reset module. When this function returns true, these functions are supported on the device:

- PLIB_RESET_NmiCounterValueSet
- PLIB_RESET_NmiCounterValueGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RESET_ExistsNmiCounter(RESET_MODULE_ID index)

PLIB_RESET_ExistsWdtoInSleep Function

Identifies whether the WdtoInSleep feature exists on the Reset module.

File

plib_reset.h

C

```
bool PLIB_RESET_ExistsWdtoInSleep(RESET_MODULE_ID index);
```

Returns

- true - The WdtoInSleep feature is supported on the device

- false - The WdtoInSleep feature is not supported on the device

Description

This function identifies whether the WdtoInSleep feature is available on the Reset module. When this function returns true, this function is supported on the device:

- PLIB_RESET_WdtTimeOutHasOccurredInSleep

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RESET_ExistsWdtoInSleep(RESET_MODULE_ID index)

e) Data Types and Constants

RESET_MODULE_ID Enumeration

Identifies the supported Reset modules.

File

help_plib_reset.h

C

```
typedef enum {
  RESET_ID_0
} RESET_MODULE_ID;
```

Members

Members	Description
RESET_ID_0	RESET Module ID 0

Description

Reset Module ID

This enumeration identifies the Reset modules that are available on the microcontroller. This is the superset of all the possible instances that might be available on a Microchip microcontroller.

Remarks

Caller should not rely on the specific numbers assigned to any of these values as they may change from one processor to the next.

Not all modules are available on all devices. Refer to the "Resets" chapter in the specific device data sheet to determine which modules are supported. The numbers used in the enumeration values will match the numbers provided in the data sheet.

RESET_REASON Enumeration

Lists the reset sources.

File

help_plib_reset.h

C

```
typedef enum {
  RESET_REASON_NONE = 0x00000000,
  RESET_REASON_POWERON = 0x00000003,
  RESET_REASON_BROWNOUT = 0x00000002,
  RESET_REASON_WDT_TIMEOUT = 0x00000010,
```

```
  RESET_REASON_SOFTWARE = 0x00000040,
  RESET_REASON_MCLR = 0x00000080,
  RESET_REASON_CONFIG_MISMATCH = 0x00000200,
  RESET_REASON_VBAT = 0x00010000,
  RESET_REASON_VBPOR = 0x00020000,
  RESET_REASON_HIGH_VOLTAGE_DETECT = 0x20000000,
  RESET_REASON_DMT_TIMEOUT = 0x00000020,
  RESET_REASON_ALL = 0x200002D3
} RESET_REASON;
```

Members

Members	Description
RESET_REASON_NONE = 0x00000000	The last reset was of unknown type
RESET_REASON_POWERON = 0x00000003	The last reset was a power on reset
RESET_REASON_BROWNOUT = 0x00000002	The last reset was a brown out reset
RESET_REASON_WDT_TIMEOUT = 0x00000010	The last reset was a watch dog timer time-out reset
RESET_REASON_SOFTWARE = 0x00000040	The last reset was a software reset
RESET_REASON_MCLR = 0x00000080	The last reset was a master clear(MCLR) reset
RESET_REASON_CONFIG_MISMATCH = 0x00000200	The last reset was a configuration mismatch reset
RESET_REASON_VBAT = 0x00010000	The last reset was a VBAT reset
RESET_REASON_VBPOR = 0x00020000	The last reset was a VBPOR reset, because of no supply or Brown-out on VBAT pin
RESET_REASON_HIGH_VOLTAGE_DETECT = 0x20000000	The last reset was high voltage detect reset
RESET_REASON_DMT_TIMEOUT = 0x00000020	The last reset was a Deadman Timer time-out reset
RESET_REASON_ALL = 0x200002D3	All reset flags are high

Description

RESET source select enumeration

This enumeration lists the possible reset sources.

Remarks

Not all reset sources exist on all devices. Please refer to the specific device data sheet for availability.

RESET_CONFIG_REG_READ_ERROR Enumeration

Lists the Configuration register read errors.

File

help_plib_reset.h

C

```
typedef enum {
  PRIMARY_CONFIG_REG_READ_ERROR,
  PRIMARY_AND_ALTERNATIVE_CONFIG_REG_READ_ERROR,
  NO_CONFIG_REG_READ_ERROR
} RESET_CONFIG_REG_READ_ERROR;
```

Members

Members	Description
PRIMARY_CONFIG_REG_READ_ERROR	An error occurred during the read of primary configuration registers
PRIMARY_AND_ALTERNATIVE_CONFIG_REG_READ_ERROR	An error occurred during the read of primary and alternate configuration register
NO_CONFIG_REG_READ_ERROR	No error occurred during the read of configuration registers

Description

RESET Config Register Read Error Enumeration

This enumeration lists the possible errors while reading Configuration registers.

Remarks

Not all errors exist on all devices. Please refer to the specific device data sheet for availability.

RESET_NMI_COUNT_TYPE Type

Defines NMI counter data type

File

plib_reset.h

C

```
typedef unsigned int RESET_NMI_COUNT_TYPE;
```

Description

RESET_NMI_COUNT_TYPE data type

NMI counter data type definition.

RESET_NMI_REASON Enumeration

Lists the NMI reasons.

File

help_plib_reset.h

C

```
typedef enum {
  WDTO_NMI,
  DMTO_NMI,
  SOFTWARE_NMI,
  GLOBAL_NMI,
  LVD_NMI,
  CF_NMI,
  WDTS_NMI
} RESET_NMI_REASON;
```

Members

Members	Description
WDTO_NMI	Watch Dog Timer time-out has caused NMI
DMTO_NMI	Deadman Timer time-out has caused NMI
SOFTWARE_NMI	Software triggered NMI will be generated
GLOBAL_NMI	General NMI or user-initiated NMI has occurred
LVD_NMI	Low Voltage Detection Condition has caused NMI
CF_NMI	Clock Failure has caused NMI
WDTS_NMI	Watch Dog Timer in Sleep has caused NMI

Description

NMI Reason enumeration

This enumeration lists the possible NMI sources.

Remarks

Not all NMI sources exist on all devices. Please refer to the specific device data sheet for availability.

Files

Files

Name	Description
plib_reset.h	Defines the Reset Peripheral Library interface.
help_plib_reset.h	This is file help_plib_reset.h.

Description

This section lists the source and header files used by the library.

plib_reset.h

Defines the Reset Peripheral Library interface.

Functions

	Name	Description
	PLIB_RESET_ConfigRegReadErrorGet	Gets the Configuration register read error.
	PLIB_RESET_ExistsConfigRegReadError	Identifies whether the ConfigRegReadError feature exists on the Reset module.
	PLIB_RESET_ExistsNmiControl	Identifies whether the NmiControl feature exists on the Reset module.
	PLIB_RESET_ExistsNmiCounter	Identifies whether the NmiCounter feature exists on the Reset module.
	PLIB_RESET_ExistsResetReasonStatus	Identifies whether the ResetReasonStatus feature exists on the Reset module.
	PLIB_RESET_ExistsSoftwareResetTrigger	Identifies whether the SoftwareResetTrigger feature exists on the Reset module.
	PLIB_RESET_ExistsWdtoInSleep	Identifies whether the WdtoInSleep feature exists on the Reset module.
	PLIB_RESET_NmiCounterValueGet	Gets the NMI counter value.
	PLIB_RESET_NmiCounterValueSet	Sets the NMI counter.
	PLIB_RESET_NmiEventClear	Clears the NMI event
	PLIB_RESET_NmiEventTrigger	Triggers the NMI event.
	PLIB_RESET_NmiReasonGet	Returns the reason for the Non-Maskable Interrupt (NMI).
	PLIB_RESET_ReasonClear	Clears the RCON register.
	PLIB_RESET_ReasonGet	Returns the reason for a reset.
	PLIB_RESET_SoftwareResetEnable	Enables the software reset.
	PLIB_RESET_WdtTimeOutHasOccurredInSleep	Returns the state of the device when WDT time-out occurred

Types

	Name	Description
	RESET_NMI_COUNT_TYPE	Defines NMI counter data type

Description

Reset Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Reset Peripheral Library for Microchip microcontrollers. The definitions in this file are for the Reset Controller module.

File Name

plib_reset.h

Company

Microchip Technology Inc.

help_plib_reset.h

Enumerations

	Name	Description
	RESET_CONFIG_REG_READ_ERROR	Lists the Configuration register read errors.
	RESET_MODULE_ID	Identifies the supported Reset modules.
	RESET_NMI_REASON	Lists the NMI reasons.
	RESET_REASON	Lists the reset sources.

Description

This is file help_plib_reset.h.

RTCC Peripheral Library

This section describes the Real-Time Clock and Calendar (RTCC) Peripheral Library.

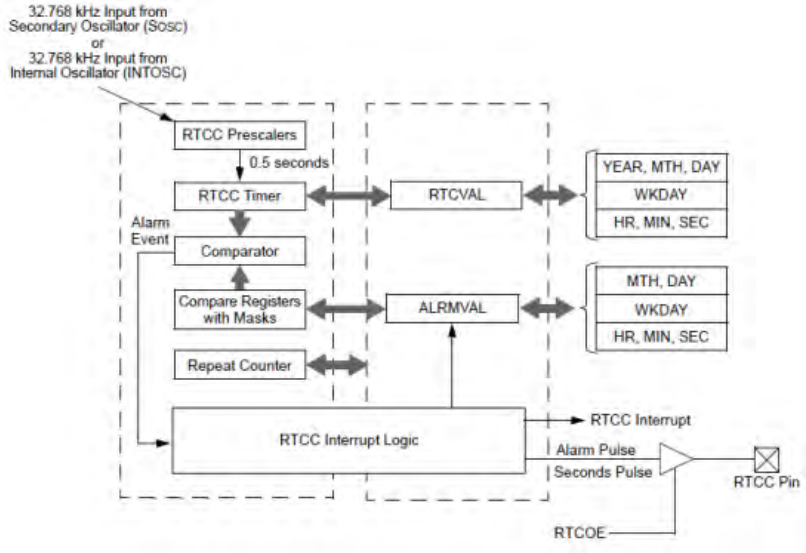
Introduction

This module provides real-time clock and calendar functions. The RTCC is intended for applications where accurate time must be maintained for extended periods with minimum to no intervention from the CPU. The module is optimized for low-power usage to provide extended battery life while keeping track of time.

Description

The RTCC module is a 100-year clock and calendar with automatic leap year detection. The range of the clock is from 00:00:00 (midnight) on January 1, 2000 to 23:59:59 on December 31, 2099. The hours are available in 24-hour (military time) format. The clock provides a granularity of one second with half-second visibility to the user.

RTCC Block Diagram



Operating Modes

Note: Please refer to the **"RTCC"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine which features are supported by your device.

RTCC Mode

The RTCC module is intended to be clocked by an external real-time clock crystal oscillating at 32.768 kHz. The prescaler divides the crystal oscillator frequency to produce a 1 Hz frequency for the clock and calendar. The current Date and Time are stored in a BCD counter.

Alarm Mode

The RTCC module provides an alarm function that is configurable from a half-second to one year. After the alarm is enabled, the RTCC module can be configured to repeat the alarm at preconfigured intervals. The indefinite repetition of the alarm is provided through the Chime feature.

Using the Library

This topic describes the basic architecture of the RTCC Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_rtcc.h`

The interface to the RTCC Peripheral Library is defined in the `plib_rtcc.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the RTCC Peripheral Library should include `peripheral.h`.

Library File: The RTCC Peripheral Library archive (`.a`) file is installed with MPLAB Harmony.

Please refer to the What is MPLAB Harmony? section for information on how the peripheral interacts with the framework.

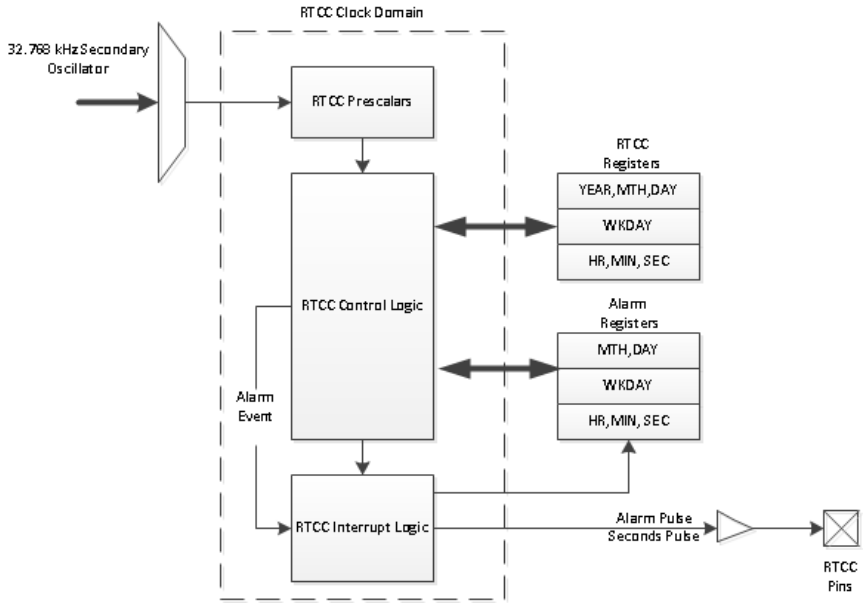
Hardware Abstraction Model

This library provides a low-level abstraction of the RTCC module on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

The RTCC peripheral library provides interface routines to interact with the blocks shown in the following diagram.

Hardware Abstraction Model



The **RTCC Control Logic** provides the capability to operate the RTCC module in the RTCC and Alarm modes. The control logic also handles the comparison and the counter increments, which in turn control the alarm generation. This module is also responsible for the generation of a square wave at the RTCC output pin. In addition, the RTCC module provides the RTCC drift calibration.

The **RTCC Interrupt Logic** is primarily used in alarm generation. The various configurations of the alarm and their repetition period may be defined.

The **RTCC Registers** store the actual date and time. Separate registers are present for RTCC and alarm functionality.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the RTCC module.

Library Interface Section	Description
General Functions	Provides the setup and configuration of general functionalities in the RTCC module. This section also covers the drift calibration.
RTCC Mode Functions	Provides configuration of the RTCC-related registers. Updating the Date and Time registers along with reading them accurately is performed.
Alarm Mode Functions	Provides configuration of the Alarm-related registers. Updating the Date and Time registers along with reading them accurately is performed. In addition, the rate at which an alarm occurs and the frequency is also configured in this mode.
Other Functions	Provides additional RTCC functions.
Feature Existence Functions	Provides functions that determine whether certain features exist on a device.

How the Library Works

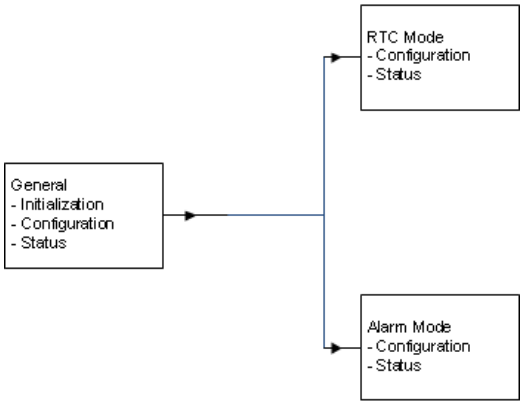
Provides information on how the library works.

Description

The usage model for this library is explained in the following sections.

The following diagram describes the major components of the usage model.

Usage Model



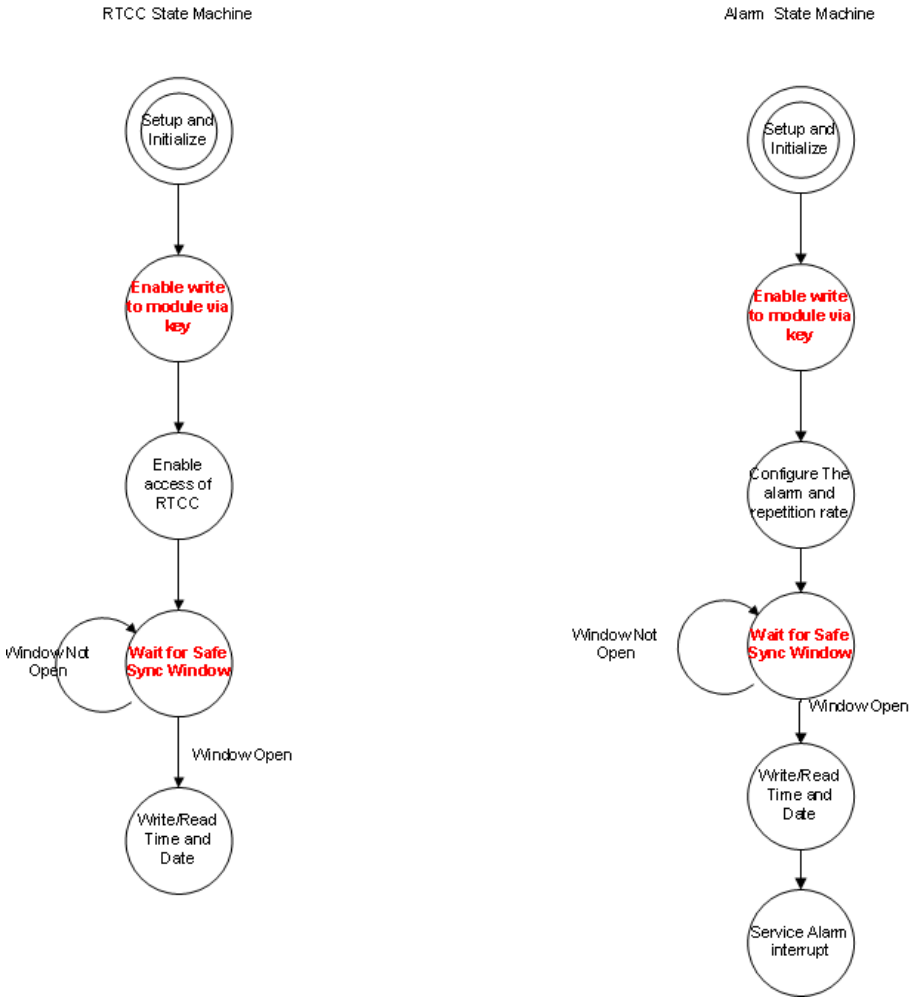
State Machine

This RTCC state machine is provided to give a general idea of the usage model of the peripheral library. Refer to the usage model for more detailed steps for the scenario that is being used.

Description

The following state machine diagram is for RTCC mode and Alarm Mode during normal operation.

RTCC State Machine



State	Associated Function
Setup and Initialization	Refer to mode of RTCC for detailed instructions of setup.

Enable Write via Key Sequence	For RTCC to perform any function, the module has to be enabled via a series of commands in a special sequence. This is abstracted and is achieved using PLIB_RTCC_WriteEnable.
Enable Access of RTC	These include the functions needed to set up the RTCC/Alarm, which will be explained in detail in the following sections.
Wait for Safe Sync Window	To update the RTCC on-the-fly, a safe window period is available, corresponding to 32 clock cycles called RTSYNC. Further sections will explain the functionality in greater detail.
Write/Read Date and Time	The application may read or write the date and time using PLIB_RTCC_RTCDateGet and PLIB_RTCC_RTCTimeGet or PLIB_RTCC_RTCDateSet and PLIB_RTCC_RTCTimeSet, among others. These functions are device-specific and may not be available for all devices.

RTCC Mode Operations

This section describes the RTCC mode of operation of the RTCC module.

Note: Please refer to the **"RTCC"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine which features are supported by your device.

Description

Enabling the RTCC Module for Write Operations

To perform a write to any of the RTCC timer registers the RTCWREN bit must be set. It is recommended that this bit be reset unless a write operation is specifically required.

A sequence of commands, each varying across processor families must be executed to set the RTCWREN.

Example: Enabling a Write

```
// Assume Interrupts are disabled.
// Assume the DMA controller is suspended

PLIB_RTCC_WriteEnable(MY_RTCC_INSTANCE);

// where, MY_RTCC_INSTANCE - is a specific instance of the hardware peripheral.

// This API performs the writing of the sequence
// 0xaa996655 and 0x556699aa to the SYSKET in MCU32
// and 0x55 and 0xaa in case of MCU 16 and MCU 8
// This API then sets the RTCWREN.
```

Updating RTCC Time and Date

1. Turn off the RTCC using the API PLIB_RTCC_Disable.
2. Wait for the sync clock to turn off by reading the status of PLIB_RTCC_RTCSyncStatusGet (this operation may not be required on all devices).
3. Update the Date and Time registers using PLIB_RTCC_RTCDateSet and PLIB_RTCC_RTCTimeSet.
4. Turn on the RTCC module using PLIB_RTCC_Enable.

Example: Updating RTCC Time and Date

```
// Assume Write Enable has been performed correctly
unsigned long time = 0x04153300; // Set time 04 hrs 15 mins and 33 sec
unsigned long date = 0x06102705; // Set date to Friday 27 Oct 2006

PLIB_RTCC_Disable(MY_RTCC_INSTANCE);

// where, MY_RTCC_INSTANCE - is a specific instance of the hardware peripheral.

while(PLIB_RTCC_RTCSyncStatusGet(MY_RTCC_INSTANCE)); // Wait for clock to turn off

PLIB_RTCC_RTCTimeSet(MY_RTCC_INSTANCE, time);  // Update the Time

PLIB_RTCC_RTCDateSet(MY_RTCC_INSTANCE, date);  // Update the Date

PLIB_RTCC_Enable(MY_RTCC_INSTANCE);
```

Updating RTCC Time and Date using RTSYNC Window

1. Wait for the sync clock to turn off by reading the status of PLIB_RTCC_RTCSyncStatusGet.
2. Update the RTC Date and Time registers using PLIB_RTCC_RTCDateSet and PLIB_RTCC_RTCTimeSet.

Example: Updating RTCC Time and Date Using RTSYNC Window

```
// Assume Write Enable has been performed correctly
unsigned long time = 0x04153300; // Set time 04 hrs 15 mins and 33 sec
unsigned long date = 0x06102705; // Set date to Friday 27 Oct 2006

// where, MY_RTCC_INSTANCE - is a specific instance of the hardware peripheral.

//Disable Critical Interrupts here ....

while(PLIB_RTCC_RTCSyncStatusGet(MY_RTCC_INSTANCE)); // Wait for clock to turn off

PLIB_RTCC_RTCTimeSet(MY_RTCC_INSTANCE, time);  // Update the Time

PLIB_RTCC_RTCDateSet(MY_RTCC_INSTANCE, date);  // Update the Date

//Enable Critical Interrupts here ....
```

Updating RTCC Time and Date Using Register Pointers

1. Turn off the RTCC using PLIB_RTCC_Disable.
2. Identify whether the RTCTimeValue and RTCDateValue features exist on the RTCC module using PLIB_RTCC_ExistsRTCTime and PLIB_RTCC_ExistsRTCDate.
3. Update the RTC Date and Time registers using PLIB_RTCC_RTCDateSet
4. and PLIB_RTCC_RTCtimeSet.
5. Turn on the RTCC module using PLIB_RTCC_Enable.

Example: Updating RTCC Time and Date Using Register Pointers

```
// Assume Write Enable has been performed correctly

PLIB_RTCC_Disable(MY_RTCC_INSTANCE);

// where, MY_RTCC_INSTANCE - is a specific instance of the hardware peripheral.

PLIB_RTCC_RTCYearSet(MY_RTCC_INSTANCE, 0x0007);   // Update the Year

PLIB_RTCC_RTCMonthSet(MY_RTCC_INSTANCE,0x10);    // Set Month to October

PLIB_RTCC_RTCDaySet(MY_RTCC_INSTANCE,0x28);      // Set Day to the 27th

PLIB_RTCC_RTCWeekDaySet(MY_RTCC_INSTANCE,0x01);  // Set the Day of the Week to Sunday

PLIB_RTCC_RTCHourSet(MY_RTCC_INSTANCE,0x10);     // Set the Hour value to 10

PLIB_RTCC_RTCMinuteSet(MY_RTCC_INSTANCE,0x00);   // Set Minute value to 0

PLIB_RTCC_RTCSecondSet(MY_RTCC_INSTANCE,0x00);   // Set Seconds value to 0

PLIB_RTCC_Enable(MY_RTCC_INSTANCE);
```

Alarm Mode Operations

This section describes the Alarm mode of operation of the RTCC module.

Note: Please refer to the **"RTCC"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine which features are supported by your device.

Description

Configuring the One-Time-Per-Day Alarm

1. Turn off the Alarm and also the chime, alarm repeats, and masks using PLIB_RTCC_AlarmDisable.
2. Wait for the sync clock to turn off by reading the status of PLIB_RTCC_AlarmSyncStatusGet (This operation may not be required on all devices).
3. Update the Alarm Date and Time registers using PLIB_RTCC_AlarmTimeSet and PLIB_RTCC_AlarmDateSet.
4. Set the alarm mask to every half-second and the repeat counter to zero using PLIB_RTCC_AlarmMaskModeSelect and PLIB_RTCC_AlarmRepeatCountSet, respectively.
5. Turn on the RTCC Alarm module using PLIB_RTCC_AlarmEnable.

Example: Configuring the One-Time-Per-Day Alarm

```
// Assume Write Enable has been performed correctly
unsigned long time = 0x04153300; // Set time 04 hrs 15 mins and 33 sec
unsigned long date = 0x06102705; // Set date to Friday 27 Oct 2006

PLIB_RTCC_AlarmDisable(MY_RTCC_INSTANCE);

// where, MY_RTCC_INSTANCE - is a specific instance of the hardware peripheral.

while(PLIB_RTCC_AlarmSyncStatusGet(MY_RTCC_INSTANCE)); // Wait for clock to turn off

PLIB_RTCC_AlarmTimeSet(MY_RTCC_INSTANCE, time);  // Update the Time

PLIB_RTCC_AlarmDateSet(MY_RTCC_INSTANCE, date);  // Update the Date

PLIB_RTCC_AlarmMaskModeSelect(MY_RTCC_INSTANCE, RTCC_ALARM_EVERY_HALF_SECOND);

PLIB_RTCC_AlarmRepeatCountSet(MY_RTCC_INSTANCE, 0 /*Number of repetitions*/ );

PLIB_RTCC_AlarmEnable(MY_RTCC_INSTANCE);
```

Configuring the Repeat Alarm

1. Turn off the Alarm and also the Chime, alarm repeats, and masks using PLIB_RTCC_AlarmDisable.
2. Wait for the sync clock to turn off by reading the status of PLIB_RTCC_AlarmSyncStatusGet (this operation may not be required on all devices).
3. Update the Alarm Date and Time registers using PLIB_RTCC_AlarmTimeSet and PLIB_RTCC_AlarmDateSet.
4. Set the alarm mask to every half-second and the repeat counter to 10 using PLIB_RTCC_AlarmMaskModeSelect and PLIB_RTCC_AlarmRepeatCountSet, respectively.
5. Turn on the RTCC Alarm module using PLIB_RTCC_AlarmEnable.

Example: Configuring the Repeat Alarm

```
// Assume Write Enable has been performed correctly
unsigned long time = 0x04153300; // Set time 04 hrs 15 mins and 33 sec
unsigned long date = 0x06102705; // Set date to Friday 27 Oct 2006

PLIB_RTCC_AlarmDisable(MY_RTCC_INSTANCE);

// where, MY_RTCC_INSTANCE - is a specific instance of the hardware peripheral.

while(PLIB_RTCC_AlarmSyncStatusGet(MY_RTCC_INSTANCE)); // Wait for clock to turn off

PLIB_RTCC_AlarmTimeSet(MY_RTCC_INSTANCE, time);  // Update the Time

PLIB_RTCC_AlarmDateSet(MY_RTCC_INSTANCE, date);  // Update the Date

PLIB_RTCC_AlarmMaskModeSelect(MY_RTCC_INSTANCE, RTCC_ALARM_EVERY_HALF_SECOND);

PLIB_RTCC_AlarmRepeatCountSet(MY_RTCC_INSTANCE, 10 /*No of repetitions*/ );

PLIB_RTCC_AlarmEnable(MY_RTCC_INSTANCE);
```

Configuring the Indefinite One-Per-Day Alarm

1. Turn off the Alarm and also the Chime, alarm repeats and masks using PLIB_RTCC_AlarmDisable.
2. Wait for the sync clock to turn off by reading the status of PLIB_RTCC_AlarmSyncStatusGet (This operation may not be required on all devices).
3. Update the Alarm Date and Time registers using PLIB_RTCC_AlarmTimeSet and PLIB_RTCC_AlarmDateSet.
4. Set the alarm mask to every half-second and the repeat counter to '0' using PLIB_RTCC_AlarmMaskModeSelect and PLIB_RTCC_AlarmRepeatCountSet, respectively.
5. Turn on the RTCC Alarm module using PLIB_RTCC_AlarmEnable and enable chime using PLIB_RTCC_AlarmChimeEnable.

Example: Configuring the Indefinite One-Per-Day Alarm

```
// Assume Write Enable has been performed correctly
unsigned long time = 0x04153300; // Set time 04 hrs 15 mins and 33 sec
unsigned long date = 0x06102705; // Set date to Friday 27 Oct 2006

PLIB_RTCC_AlarmDisable(MY_RTCC_INSTANCE);

// where, MY_RTCC_INSTANCE - is a specific instance of the hardware peripheral.

while(PLIB_RTCC_AlarmSyncStatusGet(MY_RTCC_INSTANCE)); // Wait for clock to turn off
```

```
PLIB_RTCC_AlarmTimeSet(MY_RTCC_INSTANCE, time);  // Update the Time

PLIB_RTCC_AlarmDateSet(MY_RTCC_INSTANCE, date);  // Update the Date

PLIB_RTCC_AlarmMaskModeSelect(MY_RTCC_INSTANCE, RTCC_ALARM_EVERY_HALF_SECOND);

PLIB_RTCC_AlarmRepeatCountSet(MY_RTCC_INSTANCE, 0 /*No of repetitions*/ );

PLIB_RTCC_AlarmEnable(MY_RTCC_INSTANCE);

PLIB_RTCC_AlarmChimeEnable(MY_RTCC_INSTANCE);
```

Other Functionality

This section describes the Drift Calibration mode of operation of the RTCC module.

Note: Please refer to the **"RTCC"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine which features are supported by your device.

Description

The real-time crystal input can be calibrated using the periodic auto-adjust feature. When properly calibrated, the RTCC module can provide an error of less than 0.66 seconds per month. Calibration has the ability to eliminate an error of up to 260 ppm.

The calibration is accomplished by finding the number of error clock pulses and writing this value into the calibration bit fields using PLIB_RTCC_DriftCalibrateSet.

Drift Calibration

1. Using another timer resource, the user must find the error of the 32.768 kHz crystal.
2. Once the error is known, it must be converted to the number of error clock pulses per minute, as shown by ***(Ideal Frequency(32,758) - Measured Frequency) * 60 = Error Clocks Per Minute***.
3. If the error is negative, the input to PLIB_RTCC_DriftCalibrateSet is negative. Likewise, if the error is positive, the input is positive. The negative and positive values are the actual number of clock pulses to be added or subtracted from the timer counter per minute.

Example: Configuring the One-Time-Per-Day Alarm

```
// Assume Write Enable has been performed correctly
// Assume steps 1 and 2 are performed and the error is determined.

int driftValue = 0x3FD   // 10 bits Adjustment, -3 in value
int T0,T1;

do
{
    T0 = PLIB_RTCC_RTCTimeGet(MY_RTCC_INSTANCE);
    T1 = PLIB_RTCC_RTCTimeGet(MY_RTCC_INSTANCE);
    // where, MY_RTCC_INSTANCE is a specific instance of the hardware peripheral
}while(T0!=T1)     // Read Valid Time Value

if((T0 & 0XFF) == 0) // we are at seconds exactly 00, wait for auto adjust
{
    while PLIB_RTCC_HalfSecondStatusGet(MY_RTCC_INSTANCE); // Wait for the second Half
}

PLIB_RTCC_DriftCalibrateSet(MY_RTCC_INSTANCE, 0x00); //Clear the calibration

PLIB_RTCC_DriftCalibrateSet(MY_RTCC_INSTANCE, 0xdriftValue);
```

Configuring the Library

The library is configured for the supported RTCC modules when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Functions

	Name	Description
	PLIB_RTCC_ClockOutputDisable	Disables the specific RTCC module's output pin.
	PLIB_RTCC_ClockOutputEnable	Enables the specific RTCC module's output pin.
	PLIB_RTCC_ClockRunningStatus	Provides the status of the RTCC clock.

b) RTCC Mode Functions

	Name	Description
	PLIB_RTCC_Disable	Disables the specific RTCC module on the device.
	PLIB_RTCC_Enable	Enables the specific RTCC module on the device.
	PLIB_RTCC_WriteDisable	Disables writing to the specific RTCC module's value registers.
	PLIB_RTCC_WriteEnable	Enables writing to the specific RTCC module's value registers.
	PLIB_RTCC_RTCDateGet	Returns the contents of the specific RTCC module's Date register.
	PLIB_RTCC_RTCDateSet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCDayGet	Returns the contents of the Days bits in the specific RTCC module's Date register.
	PLIB_RTCC_RTCDaySet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCHourGet	Returns the contents of the Hours bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCHourSet	Writes the contents of the Hours bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCMinuteGet	Returns the contents of the Minutes bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCMinuteSet	Writes the contents of Minutes bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCMonthGet	Returns the contents of the Months bits in the specific RTCC module's Date register.
	PLIB_RTCC_RTCMonthSet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCSecondGet	The function returns the contents of the Seconds bits in the specific RTCC device's Time register.
	PLIB_RTCC_RTCSecondSet	Writes the contents of Seconds bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCTimeGet	Returns the contents of the specific RTCC module's Time register.
	PLIB_RTCC_RTCTimeSet	Writes to the specific RTCC module's Time register.
	PLIB_RTCC_RTCWeekDayGet	Returns the contents of the WeekDay bits in the specific RTCC module's Date register.
	PLIB_RTCC_RTCWeekDaySet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCYearGet	Returns the contents of the Year bits in the specific RTCC module's Date register.
	PLIB_RTCC_RTCYearSet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCSyncStatusGet	The function returns the synchronization status bit.

c) Alarm Mode Functions

	Name	Description
	PLIB_RTCC_AlarmChimeDisable	Disables the specific RTCC module's chime.
	PLIB_RTCC_AlarmChimeEnable	Enables the specific RTCC module's chime.
	PLIB_RTCC_AlarmDateGet	Returns the contents of the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmDateSet	Writes to the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmDayGet	Returns the contents of the Day bits in the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmDaySet	Writes to the specific RTCC module's Alarm Date value register.
	PLIB_RTCC_AlarmDisable	Disables the specific RTCC module's alarm.
	PLIB_RTCC_AlarmEnable	Enables the specific RTCC module's alarm.
	PLIB_RTCC_AlarmHourGet	Returns the contents of Hours bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmHourSet	The function returns the contents of Hours bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmMaskModeSelect	Sets the specific RTCC module's alarm mask Configuration bits.
	PLIB_RTCC_AlarmMinuteGet	Returns the contents of Minutes bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmMinuteSet	Returns the contents of the Minutes bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmMonthGet	Returns the contents of the Month bits in the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmMonthSet	Writes to the specific RTCC module's Alarm Date register.

	PLIB_RTCC_AlarmPulseInitialGet	Returns the state of the initial alarm pulse.
	PLIB_RTCC_AlarmPulseInitialSet	Enables the determination of the initial alarm pulse.
	PLIB_RTCC_AlarmRepeatCountGet	Reads the specific RTCC module's alarm repeat counter.
	PLIB_RTCC_AlarmRepeatCountSet	Sets the specific RTCC module's alarm repeat counter.
	PLIB_RTCC_AlarmSecondGet	Returns the contents of the Seconds bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmSecondSet	Returns the contents of Seconds bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmTimeGet	Returns the contents of the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmTimeSet	Writes to the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmValueRegisterPointer	Sets the specific RTCC module's Alarm register pointer.
	PLIB_RTCC_AlarmWeekDayGet	Returns the contents of the WeekDay bits in the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmWeekDaySet	Writes to the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmSyncStatusGet	The function returns the synchronization status bit.

d) Other Functions

	Name	Description
	PLIB_RTCC_ClockSourceSelect	Selects the clock source for the RTCC module.
	PLIB_RTCC_DriftCalibrateGet	Reads the specific RTCC module's drift calibration bits.
	PLIB_RTCC_DriftCalibrateSet	Sets the specific RTCC module's drift calibration bits.
	PLIB_RTCC_HalfSecondStatusGet	The function returns the half second status bit.
	PLIB_RTCC_OutputSelect	Selects which signal will be presented on the RTCC pin
	PLIB_RTCC_StopInIdleDisable	Continues normal RTCC operation when the device enters Idle mode.
	PLIB_RTCC_StopInIdleEnable	Disables access to the RTCC module by the Peripheral Bus Clock (PBCLK) when the CPU enters Idle mode.

e) Feature Existence Functions

	Name	Description
	PLIB_RTCC_ExistsAlarmChimeControl	Identifies whether the AlarmChimeControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmControl	Identifies whether the AlarmControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmDate	Identifies whether the AlarmDate feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmMaskControl	Identifies whether the AlarmMaskControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmPulseInitial	Identifies whether the AlarmPulseInitial feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmRepeatControl	Identifies whether the AlarmRepeatControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmTime	Identifies whether the AlarmTime feature exists on the RTCC module.
	PLIB_RTCC_ExistsCalibration	Identifies whether the Calibration feature exists on the RTCC module.
	PLIB_RTCC_ExistsClockRunning	Identifies whether the ClockRunning feature exists on the RTCC module.
	PLIB_RTCC_ExistsClockSelect	Identifies whether the ClockSelect feature exists on the RTCC module.
	PLIB_RTCC_ExistsEnableControl	Identifies whether the EnableControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsHalfSecond	Identifies whether the HalfSecond feature exists on the RTCC module.
	PLIB_RTCC_ExistsOutputControl	Identifies whether the OutputControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsOutputSelect	Identifies whether the OutputSelect feature exists on the RTCC module.
	PLIB_RTCC_ExistsRTCDate	Identifies whether the RTCDateValue feature exists on the RTCC module.
	PLIB_RTCC_ExistsRTCTime	Identifies whether the RTCTimeValue feature exists on the RTCC module.
	PLIB_RTCC_ExistsStopInIdleControl	Identifies whether the StopInIdle feature exists on the RTCC module.
	PLIB_RTCC_ExistsSynchronization	Identifies whether the Synchronization feature exists on the RTCC module.
	PLIB_RTCC_ExistsWriteEnable	Identifies whether the WriteEnable feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmSynchronization	Identifies whether the AlarmSynchronization feature exists on the RTCC module.

f) Data Types and Constants

	Name	Description
	RTCC_ALARM_MASK_CONFIGURATION	Data type defining the different configurations for the alarm mask bits.

	RTCC_MODULE_ID	Enumeration: RTCC_MODULE_ID This enumeration defines number of modules which are available on the microcontroller. This is the superset of all of the possible instances that may be available on the Microchip microcontrollers. Refer to the data sheet to get the correct number of modules defined for desired microcontroller.
	RTCC_VALUE_REGISTER_POINTER	Data type defining the different configurations by which the RTCC Date and Time Registers can be accessed.

Description

This section describes the Application Programming Interface (API) functions of the RTCC Peripheral Library.

Refer to each section for a detailed description.

a) General Functions

PLIB_RTCC_ClockOutputDisable Function

Disables the specific RTCC module's output pin.

File

plib_rtcc.h

C

```
void PLIB_RTCC_ClockOutputDisable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific RTCC module's output pin.

Remarks

This function implements an operation of the OutputControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsOutputControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_ClockOutputDisable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_ClockOutputDisable (RTCC_MODULE_ID index)

PLIB_RTCC_ClockOutputEnable Function

Enables the specific RTCC module's output pin.

File

plib_rtcc.h

C

```
void PLIB_RTCC_ClockOutputEnable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific RTCC module's output and generates a square wave using either the alarm or the 1 Hz clock output on the RTCC pin.

Remarks

This function implements an operation of the OutputControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsOutputControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_ClockOutputEnable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_ClockOutputEnable (RTCC_MODULE_ID index)

PLIB_RTCC_ClockRunningStatus Function

Provides the status of the RTCC clock.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ClockRunningStatus(RTCC_MODULE_ID index);
```

Returns

The status of the RTCC clock.

Description

This function provides the status of the RTCC clock.

Remarks

This function implements an operation of the ClockRunning feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsClockRunning in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
bool status;
status = PLIB_RTCC_ClockRunningStatus(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_RTCC_ClockRunningStatus (RTCC_MODULE_ID index)

b) RTCC Mode Functions

PLIB_RTCC_Disable Function

Disables the specific RTCC module on the device.

File

plib_rtcc.h

C

```
void PLIB_RTCC_Disable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific RTCC module on the device.

Remarks

This function implements an operation of the EnableControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsEnableControl in your application to automatically determine whether this feature is available.

Preconditions

The RTCC module should be unlocked for writing using the function PLIB_RTCC_WriteEnable before this function is called.

Example

```
PLIB_RTCC_Disable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_Disable (RTCC_MODULE_ID index)

PLIB_RTCC_Enable Function

Enables the specific RTCC module on the device.

File

plib_rtcc.h

C

```
void PLIB_RTCC_Enable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific RTCC module on the device.

Remarks

By calling this function, the RTCC pins are controlled by the RTCC module. The RTCC module will continue to function when the device is held in reset.

This function implements an operation of the EnableControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsEnableControl in your application to automatically determine whether this feature is available.

Preconditions

The RTCC module should be unlocked for writing using the function PLIB_RTCC_WriteEnable before this function is called.

Example

```
PLIB_RTCC_Enable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_Enable (RTCC_MODULE_ID index)

PLIB_RTCC_WriteDisable Function

Disables writing to the specific RTCC module's value registers.

File

plib_rtcc.h

C

```
void PLIB_RTCC_WriteDisable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function disables writing to the specific RTCC module's value registers.

Remarks

This function implements an operation of the WriteEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsWriteEnable in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_WriteDisable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_WriteDisable (RTCC_MODULE_ID index)

PLIB_RTCC_WriteEnable Function

Enables writing to the specific RTCC module's value registers.

File

plib_rtcc.h

C

```
void PLIB_RTCC_WriteEnable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function enables writing to the specific RTCC module's value registers.

Remarks

This function implements an operation of the WriteEnable feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsWriteEnable in your application to automatically determine whether this feature is available.

Preconditions

The SYSLOCK unlock sequence must be executed prior to calling this function by calling the PLIB_CORE_SysUnlock function.

Example

```
PLIB_RTCC_WriteEnable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_WriteEnable (RTCC_MODULE_ID index)

PLIB_RTCC_RTCDateGet Function

Returns the contents of the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCDateGet(RTCC_MODULE_ID index);
```

Returns

Date register contents.

Description

The function returns the contents of the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Date;
Date = PLIB_RTCC_RTCDateGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCDateGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCDateSet Function

Writes to the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCDateSet(RTCC_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

The function writes to the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t data = 0x06102705;     //Date = 27 Oct 2006 Friday
PLIB_RTCC_RTCDateSet(RTCC_ID_0, data);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_RTCDateSet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_RTCDayGet Function

Returns the contents of the Days bits in the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCDayGet(RTCC_MODULE_ID index);
```

Returns

Days bits in the Date register.

Description

The function returns the contents of the Days bits in the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Day;
Day = PLIB_RTCC_RTCDayGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCDayGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCDaySet Function

Writes to the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCDaySet(RTCC_MODULE_ID index, uint32_t day);
```

Returns

None.

Description

The function writes to the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t Day = 0x27;        //Day = 27th of the month
PLIB_RTCC_RTCDaySet(RTCC_ID_0, Day);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
day	The BCD value of the day to set in the Date register

Function

void PLIB_RTCC_RTCDaySet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_RTCHourGet Function

Returns the contents of the Hours bits in the specific RTCC module's Time register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCHourGet(RTCC_MODULE_ID index);
```

Returns

BCD value of the Hours bits in the Time register.

Description

The function returns the contents of the Hours bits in the specific RTCC module's Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCTime in your application to automatically determine whether this feature is available.

Example

```
uint32_t Hour;
Hour = PLIB_RTCC_RTCHourGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCHourGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCHourSet Function

Writes the contents of the Hours bits in the specific RTCC module's Time register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCHourSet(RTCC_MODULE_ID index, uint32_t hour);
```

Returns

None.

Description

The function writes the contents of the Hours bits in the specific RTCC module's Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Hour = 0x04;
PLIB_RTCC_RTCHourSet(RTCC_ID_0, Hour);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
hour	BCD value to be written to the Hours bits in the Time register

Function

uint32_t PLIB_RTCC_RTCHourSet (RTCC_MODULE_ID index, uint32_t hour)

PLIB_RTCC_RTCMinuteGet Function

Returns the contents of the Minutes bits in the specific RTCC module's Time register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCMinuteGet(RTCC_MODULE_ID index);
```

Returns

BCD value of the Minutes bits in the Time register.

Description

The function returns the contents of the Minutes bits in the specific RTCC module's Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Minute;
Minute = PLIB_RTCC_RTCMinuteGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCMinuteGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCMinuteSet Function

Writes the contents of Minutes bits in the specific RTCC module's Time register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCMinuteSet(RTCC_MODULE_ID index, uint32_t minute);
```

Returns

None.

Description

The function writes the contents of these bits in the specific RTCC module's Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Minute = 0x15;
PLIB_RTCC_RTCMinuteSet(RTCC_ID_0, Minute);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
minute	BCD value to be written to the Minutes bits in the Time register

Function

uint32_t PLIB_RTCC_RTCMinuteSet (RTCC_MODULE_ID index, uint32_t minute)

PLIB_RTCC_RTCMonthGet Function

Returns the contents of the Months bits in the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCMonthGet(RTCC_MODULE_ID index);
```

Returns

Months bits in the Date register.

Description

The function returns the contents of the Months bits in the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Month;
Month = PLIB_RTCC_RTCMonthGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCMonthGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCMonthSet Function

Writes to the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCMonthSet(RTCC_MODULE_ID index, uint32_t month);
```

Returns

None.

Description

The function writes to the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t Month = 0x10;      //Month = October
PLIB_RTCC_RTCMonthSet(RTCC_ID_0, Month);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
month	The BCD value of the month to set in the Date register

Function

void PLIB_RTCC_RTCMonthSet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_RTCSecondGet Function

The function returns the contents of the Seconds bits in the specific RTCC device's Time register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCSecondGet(RTCC_MODULE_ID index);
```

Returns

BCD value of the Seconds bits in the Time register.

Description

The function returns the contents of the Seconds bits in the specific RTCC module's Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Second;
Second = PLIB_RTCC_RTCSecondGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCSecondGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCSecondSet Function

Writes the contents of Seconds bits in the specific RTCC module's Time register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCSecondSet(RTCC_MODULE_ID index, uint32_t second);
```

Returns

None.

Description

The function writes the contents of the Seconds bits in the specific RTCC module's Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Second = 0x33;
PLIB_RTCC_RTCSecondSet(RTCC_ID_0, Second);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
second	BCD value to be written to the Seconds bits in the Time register

Function

uint32_t PLIB_RTCC_RTCSecondSet (RTCC_MODULE_ID index, uint32_t second)

PLIB_RTCC_RTCTimeGet Function

Returns the contents of the specific RTCC module's Time register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCTimeGet(RTCC_MODULE_ID index);
```

Returns

Time register contents.

Description

The function returns the contents of the specific RTCC module's Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCTime in your application to automatically determine whether this feature is available.

Example

```
uint32_t time;
time = PLIB_RTCC_RTCTimeGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCTimeGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCTimeSet Function

Writes to the specific RTCC module's Time register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCTimeSet(RTCC_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

The function writes to the specific RTCC module's Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the RTCTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCTime in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Time register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t data = 0x04153300;     // Time = 4 hours, 15 minutes, and 33 seconds
PLIB_RTCC_RTCTimeSet(RTCC_ID_0, data);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_RTCTimeSet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_RTCWeekDayGet Function

Returns the contents of the WeekDay bits in the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCWeekDayGet(RTCC_MODULE_ID index);
```

Returns

WeekDay field in the Date register.

Description

The function returns the contents of the WeekDay bits in the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t WeekDay;
WeekDay = PLIB_RTCC_RTCWeekDayGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCWeekDayGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCWeekDaySet Function

Writes to the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCWeekDaySet(RTCC_MODULE_ID index, uint32_t weekday);
```

Returns

None.

Description

The function writes to the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t WeekDay = 0x05;        //WeekDay = Friday
PLIB_RTCC_RTCWeekDaySet(RTCC_ID_0, WeekDay);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
weekday	The BCD value of the weekday to set in the Date register

Function

void PLIB_RTCC_RTCWeekDaySet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_RTCYearGet Function

Returns the contents of the Year bits in the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_RTCYearGet(RTCC_MODULE_ID index);
```

Returns

Year bits in the Date register.

Description

The function returns the contents of the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Year;
Year = PLIB_RTCC_RTCYearGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_RTCYearGet (RTCC_MODULE_ID index)

PLIB_RTCC_RTCYearSet Function

Writes to the specific RTCC module's Date register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_RTCYearSet(RTCC_MODULE_ID index, uint32_t year);
```

Returns

None.

Description

The function writes to the specific RTCC module's Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the RTCDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsRTCDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t Year = 0x06;       //Year = 2006
PLIB_RTCC_RTCYearSet(RTCC_ID_0, Year);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
year	The BCD value of the year to set in the Date register

Function

void PLIB_RTCC_RTCYearSet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_RTCSyncStatusGet Function

The function returns the synchronization status bit.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_RTCSyncStatusGet(RTCC_MODULE_ID index);
```

Returns

- true - Date and time will change within 32 RTCC clocks
- false - Date and time are safe to read, and will not change soon

Description

The function returns the synchronization status bit, which is used to determine whether it is safe to read the date/time values, or if the values will change within 32 RTCC clocks.

Remarks

This bit is read-only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsSynchronization in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_RTCC_RTCSyncStatusGet(RTCC_ID_0))
{
...
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_RTCC_RTCSyncStatusGet (RTCC_MODULE_ID index)

c) Alarm Mode Functions

PLIB_RTCC_AlarmChimeDisable Function

Disables the specific RTCC module's chime.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmChimeDisable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific RTCC module's chime. The alarm repeat count value bits stop once they reach zero.

Remarks

This function implements an operation of the AlarmChimeControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmChimeControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_AlarmChimeDisable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_AlarmChimeDisable (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmChimeEnable Function

Enables the specific RTCC module's chime.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmChimeEnable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific RTCC module's chime. The alarm repeat count bits are allowed to rollover.

Remarks

This function implements an operation of the AlarmChimeControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmChimeControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_AlarmChimeEnable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_AlarmChimeEnable (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmDateGet Function

Returns the contents of the specific RTCC module's Alarm Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_AlarmDateGet(RTCC_MODULE_ID index);
```

Returns

Value register.

Description

The function returns the contents of the specific RTCC module's Alarm Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Date;
Date = PLIB_RTCC_AlarmDateGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_AlarmDateGet (AlarmC_MODULE_ID index)

PLIB_RTCC_AlarmDateSet Function

Writes to the specific RTCC module's Alarm Date register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmDateSet(RTCC_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

The function writes to the specific RTCC module's Alarm Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the AlarmDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Alarm Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t data = 0x06102705;     //Date = 27 Oct 2006 Friday
PLIB_RTCC_AlarmDateSet(RTCC_ID_0, data);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	The value to set the Alarm Date register to, in BCD format

Function

void PLIB_RTCC_AlarmDateSet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_AlarmDayGet Function

Returns the contents of the Day bits in the specific RTCC module's Alarm Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_AlarmDayGet(RTCC_MODULE_ID index);
```

Returns

Days bits in the Alarm Date register.

Description

The function returns the contents of Day bits in the specific RTCC module's Alarm Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Day;
Day = PLIB_RTCC_AlarmDayGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_AlarmDayGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmDaySet Function

Writes to the specific RTCC module's Alarm Date value register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmDaySet(RTCC_MODULE_ID index, uint32_t day);
```

Returns

None.

Description

The function writes to the specific RTCC module's Alarm Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the AlarmDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Alarm Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t Day = 0x27;        //Day = 27th of the month
PLIB_RTCC_AlarmDaySet(RTCC_ID_0, Day);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
day	The BCD value of the day to set in the Alarm Date register

Function

void PLIB_RTCC_AlarmDaySet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_AlarmDisable Function

Disables the specific RTCC module's alarm.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmDisable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific RTCC module's alarm. RTCC Alarm bit shouldn't be modified when RTCC on bit is enabled and PLIB_RTCC_AlarmSyncStatusGet (ALRMSYNC bit) returns true. Meaning the check RTCC ON (RTCCON<15>) bit and the ALRMSYNC bit should be equal to '1'.

Remarks

This function implements an operation of the AlarmControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// check RTCC enable bit and PLIB_RTCC_AlarmSyncStatusGet return value and
// then modify the Alarm bit.
PLIB_RTCC_AlarmDisable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_AlarmDisable (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmEnable Function

Enables the specific RTCC module's alarm.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmEnable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific RTCC module's alarm. RTCC Alarm bit shouldn't be modified when RTCC on bit is enabled and

PLIB_RTCC_AlarmSyncStatusGet (ALRMSYNC bit) returns true. Meaning the check RTCC ON (RTCCON<15>) bit and the ALRMSYNC bit should be equal to '1'.

Remarks

The alarm enable bit is cleared automatically after an alarm event whenever the alarm is not set up to repeat, and chime is disabled.

This function implements an operation of the AlarmControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// check RTCC enable bit and PLIB_RTCC_AlarmSyncStatusGet return value and
// then modify the Alarm bit.
PLIB_RTCC_AlarmEnable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_AlarmEnable (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmHourGet Function

Returns the contents of Hours bits in the specific RTCC module's Alarm Time register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_AlarmHourGet(RTCC_MODULE_ID index);
```

Returns

BCD value of the Hours bits in the Alarm Time register.

Description

The function returns the contents of the Hours bits in the specific RTCC module's Alarm Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Hour;
Hour = PLIB_RTCC_AlarmHourGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_AlarmHourGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmHourSet Function

The function returns the contents of Hours bits in the specific RTCC module's Alarm Time register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmHourSet(RTCC_MODULE_ID index, uint32_t hour);
```

Returns

None

Description

Returns the contents of the Hours bits in the specific RTCC module's Alarm Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Hour = 0x04;
PLIB_RTCC_AlarmHourSet(RTCC_ID_0, Hour);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
hour	BCD value to be written to the Hours bits in the Alarm Time register

Function

uint32_t PLIB_RTCC_AlarmHourSet (RTCC_MODULE_ID index, uint32_t hour)

PLIB_RTCC_AlarmMaskModeSelect Function

Sets the specific RTCC module's alarm mask Configuration bits.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmMaskModeSelect(RTCC_MODULE_ID index, RTCC_ALARM_MASK_CONFIGURATION data);
```

Returns

None.

Description

This function sets the specific RTCC module's alarm mask Configuration bits.

Remarks

The actual definition of this enumeration is device-specific.

This function implements an operation of the AlarmMaskControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmMaskControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t data = 0;
PLIB_RTCC_AlarmMaskModeSelect(RTCC_ID_0, RTCC_ALARM_EVERY_HALF_SECOND);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Alarm mask Configuration bits

Function

void PLIB_RTCC_AlarmMaskModeSelect (RTCC_MODULE_ID index, RTCC_ALARM_MASK_CONFIGURATION data)

PLIB_RTCC_AlarmMinuteGet Function

Returns the contents of Minutes bits in the specific RTCC module's Alarm Time register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_AlarmMinuteGet(RTCC_MODULE_ID index);
```

Returns

BCD value of the Minutes bits in the Alarm Time register.

Description

The function returns the contents of the field in the specific RTCC module's Alarm Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Minute;
Minute = PLIB_RTCC_AlarmMinuteGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_AlarmMinuteGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmMinuteSet Function

Returns the contents of the Minutes bits in the specific RTCC module's Alarm Time register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmMinuteSet(RTCC_MODULE_ID index, uint32_t minute);
```

Returns

None

Description

The function returns the contents of the Minutes bits in the specific RTCC module's Alarm Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Minute = 0x15;
PLIB_RTCC_AlarmMinuteSet(RTCC_ID_0, Minute);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
minute	BCD value to be written to the Minutes bits in the Alarm Time register

Function

uint32_t PLIB_RTCC_AlarmMinuteSet (RTCC_MODULE_ID index, uint32_t minute)

PLIB_RTCC_AlarmMonthGet Function

Returns the contents of the Month bits in the specific RTCC module's Alarm Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_AlarmMonthGet(RTCC_MODULE_ID index);
```

Returns

Months bits in the Date register.

Description

The function returns the contents of the Months bits in the specific RTCC module's Alarm Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Month;
Month = PLIB_RTCC_AlarmMonthGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_AlarmMonthGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmMonthSet Function

Writes to the specific RTCC module's Alarm Date register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmMonthSet(RTCC_MODULE_ID index, uint32_t month);
```

Returns

None.

Description

The function writes to the specific RTCC module's Alarm Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the AlarmDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Alarm Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t Month = 0x10;      //Month = October
PLIB_RTCC_AlarmMonthSet(RTCC_ID_0, Month);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
month	The BCD value of the month to set in the Alarm Date register

Function

void PLIB_RTCC_AlarmMonthSet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_AlarmPulseInitialGet Function

Returns the state of the initial alarm pulse.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_AlarmPulseInitialGet(RTCC_MODULE_ID index);
```

Returns

- 1 - Logical High
- 0 - Logical Low

Description

This function returns the state of the initial alarm pulse.

Remarks

This function implements an operation of the AlarmPulseInitial feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmPulseInitial in your application to automatically determine whether this feature is available.

Preconditions

The ALRMEN bit should be '1' indicating the PLIB_RTCC_AlarmEnable function was called.

Example

```
bool PulseValue;
PulseValue = PLIB_RTCC_AlarmPulseInitialGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_RTCC_AlarmPulseInitialGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmPulseInitialSet Function

Enables the determination of the initial alarm pulse.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmPulseInitialSet(RTCC_MODULE_ID index, bool data);
```

Returns

None.

Description

This function enables the determination of initial alarm pulse.

Remarks

This function implements an operation of the AlarmPulseInitial feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmPulseInitial in your application to automatically determine whether this feature is available.

Preconditions

The ALRMEN bit should be '0' indicating the PLIB_RTCC_AlarmDisable was called. This function must not be called when the RTCC is ON and the Alarm Sync is 1.

Example

```
bool data = 0;
PLIB_RTCC_AlarmPulseInitialSet(RTCC_ID_0, data);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_AlarmPulseInitialSet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmRepeatCountGet Function

Reads the specific RTCC module's alarm repeat counter.

File

plib_rtcc.h

C

```
uint8_t PLIB_RTCC_AlarmRepeatCountGet(RTCC_MODULE_ID index);
```

Returns

uint8_t - The current value of the alarm repeat counter

Description

This function reads the specific RTCC module's alarm repeat counter.

Remarks

The counter decrements on any alarm event. The counter is prevented from rolling over unless chime is enabled.

This function implements an operation of the AlarmRepeatControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmRepeatControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t currentCount;
currentCount = PLIB_RTCC_AlarmRepeatCountGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_RTCC_AlarmRepeatCountGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmRepeatCountSet Function

Sets the specific RTCC module's alarm repeat counter.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmRepeatCountSet(RTCC_MODULE_ID index, uint8_t data);
```

Returns

None.

Description

This function sets the specific RTCC module's alarm repeat counter.

Remarks

The counter decrements on any alarm event. The counter is prevented from rolling over unless chime is enabled.

This function implements an operation of the AlarmRepeatControl feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmRepeatControl in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t data = 0xFF;
PLIB_RTCC_AlarmRepeatCountSet(RTCC_ID_0, data);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Alarm repeat counter bits

Function

void PLIB_RTCC_AlarmRepeatCountSet (RTCC_MODULE_ID index, uint8_t data)

PLIB_RTCC_AlarmSecondGet Function

Returns the contents of the Seconds bits in the specific RTCC module's Alarm Time register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_AlarmSecondGet(RTCC_MODULE_ID index);
```

Returns

BCD value of the Seconds bits in the Alarm Time register.

Description

The function returns the contents of the Seconds bits in the specific RTCC module's Alarm Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Second;
Second = PLIB_RTCC_AlarmSecondGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_AlarmSecondGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmSecondSet Function

Returns the contents of Seconds bits in the specific RTCC module's Alarm Time register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmSecondSet(RTCC_MODULE_ID index, uint32_t second);
```

Returns

None

Description

The function returns the contents of the field in the specific RTCC module's Alarm Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t Second = 0x33;
PLIB_RTCC_AlarmSecondSet(RTCC_ID_0, Second);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
second	BCD value to be written to the Seconds bits in the Alarm Time register

Function

uint32_t PLIB_RTCC_AlarmSecondSet (RTCC_MODULE_ID index, uint32_t second)

PLIB_RTCC_AlarmTimeGet Function

Returns the contents of the specific RTCC module's Alarm Time register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_AlarmTimeGet(RTCC_MODULE_ID index);
```

Returns

Value register.

Description

The function returns the contents of the specific RTCC module's Alarm Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmTime in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t time;
time = PLIB_RTCC_AlarmTimeGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_AlarmTimeGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmTimeSet Function

Writes to the specific RTCC module's Alarm Time register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmTimeSet(RTCC_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

The function writes to the specific RTCC module's Alarm Time register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the AlarmTime feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmTime in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Alarm Time register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t data = 0x04153300;     // Time = 4 hours, 15 minutes, and 33 seconds
PLIB_RTCC_AlarmTimeSet(RTCC_ID_0, data);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_AlarmTimeSet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_AlarmValueRegisterPointer Function

Sets the specific RTCC module's Alarm register pointer.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmValueRegisterPointer(RTCC_MODULE_ID index, uint8_t data);
```

Returns

None.

Description

This function sets the specific RTCC module's Alarm register pointer.

Remarks

None.

Preconditions

None.

Example

```
uint8_t data = 2;
PLIB_RTCC_AlarmValueRegisterPointer(RTCC_ID_0, data);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Alarm register pointer

Function

void PLIB_RTCC_AlarmValueRegisterPointer (RTCC_MODULE_ID index, uint8_t data)

PLIB_RTCC_AlarmWeekDayGet Function

Returns the contents of the WeekDay bits in the specific RTCC module's Alarm Date register.

File

plib_rtcc.h

C

```
uint32_t PLIB_RTCC_AlarmWeekDayGet(RTCC_MODULE_ID index);
```

Returns

WeekDay bits in the Alarm Date register.

Description

The function returns the contents of Weekday bits in the specific RTCC module's Alarm Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

This function implements an operation of the AlarmDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmDate in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint32_t WeekDay;
WeekDay = PLIB_RTCC_AlarmWeekDayGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_RTCC_AlarmWeekDayGet (RTCC_MODULE_ID index)

PLIB_RTCC_AlarmWeekDaySet Function

Writes to the specific RTCC module's Alarm Date register.

File

plib_rtcc.h

C

```
void PLIB_RTCC_AlarmWeekDaySet(RTCC_MODULE_ID index, uint32_t weekday);
```

Returns

None.

Description

The function writes to the specific RTCC module's Alarm Date register. Please refer to the specific device data sheet for the exact sequence of digits.

Remarks

A write to this register is only allowed when access is allowed by using the PLIB_RTCC_WriteEnable function.

This function implements an operation of the AlarmDate feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmDate in your application to automatically determine whether this feature is available.

Preconditions

Prior to writing to the Alarm Date register, an RTCC write must be enabled using the exact sequences required by the device.

Example

```
uint32_t WeekDay = 0x05;        //WeekDay = Friday
PLIB_RTCC_AlarmWeekDaySet(RTCC_ID_0, WeekDay);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
weekday	The BCD value of the weekday to set in the field of the Alarm Date register

Function

void PLIB_RTCC_AlarmWeekDaySet (RTCC_MODULE_ID index, uint32_t data)

PLIB_RTCC_AlarmSyncStatusGet Function

The function returns the synchronization status bit.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_AlarmSyncStatusGet(RTCC_MODULE_ID index);
```

Returns

- true - Alarm repeat count may change as a result of a half-second rollover during a read.
- false - Alarm repeat count is safe to read, and will not change in less than 32 RTC clocks.

Description

The function returns the synchronization status bit, which is used to determine whether it is safe to read the date/time values, or if the values will change within 32 RTCC clocks.

Remarks

This bit is read-only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsAlarmSynchronization in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_RTCC_AlarmSyncStatusGet(RTCC_ID_0))
{
...
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_RTCC_AlarmSyncStatusGet (RTCC_MODULE_ID index)

d) Other Functions

PLIB_RTCC_ClockSourceSelect Function

Selects the clock source for the RTCC module.

File

plib_rtcc.h

C

```
void PLIB_RTCC_ClockSourceSelect(RTCC_MODULE_ID index, RTCC_CLOCK_SOURCE_SELECT source);
```

Returns

None.

Description

This function determines which clock source the RTCC module will use depending on the features of the device.

Remarks

This function implements an operation of the ClockSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsClockSelect in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_ClockSourceSelect(RTCC_ID_0, RTCC_CLOCK_SOURCE_SELECT_NONE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
source	Which clock source will be used

Function

void PLIB_RTCC_ClockSourceSelect (RTCC_MODULE_ID index, RTCC_CLOCK_SOURCE_SELECT source)

PLIB_RTCC_DriftCalibrateGet Function

Reads the specific RTCC module's drift calibration bits.

File

plib_rtcc.h

C

```
uint16_t PLIB_RTCC_DriftCalibrateGet(RTCC_MODULE_ID index);
```

Returns

uint16_t - The current drift calibration value

Description

This function reads the specific RTCC module's drift calibration bits.

Remarks

This function implements an operation of the Calibration feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCalibration in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t calibrationbits;
calibrationbits = PLIB_RTCC_DriftCalibrateGet(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint16_t PLIB_RTCC_DriftCalibrateGet (RTCC_MODULE_ID index)

PLIB_RTCC_DriftCalibrateSet Function

Sets the specific RTCC module's drift calibration bits.

File

plib_rtcc.h

C

```
void PLIB_RTCC_DriftCalibrateSet(RTCC_MODULE_ID index, uint16_t calibrationbits);
```

Returns

None.

Description

This function sets the specific RTCC module's drift calibration bits. The error between the system clock and the external clock has to be computed and calibration input must be provided to this function.

Remarks

This function implements an operation of the Calibration feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsCalibration in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
uint16_t calibrationbits = 3; //Positive 3 adjustment derived from the formula
                              // Error = (Ideal Freq(32758) - Measured)*60;
PLIB_RTCC_DriftCalibrateSet(RTCC_ID_0, calibrationbits);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
calibrationbits	Drift calibration bits

Function

void PLIB_RTCC_DriftCalibrateSet (RTCC_MODULE_ID index, uint16_t calibrationbits)

PLIB_RTCC_HalfSecondStatusGet Function

The function returns the half second status bit.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_HalfSecondStatusGet(RTCC_MODULE_ID index);
```

Returns

- true - Second half period of a second
- false - First half period of a second

Description

The function returns the half second status bit, which is used in the calibration procedure. When the seconds byte is zero, the calibration value must be updated when the half second bit becomes '1'.

Remarks

This bit is read-only. It is cleared to '0' on a write to the seconds value. This function implements an operation of the HalfSecond feature. This

feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsHalfSecond in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Wait for the half second status bit to be '1'.
while(PLIB_RTCC_HalfSecondStatusGet(RTCC_ID_0));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_RTCC_HalfSecondStatusGet (RTCC_MODULE_ID index)

PLIB_RTCC_OutputSelect Function

Selects which signal will be presented on the RTCC pin

File

plib_rtcc.h

C

```
void PLIB_RTCC_OutputSelect(RTCC_MODULE_ID index, RTCC_OUTPUT_SELECT data);
```

Returns

None.

Description

This function selects which signal will be presented on the RTCC pin.

Remarks

The RTCC module's output pin should be enabled using the function PLIB_RTCC_OutputEnable.

This function implements an operation of the OutputSelect feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsOutputSelect in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_OutputSelect(RTCC_ID_0, RTCC_OUTPUT_SECONDS_CLOCK);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Enumerated value of which signal to present

Function

void PLIB_RTCC_OutputSelect (RTCC_MODULE_ID index, RTCC_OUTPUT_SELECT data)

PLIB_RTCC_StopInIdleDisable Function

Continues normal RTCC operation when the device enters Idle mode.

File

plib_rtcc.h

C

```
void PLIB_RTCC_StopInIdleDisable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function continues normal RTCC operation when the device enters Idle mode.

Remarks

None.

This function implements an operation of the StopInIdle feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsStopInIdle in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_StopInIdleDisable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_StopInIdleDisable(RTCC_MODULE_ID index)

PLIB_RTCC_StopInIdleEnable Function

Disables access to the RTCC module by the Peripheral Bus Clock (PBCLK) when the CPU enters Idle mode.

File

plib_rtcc.h

C

```
void PLIB_RTCC_StopInIdleEnable(RTCC_MODULE_ID index);
```

Returns

None.

Description

This function disables access to the RTCC module by the PBCLK when the CPU is in Idle mode.

Remarks

This function implements an operation of the StopInIdle feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_RTCC_ExistsStopInIdle in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_RTCC_StopInIdleEnable(RTCC_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_RTCC_StopInIdleEnable(RTCC_MODULE_ID index)

e) Feature Existence Functions

PLIB_RTCC_ExistsAlarmChimeControl Function

Identifies whether the AlarmChimeControl feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsAlarmChimeControl(RTCC_MODULE_ID index);
```

Returns

- true - The AlarmChimeControl feature is supported on the device
- false - The AlarmChimeControl feature is not supported on the device

Description

This function identifies whether the AlarmChimeControl feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_AlarmChimeEnable
- PLIB_RTCC_AlarmChimeDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsAlarmChimeControl(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsAlarmControl Function

Identifies whether the AlarmControl feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsAlarmControl(RTCC_MODULE_ID index);
```

Returns

- true - The AlarmControl feature is supported on the device
- false - The AlarmControl feature is not supported on the device

Description

This function identifies whether the AlarmControl feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_AlarmEnable
- PLIB_RTCC_AlarmDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsAlarmControl(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsAlarmDate Function

Identifies whether the AlarmDate feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsAlarmDate(RTCC_MODULE_ID index);
```

Returns

- true - The AlarmDate feature is supported on the device
- false - The AlarmDate feature is not supported on the device

Description

This function identifies whether the AlarmDate feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_AlarmDateGet
- PLIB_RTCC_AlarmDateSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsAlarmDate(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsAlarmMaskControl Function

Identifies whether the AlarmMaskControl feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsAlarmMaskControl(RTCC_MODULE_ID index);
```

Returns

- true - The AlarmMaskControl feature is supported on the device
- false - The AlarmMaskControl feature is not supported on the device

Description

This function identifies whether the AlarmMaskControl feature is available on the RTCC module. When this interface returns true, this function is supported on the device:

- PLIB_RTCC_AlarmMaskModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsAlarmMaskControl(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsAlarmPulseInitial Function

Identifies whether the AlarmPulseInitial feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsAlarmPulseInitial(RTCC_MODULE_ID index);
```

Returns

- true - The AlarmPulseInitial feature is supported on the device
- false - The AlarmPulseInitial feature is not supported on the device

Description

This function identifies whether the AlarmPulseInitialValue feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_AlarmPulseInitialSet
- PLIB_RTCC_AlarmPulseInitialGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsAlarmPulseInitial(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsAlarmRepeatControl Function

Identifies whether the AlarmRepeatControl feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsAlarmRepeatControl(RTCC_MODULE_ID index);
```

Returns

- true - The AlarmRepeatControl feature is supported on the device
- false - The AlarmRepeatControl feature is not supported on the device

Description

This function identifies whether the AlarmRepeatControl feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_AlarmRepeatCountSet
- PLIB_RTCC_AlarmRepeatCountRead

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsAlarmRepeatControl(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsAlarmTime Function

Identifies whether the AlarmTime feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsAlarmTime(RTCC_MODULE_ID index);
```

Returns

- true - The AlarmTime feature is supported on the device
- false - The AlarmTime feature is not supported on the device

Description

This function identifies whether the AlarmTime feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_AlarmTimeGet
- PLIB_RTCC_AlarmTimeSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsAlarmTime(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsCalibration Function

Identifies whether the Calibration feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsCalibration(RTCC_MODULE_ID index);
```

Returns

- true - The Calibration feature is supported on the device
- false - The Calibration feature is not supported on the device

Description

This function identifies whether the Calibration feature is available on the RTCC module. When this interface returns true, this function is supported on the device:

- PLIB_RTCC_DriftCalibrate

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsCalibration(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsClockRunning Function

Identifies whether the ClockRunning feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsClockRunning(RTCC_MODULE_ID index);
```

Returns

- true - The ClockRunning feature is supported on the device
- false - The ClockRunning feature is not supported on the device

Description

This function identifies whether the ClockRunning feature is available on the RTCC module. When this interface returns true, this function is supported on the device:

- PLIB_RTCC_ClockRunningStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsClockRunning(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsClockSelect Function

Identifies whether the ClockSelect feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsClockSelect(RTCC_MODULE_ID index);
```

Returns

- true - The ClockSelect feature is supported on the device
- false - The ClockSelect feature is not supported on the device

Description

This function identifies whether the ClockSelect feature is available on the RTCC module. When this interface returns true, this function is supported on the device:

- PLIB_RTCC_SourceClockSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsClockSelect(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsEnableControl(RTCC_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_Enable
- PLIB_RTCC_Disable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsEnableControl(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsHalfSecond Function

Identifies whether the HalfSecond feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsHalfSecond(RTCC_MODULE_ID index);
```

Returns

- true - The HalfSecond feature is supported on the device
- false - The HalfSecond feature is not supported on the device

Description

This function identifies whether the HalfSecond feature is available on the RTCC module. When this interface returns true, this function is supported on the device:

- PLIB_RTCC_HalfSecondStatusBit

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsHalfSecond(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsOutputControl Function

Identifies whether the OutputControl feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsOutputControl(RTCC_MODULE_ID index);
```

Returns

- true - The OutputControl feature is supported on the device
- false - The OutputControl feature is not supported on the device

Description

This function identifies whether the OutputControl feature is available on the RTCC module. When this interface returns true, this function is supported on the device:

- PLIB_RTCC_ClockOutputEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsOutputControl(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsOutputSelect Function

Identifies whether the OutputSelect feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsOutputSelect(RTCC_MODULE_ID index);
```

Returns

- true - The OutputSelect feature is supported on the device
- false - The OutputSelect feature is not supported on the device

Description

This function identifies whether the OutputSelect feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_SecondsClockOutputSelect
- PLIB_RTCC_AlarmPulseOutputSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsOutputSelect(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsRTCDate Function

Identifies whether the RTCDateValue feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsRTCDate(RTCC_MODULE_ID index);
```

Returns

- true - The RTCDate feature is supported on the device
- false - The RTCDate feature is not supported on the device

Description

This function identifies whether the RTCDateValue feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_RTCDateGet
- PLIB_RTCC_RTCDateSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsRTCDate(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsRTCTime Function

Identifies whether the RTCTimeValue feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsRTCTime(RTCC_MODULE_ID index);
```

Returns

- true - The RTCTime feature is supported on the device
- false - The RTCTime feature is not supported on the device

Description

This function identifies whether the RTCTimeValue feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_RTCTimeGet
- PLIB_RTCC_RTCTimeSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsRTCTime(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsStopInIdleControl Function

Identifies whether the StopInIdle feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsStopInIdleControl(RTCC_MODULE_ID index);
```

Returns

- true - The StopInIdle feature is supported on the device
- false - The StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_StopInIdleEnable
- PLIB_RTCC_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsStopInIdleControl(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsSynchronization Function

Identifies whether the Synchronization feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsSynchronization(RTCC_MODULE_ID index);
```

Returns

- true - The Synchronization feature is supported on the device
- false - The Synchronization feature is not supported on the device

Description

This function identifies whether the Synchronization feature is available on the RTCC module. When this interface returns true, this function is supported on the device:

- PLIB_RTCC_RTCSyncStatusGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsSynchronization(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsWriteEnable Function

Identifies whether the WriteEnable feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsWriteEnable(RTCC_MODULE_ID index);
```

Returns

- true - The WriteEnable feature is supported on the device
- false - The WriteEnable feature is not supported on the device

Description

This function identifies whether the WriteEnable feature is available on the RTCC module. When this interface returns true, these functions are supported on the device:

- PLIB_RTCC_WriteEnable
- PLIB_RTCC_WriteDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsWriteEnable(RTCC_MODULE_ID index)

PLIB_RTCC_ExistsAlarmSynchronization Function

Identifies whether the AlarmSynchronization feature exists on the RTCC module.

File

plib_rtcc.h

C

```
bool PLIB_RTCC_ExistsAlarmSynchronization(RTCC_MODULE_ID index);
```

Returns

- true - The AlarmSynchronization feature is supported on the device
- false - The AlarmSynchronization feature is not supported on the device

Description

This function identifies whether the AlarmSynchronization feature is available on the RTCC module. When this interface returns true, this function is supported on the device:

- PLIB_RTCC_AlarmSyncGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_RTCC_ExistsAlarmSynchronization(RTCC_MODULE_ID index)

f) Data Types and Constants

RTCC_ALARM_MASK_CONFIGURATION Enumeration

Data type defining the different configurations for the alarm mask bits.

File

plib_rtcc_help.h

C

```
typedef enum {
  RTCC_ALARM_EVERY_HALF_SECOND,
  RTCC_ALARM_EVERY_SECOND,
  RTCC_ALARM_EVERY_10_SECONDS,
  RTCC_ALARM_EVERY_MINUTE,
  RTCC_ALARM_EVERY_10_MINUTES,
  RTCC_ALARM_EVERY_HOUR,
  RTCC_ALARM_ONCE_A_DAY,
  RTCC_ALARM_ONCE_A_WEEK,
  RTCC_ALARM_ONCE_A_MONTH,
  RTCC_ALARM_ONCE_A_YEAR
} RTCC_ALARM_MASK_CONFIGURATION;
```

Members

Members	Description
RTCC_ALARM_EVERY_HALF_SECOND	Alarm every half second
RTCC_ALARM_EVERY_SECOND	Alarm every second
RTCC_ALARM_EVERY_10_SECONDS	Alarm every 10 seconds
RTCC_ALARM_EVERY_MINUTE	Alarm every minute
RTCC_ALARM_EVERY_10_MINUTES	Alarm every 10 minutes
RTCC_ALARM_EVERY_HOUR	Alarm every hour
RTCC_ALARM_ONCE_A_DAY	Alarm every day
RTCC_ALARM_ONCE_A_WEEK	Alarm every week
RTCC_ALARM_ONCE_A_MONTH	Alarm every month
RTCC_ALARM_ONCE_A_YEAR	Alarm every year

Description

Alarm Mask Configuration

This data type defines the different configurations for accessing the alarm mask Configuration bits.

Remarks

The actual definition of this enumeration is device-specific.

RTCC_MODULE_ID Enumeration

File

plib_rtcc_help.h

C

```
typedef enum {
  RTCC_ID_1,
  RTCC_NUMBER_OF_MODULES
} RTCC_MODULE_ID;
```

Members

Members	Description
RTCC_NUMBER_OF_MODULES	The total number of modules available.

Description

Enumeration: RTCC_MODULE_ID

This enumeration defines number of modules which are available on the microcontroller. This is the superset of all of the possible instances that may be available on the Microchip microcontrollers.

Refer to the data sheet to get the correct number of modules defined for desired microcontroller.

RTCC_VALUE_REGISTER_POINTER Enumeration

Data type defining the different configurations by which the RTCC Date and Time Registers can be accessed.

File

plib_rtcc_help.h

C

```
typedef enum {
  RTCC_REG_YEAR,
  RTCC_REG_DAY_MONTH,
  RTCC_REG_HOURS_WEEKDAY,
  RTCC_REG_MINUTES_SECONDS
} RTCC_VALUE_REGISTER_POINTER;
```

Members

Members	Description
RTCC_REG_YEAR	The year register is being pointed
RTCC_REG_DAY_MONTH	The day and month register is being pointed
RTCC_REG_HOURS_WEEKDAY	The hours and weekday register is being pointed
RTCC_REG_MINUTES_SECONDS	The minutes and seconds register is being pointed

Description

Value Register Pointer

This data type defines the different configurations by which the RTCC Date and Time Registers can be accessed.

Remarks

The actual definition of this enumeration is device-specific.

Files

Files

Name	Description
plib_rtcc.h	RTCC Peripheral Library interface header for RTCC common definitions.
plib_rtcc_help.h	This is file plib_rtcc_help.h.

Description

This section lists the source and header files used by the library.

plib_rtcc.h

RTCC Peripheral Library interface header for RTCC common definitions.

Functions

	Name	Description
	PLIB_RTCC_AlarmChimeDisable	Disables the specific RTCC module's chime.
	PLIB_RTCC_AlarmChimeEnable	Enables the specific RTCC module's chime.
	PLIB_RTCC_AlarmDateGet	Returns the contents of the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmDateSet	Writes to the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmDayGet	Returns the contents of the Day bits in the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmDaySet	Writes to the specific RTCC module's Alarm Date value register.
	PLIB_RTCC_AlarmDisable	Disables the specific RTCC module's alarm.
	PLIB_RTCC_AlarmEnable	Enables the specific RTCC module's alarm.
	PLIB_RTCC_AlarmHourGet	Returns the contents of Hours bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmHourSet	The function returns the contents of Hours bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmMaskModeSelect	Sets the specific RTCC module's alarm mask Configuration bits.
	PLIB_RTCC_AlarmMinuteGet	Returns the contents of Minutes bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmMinuteSet	Returns the contents of the Minutes bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmMonthGet	Returns the contents of the Month bits in the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmMonthSet	Writes to the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmPulseInitialGet	Returns the state of the initial alarm pulse.
	PLIB_RTCC_AlarmPulseInitialSet	Enables the determination of the initial alarm pulse.

	PLIB_RTCC_AlarmRepeatCountGet	Reads the specific RTCC module's alarm repeat counter.
	PLIB_RTCC_AlarmRepeatCountSet	Sets the specific RTCC module's alarm repeat counter.
	PLIB_RTCC_AlarmSecondGet	Returns the contents of the Seconds bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmSecondSet	Returns the contents of Seconds bits in the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmSyncStatusGet	The function returns the synchronization status bit.
	PLIB_RTCC_AlarmTimeGet	Returns the contents of the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmTimeSet	Writes to the specific RTCC module's Alarm Time register.
	PLIB_RTCC_AlarmValueRegisterPointer	Sets the specific RTCC module's Alarm register pointer.
	PLIB_RTCC_AlarmWeekDayGet	Returns the contents of the WeekDay bits in the specific RTCC module's Alarm Date register.
	PLIB_RTCC_AlarmWeekDaySet	Writes to the specific RTCC module's Alarm Date register.
	PLIB_RTCC_ClockOutputDisable	Disables the specific RTCC module's output pin.
	PLIB_RTCC_ClockOutputEnable	Enables the specific RTCC module's output pin.
	PLIB_RTCC_ClockRunningStatus	Provides the status of the RTCC clock.
	PLIB_RTCC_ClockSourceSelect	Selects the clock source for the RTCC module.
	PLIB_RTCC_Disable	Disables the specific RTCC module on the device.
	PLIB_RTCC_DriftCalibrateGet	Reads the specific RTCC module's drift calibration bits.
	PLIB_RTCC_DriftCalibrateSet	Sets the specific RTCC module's drift calibration bits.
	PLIB_RTCC_Enable	Enables the specific RTCC module on the device.
	PLIB_RTCC_ExistsAlarmChimeControl	Identifies whether the AlarmChimeControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmControl	Identifies whether the AlarmControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmDate	Identifies whether the AlarmDate feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmMaskControl	Identifies whether the AlarmMaskControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmPulseInitial	Identifies whether the AlarmPulseInitial feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmRepeatControl	Identifies whether the AlarmRepeatControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmSynchronization	Identifies whether the AlarmSynchronization feature exists on the RTCC module.
	PLIB_RTCC_ExistsAlarmTime	Identifies whether the AlarmTime feature exists on the RTCC module.
	PLIB_RTCC_ExistsCalibration	Identifies whether the Calibration feature exists on the RTCC module.
	PLIB_RTCC_ExistsClockRunning	Identifies whether the ClockRunning feature exists on the RTCC module.
	PLIB_RTCC_ExistsClockSelect	Identifies whether the ClockSelect feature exists on the RTCC module.
	PLIB_RTCC_ExistsEnableControl	Identifies whether the EnableControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsHalfSecond	Identifies whether the HalfSecond feature exists on the RTCC module.
	PLIB_RTCC_ExistsOutputControl	Identifies whether the OutputControl feature exists on the RTCC module.
	PLIB_RTCC_ExistsOutputSelect	Identifies whether the OutputSelect feature exists on the RTCC module.
	PLIB_RTCC_ExistsRTCDate	Identifies whether the RTCDateValue feature exists on the RTCC module.
	PLIB_RTCC_ExistsRTCTime	Identifies whether the RTCTimeValue feature exists on the RTCC module.
	PLIB_RTCC_ExistsStopInIdleControl	Identifies whether the StopInIdle feature exists on the RTCC module.
	PLIB_RTCC_ExistsSynchronization	Identifies whether the Synchronization feature exists on the RTCC module.
	PLIB_RTCC_ExistsWriteEnable	Identifies whether the WriteEnable feature exists on the RTCC module.
	PLIB_RTCC_HalfSecondStatusGet	The function returns the half second status bit.
	PLIB_RTCC_OutputSelect	Selects which signal will be presented on the RTCC pin
	PLIB_RTCC_RTCDateGet	Returns the contents of the specific RTCC module's Date register.
	PLIB_RTCC_RTCDateSet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCDayGet	Returns the contents of the Days bits in the specific RTCC module's Date register.
	PLIB_RTCC_RTCDaySet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCHourGet	Returns the contents of the Hours bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCHourSet	Writes the contents of the Hours bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCMinuteGet	Returns the contents of the Minutes bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCMinuteSet	Writes the contents of Minutes bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCMonthGet	Returns the contents of the Months bits in the specific RTCC module's Date register.
	PLIB_RTCC_RTCMonthSet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCSecondGet	The function returns the contents of the Seconds bits in the specific RTCC device's Time register.
	PLIB_RTCC_RTCSecondSet	Writes the contents of Seconds bits in the specific RTCC module's Time register.
	PLIB_RTCC_RTCSyncStatusGet	The function returns the synchronization status bit.

	PLIB_RTCC_RTCTimeGet	Returns the contents of the specific RTCC module's Time register.
	PLIB_RTCC_RTCTimeSet	Writes to the specific RTCC module's Time register.
	PLIB_RTCC_RTCWeekDayGet	Returns the contents of the WeekDay bits in the specific RTCC module's Date register.
	PLIB_RTCC_RTCWeekDaySet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_RTCYearGet	Returns the contents of the Year bits in the specific RTCC module's Date register.
	PLIB_RTCC_RTCYearSet	Writes to the specific RTCC module's Date register.
	PLIB_RTCC_StopInIdleDisable	Continues normal RTCC operation when the device enters Idle mode.
	PLIB_RTCC_StopInIdleEnable	Disables access to the RTCC module by the Peripheral Bus Clock (PBCLK) when the CPU enters Idle mode.
	PLIB_RTCC_WriteDisable	Disables writing to the specific RTCC module's value registers.
	PLIB_RTCC_WriteEnable	Enables writing to the specific RTCC module's value registers.

Description

Real-Time Clock and Calendar (RTCC) Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the RTCC Peripheral Library for all families of Microchip microcontrollers. The definitions in this file are common to the RTCC peripheral.

File Name

plib_rtcc.h

Company

Microchip Technology Inc.

plib_rtcc_help.h

Enumerations

	Name	Description
	RTCC_ALARM_MASK_CONFIGURATION	Data type defining the different configurations for the alarm mask bits.
	RTCC_MODULE_ID	Enumeration: RTCC_MODULE_ID This enumeration defines number of modules which are available on the microcontroller. This is the superset of all of the possible instances that may be available on the Microchip microcontrollers. This is file plib_rtcc_help.h.

System Bus Peripheral Library

This section describes the System Bus Peripheral Library.

Introduction

This library provides a low-level abstraction of the System Bus on Microchip microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences from one microcontroller variant to another.

Description

The System Bus is a multi-layer crossbar switching matrix that connects initiators to targets. An initiator is a device or peripheral that initiates a data transfer to or from a target. Examples of initiators include the CPU, DMA and Ethernet controller. A target is a memory, bus or peripheral that sends or receives data to/from an initiator.

The System Bus allows the system programmer to control which initiators can access each target by defining permission groups for each initiator. Each target has one or more regions (physical address spaces) that can be individually programmed to allow access to different permission groups. By setting initiator permission groups and target region read/write permissions, the system programmer can allow or deny task or program access to system resources.

Using the Library

This topic describes the basic architecture of the System Bus Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_sb.h`

The interface to the System Bus Peripheral library is defined in the `plib_sb.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the System Bus Peripheral library must include `peripheral.h`.

Library File:

The System Bus Peripheral library archive (`.a`) file is installed with MPLAB Harmony.

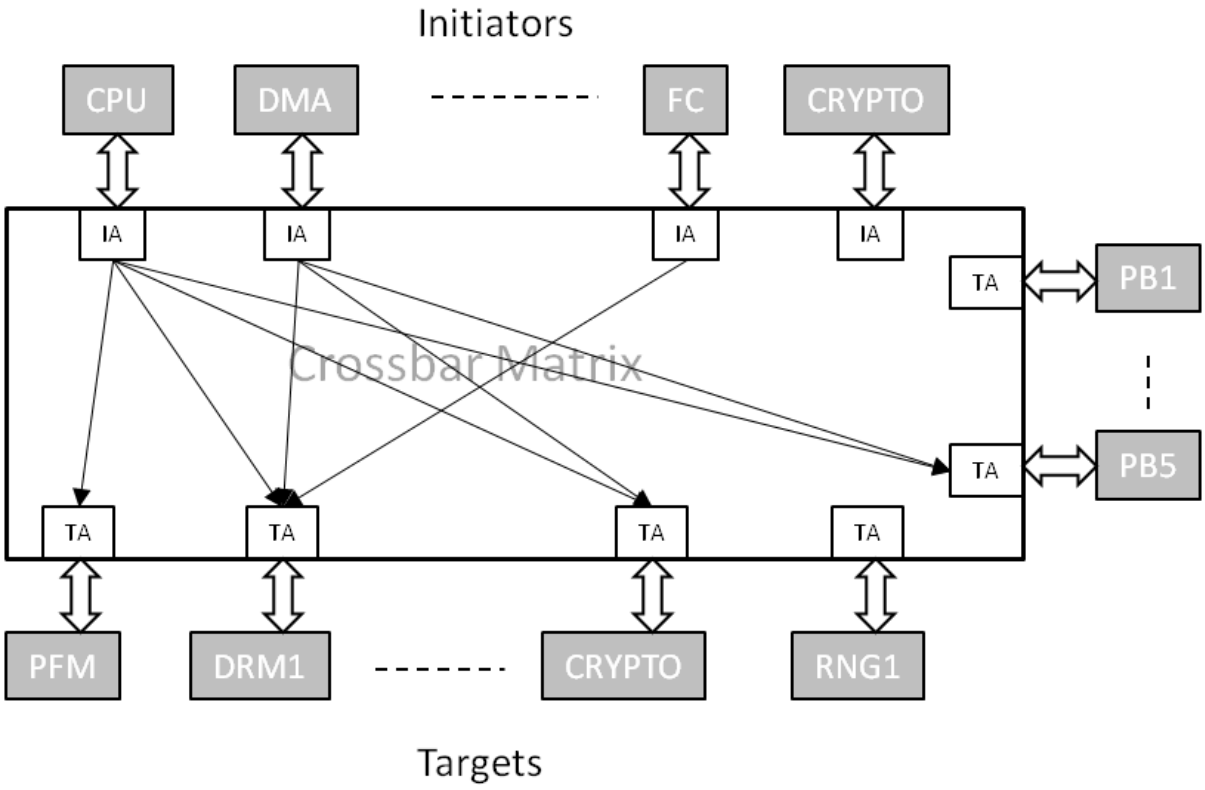
Please refer to the What is MPLAB Harmony? section for how the peripheral interacts with the framework.

Hardware Abstraction Model

This library provides the low-level abstraction of the System Bus on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in the software and introduces the library interface.

Description

System Bus Software Abstraction Block Diagram



Hardware Abstraction Model

The System Bus Peripheral Library provides interface routines to initialize the bus matrix such that:

- Initiator permission groups are assigned
- Target regions are defined and given read/write access permissions
- Errors are identified, logged and cleared when a permission group violation occurs
- CPU and DMA priorities are set

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the System Bus module.

Library Interface Section	Description
Target Initialization Functions	This section provides target initialization functions.
PGV Error Functions	This section provides PGV error functions.
Other Functions	This section provides additional System Bus functions.
Feature Existence Functions	This section provides functions that determine whether certain features exist.

How the Library Works

The System Bus is a crossbar interconnect matrix that provides for simultaneous data transfer between the CPU, memory, and various peripherals on the PIC32 device. In addition, it provides a protection mechanism that allows trusted code to define and restrict access to memory regions and peripherals. A typical application would be a secure bootloader that prevents a third party or untrusted application from accessing regions of Flash memory that contain privileged code or information. The protection mechanism works by dividing the target physical address space into regions, each of which may be accessed by one or more initiators. Individual targets may have one or more regions. Each region can be individually programmed to allow read or write access to one or more permission groups. Each initiator is assigned to a permission group.

This library provides interface routines to initialize the System Bus and initiator permission groups. On reset or NMI, the CPU is assigned to permission group 0 (full access).

Note: Refer to the **"CPU"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for information on target region mapping and initiator permission groups for a specific device.

Initiator Initialization

Initializing the initiators for the System Bus is a two-step process:

- Set CPU and DMA priorities (if needed)
- Assign permission groups to each initiator

Priority assignments for CPU and DMA

By default, the System Bus uses a least-recently-serviced (LRS) priority arbitration scheme for most initiators, including the CPU and DMA. For applications that require low latency, the user may set the CPU and/or DMA arbitration to fixed high priority. For the CPU, fixed high priority means that the CPU gets arbitration preference while servicing an interrupt over all initiators using LRS arbitration.

Priority is set using the PLIB_SB_CPUPrioritySet and PLIB_SB_DMAPrioritySet library functions.

Initiator permission groups

At reset, all initiators default to permission group 0. Each target region can be individually programmed to allow read or write access to any or all permission groups. By assigning permission groups to initiators and restricting target region read/write access based on permission group, it is possible to restrict initiator access to target regions during normal operations.

Permission groups are assigned using the library function PLIB_SB_InitPermGrpSet.

Target Initialization

Each System Bus target resides in a physical address space that contains one or more regions. Regions are used to provide separate access permissions for different areas within a target address space. Region 0 for any target is defined as the entire address space for that target. At reset, region 0 for all targets is accessible by any initiator with group 0 permissions.

Target regions are defined by base (physical) address and size. Read and write permissions are programmed individually for each region. The number of regions for each target varies, depending on the target. Some regions have fixed addresses, sizes and/or permissions. For example, region 0 for all targets encompasses the entire address space for the target, so the address and size are preprogrammed. Similarly, write permission for PFM is disabled for all initiators except the Flash controller.

Target region initialization is a four step process:

1. Set the base address of a region using PLIB_SB_PGRegionAddrSet. This function takes an enumerated value for the target region. Only valid target regions should be enumerated for any specific device.
2. Set the size of the region using PLIB_SB_PGRegionSizeSet.
3. Set the read permissions using PLIB_SB_PGRegionReadPermSet.
4. Set the write permissions using PLIB_SB_PGRegionWritePermSet.

Note: Please refer to the **"Memory Organization"** chapter in the specific device data sheet or the family reference manual section specified that chapter for information on target region mapping and initiator permission groups.

PGV Error Handling

A permission group violation (PGV) occurs when an initiator attempts to access a target without the proper permissions. Any permission group violation will trigger an interrupt to the CPU. If enabled, the System Bus will report a PGV to the error log registers in the System Bus. The PGV interrupt handler can then use this library to retrieve information about the violation and act accordingly.

By default, error reporting is disabled in the System Bus and must be enabled during the start-up or boot code. Errors are divided into two categories: primary and secondary. Primary errors are errors arising from secure accesses, such as trying to access a target region without the proper permissions. Secondary errors are errors arising from non-secure accesses, such as trying to access a memory location outside of a target region.

PIC32 devices support logging of primary errors only. Primary error logging is enabled using the library function PLIB_SB_PGVErrorReportPrimaryEnable. Primary error reporting can be disabled using the library function PLIB_SB_PGVErrorReportPrimaryDisable. Error logging must be enabled or disabled separately for each target.

Once a permission group violation error is logged, the user can use this library to retrieve information from the System Bus error log registers. Each target has its own set of error log registers. The error information available and the library API used to retrieve it are shown in the following table.

Error Log Data	System Bus Peripheral Library Function
Has the specified target reported an error?	PLIB_SB_PGVErrorStatus
Has the specified target reported more than one error since last cleared?	PLIB_SB_PGVErrorMulti
Type of error.	PLIB_SB_PGVErrorCode
Initiator ID.	PLIB_SB_PGVErrorInitiatorID
OCP command code of the transaction.	PLIB_SB_PGVErrorCommandCode

The region number of the specified target accessed during the violation.	PLIB_SB_PGVErrorRegion
Permission group of initiator that caused the violation.	PLIB_SB_PGVErrorPermissionGroup

Once an error is logged, it needs to be cleared by software before any data for a subsequent violation can be logged (for the same target). This is typically done in the exception handler that reads the data. Which function is used depends on whether a single or multiple error violation occurred. Single violations are cleared with PLIB_SB_PGVErrorClearSingle, and multiple violations are cleared with PLIB_SB_PGVErrorClearMulti.

Configuring the Library

The library is configured for the supported System Bus module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) Target Initialization Functions

	Name	Description
	PLIB_SB_PGRegionAddrGet	Returns the base address for a permission group region within a target's physical address space.
	PLIB_SB_PGRegionAddrSet	Sets the base address for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionReadPermClear	Clears the permission bit(s) corresponding to the requested read permissions for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionReadPermSet	Sets the permission bit(s) corresponding to the requested read permissions for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionSizeGet	Returns the size for a permission group region within a target's physical address space.
	PLIB_SB_PGRegionSizeSet	Sets the size for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionWritePermClear	Clears the permission bit(s) corresponding to the requested write permissions for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionWritePermSet	Sets the permission bit(s) corresponding to the requested write permissions for a permission group region within a target's physical address space. Not all regions are programmable.

b) PGV Error Functions

	Name	Description
	PLIB_SB_PGVErrorClearMulti	Clears multiple permission group errors for the specified target.
	PLIB_SB_PGVErrorClearSingle	Clears a single permission group error for the specified target.
	PLIB_SB_PGVErrorCode	Returns a value corresponding to the type of error logged for the specified target.
	PLIB_SB_PGVErrorCommandCode	Returns the OCP command code of the transaction that caused the protection violation for the specified target.
	PLIB_SB_PGVErrorInitiatorID	Returns the ID of the Initiator that caused the protection violation
	PLIB_SB_PGVErrorLogClearMulti	Clears a multiple protection group violations error from the specified target error log register.
	PLIB_SB_PGVErrorLogClearSingle	Clears a single protection group violation error from the specified target error log register.
	PLIB_SB_PGVErrorMulti	Indicates if more than one permission group violation has occurred since last cleared.
	PLIB_SB_PGVErrorPermissionGroup	Returns the permission group of the protection region in a target address space that caused the protection violation for the specified target.
	PLIB_SB_PGVErrorRegion	Returns the number of the protection region in the specified target address space that caused the protection violation.
	PLIB_SB_PGVErrorReportPrimaryDisable	Disables primary permission group error reporting for the specified target to the SB flag register.
	PLIB_SB_PGVErrorReportPrimaryEnable	Enables primary permission group error reporting for the specified target to the SB flag register.
	PLIB_SB_PGVErrorStatus	Identifies whether a permission group violation has been reported for the specified target.
	PLIB_SB_PGVErrGroup0Status	Identifies whether a permission group violation has been reported for the Target Group 0.
	PLIB_SB_PGVErrGroup1Status	Identifies whether a permission group violation has been reported for the Target Group 1.

	PLIB_SB_PGVErrGroup2Status	Identifies whether a permission group violation has been reported for the Target Group 2.
	PLIB_SB_PGVErrGroup3Status	Identifies whether a permission group violation has been reported for the Target Group 3.
	PLIB_SB_PGVErrGroupStatus	Identifies whether a permission group violation has been reported for the specified target group.

c) Other Functions

	Name	Description
	PLIB_SB_CPUPrioritySet	Sets the CPU arbitration policy to SRAM when servicing an interrupt
	PLIB_SB_DMAPrioritySet	Sets the DMA arbitration policy
	PLIB_SB_InitPermGrpSet	Sets the read/write permission group(s) for an initiator. The region must also allow read/write access for the permission group for a read/write to occur.

d) Feature Existence Functions

	Name	Description
	PLIB_SB_ExistsCPUPriority	Identifies whether the CPUPriority feature exists on the System Bus module.
	PLIB_SB_ExistsDMAPriority	Identifies whether the DMAPriority feature exists on the System Bus module.
	PLIB_SB_ExistsInitPermGrp	Identifies whether the InitPermGrp feature exists on the System Bus module.
	PLIB_SB_ExistsPGRegAddr	Identifies whether the PGRegAddr feature exists on the System Bus module.
	PLIB_SB_ExistsPGRegRdPerm	Identifies whether the PGRegRdPerm feature exists on the System Bus module.
	PLIB_SB_ExistsPGRegSize	Identifies whether the PGRegSize feature exists on the System Bus module.
	PLIB_SB_ExistsPGRegWrPerm	Identifies whether the PGRegWrPerm feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrClear	Identifies whether the PGVErrClear feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrClrMulti	Identifies whether the PGVErrClrMulti feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrClrSingle	Identifies whether the PGVErrClrSingle feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrCmdCode	Identifies whether the PGVErrCmdCode feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrInitID	Identifies whether the PGVErrInitID feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrPG	Identifies whether the PGVErrPG feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrRegion	Identifies whether the PGVErrRegion feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrRptPri	Identifies whether the PGVErrRptPri feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrStatus	Identifies whether the PGVErrStatus feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrGroup0Status	Identifies whether the PGVErrGroup0Status feature exists on the SB module
	PLIB_SB_ExistsPGVErrGroup1Status	Identifies whether the PGVErrGroup1Status feature exists on the SB module
	PLIB_SB_ExistsPGVErrGroup2Status	Identifies whether the PGVErrGroup2Status feature exists on the SB module
	PLIB_SB_ExistsPGVErrGroup3Status	Identifies whether the PGVErrGroup3Status feature exists on the SB module
	PLIB_SB_ExistsPGVErrGroupStatus	Identifies whether the PGVErrGroupStatus feature exists on the SB module

e) Data Types and Constants

	Name	Description
	PLIB_SB_ARB_POLICY	This enumeration lists the possible arbitration policies that can be assigned to the CPU and DMA for SRAM access.
	PLIB_SB_ERROR	Lists the possible System Bus Transaction Error Codes.
	PLIB_SB_INIT_ID	Lists the possible System Bus Initiator IDs.
	PLIB_SB_INIT_PG	Lists the possible Initiator permission groups
	PLIB_SB_OCP_CMD_CODE	Lists the possible OCP Command codes.
	PLIB_SB_PG_INITIATOR	Lists the possible permission group Initiators.
	PLIB_SB_REGION_PG	This enumeration lists the possible permission groups assigned to a region for read and/or write access.
	PLIB_SB_TGT_ID	Lists the possible System Bus Target IDs.
	PLIB_SB_TGT_REGION	Lists the programmable target regions.
	SB_MODULE_ID	Lists the possible Module IDs for the System Bus.

Description

This section describes the Application Programming Interface (API) functions of the System Bus Peripheral Library.

Refer to each section for a detailed description.

a) Target Initialization Functions

PLIB_SB_PGRegionAddrGet Function

Returns the base address for a permission group region within a target's physical address space.

File

plib_sb.h

C

```
uint32_t PLIB_SB_PGRegionAddrGet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region);
```

Returns

uint32_t - The base address of the region.

Description

This function returns the base address for a permission group region within a target's physical address space.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
uint32_t T1R6BaseAddress;
T1R6BaseAddress = PLIB_SB_PGRegionAddrGet(SB_ID_1, PLIB_T1_REGION_6);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
region	The region for which the address is returned.

Function

uint32_t PLIB_SB_PGRegionAddrGet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region)

PLIB_SB_PGRegionAddrSet Function

Sets the base address for a permission group region within a target's physical address space. Not all regions are programmable.

File

plib_sb.h

C

```
void PLIB_SB_PGRegionAddrSet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region, uint32_t phys_addr);
```

Returns

None.

Description

This function sets the base address for a permission group region within a target's physical address space. Not all regions are programmable.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Region 0 of all targets have a defined start address which may not be changed. Some regions (such as those containing peripheral SFRs) are fixed and may not be changed. Please refer to the specific device data sheet for details.

Preconditions

None.

Example

```
// Set up two regions in PFM with full read and write permission
#define REGION_5_BASE_ADDR  0x1D000000
#define REGION_6_BASE_ADDR  (REGION5_BASE_ADDR + (32*1024))
#define REGION_5_SIZE       0x06 // 32KB
#define REGION_6_SIZE       0x05 // 16KB
#define FULL_PERM           (REGION_PG_0 | REGION_PG_1 | REGION_PG_2 | REGION_PG_3)

PLIB_SB_PGRegionAddrSet(SB_ID_1, PLIB_SB_T1_REGION_5, REGION_5_BASE_ADDR);
PLIB_SB_PGRegionAddrSet(SB_ID_1, PLIB_SB_T1_REGION_6, REGION_6_BASE_ADDR);

PLIB_SB_PGRegionSizeSet(SB_ID_1, PLIB_SB_T1_REGION_5, REGION_5_SIZE);
PLIB_SB_PGRegionSizeSet(SB_ID_1, PLIB_SB_T1_REGION_6, REGION_6_SIZE);

PLIB_SB_PGRegionReadPermSet(SB_ID_1, PLIB_T1_REGION_5, FULL_PERM);
PLIB_SB_PGRegionReadPermSet(SB_ID_1, PLIB_T1_REGION_6, FULL_PERM);

PLIB_SB_PGRegionWritePermSet(SB_ID_1, PLIB_T1_REGION_5, FULL_PERM);
PLIB_SB_PGRegionWritePermSet(SB_ID_1, PLIB_T1_REGION_6, FULL_PERM);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
region	The region for which the base address is set.
phys_addr	The base address of the region. Must be aligned to the intended size of the region.

Function

void PLIB_SB_PGRegionAddrSet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region,

uint32_t phys_addr)

PLIB_SB_PGRegionReadPermClear Function

Clears the permission bit(s) corresponding to the requested read permissions for a permission group region within a target's physical address space. Not all regions are programmable.

File

plib_sb.h

C

```
void PLIB_SB_PGRegionReadPermClear(SB_MODULE_ID index, PLIB_SB_TGT_REGION region, PLIB_SB_REGION_PG
readPerm);
```

Returns

None.

Description

This function clears the permission bit(s) corresponding to the requested read permissions for a permission group region within a target's physical address space. Not all regions are programmable.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Default reset value for all programmable regions is read permission for all groups.

Preconditions

None.

Example

See the code example for PLIB_SB_PGRegionAddrSet.

Parameters

Parameters	Description
index	Identifier for the device instance.

region	The region number within the target's address space to be given permissions. Not all regions are programmable.
readPerm	Bitwise OR of the groups given read permission for the region.

Function

void PLIB_SB_PGRegionReadPermClear(SB_MODULE_ID index, PLIB_SB_TGT_REGION region,
PLIB_SB_REGION_PG readPerm)

PLIB_SB_PGRegionReadPermSet Function

Sets the permission bit(s) corresponding to the requested read permissions for a permission group region within a target's physical address space. Not all regions are programmable.

File

plib_sb.h

C

```
void PLIB_SB_PGRegionReadPermSet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region, PLIB_SB_REGION_PG readPerm);
```

Returns

None.

Description

This function sets the permission bit(s) corresponding to the requested read permissions for a permission group region within a target's physical address space. Not all regions are programmable.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Default reset value for all programmable regions is read permission for all groups.

Preconditions

None.

Example

See the code example for PLIB_SB_PGRegionAddrSet.

Parameters

Parameters	Description
index	Identifier for the device instance.
region	The region number within the target's address space to be given permissions. Not all regions are programmable.
readPerm	Bitwise OR of the groups given read permission for the region.

Function

void PLIB_SB_PGRegionReadPermSet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region,
PLIB_SB_REGION_PG readPerm)

PLIB_SB_PGRegionSizeGet Function

Returns the size for a permission group region within a target's physical address space.

File

plib_sb.h

C

```
uint32_t PLIB_SB_PGRegionSizeGet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region);
```

Returns

The size of the region.

Description

This function returns the size for a permission group region within a target's physical address space. Not all regions are programmable.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Region 0 of all targets encompasses the entire address range of the target, and may not be changed. Some regions (such as those containing peripheral SFRs) may not be changed. Please refer to the specific device data sheet for details.

Preconditions

None.

Example

```
uint32_t T1R6Size;
T1R6Size = PLIB_SB_PGRegionSizeGet(SB_ID_1, PLIB_T1_REGION_6);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
region	The region for which the size is to be set. Not all regions are programmable.

Function

uint32_t PLIB_SB_PGRegionSizeGet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region)

PLIB_SB_PGRegionSizeSet Function

Sets the size for a permission group region within a target's physical address space. Not all regions are programmable.

File

plib_sb.h

C

```
void PLIB_SB_PGRegionSizeSet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region, uint32_t size);
```

Returns

None.

Description

This function sets the size for a permission group region within a target's physical address space. Not all regions are programmable.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Region 0 of all targets encompasses the entire address range of the target, and may not be changed. Some regions (such as those containing peripheral SFRs) may not be changed. Please refer to the specific device data sheet for details.

Preconditions

None.

Example

See the code example for PLIB_SB_PGRegionAddrSet.

Parameters

Parameters	Description
index	Identifier for the device instance.
region	The region for which the size is to be set. Not all regions are programmable.
size	The actual size of the region being programmed is calculated as
follows	2**(size-1)*1024 bytes

Function

void PLIB_SB_PGRegionSizeSet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region, uint32_t size)

PLIB_SB_PGRegionWritePermClear Function

Clears the permission bit(s) corresponding to the requested write permissions for a permission group region within a target's physical address space. Not all regions are programmable.

File

plib_sb.h

C

```
void PLIB_SB_PGRegionWritePermClear(SB_MODULE_ID index, PLIB_SB_TGT_REGION region, PLIB_SB_REGION_PG
writePerm);
```

Returns

None.

Description

This function clears the permission bit(s) corresponding to the requested write permissions for a permission group region within a target's physical address space. Not all regions are programmable.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Default reset value for all programmable regions is write permission for all groups. Some regions may not be programmable by all initiators (flash, for example). Please refer to the specific device data sheet for details.

Preconditions

None.

Example

See the code example for PLIB_SB_PGRegionAddrSet.

Parameters

Parameters	Description
index	Identifier for the device instance.
region	The region number within the target's address space to be given permissions. Not all regions are programmable.
writePerm	Bitwise OR of the groups given read permission for the region.

Function

void PLIB_SB_PGRegionWritePermClear(SB_MODULE_ID index, PLIB_SB_TGT_REGION region,
PLIB_SB_REGION_PG writePerm)

PLIB_SB_PGRegionWritePermSet Function

Sets the permission bit(s) corresponding to the requested write permissions for a permission group region within a target's physical address space. Not all regions are programmable.

File

plib_sb.h

C

```
void PLIB_SB_PGRegionWritePermSet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region, PLIB_SB_REGION_PG
writePerm);
```

Returns

None.

Description

This function sets the permission bit(s) corresponding to the requested write permissions for a permission group region within a target's physical address space. Not all regions are programmable.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Default reset value for all programmable regions is write permission for all groups. Some regions may not be programmable by all initiators (flash, for example). Please refer to the specific device data sheet for details.

Preconditions

None.

Example

See the code example for PLIB_SB_PGRegionAddrSet.

Parameters

Parameters	Description
index	Identifier for the device instance.
region	The region number within the target's address space to be given permissions. Not all regions are programmable.
writePerm	Bitwise OR of the groups given read permission for the region.

Function

void PLIB_SB_PGRegionWritePermSet(SB_MODULE_ID index, PLIB_SB_TGT_REGION region,
PLIB_SB_REGION_PG writePerm)

b) PGV Error Functions

PLIB_SB_PGVErrorClearMulti Function

Clears multiple permission group errors for the specified target.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrorClearMulti(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

mult - Returns the value of the CLEAR bit in the SBTxECLRM register for the specified target. The act of reading this bit clears the error.

Description

This function clears multiple permission group errors for the specified target.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool mult;
mult = PLIB_SB_PGVErrorClearMulti(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target.

Function

bool PLIB_SB_PGVErrorClearMulti(SB_MODULE_ID index, PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorClearSingle Function

Clears a single permission group error for the specified target.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrorClearSingle(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

sing - Returns the value of the CLEAR bit in the SBTxECLRM register for the specified target. The act of reading this bit clears the error.

Description

This function clears a single permission group error for the specified target.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool sing;
sing = PLIB_SB_PGVErrorClearSingle(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target.

Function

bool PLIB_SB_PGVErrorClearSingle(SB_MODULE_ID index, PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorCode Function

Returns a value corresponding to the type of error logged for the specified target.

File

plib_sb.h

C

```
PLIB_SB_ERROR PLIB_SB_PGVErrorCode(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

PLIB_SB_ERROR enumeration representing the type of SB error logged states.

Description

This function returns a value corresponding to the type of error logged for the specified target.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
PLIB_SB_ERROR error;
error = PLIB_SB_ERROR PLIB_SB_PGVErrorCode(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target to be read.

Function

PLIB_SB_ERROR PLIB_SB_PGVErrorCode(SB_MODULE_ID index, PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorCommandCode Function

Returns the OCP command code of the transaction that caused the protection violation for the specified target.

File

plib_sb.h

C

```
PLIB_SB_OCP_CMD_CODE PLIB_SB_PGVErrorCommandCode(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

OCP command code

Description

This function returns the OCP command code of the transaction that caused the protection violation for the specified target.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
PLIB_SB_OCP_CMD_CODE commandCode;
commandCode = PLIB_SB_PGVErrorCommandCode(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target.

Function

PLIB_SB_OCP_CMD_CODE PLIB_SB_PGVErrorCommandCode(SB_MODULE_ID index , PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorInitiatorID Function

Returns the ID of the Initiator that caused the protection violation

File

plib_sb.h

C

```
PLIB_SB_INIT_ID PLIB_SB_PGVErrorInitiatorID(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

An enumerated value representing the ID of the initiator that caused the protection violation.

Description

This function returns the ID of the Initiator that caused the protection violation.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
PLIB_SB_INIT_ID id;
id = PLIB_SB_PGVErrorInitiatorID(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target.

Function

PLIB_SB_INIT_ID PLIB_SB_PGVErrorInitiatorID(SB_MODULE_ID index , PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorLogClearMulti Function

Clears a multiple protection group violations error from the specified target error log register.

File

plib_sb.h

C

```
void PLIB_SB_PGVErrorLogClearMulti(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

None.

Description

This function clears a multiple protection group violations error from the specified target error log register. Multiple errors are cleared by writing a '1' to both the MULTI and CODE fields of the SBTxELOG1 register for the specified target.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
PLIB_SB_PGVErrorLogClearMulti(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target to be cleared.

Function

void PLIB_SB_PGVErrorLogClearMulti(SB_MODULE_ID index, PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorLogClearSingle Function

Clears a single protection group violation error from the specified target error log register.

File

plib_sb.h

C

```
void PLIB_SB_PGVErrorLogClearSingle(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

None.

Description

This function clears a single protection group violation error from the specified target error log register. Single errors are cleared by writing a '1' to the CODE field of the SBTxELOG1 register for the specified target.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
PLIB_SB_PGVErrorLogClearSingle(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target to be cleared.

Function

void PLIB_SB_PGVErrorLogClearSingle(SB_MODULE_ID index, PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorMulti Function

Indicates if more than one permission group violation has occurred since last cleared.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrorMulti(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

- true - Multiple permission group violations.
- false - Single or no permission group violations.

Description

This function indicates if more than one permission group violation has occurred since last cleared.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool multiPGV;
multiPGV = PLIB_SB_PGVErrorMulti(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target to be read.

Function

bool PLIB_SB_PGVErrorMulti(SB_MODULE_ID index , PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorPermissionGroup Function

Returns the permission group of the protection region in a target address space that caused the protection violation for the specified target.

File

plib_sb.h

C

```
int PLIB_SB_PGVErrorPermissionGroup(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

None.

Description

This function returns the permission group of the protection region in a target address space that caused the protection violation for the specified target.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
int pg;
pg = PLIB_SB_PGVErrorPermissionGroup(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target.

Function

int PLIB_SB_PGVErrorPermissionGroup(SB_MODULE_ID index , PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorRegion Function

Returns the number of the protection region in the specified target address space that caused the protection violation.

File

plib_sb.h

C

```
int PLIB_SB_PGVErrorRegion(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

Region number in target address space or -1 on unrecognized target.

Description

This function returns the number of the protection region in the specified target address space that caused the protection violation. Note that if there are no other region matches, region 0 (the default region that spans the entire target address space) will always match, and this function will return 0.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
int region;
```

```
region = PLIB_SB_PGVErrorRegion(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target.

Function

int PLIB_SB_PGVErrorRegion(SB_MODULE_ID index, PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorReportPrimaryDisable Function

Disables primary permission group error reporting for the specified target to the SB flag register.

File

plib_sb.h

C

```
void PLIB_SB_PGVErrorReportPrimaryDisable(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

None.

Description

This function disables primary permission group error reporting for the specified target to the SB flag register.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Reporting of primary errors is disabled at reset.

Preconditions

None.

Example

```
PLIB_SB_PGVErrorReportPrimaryDisable(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target.

Function

void PLIB_SB_PGVErrorReportPrimaryDisable(SB_MODULE_ID index, PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorReportPrimaryEnable Function

Enables primary permission group error reporting for the specified target to the SB flag register.

File

plib_sb.h

C

```
void PLIB_SB_PGVErrorReportPrimaryEnable(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

None.

Description

This function enables primary permission group error reporting for the specified target to the SB flag register.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Reporting of primary errors is disabled at reset.

Preconditions

None.

Example

```
PLIB_SB_PGVErrorReportPrimaryEnable(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	The target.

Function

void PLIB_SB_PGVErrorReportPrimaryEnable(SB_MODULE_ID index , PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrorStatus Function

Identifies whether a permission group violation has been reported for the specified target.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrorStatus(SB_MODULE_ID index, PLIB_SB_TGT_ID target);
```

Returns

- true - Target is reporting a permission group violation.
- false - Target is not reporting a permission group violation.

Description

This function identifies whether a permission group violation has been reported for the specified target.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool sbPgv;
sbPgv = PLIB_SB_PGVErrorStatus(SB_ID_1, PLIB_SB_TGT_ID_T0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
target	Target to be checked.

Function

bool PLIB_SB_PGVErrorStatus (SB_MODULE_ID index , PLIB_SB_TGT_ID target)

PLIB_SB_PGVErrGroup0Status Function

Identifies whether a permission group violation has been reported for the Target Group 0.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrGroup0Status(SB_MODULE_ID index, PLIB_SB_PGV_GROUP0_TGT targetId);
```

Returns

- true - Target is reporting a permission group violation.
- false - Target is not reporting a permission group violation.

Description

This function identifies whether a permission group violation has been reported for Target Group 0.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool sbPgv;
sbPgv = PLIB_SB_PGVErrGroup0Status(SB_ID_0, PLIB_SB_PGV_GROUP0_T1_PGV);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
targetId	Target to be checked.

Function

bool PLIB_SB_PGVErrGroup0Status(SB_MODULE_ID index, PLIB_SB_PGV_GROUP0_TGT targetId);

PLIB_SB_PGVErrGroup1Status Function

Identifies whether a permission group violation has been reported for the Target Group 1.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrGroup1Status(SB_MODULE_ID index, PLIB_SB_PGV_GROUP1_TGT targetId);
```

Returns

- true - Target is reporting a permission group violation.
- false - Target is not reporting a permission group violation.

Description

This function identifies whether a permission group violation has been reported for Target Group 1.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool sbPgv;
sbPgv = PLIB_SB_PGVErrGroup1Status(SB_ID_0, PLIB_SB_PGV_GROUP1_T11_PGV);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
targetId	Target to be checked.

Function

bool PLIB_SB_PGVErrGroup1Status(SB_MODULE_ID index, PLIB_SB_PGV_GROUP1_TGT targetId);

PLIB_SB_PGVErrGroup2Status Function

Identifies whether a permission group violation has been reported for the Target Group 2.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrGroup2Status(SB_MODULE_ID index, PLIB_SB_PGV_GROUP2_TGT targetId);
```

Returns

- true - Target is reporting a permission group violation.
- false - Target is not reporting a permission group violation.

Description

This function identifies whether a permission group violation has been reported for Target Group 2.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool sbPgv;
sbPgv = PLIB_SB_PGVErrGroup2Status(SB_ID_0, PLIB_SB_PGV_GROUP2_T14_PGV);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
targetId	Target to be checked.

Function

bool PLIB_SB_PGVErrGroup2Status(SB_MODULE_ID index, PLIB_SB_PGV_GROUP2_TGT targetId);

PLIB_SB_PGVErrGroup3Status Function

Identifies whether a permission group violation has been reported for the Target Group 3.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrGroup3Status(SB_MODULE_ID index, PLIB_SB_PGV_GROUP3_TGT targetId);
```

Returns

- true - Target is reporting a permission group violation.
- false - Target is not reporting a permission group violation.

Description

This function identifies whether a permission group violation has been reported for Target Group 3.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool sbPgv;
sbPgv = PLIB_SB_PGVErrGroup3Status(SB_ID_0, PLIB_SB_PGV_GROUP3_T16_PGV);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
targetId	Target to be checked.

Function

bool PLIB_SB_PGVErrGroup3Status(SB_MODULE_ID index, PLIB_SB_PGV_GROUP3_TGT targetId);

PLIB_SB_PGVErrGroupStatus Function

Identifies whether a permission group violation has been reported for the specified target group.

File

plib_sb.h

C

```
bool PLIB_SB_PGVErrGroupStatus(SB_MODULE_ID index, PLIB_SB_PGV_GROUP_ID groupId);
```

Returns

- true - Target group is reporting a permission group violation.
- false - Target group is not reporting a permission group violation.

Description

This function identifies whether a permission group violation has been reported for the specified target group.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

Preconditions

None.

Example

```
bool sbPgv;
sbPgv = PLIB_SB_PGVErrGroupStatus(SB_ID_0, PLIB_SB_PGV_GROUP0);
```

Parameters

Parameters	Description
index	Identifier for the device instance.
groupId	Target group to be checked.

Function

bool PLIB_SB_PGVErrGroupStatus(SB_MODULE_ID index, PLIB_SB_PGV_GROUP_ID groupId);

c) Other Functions

PLIB_SB_CPUPrioritySet Function

Sets the CPU arbitration policy to SRAM when servicing an interrupt

File

plib_sb.h

C

```
void PLIB_SB_CPUPrioritySet(SB_MODULE_ID index, PLIB_SB_ARB_POLICY priority);
```

Returns

None.

Description

This function sets the CPU arbitration policy to SRAM when servicing an interrupt.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

This function writes to the soft configuration register CFGCON, which is not part of the SB. This should be done by the boot code prior to programming the SB. Note that the system must be unlocked before the priority can be set.

Default at reset is PRIORITY_LRS.

Preconditions

System must be unlocked before the priority can be set.

Example

```
PLIB_SB_PriorityUnlock();
PLIB_SB_CPUPrioritySet(SB_ID_1, PRIORITY_HI);
```

Parameters

Parameters	Description
priority	Use either high priority or least-recently-serviced algorithm.

Function

void PLIB_SB_CPUPrioritySet(SB_MODULE_ID index, PLIB_SB_ARB_POLICY priority)

PLIB_SB_DMAPrioritySet Function

Sets the DMA arbitration policy

File

plib_sb.h

C

```
void PLIB_SB_DMAPrioritySet(SB_MODULE_ID index, PLIB_SB_ARB_POLICY priority);
```

Returns

None.

Description

This function sets the DMA arbitration.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

This function writes to the soft configuration register CFGCON, which is not part of the SB. This should be done by the boot code prior to programming the SB. Note that the system must be unlocked before the priority can be set.

Default at reset is PRIORITY_LRS.

Preconditions

System must be unlocked before the priority can be set.

Example

```
PLIB_SB_PriorityUnlock();
void PLIB_SB_DMAPrioritySet(SB_ID_1, PRIORITY_HI);
```

Parameters

Parameters	Description
priority	Use either high priority or least-recently-serviced algorithm.

Function

void PLIB_SB_DMAPrioritySet(SB_MODULE_ID index, PLIB_SB_ARB_POLICY priority)

PLIB_SB_InitPermGrpSet Function

Sets the read/write permission group(s) for an initiator. The region must also allow read/write access for the permission group for a read/write to occur.

File

plib_sb.h

C

```
void PLIB_SB_InitPermGrpSet(SB_MODULE_ID index, PLIB_SB_PG_INITIATOR initiator, PLIB_SB_INIT_PG pg);
```

Returns

None.

Description

This function sets the read/write permission group(s) for an initiator. The region must also allow read/write access for the permission group for a read/write to occur.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet for availability.

This function writes to the soft configuration register CFGPG, which is not part of the SB. Permission groups should be assigned by the boot code prior to programming the SB.

Default permission group at reset for all initiators is 0.

After an NMI, the CPU permission group reverts to 0. All other initiator permission groups remain unchanged.

The effective CPU permission group value in debug mode is controlled by boot configuration value DBGPER[2:0]. If DBGPER denies access to the group CPU1PG selects, the effective value selects group 3.

Preconditions

None.

Example

```
PLIB_SB_InitPermGrpSet(SB_ID_1, PLIB_SB_PG_INITIATOR_CPU, PLIB_SB_INIT_PG_1);
```

Parameters

Parameters	Description
initiator	The initiator for which permission groups are assigned.
pg	The permission group(s) to which the initiator is assigned.

Function

void PLIB_SB_InitPermGrpSet(SB_MODULE_ID index, PLIB_SB_PG_INITIATOR initiator, PLIB_SB_INIT_PG pg)

d) Feature Existence Functions

PLIB_SB_ExistsCPUPriority Function

Identifies whether the CPUPriority feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsCPUPriority(SB_MODULE_ID index);
```

Returns

- true - The CPUPriority feature is supported on the device
- false - The CPUPriority feature is not supported on the device

Description

This function identifies whether the CPUPriority feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_CPUPrioritySet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsCPUPriority(SB_MODULE_ID index)

PLIB_SB_ExistsDMAPriority Function

Identifies whether the DMAPriority feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsDMAPriority(SB_MODULE_ID index);
```

Returns

- true - The DMAPriority feature is supported on the device
- false - The DMAPriority feature is not supported on the device

Description

This function identifies whether the DMAPriority feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_DMAPrioritySet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsDMAPriority(SB_MODULE_ID index)

PLIB_SB_ExistsInitPermGrp Function

Identifies whether the InitPermGrp feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsInitPermGrp(SB_MODULE_ID index);
```

Returns

- true - The InitPermGrp feature is supported on the device
- false - The InitPermGrp feature is not supported on the device

Description

This function identifies whether the InitPermGrp feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_InitPermGrpSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsInitPermGrp(SB_MODULE_ID index)

PLIB_SB_ExistsPGRegAddr Function

Identifies whether the PGRegAddr feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGRegAddr(SB_MODULE_ID index);
```

Returns

- true - The PGRegAddr feature is supported on the device
- false - The PGRegAddr feature is not supported on the device

Description

This function identifies whether the PGRegAddr feature is available on the System Bus module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGRegionAddrSet
- PLIB_SB_PGRegionAddrGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGRegAddr(SB_MODULE_ID index)

PLIB_SB_ExistsPGRegRdPerm Function

Identifies whether the PGRegRdPerm feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGRegRdPerm(SB_MODULE_ID index);
```

Returns

- true - The PGRegRdPerm feature is supported on the device
- false - The PGRegRdPerm feature is not supported on the device

Description

This function identifies whether the PGRegRdPerm feature is available on the System Bus module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGRegionReadPermSet
- PLIB_SB_PGRegionReadPermClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGRegRdPerm(SB_MODULE_ID index)

PLIB_SB_ExistsPGRegSize Function

Identifies whether the PGRegSize feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGRegSize(SB_MODULE_ID index);
```

Returns

- true - The PGRegSize feature is supported on the device
- false - The PGRegSize feature is not supported on the device

Description

This function identifies whether the PGRegSize feature is available on the System Bus module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGRegionSizeSet
- PLIB_SB_PGRegionSizeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGRegSize(SB_MODULE_ID index)

PLIB_SB_ExistsPGRegWrPerm Function

Identifies whether the PGRegWrPerm feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGRegWrPerm(SB_MODULE_ID index);
```

Returns

- true - The PGRegWrPerm feature is supported on the device
- false - The PGRegWrPerm feature is not supported on the device

Description

This function identifies whether the PGRegWrPerm feature is available on the System Bus module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGRegionWritePermSet
- PLIB_SB_PGRegionWritePermClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGRegWrPerm(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrClear Function

Identifies whether the PGVErrClear feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrClear(SB_MODULE_ID index);
```

Returns

- true - The PGVErrClear feature is supported on the device
- false - The PGVErrClear feature is not supported on the device

Description

This function identifies whether the PGVErrClear feature is available on the System Bus module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGVErrorMulti
- PLIB_SB_PGVErrorCode
- PLIB_SB_PGVErrorLogClearSingle
- PLIB_SB_PGVErrorLogClearMulti

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrClear(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrClrMulti Function

Identifies whether the PGVErrClrMulti feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrClrMulti(SB_MODULE_ID index);
```

Returns

- true - The PGVErrClrMulti feature is supported on the device
- false - The PGVErrClrMulti feature is not supported on the device

Description

This function identifies whether the PGVErrClrMulti feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_PGVErrorClearMulti

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrClrMulti(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrClrSingle Function

Identifies whether the PGVErrClrSingle feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrClrSingle(SB_MODULE_ID index);
```

Returns

- true - The PGVErrClrSingle feature is supported on the device
- false - The PGVErrClrSingle feature is not supported on the device

Description

This function identifies whether the PGVErrClrSingle feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_PGVErrorClearSingle

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrClrSingle(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrCmdCode Function

Identifies whether the PGVErrCmdCode feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrCmdCode(SB_MODULE_ID index);
```

Returns

- true - The PGVErrCmdCode feature is supported on the device
- false - The PGVErrCmdCode feature is not supported on the device

Description

This function identifies whether the PGVErrCmdCode feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_PGVErrorCommandCode

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrCmdCode(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrInitID Function

Identifies whether the PGVErrInitID feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrInitID(SB_MODULE_ID index);
```

Returns

- true - The PGVErrInitID feature is supported on the device
- false - The PGVErrInitID feature is not supported on the device

Description

This function identifies whether the PGVErrInitID feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_PGVErrorInitiatorID

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrInitID(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrPG Function

Identifies whether the PGVErrPG feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrPG(SB_MODULE_ID index);
```

Returns

- true - The PGVErrPG feature is supported on the device
- false - The PGVErrPG feature is not supported on the device

Description

This function identifies whether the PGVErrPG feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_PGVErrorPermissionGroup

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrPG(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrRegion Function

Identifies whether the PGVErrRegion feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrRegion(SB_MODULE_ID index);
```

Returns

- true - The PGVErrRegion feature is supported on the device
- false - The PGVErrRegion feature is not supported on the device

Description

This function identifies whether the PGVErrRegion feature is available on the System Bus module. When this function returns true, this function is supported on the device:

- PLIB_SB_PGVErrorRegion

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrRegion(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrRptPri Function

Identifies whether the PGVErrRptPri feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrRptPri(SB_MODULE_ID index);
```

Returns

- true - The PGVErrRptPri feature is supported on the device
- false - The PGVErrRptPri feature is not supported on the device

Description

This function identifies whether the PGVErrRptPri feature is available on the System Bus module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGVErrorReportPrimaryEnable
- PLIB_SB_PGVErrorReportPrimaryDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrRptPri(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrStatus Function

Identifies whether the PGVErrStatus feature exists on the System Bus module.

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrStatus(SB_MODULE_ID index);
```

Returns

- true - The PGVErrStatus feature is supported on the device
- false - The PGVErrStatus feature is not supported on the device

Description

This function identifies whether the PGVErrStatus feature is available on the System Bus module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGVErrorStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrStatus(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrGroup0Status Function

Identifies whether the PGVErrGroup0Status feature exists on the SB module

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrGroup0Status(SB_MODULE_ID index);
```

Returns

- true - The PGVErrGroup0Status feature is supported on the device
- false - The PGVErrGroup0Status feature is not supported on the device

Description

This function identifies whether the PGVErrGroup0Status feature is available on the SB module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGVErrGroup0Status

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrGroup0Status(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrGroup1Status Function

Identifies whether the PGVErrGroup1Status feature exists on the SB module

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrGroup1Status(SB_MODULE_ID index);
```

Returns

- true - The PGVErrGroup1Status feature is supported on the device
- false - The PGVErrGroup1Status feature is not supported on the device

Description

This function identifies whether the PGVErrGroup1Status feature is available on the SB module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGVErrGroup1Status

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrGroup1Status(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrGroup2Status Function

Identifies whether the PGVErrGroup2Status feature exists on the SB module

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrGroup2Status(SB_MODULE_ID index);
```

Returns

- true - The PGVErrGroup2Status feature is supported on the device
- false - The PGVErrGroup2Status feature is not supported on the device

Description

This function identifies whether the PGVErrGroup2Status feature is available on the SB module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGVErrGroup2Status

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrGroup2Status(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrGroup3Status Function

Identifies whether the PGVErrGroup3Status feature exists on the SB module

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrGroup3Status(SB_MODULE_ID index);
```

Returns

- true - The PGVErrGroup3Status feature is supported on the device
- false - The PGVErrGroup3Status feature is not supported on the device

Description

This function identifies whether the PGVErrGroup3Status feature is available on the SB module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGVErrGroup3Status

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrGroup3Status(SB_MODULE_ID index)

PLIB_SB_ExistsPGVErrGroupStatus Function

Identifies whether the PGVErrGroupStatus feature exists on the SB module

File

plib_sb.h

C

```
bool PLIB_SB_ExistsPGVErrGroupStatus(SB_MODULE_ID index);
```

Returns

- true - The PGVErrGroupStatus feature is supported on the device
- false - The PGVErrGroupStatus feature is not supported on the device

Description

This function identifies whether the PGVErrGroupStatus feature is available on the SB module. When this function returns true, these functions are supported on the device:

- PLIB_SB_PGVErrGroupStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SB_ExistsPGVErrGroupStatus(SB_MODULE_ID index)

e) Data Types and Constants

PLIB_SB_ARB_POLICY Enumeration

This enumeration lists the possible arbitration policies that can be assigned to the CPU and DMA for SRAM access.

File

help_plib_sb.h

C

```
typedef enum {
  PRIORITY_LRS,
  PRIORITY_HI
} PLIB_SB_ARB_POLICY;
```

Members

Members	Description
PRIORITY_LRS	Least Recently Serviced Arbitration
PRIORITY_HI	High Priority

Description

System Bus Arbitration Policy

This enumeration lists the possible arbitration policies that can be assigned to the CPU and DMA for SRAM access.

PLIB_SB_ERROR Enumeration

Lists the possible System Bus Transaction Error Codes.

File

help_plib_sb.h

C

```
typedef enum {
  PLIB_SB_ERROR_NONE,
  PLIB_SB_ERROR_PGV
} PLIB_SB_ERROR;
```

Members

Members	Description
PLIB_SB_ERROR_NONE	No Error
PLIB_SB_ERROR_PGV	Permission Group Violation

Description

PG Error Code

This enumeration lists the possible transaction error codes for the System Bus.

PLIB_SB_INIT_ID Enumeration

Lists the possible System Bus Initiator IDs.

File

help_plib_sb.h

C

```
typedef enum {
  PLIB_SB_INIT_ID_NONE,
  PLIB_SB_INIT_ID_CPU_LRS,
  PLIB_SB_INIT_ID_CPU_HI,
  PLIB_SB_INIT_ID_DMA1_RD_LRS,
  PLIB_SB_INIT_ID_DMA1_RD_HI,
```

```
  PLIB_SB_INIT_ID_DMA1_WR_LRS,
  PLIB_SB_INIT_ID_DMA1_WR_HI,
  PLIB_SB_INIT_ID_USB1,
  PLIB_SB_INIT_ID_ETH1_RD,
  PLIB_SB_INIT_ID_ETH1_WR,
  PLIB_SB_INIT_ID_CAN1,
  PLIB_SB_INIT_ID_CAN2,
  PLIB_SB_INIT_ID_SQI1,
  PLIB_SB_INIT_ID_FLASH_CTL,
  PLIB_SB_INIT_ID_CRYPTO
} PLIB_SB_INIT_ID;
```

Description

System Bus Initiator ID

This enumeration lists the possible System Bus Initiator IDs. This ID is used for self-reporting and error logging. LRS and HI are System Bus arbitration schemes set by the soft configuration register CFGCON.

PLIB_SB_INIT_PG Enumeration

Lists the possible Initiator permission groups

File

help_plib_sb.h

C

```
typedef enum {
  PLIB_SB_INIT_PG_0,
  PLIB_SB_INIT_PG_1,
  PLIB_SB_INIT_PG_2,
  PLIB_SB_INIT_PG_3
} PLIB_SB_INIT_PG;
```

Members

Members	Description
PLIB_SB_INIT_PG_0	Privilege Group 0
PLIB_SB_INIT_PG_1	Privilege Group 1
PLIB_SB_INIT_PG_2	Privilege Group 2
PLIB_SB_INIT_PG_3	Privilege Group 3

Description

System Bus Initiator Permission Groups

This enumeration lists the possible initiator permission groups for the System Bus.

Remarks

These values are used to program the CFGPG soft configuration register, which is not part of the System Bus. This should be done by the boot code to set up the desired initiator permissions prior to programming the System Bus.

PLIB_SB_OCP_CMD_CODE Enumeration

Lists the possible OCP Command codes.

File

help_plib_sb.h

C

```
typedef enum {
  PLIB_SB_OCP_CMD_IDLE,
  PLIB_SB_OCP_CMD_WRITE,
  PLIB_SB_OCP_CMD_READ,
  PLIB_SB_OCP_CMD_READEX,
  PLIB_SB_OCP_CMD_WRITE_NON_POST,
  PLIB_SB_OCP_CMD_BROADCAST
} PLIB_SB_OCP_CMD_CODE;
```

Description

OCP Command Codes

This enumeration lists the possible OCP command codes. An OCP command code is logged when a transaction violation occurs. The command code of the offending command can then be read.

PLIB_SB_PG_INITIATOR Enumeration

Lists the possible permission group Initiators.

File

help_plib_sb.h

C

```
typedef enum {
  PLIB_SB_PG_INITIATOR_CPU,
  PLIB_SB_PG_INITIATOR_DMA1,
  PLIB_SB_PG_INITIATOR_USB1,
  PLIB_SB_PG_INITIATOR_CAN1,
  PLIB_SB_PG_INITIATOR_CAN2,
  PLIB_SB_PG_INITIATOR_ETH1,
  PLIB_SB_PG_INITIATOR_SQI1,
  PLIB_SB_PG_INITIATOR_FLASH_CTL,
  PLIB_SB_PG_INITIATOR_CRYPTO
} PLIB_SB_PG_INITIATOR;
```

Description

System Bus Initiators

This enumeration lists the possible permission group Initiators.

PLIB_SB_REGION_PG Enumeration

This enumeration lists the possible permission groups assigned to a region for read and/or write access.

File

help_plib_sb.h

C

```
typedef enum {
  REGION_PG_0,
  REGION_PG_1,
  REGION_PG_2,
  REGION_PG_3
} PLIB_SB_REGION_PG;
```

Members

Members	Description
REGION_PG_0	Privilege Group 0 has read/write permission
REGION_PG_1	Privilege Group 1 has read/write permission
REGION_PG_2	Privilege Group 2 has read/write permission
REGION_PG_3	Privilege Group 3 has read/write permission

Description

System Bus Region Permission Groups

Lists the possible permission groups assigned to a region for read and/or write access.

PLIB_SB_TGT_ID Enumeration

Lists the possible System Bus Target IDs.

File

help_plib_sb.h

C

```
typedef enum {
  PLIB_SB_TGT_ID_T0,
  PLIB_SB_TGT_ID_T1,
  PLIB_SB_TGT_ID_T2,
  PLIB_SB_TGT_ID_T3,
  PLIB_SB_TGT_ID_T4,
  PLIB_SB_TGT_ID_T5,
  PLIB_SB_TGT_ID_T6,
  PLIB_SB_TGT_ID_T7,
  PLIB_SB_TGT_ID_T8,
  PLIB_SB_TGT_ID_T9,
  PLIB_SB_TGT_ID_T10,
  PLIB_SB_TGT_ID_T11,
  PLIB_SB_TGT_ID_T12,
  PLIB_SB_TGT_ID_T13
} PLIB_SB_TGT_ID;
```

Members

Members	Description

Functions

	Name	Description
	PLIB_SB_CPUPrioritySet	Sets the CPU arbitration policy to SRAM when servicing an interrupt
	PLIB_SB_DMAPrioritySet	Sets the DMA arbitration policy
	PLIB_SB_ExistsCPUPriority	Identifies whether the CPUPriority feature exists on the System Bus module.
	PLIB_SB_ExistsDMAPriority	Identifies whether the DMAPriority feature exists on the System Bus module.
	PLIB_SB_ExistsInitPermGrp	Identifies whether the InitPermGrp feature exists on the System Bus module.
	PLIB_SB_ExistsPGRegAddr	Identifies whether the PGRegAddr feature exists on the System Bus module.
	PLIB_SB_ExistsPGRegRdPerm	Identifies whether the PGRegRdPerm feature exists on the System Bus module.
	PLIB_SB_ExistsPGRegSize	Identifies whether the PGRegSize feature exists on the System Bus module.
	PLIB_SB_ExistsPGRegWrPerm	Identifies whether the PGRegWrPerm feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrClear	Identifies whether the PGVErrClear feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrClrMulti	Identifies whether the PGVErrClrMulti feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrClrSingle	Identifies whether the PGVErrClrSingle feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrCmdCode	Identifies whether the PGVErrCmdCode feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrGroup0Status	Identifies whether the PGVErrGroup0Status feature exists on the SB module
	PLIB_SB_ExistsPGVErrGroup1Status	Identifies whether the PGVErrGroup1Status feature exists on the SB module
	PLIB_SB_ExistsPGVErrGroup2Status	Identifies whether the PGVErrGroup2Status feature exists on the SB module
	PLIB_SB_ExistsPGVErrGroup3Status	Identifies whether the PGVErrGroup3Status feature exists on the SB module

	PLIB_SB_ExistsPGVErrGroupStatus	Identifies whether the PGVErrGroupStatus feature exists on the SB module
	PLIB_SB_ExistsPGVErrInitID	Identifies whether the PGVErrInitID feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrPG	Identifies whether the PGVErrPG feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrRegion	Identifies whether the PGVErrRegion feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrRptPri	Identifies whether the PGVErrRptPri feature exists on the System Bus module.
	PLIB_SB_ExistsPGVErrStatus	Identifies whether the PGVErrStatus feature exists on the System Bus module.
	PLIB_SB_InitPermGrpSet	Sets the read/write permission group(s) for an initiator. The region must also allow read/write access for the permission group for a read/write to occur.
	PLIB_SB_PGRegionAddrGet	Returns the base address for a permission group region within a target's physical address space.
	PLIB_SB_PGRegionAddrSet	Sets the base address for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionReadPermClear	Clears the permission bit(s) corresponding to the requested read permissions for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionReadPermSet	Sets the permission bit(s) corresponding to the requested read permissions for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionSizeGet	Returns the size for a permission group region within a target's physical address space.
	PLIB_SB_PGRegionSizeSet	Sets the size for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionWritePermClear	Clears the permission bit(s) corresponding to the requested write permissions for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGRegionWritePermSet	Sets the permission bit(s) corresponding to the requested write permissions for a permission group region within a target's physical address space. Not all regions are programmable.
	PLIB_SB_PGVErrGroup0Status	Identifies whether a permission group violation has been reported for the Target Group 0.
	PLIB_SB_PGVErrGroup1Status	Identifies whether a permission group violation has been reported for the Target Group 1.
	PLIB_SB_PGVErrGroup2Status	Identifies whether a permission group violation has been reported for the Target Group 2.
	PLIB_SB_PGVErrGroup3Status	Identifies whether a permission group violation has been reported for the Target Group 3.
	PLIB_SB_PGVErrGroupStatus	Identifies whether a permission group violation has been reported for the specified target group.
	PLIB_SB_PGVErrorClearMulti	Clears multiple permission group errors for the specified target.
	PLIB_SB_PGVErrorClearSingle	Clears a single permission group error for the specified target.
	PLIB_SB_PGVErrorCode	Returns a value corresponding to the type of error logged for the specified target.
	PLIB_SB_PGVErrorCommandCode	Returns the OCP command code of the transaction that caused the protection violation for the specified target.
	PLIB_SB_PGVErrorInitiatorID	Returns the ID of the Initiator that caused the protection violation
	PLIB_SB_PGVErrorLogClearMulti	Clears a multiple protection group violations error from the specified target error log register.
	PLIB_SB_PGVErrorLogClearSingle	Clears a single protection group violation error from the specified target error log register.
	PLIB_SB_PGVErrorMulti	Indicates if more than one permission group violation has occurred since last cleared.
	PLIB_SB_PGVErrorPermissionGroup	Returns the permission group of the protection region in a target address space that caused the protection violation for the specified target.
	PLIB_SB_PGVErrorRegion	Returns the number of the protection region in the specified target address space that caused the protection violation.
	PLIB_SB_PGVErrorReportPrimaryDisable	Disables primary permission group error reporting for the specified target to the SB flag register.
	PLIB_SB_PGVErrorReportPrimaryEnable	Enables primary permission group error reporting for the specified target to the SB flag register.
	PLIB_SB_PGVErrorStatus	Identifies whether a permission group violation has been reported for the specified target.

Description

This file is used for documentation purposes

SPI Peripheral Library

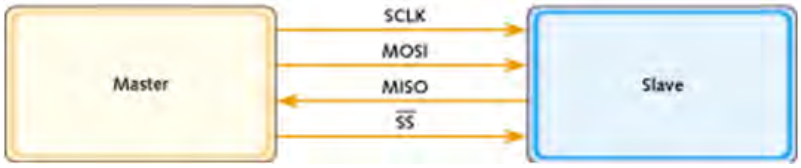
This section describes the Serial Peripheral Interface (SPI) Peripheral Library.

Introduction

This library provides a low-level abstraction of the Serial Peripheral Interface (SPI) module that is available on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, there by hiding differences from one microcontroller variant to another.

Description

The Serial Peripheral Interface (SPI) module is a synchronous serial interface useful for communicating with other peripherals or microcontroller device. These peripheral devices may be serial EEPROMs, shift registers, display drivers, analog-to-digital converters, etc.



SPI is a synchronous serial data link operating at full duplex Master/slave relationship.

Two data lines:

- MOSI – Master Data Output, Slave Data Input
- MISO – Master Data Input, Slave Data Output

Two control lines:

- SCLK – Clock
- /SS – Slave Select (no addressing)

Devices communicate in Master/Slave mode where the master device initiates the data frame. Multiple slave devices are allowed with individual slave select (Chip Select) lines. The SPI is sometimes referred to as a "four-wire" serial bus, contrasting with three-, two-, and one-wire serial buses.

Using the Library

This topic describes the basic architecture of the SPI Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_spi.h`

The interface to the SPI Peripheral Library is defined in the `plib_spi.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the SPI Peripheral library must include `peripheral.h`.

Library File:

The SPI Peripheral Library is part of the processor-specific peripheral library archive (`.a`) file installed with the compiler. Libraries in this archive are automatically available to the linker (in the default search path) for any project built using the Microchip compiler.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

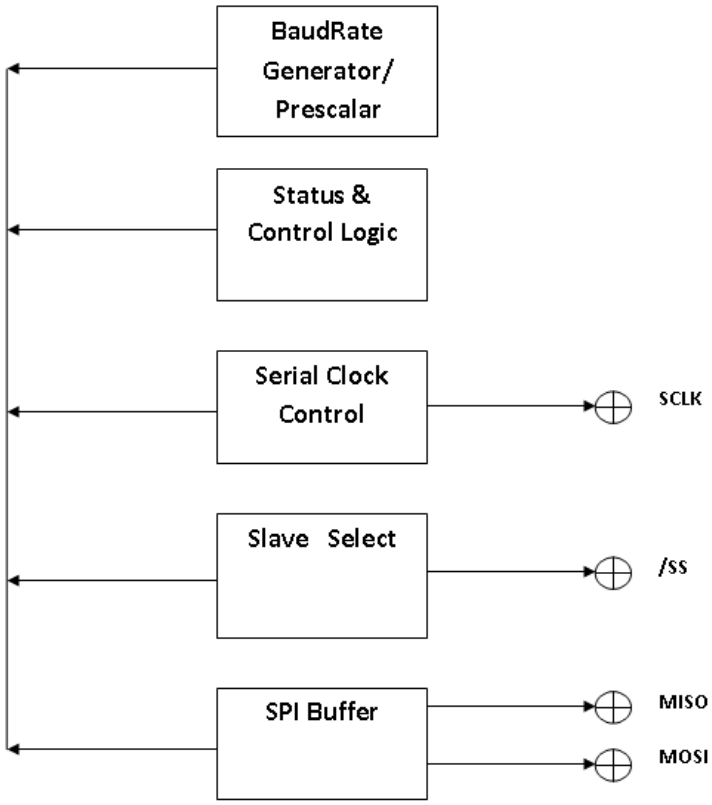
Hardware Abstraction Model

This library provides a low-level abstraction of the SPI module on the Microchip family microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in software and introduces the library's interface.

Description

The SPI Peripheral Library provides interface routines to interact with the blocks shown in the following diagram.

Hardware Abstraction Model



The Serial Peripheral Interface (API) module is a synchronous serial interface useful for communicating with external peripherals and other microcontroller devices.

The SPI bus specifies four logic signals:

- SCLK: serial clock (output from master)
- MOSI: master output, slave input (output from master)
- MISO: master input, slave output (output from slave)
- /SS: slave select (active low, output from master); on certain devices, this pin is implemented using general purpose I/O (GPIO)

The SPI bus can operate with a single master device and with one or more slave devices. To begin a communication, the master first configures the clock, using a frequency less than or equal to the maximum frequency the slave device supports. In addition to setting the clock frequency, the master must also configure the clock polarity and phase with respect to the data.

The master then transmits the appropriate chip select bit for the desired chip to a logic '0'. A logic '0' is transmitted because the Chip Select line (/SS) is active low, meaning its off state is a logic '1'; the on state is asserted with a logic 0. The master issues the clock cycles.

During each SPI clock cycle, a full duplex data transmission occurs:

- The master sends a bit on the MOSI line; the slave reads it from that same line
- The slave sends a bit on the MISO line; the master reads it from that same line

Transmissions may involve any number of clock cycles. When there are no more data to be transmitted, the master stops toggling its clock. Normally, it then deselects the slave.

The **Baud Rate Generator/Prescaler** controls the timing, the desired baud rate can be programmed in the baud rate controller.

In the Master mode, the **clock** becomes the serial clock and is provided to external devices via the SCK pin (the clock can be prescaled by the primary prescaler and the secondary prescaler if device supports).

The **Buffers** are for data transmitted or received by the SPI module over the MISO and MOSI line synchronized with the SCK line by the clock control logic.

The **Status and Control logic**, provide the capability to control different ways of enabling or disabling the master and slave. It also can provides status about the transmitter and receiver.

Active-Low **Slave Select** or Frame Synchronization I/O Pulse allows for a Synchronous Slave mode.

The SPI module supports the following four SPI modes.

- **Standard Mode:** In this mode of operation, data can be thought of as taking a direct path between the Most Significant bit (MSb) of one module's shift register and the Least Significant bit (LSb) of the other, and then into the appropriate Transmit or Receive Buffer. The master provides the serial clock and synchronization signals required to the slave device.
- **Enhanced Buffer Mode:** The operation of this mode is very similar to that of Standard mode. The difference is that data can be thought of as moving from the Shift register to a receive FIFO buffer and moving from the transmit FIFO buffer to the Shift register.
- **Framed Mode:** In this mode of operation, the Frame Master controls the generation of the frame synchronization pulse and provides this pulse to other devices at the Slave Select (/SS) pin. The SPI clock is generated by the SPI Master and is continuously running. The SPI slave module uses a frame synchronization pulse received at the SS pin.

- **Audio Protocol Mode:** The SPI module provides support to the audio protocol modes; with this mode, the SPI module can be interfaced to most codec devices available today to provide PIC microcontroller-based audio solution

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the SPI module.

Library Interface Section	Description
General Configuration and Status Functions	This section provides a set of functions and data types for configuring the SPI and to read the status of the SPI.
Data Transfer Functions	This section provides a set of functions and data types for Reading and Writing the SPI buffer values.
Transmitter Functions	This section provides a set of functions for transmitter.
Receiver Functions	This section provides a set of functions for receiver.
Framed Mode Functions	Provides control, status, and data transfer routines for Framed SPI mode.
Audio Mode Functions	Provides control, status routines to support audio protocol functionality.
Feature Existence Functions	Provides functions that determine whether certain features exist on a device.

Note: Not all modes are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

How the Library Works

Provides information on how the library works.

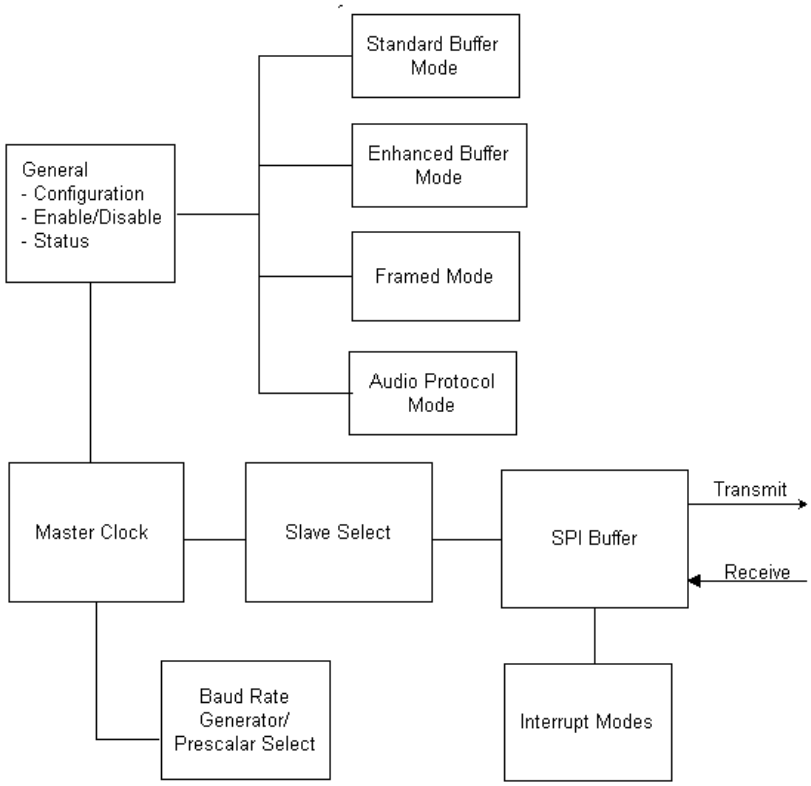
Description

The SPI module has the following operating modes:

- Standard SPI
- Enhanced Buffer SPI
- Framed SPI
- Audio Protocol Interface

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

The following diagram shows the general architecture of the SPI Peripheral Library.



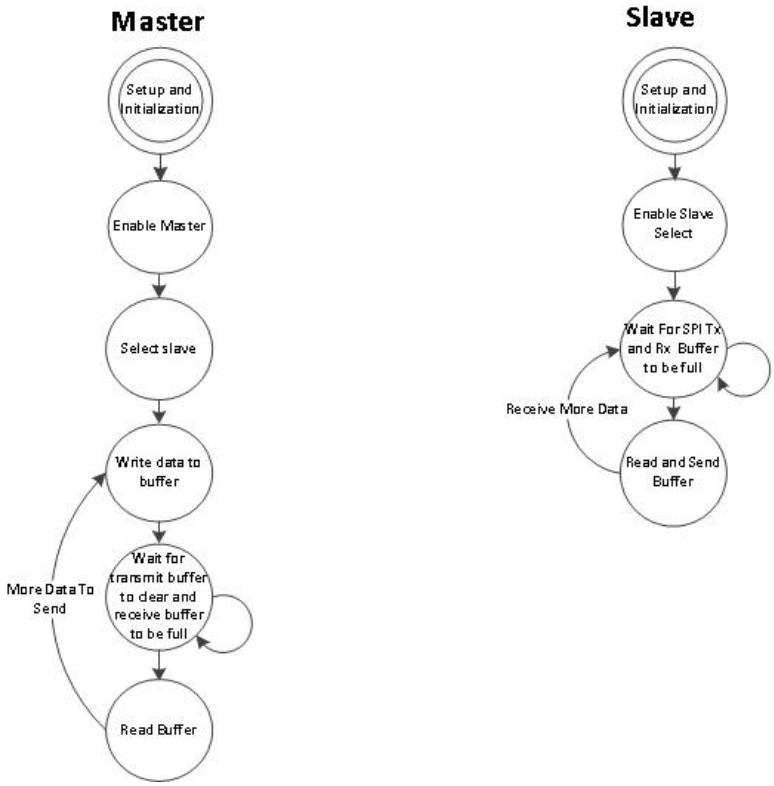
State Machine

This state machine is provided to give a general idea of the usage model of the peripheral library. Refer to the usage model for more detailed steps for the scenario that is being used.

Description

SPI State Machine

The following state machine diagrams shows the transmission and reception during normal operation.



SPI Routines

State	Associated Function
Setup and Initialization	Initialize the SPI by setting prescaler/baud rate generator, interrupt modes.
Enable Master	Once the SPI has been appropriately set up and initialized, the state machine enables Master mode (PLIB_SPI_MasterEnable).
Select Slave	Select slave by pulling the /SSx pin low to transmit the data.
Write Data To Transfer	Write data to the buffer to transmit using PLIB_SPI_BufferWrite.
Wait for Transmit Buffer to Clear	Buffer Data will be transmitted to transmit buffer and transmit buffer flag will be full. The state machine waits for transmit buffer to clear. Check for status by calling PLIB_SPI_TransmitBufferIsFull.
Wait for Receive Buffer Full to Set	Slave sends received data back to master. Upon data received receive buffer flag will set. The state machine waits for Receive buffer to clear. Check for status by calling PLIB_SPI_ReceiverBufferIsFull.
Read Buffer	Read the buffer using PLIB_SPI_BufferRead.
Enable Slave Select	Enable slave select by calling PLIB_SPI_PinEnable.

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Standard SPI Mode

In Standard (legacy) Master and Slave modes, data can be thought of as taking a direct path between the Most Significant bit (MSb) of one module's shift register and the Least Significant bit (LSb) of the other, and then into the appropriate Transmit or Receive buffer. The module configured as the master module provides the serial clock and synchronization signals (as required) to the slave device.

Standard Master Mode

In Standard Master mode, the input clock is used as the serial clock. The serial clock is output via the SCK pin to slave devices. Clock pulses are only generated when there is data to be transmitted.

Description

Setup

1. Select on which edge of the clock data transmission occurs, using PLIB_SPI_OutputDataPhaseSelect and PLIB_SPI_ClockPolaritySelect.
2. Set SPI baud rate using PLIB_SPI_BaudRateSet.
3. If the module needs to operate as a Master, use PLIB_SPI_MasterEnable.

Example: Standard Master Mode Communication Setup

```
#define MY_SPI_ID            SPI_ID_1
#define PERIPHERAL_BUS_CLK   80000000
#define SPI_BAUD_RATE        10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional: Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear (MY_SPI_ID);

// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID, SPI_PIN_SLAVE_SELECT|SPI_PIN_DATA_OUT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);
PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_MasterEnable(MY_SPI_ID);
PLIB_SPI_FramedCommunicationDisable(MY_SPI_ID);

// Optional: Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer.

1. Data to be transmitted is written to the SPI buffer (PLIB_SPI_BufferWrite).
2. When contents of buffer are moved to the shift register, the SPI transmit buffer full flag is cleared (this can be verified using PLIB_SPI_TransmitBufferIsFull).
3. A series of 8/16/32 clock pulses shifts out 8/16/32 bits of transmit data from the shift register to the data out (SDO) pin and simultaneously shifts in the data at the data in (SDI) pin into the shift register.
4. When the transfer is complete, the following events occur:
   - The SPI interrupt flag is set. Interrupts will occur if SPI interrupts are enabled. The SPI interrupt flag is not cleared automatically by the hardware.
   - Also, when the ongoing transmit and receive operation is completed, the contents of the shift register are moved to the SPI receive register.
   - The SPI receive buffer full flag (PLIB_SPI_ReceiverBufferIsFull) is set by the module, indicating that the receive buffer is full. Once the SPI buffer is read by the user application using PLIB_SPI_BufferRead, the hardware clears the SPI receive buffer full flag.
5. If the SPI receive buffer full flag is set when the SPI module needs to transfer data from SPI shift register to SPI receive buffer, the module will set the SPI receive overflow flag (PLIB_SPI_ReceiverHasOverflowed), indicating an overflow condition.
6. Data to be transmitted can be written to SPI buffer (PLIB_SPI_BufferWrite) by the user software at any time as long as the SPI Transmit buffer full flag is clear (PLIB_SPI_TransmitBufferIsFull). The write can occur while SPI shift register is shifting out the previously written data, allowing continuous transmission.

Example: Standard Master Mode Communication Transfer

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

data = 0x00ac;

// write to buffer for TX
PLIB_SPI_BufferWrite (MY_SPI_ID,data);

// Either Poll for Receiver buffer to be full using
// PLIB_SPI_ReceiverBufferIsFull or wait for the interrupt
```

```
// Read the received value
data = PLIB_SPI_BufferRead (MY_SPI_ID);
```

Notes:

1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Standard Slave Mode

Describes Standard Slave mode.

Description

Slave Select Synchronization

The Slave Select pin (/SS) allows for Synchronous Slave mode. If the slave select is enabled (PLIB_SPI_PinEnable), transmission and reception are enabled in Slave mode only if the /SS pin is driven to a low state. The port output or other peripheral outputs must not be driven to allow the /SS pin to function as an input. If the slave select is enabled and the /SS pin is driven high, the data output (SDO) pin is no longer driven and will tri-state even if the module is in the middle of a transmission. An aborted transmission will be retried the next time the /SS pin is driven low, using the data held in the SPI Transmit buffer. If slave select is not enabled, the /SS pin does not affect the module operation in Slave mode.

SPI Transmit Buffer Full Status Operation

The function of the SPI Transmit buffer full (PLIB_SPI_TransmitBufferIsFull) is different in the Slave mode of operation. If slave select is disabled (PLIB_SPI_PinDisable), the PLIB_SPI_TransmitBufferIsFull returns a '1' when the SPI buffer is loaded by the user application. It is cleared when the module transfers data from SPI transmit buffer to SPI shift register. This is similar to the SPI Transmit buffer full function in Master mode.

If slave select is enabled (PLIB_SPI_PinEnable), PLIB_SPI_TransmitBufferIsFull returns a '1' when the SPI buffer is loaded by the user application. However,PLIB_SPI_TransmitBufferIsFull returns zero only when the SPI module completes data transmission. A transmission will be aborted when the Slave Select pin goes high and may be retried at a later time. Each data word is held in SPI transmit buffer until all bits are transmitted to the receiver.

Setup

In Standard Slave mode, data is transmitted and received as the external clock pulses appear on the SCK pin. The clock polarity and clock edge (PLIB_SPI_ClockPolaritySelect) determine upon which edge of the clock data transmission occurs.

Example: Standard Slave Mode Communication Setup

```
#define MY_SPI_ID            SPI_ID_1
#define PERIPHERAL_BUS_CLK   80000000
#define SPI_BAUD_RATE        10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear (MY_SPI_ID);

// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID,SPI_PIN_DATA_OUT|SPI_PIN_SLAVE_SELECT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);

// SMP must be cleared when SPI is used in Slave mode
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);//clock polarity and edge is subject
to change ...
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);// ... based on
your communication mode.

PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_SlaveEnable(MY_SPI_ID);

PLIB_SPI_FramedCommunicationDisable(MY_SPI_ID);
```

```
// Optional:  Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer (PLIB_SPI_BufferWrite/ PLIB_SPI_BufferRead). The remainder of the operation of the module is identical to that of Standard Master mode.

Example: Standard Slave Mode Communication Receive

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

if(PLIB_SPI_ReceiverHasOverflowed(MY_SPI_ID))
{
   // error
   PLIB_SPI_ReceiverOverflowClear(MY_SPI_ID);// clear overflow
   data = PLIB_SPI_BufferRead (MY_SPI_ID);
}
else if (!PLIB_SPI_ReceiverBufferIsFull(MY_SPI_ID))
{
     // error
}
else
{
   data = PLIB_SPI_BufferRead (MY_SPI_ID); // read data
   while(PLIB_SPI_TransmitBufferIsFull(MY_SPI_ID));
   PLIB_SPI_BufferWrite(MY_SPI_ID, data);                // send back
}
```

Notes:

1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Enhanced Buffer SPI Mode

The operation of Enhanced Buffer Master and Slave modes is very similar to Standard Master and Slave modes. The difference is that data can be thought of as moving from the Shift register to a receive FIFO buffer and moving from the transmit FIFO buffer to the Shift register.

Enhanced Buffer Master Mode

In Enhanced Buffer Master mode (referred to as a FIFO), the input clock used as the serial clock. The serial clock is output via the SCK pin to slave devices. Clock pulses are only generated when there is data to be transmitted.

Description

Setup

1. Select on which edge of the clock data transmission occurs, using PLIB_SPI_OutputDataPhaseSelect and PLIB_SPI_ClockPolaritySelect.
2. Set SPI baud rate using PLIB_SPI_BaudRateSet.
3. If the module needs to operate as a Master, use PLIB_SPI_MasterEnable.

Example: Enhanced Master Mode Communication Setup

```
#define MY_SPI_ID            SPI_ID_1
#define PERIPHERAL_BUS_CLK   80000000
#define SPI_BAUD_RATE        10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear (MY_SPI_ID);
```

```
// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID, SPI_PIN_SLAVE_SELECT|SPI_PIN_DATA_OUT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);
PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_MasterEnable(MY_SPI_ID);

PLIB_SPI_FramedCommunicationDisable(MY_SPI_ID);
PLIB_SPI_FIFOEnable(MY_SPI_ID);

// Optional:  Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

The CPU loads data to be transmitted into the transmit buffer by writing the SPI buffer (PLIB_SPI_BufferWrite). An SPI transmission begins after the first buffer write. Up to all pending transmissions can be loaded. The number of pending transfers is indicated by the Buffer Element Count bits through PLIB_SPI_FIFOCountGet.

In Master mode, this count reflects the number of transfers pending in the transmit buffer. In Slave mode, it reflects the number of unread receptions in the receive buffer. If the Shift register is empty, the first write will immediately load the Shift register, leaving all transmit buffer locations available.

After an SPI transfer completes, the receive buffer location is updated with the received data. The CPU accesses the received data by reading the SPI buffer. After each CPU read, the SPI buffer points to the next buffer location. SPI transfers continue until all pending data transfers have completed.

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer.

1. Data to be transmitted is written to the SPI buffer (PLIB_SPI_BufferWrite) and is loaded into the next available transmit buffer location.
2. The SPI transmit buffer full flag (PLIB_SPI_TransmitBufferIsFull) and SPI interrupt flag are set after pending transfers are loaded.
3. The current buffer location's contents are moved to the Shift register. The SPI transmit buffer is cleared by the module if a buffer location is available for a CPU write.
4. A series of 8/16/32 clock pulses shifts out 8/16/32 bits of transmit data from the shift register to the data out (SDO) pin and simultaneously shifts in the data at the data in (SDI) pin into the shift register.
5. When the transfer is complete, the following events occur:
   - The contents of the SPI shift register are moved into the next available location in the receive buffer.
   - If the last unread location is written by the SPI module, the SPI receive buffer full flag (PLIB_SPI_ReceiveBufferIsFull) is set, indicating that all buffer locations are full. Enable the SPI interrupts. The SPI interrupt flag is not cleared automatically by the hardware.
   - Once the SPI buffer is read (PLIB_SPI_BufferRead) by the user application, the hardware clears the SPI receive buffer full flag (PLIB_SPI_ReceiverBufferIsFull) and the SPI Buffer increments to the next unread receive buffer location. SPI buffer reads beyond the last unread location will not increment the buffer location.
6. When PLIB_SPI_ReceiverBufferIsFull is set, if the SPI module needs to transfer one more data from SPI shift register to the buffer, the module will enable the receive overflow flag (PLIB_SPI_ReceiverHasOverflowed) indicating an overflow condition.
7. Data to be transmitted can be written to the SPI buffer (PLIB_SPI_BufferWrite) by the user application at any time as long as the SPI transmit buffer full flag is clear (PLIB_SPI_TransmitBufferIsFull). Up to all pending transfers can be loaded into the buffer allowing continuous transmission.

Example: Enhanced Master Mode communication Transfer

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

data = 0x00ac;

// write to buffer for TX
PLIB_SPI_BufferWrite (MY_SPI_ID,data);

// Either Poll for Receiver buffer to be full using
// PLIB_SPI_ReceiverBufferIsFull or wait for the interrupt

// Read the received value
data = PLIB_SPI_BufferRead (MY_SPI_ID);
```

Notes:

1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Enhanced Buffer Slave Mode

Describes Enhanced Buffer Slave mode.

Description

Slave Select Synchronization

The Slave Select pin allows a Synchronous Slave mode. If the slave select enabled (PLIB_SPI_PinEnable), transmission and reception is enabled in Slave mode only if the /SS pin is driven to a low state. The port output or other peripheral outputs must not be driven to allow the /SS pin to function as an input. If the slave select is enabled and the /SS pin is driven high, the SDO pin is no longer driven and will tri-state even if the module is in the middle of a transmission. An aborted transmission will be retried the next time the /SS pin is driven low using the data held in the SPI transmit buffer. If the Slave select is disabled (PLIB_SPI_PinDisable), the /SS pin does not affect the module operation in Slave mode.

SPI Transmit Buffer Full Operation

The function of the SPI transmit buffer full flag (PLIB_SPI_TransmitBufferIsFull) is different in the Slave mode of operation. If Slave select is disabled (PLIB_SPI_PinDisable), the SPI Transmit Buffer Full flag (PLIB_SPI_TransmitBufferIsFull) is set when the last available buffer location is loaded by the user application. It is cleared when the module transfers data from the buffer to SPI status register and a buffer location is available for a CPU write. This is similar to the SPI transmit buffer in Master mode.

If Slave select is enabled (PLIB_SPI_PinEnable), the SPI transmit buffer is set when the last available buffer location is loaded by the user application. However, it is cleared only when the SPI module completes data transmission, leaving a buffer location available for a CPU write. A transmission will be aborted when the /SS pin goes high and may be retried at a later time. Each data word is held in the buffer until all bits are transmitted to the receiver.

Setup

In Slave mode, data is transmitted and received as the external clock pulses appear on the SCK pin. PLIB_SPI_OutputDataPhaseSelect and PLIB_SPI_ClockPolaritySelect determine upon which edge of the clock data transmission occurs. The rest of the operation of the module is identical to that of Enhanced Buffer Master mode.

Example: Enhanced Slave Mode communication Setup

```
#define MY_SPI_ID            SPI_ID_1
#define PERIPHERAL_BUS_CLK   80000000
#define SPI_BAUD_RATE        10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear (MY_SPI_ID);

// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);

// SMP must be cleared when SPI is used in Slave mode
PLIB_SPI_PinEnable(MY_SPI_ID,SPI_PIN_DATA_OUT|SPI_PIN_SLAVE_SELECT);
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_INPUT_SAMPLING_PHASE_AT_END);//clock polarity and edge is
subject to change ...
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);// ... based on
your communication mode.

PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_SlaveEnable(MY_SPI_ID);
PLIB_SPI_FramedCommunicationDisable(MY_SPI_ID);
PLIB_SPI_FIFOEnable(MY_SPI_ID);

// Optional:  Enable interrupts.
```

```
// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive:

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer (PLIB_SPI_BufferWrite/PLIB_SPI_BufferRead). The remainder of the operation of the module is identical to that of Enhanced Buffer Master mode.

Example: Enhanced Slave Mode communication Receive

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

if(PLIB_SPI_ReceiverHasOverflowed(MY_SPI_ID))
{
   // error
   PLIB_SPI_ReceiverOverflowClear(MY_SPI_ID);// clear overflow
   data = PLIB_SPI_BufferRead (MY_SPI_ID);
}
else if (!PLIB_SPI_ReceiverBufferIsFull(MY_SPI_ID))
{
   // error
}
else
{
   data = PLIB_SPI_BufferRead (MY_SPI_ID);       // read data
   while(PLIB_SPI_TransmitBufferIsFull(MY_SPI_ID));
   PLIB_SPI_BufferWrite(MY_SPI_ID, data);                // send back
}
```

Notes:

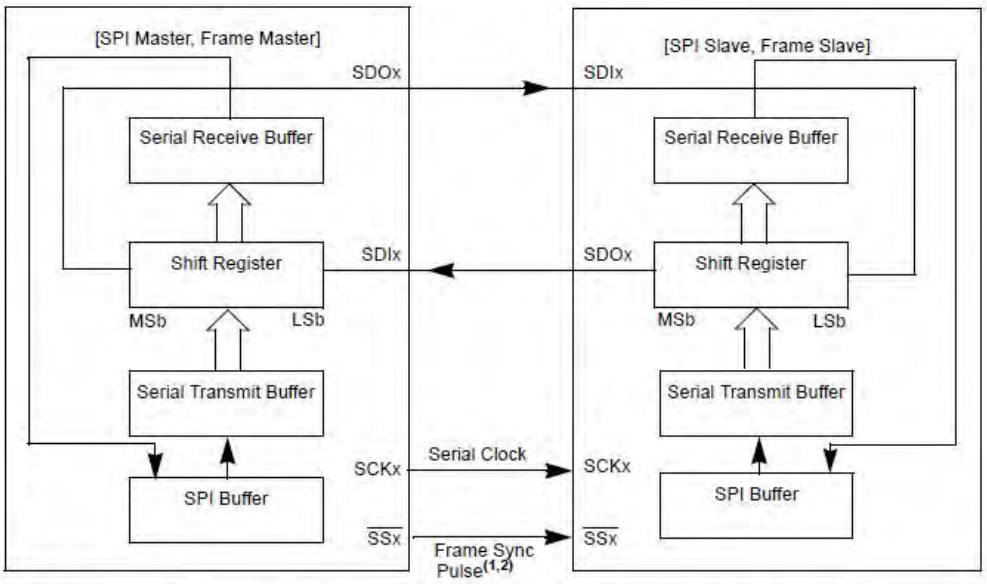
1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Framed SPI Modes

The SPI module supports a basic framed SPI protocol while operating in either Master or Slave modes.

Description

The SPI module supports two framed modes of operation. In Frame Master mode, the SPI module generates the frame synchronization pulse and provides this pulse to other devices at the /SS pin. In Frame Slave mode, the SPI module uses a frame synchronization pulse received at the /SS pin.



Note 1: In Framed SPI modes, the $\overline{SSx}$ pin is used to transmit/receive the frame synchronization pulse.
2: Framed SPI modes require the use of all four pins (i.e., using the $\overline{SSx}$ pin is not optional).

The framed SPI modes are supported in conjunction with the unframed Master and Slave modes. This makes four framed SPI configurations:

- SPI Master mode and Frame Master mode
- SPI Master mode and Frame Slave mode
- SPI Slave mode and Frame Master mode
- SPI Slave mode and Frame Slave mode

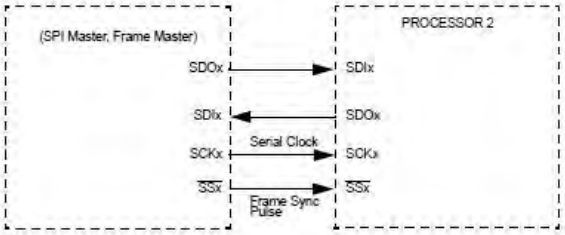
These modes determine whether or not the SPI module generates the serial clock and the frame synchronization pulse.

SPI Master Mode and Frame Master Mode

Describes Master/Frame Master mode.

Description

In Master/Frame Master mode, the SPI module generates both the clock and frame synchronization signals, as shown in the following figure.



In this mode, the serial clock is output continuously at the SCK pin, regardless of whether the module is transmitting. When the SPI buffer is written (PLIB_SPI_BufferWrite), the /SS pin will be driven to its active state on the appropriate transmit edge of the SCK clock, and remain active for one data frame. If the PLIB_SPI_FrameSyncPulseEdgeSelect function decides whether sync pulse precedes the data transmission or coincides with the beginning of the data transmission. The module starts transmitting data on the next transmit edge of the SCK.

Setup

The mode is enabled by calling PLIB_SPI_MasterEnable, PLIB_SPI_FramedCommunicationEnable and PLIB_SPI_FrameSyncPulseDirectionSelect (as output).

Example: SPI Master Mode and Frame Master Mode Communication Setup

```
#define MY_SPI_ID             SPI_ID_1
#define PERIPHERAL_BUS_CLK    80000000
#define SPI_BAUD_RATE         10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
```

```
PLIB_SPI_BufferClear (MY_SPI_ID);

// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID, SPI_PIN_SLAVE_SELECT|SPI_PIN_DATA_OUT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);
PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_MasterEnable(MY_SPI_ID);

PLIB_SPI_FramedCommunicationEnable(MY_SPI_ID);
PLIB_SPI_FrameSyncPulseDirectionSelect(MY_SPI_ID, SPI_FRAME_PULSE_DIRECTION_INPUT);

// Optional:  Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer.

Example: SPI Master Mode and Frame Master Mode Communication Transfer

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

data = 0x00ac;

// write to buffer for TX
PLIB_SPI_BufferWrite (MY_SPI_ID,data);

// Either Poll for Receiver buffer to be full using
// PLIB_SPI_ReceiverBufferIsFull or wait for the interrupt

// Read the received value
data = PLIB_SPI_BufferRead (MY_SPI_ID);
```

Notes:

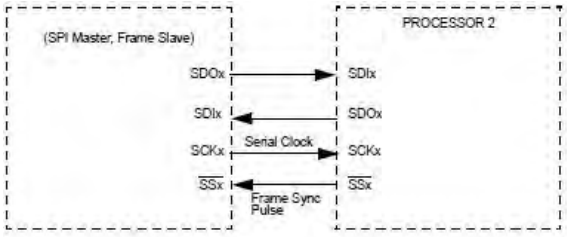
1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

SPI Master Mode and Frame Slave Mode

Describes Master/Frame Slave mode.

Description

In Master/Frame Slave mode, the module generates the clock signal but uses the slave module's frame synchronization signal for data transmission, as shown in the following figure.



In this mode, the /SS pin is an input and it is sampled on the sample edge of the SPI clock. When it is sampled in its active state, data will be transmitted on the subsequent transmit edge of the SPI clock. The SPI interrupt flag is set when the transmission is complete. The user application must make sure that the correct data is loaded into the SPI buffer for transmission before the signal is received at the /SS pin.

Setup

The mode is enabled by calling PLIB_SPI_MasterEnable, PLIB_SPI_FramedCommunicationEnable, and PLIB_SPI_FrameSyncPulseDirectionSelect.

Example: SPI Master Mode and Frame Slave Mode Communication Setup

```
#define MY_SPI_ID            SPI_ID_1
#define PERIPHERAL_BUS_CLK   80000000
#define SPI_BAUD_RATE        10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear (MY_SPI_ID);

// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID, SPI_PIN_SLAVE_SELECT|SPI_PIN_DATA_OUT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);
PLIB_SPI_FrameSyncPulseCounterSelect(MY_SPI_ID,SPI_FRAME_SYNC_PULSE_ON_EVERY_8_DATA_CHARACTER);
PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_MasterEnable(MY_SPI_ID);

PLIB_SPI_FramedCommunicationEnable(MY_SPI_ID);
PLIB_SPI_FrameSyncPulseDirectionSelect(MY_SPI_ID,SPI_FRAME_PULSE_DIRECTION_INPUT);

// Optional:  Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer.

Example: SPI Master Mode and Frame Slave Mode Communication Transfer

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

data = 0x00ac;

// write to buffer for TX
PLIB_SPI_BufferWrite (MY_SPI_ID,data);

// Either Poll for Receiver buffer to be full using
// PLIB_SPI_ReceiverBufferIsFull or wait for the interrupt

// Read the received value
data = PLIB_SPI_BufferRead (MY_SPI_ID);
```

Notes:

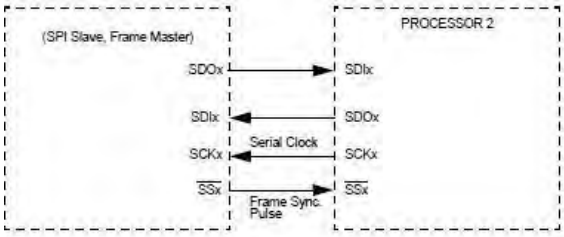
1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

SPI Slave Mode and Frame Master Mode

Describes Slave/Frame Master mode.

Description

In Slave/Frame Master mode, the module acts as the SPI slave and takes its clock from the other SPI module; however, it produces frame synchronization signals to control data transmission, as shown in the following figure.



The input SPI clock will be continuous in Slave mode. The /SS pin will be an output when the Frame sync pulse is output. Therefore, when the SPI buffer is written, the module drives the /SS pin to the active state on the appropriate transmit edge of the SPI clock for one SPI clock cycle. Data will start transmitting on the appropriate SPI clock transmit edge.

Setup

The mode is enabled by calling PLIB_SPI_SlaveEnable, PLIB_SPI_FramedCommunicationEnable, and PLIB_SPI_FrameSyncPulseDirectionSelect.

Example: SPI Slave Mode and Frame Master Mode Communication Setup

```
#define MY_SPI_ID            SPI_ID_1
#define PERIPHERAL_BUS_CLK   80000000
#define SPI_BAUD_RATE        10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear (MY_SPI_ID);

// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID,SPI_PIN_DATA_OUT|SPI_PIN_SLAVE_SELECT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);

// SMP must be cleared when SPI is used in Slave mode
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);//clock polarity and edge is subject
to change ...
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);// ... based on
your communication mode.
PLIB_SPI_FrameSyncPulseCounterSelect(MY_SPI_ID,SPI_FRAME_SYNC_PULSE_ON_EVERY_8_DATA_CHARACTER);

PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_SlaveEnable(MY_SPI_ID);
PLIB_SPI_FramedCommunicationEnable(MY_SPI_ID);
PLIB_SPI_FrameSyncPulseDirectionSelect(MY_SPI_ID,SPI_FRAME_PULSE_DIRECTION_INPUT);

// Optional:  Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer.

Example: SPI Slave Mode and Frame Master Mode Communication Receive

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

if(PLIB_SPI_ReceiverHasOverflowed(MY_SPI_ID))
{
   // error
```

```
    PLIB_SPI_ReceiverOverflowClear(MY_SPI_ID);// clear overflow
    data = PLIB_SPI_BufferRead (MY_SPI_ID);
}
else if (!PLIB_SPI_ReceiverBufferIsFull(MY_SPI_ID))
{
    // error
}
else
{
    data = PLIB_SPI_BufferRead (MY_SPI_ID);       // read data
    while(PLIB_SPI_TransmitBufferIsFull(MY_SPI_ID));
    PLIB_SPI_BufferWrite(MY_SPI_ID, data);                // send back
}
```

Notes:

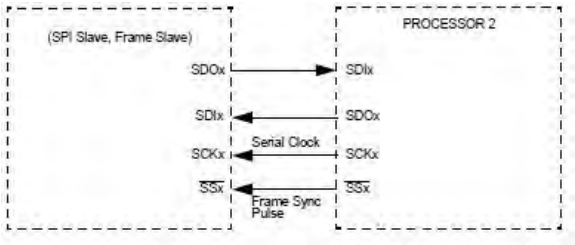
1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

SPI Slave Mode and Frame Master Mode

Describes Slave/Frame Slave mode.

Description

In Slave/Frame Slave mode, the module obtains both its clock and frame synchronization signal from the master module, as shown in the following figure.



In this mode, both the clock and Slave Select pins will be inputs. The /SS pin is sampled on the sample edge of the SPI clock. When /SS is sampled at its active state, data will be transmitted on the appropriate transmit edge of SCK.

Setup

The mode is enabled by calling PLIB_SPI_SlaveEnable,PLIB_SPI_FramedCommunicationEnable and PLIB_SPI_FrameSyncPulseDirectionSelect (as input).

Example: SPI Slave Mode and Frame Slave Mode Communication Setup

```
#define MY_SPI_ID            SPI_ID_1
#define PERIPHERAL_BUS_CLK   80000000
#define SPI_BAUD_RATE        10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear (MY_SPI_ID);

// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID,SPI_PIN_DATA_OUT|SPI_PIN_SLAVE_SELECT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);

// SMP must be cleared when SPI is used in Slave mode
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);//clock polarity and edge is subject
to change ...
```

```
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);// ... based on
your communication mode.
PLIB_SPI_FrameSyncPulseCounterSelect(MY_SPI_ID,SPI_FRAME_SYNC_PULSE_ON_EVERY_8_DATA_CHARACTER);

PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_SlaveEnable(MY_SPI_ID);

PLIB_SPI_FramedCommunicationEnable(MY_SPI_ID);
PLIB_SPI_FrameSyncPulseDirectionSelect(MY_SPI_ID,SPI_FRAME_PULSE_DIRECTION_INPUT);

// Optional:  Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer.

Example: SPI Slave Mode and Frame Slave Mode Communication Receive

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

if(PLIB_SPI_ReceiverHasOverflowed(MY_SPI_ID))
{
   // error
   PLIB_SPI_ReceiverOverflowClear(MY_SPI_ID);// clear overflow
   data = PLIB_SPI_BufferRead (MY_SPI_ID);
}
else if (!PLIB_SPI_ReceiverBufferIsFull(MY_SPI_ID))
{
   // error
}
else
{
   data = PLIB_SPI_BufferRead (MY_SPI_ID);       // read data
   while(PLIB_SPI_TransmitBufferIsFull(MY_SPI_ID));
   PLIB_SPI_BufferWrite(MY_SPI_ID, data);               // send back
}
```

Notes:

1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Audio Protocol Interface Mode

The SPI module can be interfaced to most codec devices available today to provide PIC microcontroller-based audio solutions.

Description

The SPI module provides support to the audio protocol functionality via four standard I/O pins. The four pins that make up the audio protocol interface modes are:

- SDIx: Serial Data Input for receiving sample digital audio data
- SDOx: Serial Data Output for transmitting digital audio data
- SCKx: Serial Clock (also known as bit clock)
- /SSx: Left/Right Channel Clock

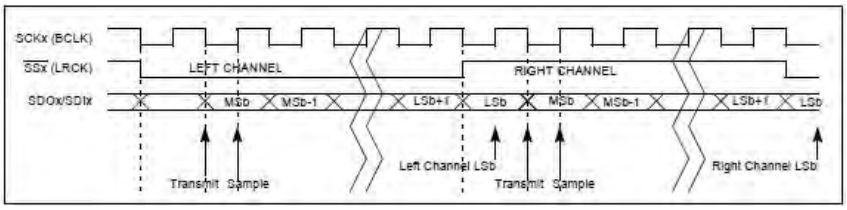
The SPI module supports four audio protocol modes and can be operated in any one of these modes:

Note: Each of the modes can additionally support some or all of the following features. Please refer to the"**Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for more information.

I2S Mode

The Inter-IC Sound (I2S) protocol enables transmission of two channels of digital audio data over a single serial interface. The I2S specification defines a half-duplex interface that supports transmit or receive, but not both at the same time. With both SDO and SDI available, full-duplex

operation is supported by this peripheral, as shown in the following figure.



Data Transmit and Clocking:

- The transmitter shifts the audio sample data's Most Significant bit (MSb) on the first falling edge of SCK after an LRCK transition
- The receiver samples the MSB on the second rising edge of SCK
- The left channel data shifts out while LRCK is low and right channel data is shifted out while LRCK is high
- The data in the left and right channel consists of a single frame

To set the module to I2S mode, the following bits must be set:

- Set SPI to I2S Mode by calling PLIB_SPI_AudioProtocolModeSelect
- Select PLIB_SPI_FrameSyncPulsePolaritySelect (as active low)
- Select PLIB_SPI_ClockPolaritySelect (as active low)

Setting these bits enables the SDO and LRCK (/SSx) transitions to occur on the falling edge of SCK (BCLK) and sampling of SDI to occur on the rising edge of SCK.

Left-Justified Mode

The Left-Justified mode is similar to I2S mode; however, in this mode, the SPI shifts the audio data's MSb on the first SCK edge that is coincident with an LRCK transition. On the receiver side, the SPI module samples the MSb on the next SCK edge.

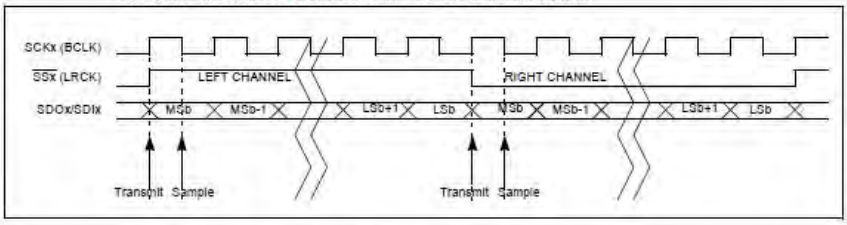
In general, a codec using justified protocols defaults to transmitting data on the rising edge of SCK and receiving data on the falling edge of SCK.

To set the module to Left-Justified mode, the following bits must to be set

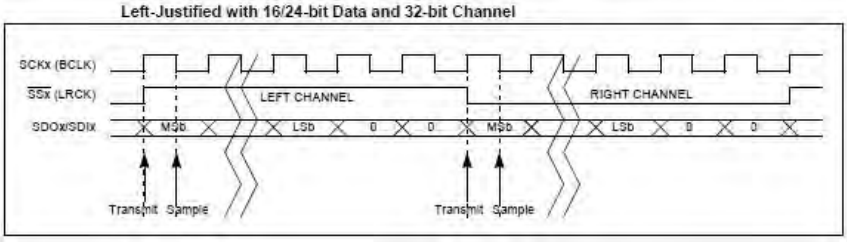
- Set SPI to Left Justified Mode by calling PLIB_SPI_AudioProtocolModeSelect
- Select PLIB_SPI_FrameSyncPulsePolaritySelect (as active high)
- Select PLIB_SPI_ClockPolaritySelect (as active high)

This enables the SDO and LRCK transitions to occur on the rising edge of SCK. Refer to the following sample waveform diagrams for 16-, 24-, and 32-bit audio data transfers.

Left-Justified with 16-bit Data/Channel or 32-bit Data/Channel



Left-Justified with 16/24-bit Data and 32-bit Channel



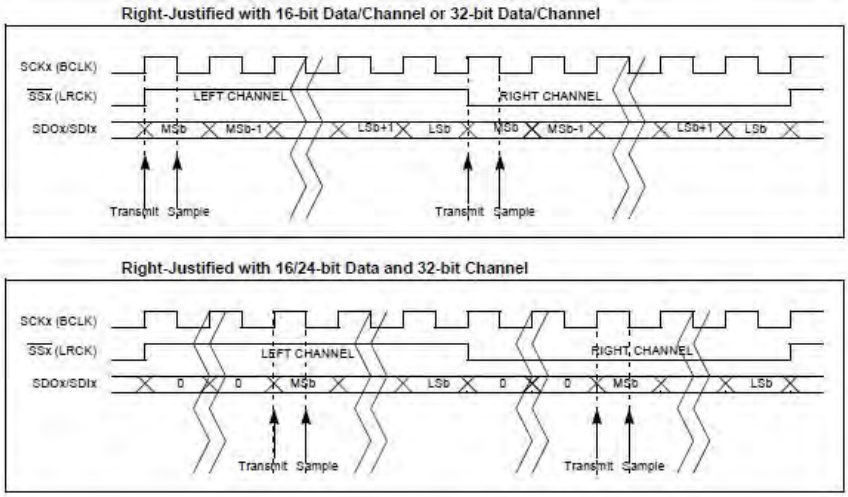
Right-Justified Mode

In Right-Justified mode, the SPI module shifts the audio sample data's MSb after aligning the data to the last clock cycle. The bits preceding the audio sample data can be driven to logic level 0 .

To set the module to Right-Justified mode, the following bits must to be set:

- Set SPI to Right Justified Mode by calling PLIB_SPI_AudioProtocolModeSelect
- Select PLIB_SPI_FrameSyncPulsePolaritySelect (as active high)
- Select PLIB_SPI_ClockPolaritySelect (as active high)

This enables the SDO and LRCK transitions to occur on the rising edge of SCK after the Least Significant bit (LSb) being aligned to the last clock cycle. Refer to the following sample waveform diagrams for 16-, 24-, and 32-bit audio data transfers.



PCM/DSP Mode

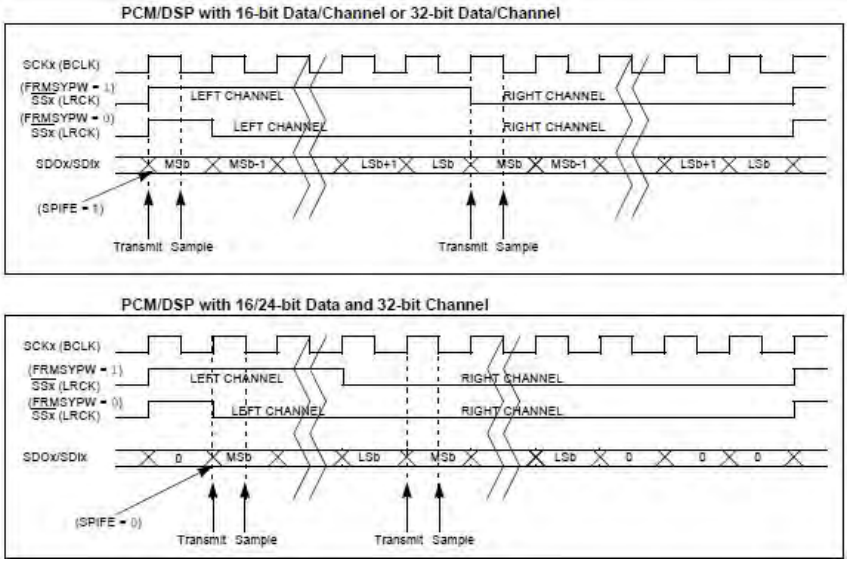
This mode modifies the behavior of LRCK and audio data spacing. In PCM/DSP mode, the LRCK can be a single bit wide (i.e., 1 SCK) or as wide as the audio data (16-, 24-, and 32-bits). The audio data is packed in the frame with the left channel data immediately followed by the right channel data. The frame length is still either 32 or 64 clocks when this device is the master.

In PCM/DSP mode, the transmitter drives the audio data's (left channel) MSb on the first or second transmit edge of SCK (after an LRCK transition). Immediately after the (left channel) LSb, the transmitter drives the (right channel) MSb.

To set the module to Left-Justified mode, the following bit must to be set:

- Set the SPI module to Right-Justified Mode by calling PLIB_SPI_AudioProtocolModeSelect

Refer to the following sample waveform for 16-, 24-, and 32-bit audio data transfers.



Mono Mode Versus Stereo Mode

The SPI module enables the audio data transmission in Mono or Stereo mode by setting PLIB_SPI_AudioTransmitModeSelect. In Stereo mode, the shift register uses each FIFO location once, which gives each channel a unique stream of data for stereo data. In Mono mode, the shift register uses each FIFO location twice, to give each channel the same mono stream of audio data.

Master Mode

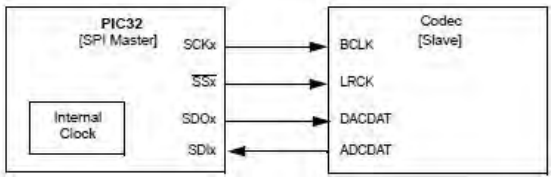
Describes Master mode for the Audio Protocol Interface mode.

Description

A few characteristics of Master mode are:

- This mode enables the device to generate SCK and LRCK pulses as long as the master mode enabled
- The SPI module generates LRCK and SCK continuously in all the cases, regardless of the transmit data while in Master mode
- The SPI module drives the leading edge of LRCK and SCK within 1 SCK period and the serial data shifts in and out continuously even when the Transmit FIFO is empty

The following figure shows a typical interface between the master and slave while in Master mode.



Setup

To configure the device in Audio Protocol Master, enable master mode through PLIB_SPI_MasterEnable and enable audio mode through PLIB_SPI_AudioProtocolEnable.

Example: Audio Mode Communication Setup

```
#define MY_SPI_ID            SPI_ID_1
#define PERIPHERAL_BUS_CLK   80000000
#define SPI_BAUD_RATE        10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear (MY_SPI_ID);

// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID, SPI_PIN_DATA_IN|SPI_PIN_DATA_OUT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);
PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_MasterEnable(MY_SPI_ID);
PLIB_SPI_AudioProtocolModeSelect(MY_SPI_ID,SPI_AUDIO_PROTOCOL_RIGHT_JUSTIFIED );

PLIB_SPI_FramedCommunicationDisable(MY_SPI_ID);
PLIB_SPI_AudioProtocolEnable(MY_SPI_ID);

// Optional:  Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer.

Example: Audio Mode Communication Transfer

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;
data = 0x00ac;

// write to buffer for TX
PLIB_SPI_BufferWrite (MY_SPI_ID,data);

// wait for transfer to complete
while(!PLIB_SPI_ReceiverBufferIsFull(MY_SPI_ID));

// Read the received value
data = PLIB_SPI_BufferRead (MY_SPI_ID);
```

Notes:

1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Slave Mode

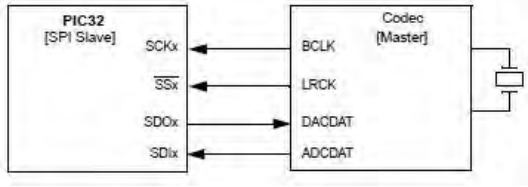
Describes Slave mode for the Audio Protocol Interface mode.

Description

A few characteristics of Slave mode are:

- This mode enables the device to receive SCK and LRCK pulses as long as slave mode is enabled
- The SPI module drives zeros out of SDO, but does not shift data out or in (SDI) until the module receives the LRCK (i.e., the edge that precedes the left channel)
- Once the module receives the leading edge of LRCK, it starts receiving data if PLIB_SPI_PinEnable (enables data in) is selected and the serial data shifts out continuously even when the TX FIFO is empty

The following figure shows the interface between a SPI module in Audio Slave Interface mode to a codec master device.



Setup

The SPI module can be configured in Audio Protocol Slave mode by setting PLIB_SPI_SlaveEnable and enabling the audio protocol through PLIB_SPI_AudioProtocolEnable.

Example: Slave Mode communication Setup

```
#define MY_SPI_ID             SPI_ID_1
#define PERIPHERAL_BUS_CLK    80000000
#define SPI_BAUD_RATE         10000000

//Disable SPI
PLIB_SPI_Disable(MY_SPI_ID);

// Optional:  Clear SPI interrupts and status flag.

//clear SPI buffer
PLIB_SPI_BufferClear(MY_SPI_ID);

// Configure General SPI Options
// Configure General SPI Options
PLIB_SPI_StopInIdleDisable(MY_SPI_ID);
PLIB_SPI_PinEnable(MY_SPI_ID,SPI_PIN_DATA_OUT|SPI_PIN_SLAVE_SELECT);
PLIB_SPI_CommunicationWidthSelect(MY_SPI_ID, SPI_COMMUNICATION_WIDTH_16BITS);

// SMP must be cleared when SPI is used in Slave mode
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_ID,SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
PLIB_SPI_ClockPolaritySelect(MY_SPI_ID, SPI_CLOCK_POLARITY_IDLE_HIGH);//clock polarity and edge is subject
to change ...
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_ID, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);// ... based on
your communication mode.

PLIB_SPI_BaudRateSet(MY_SPI_ID,PERIPHERAL_BUS_CLK,SPI_BAUD_RATE);
PLIB_SPI_SlaveEnable(MY_SPI_ID);
PLIB_SPI_AudioProtocolModeSelect(MY_SPI_ID,SPI_AUDIO_PROTOCOL_RIGHT_JUSTIFIED );

PLIB_SPI_FramedCommunicationDisable(MY_SPI_ID);
PLIB_SPI_AudioProtocolEnable(MY_SPI_ID);

// Optional:  Enable interrupts.

// Enable the module
PLIB_SPI_Enable(MY_SPI_ID);
```

Transmission and Receive

Both data to be transmitted and data that is received are respectively written into, or read from, the SPI buffer (PLIB_SPI_BufferWrite/ PLIB_SPI_BufferRead).

Example: Slave Mode communication Receive

```
#define MY_SPI_ID   SPI_ID_1

uint16_t data;

if(PLIB_SPI_ReceiverHasOverflowed(MY_SPI_ID))
{
  // error
  PLIB_SPI_ReceiverOverflowClear(MY_SPI_ID);// clear overflow
  data = PLIB_SPI_BufferRead (MY_SPI_ID);
}
else if (!PLIB_SPI_ReceiverBufferIsFull(MY_SPI_ID))
{
   // error
}
else
{
   data = PLIB_SPI_BufferRead (MY_SPI_ID);       // read data
   while(PLIB_SPI_TransmitBufferIsFull(MY_SPI_ID));
   PLIB_SPI_BufferWrite(MY_SPI_ID, data);               // send back
}
```

Notes:

1. Refer to the **"Interrupts"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details on how to clear and enable the SPI module interrupts and flags.
2. MY_SPI_ID is the SPI instance selected for use by the application developer.
3. Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Other Features

This topic describes the additional features available in the SPI Peripheral Library.

Communication Mode

The SPI module allows three types of data widths when transmitting and receiving data over a SPI bus. The selection of data width determines the minimum length of the SPI data. The user application should select the appropriate data width to maximize its data throughput. To change the mode of operation on the fly, the SPI module must be idle. If the SPI module is switched off, the new mode will be available when the module is switched on again.

The macro, PLIB_SPI_CommunicationWidthSet, allows the module to communicate in either 8-/16-/32-bit modes. The functionality will be the same for each mode, except for the number of bits that are received and transmitted.

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Power-Saving Modes

Note: Each of the following modes can additionally support some or all of the following features. Please refer to the **"Power-Saving Modes"** section of the specific device data sheet or the family reference manual section specified in that chapter for more information.

Sleep Mode

When the device enters Sleep mode, the device clock source and the entire device is shut down. The consequences of entering Sleep depend upon which mode (Master or Slave) the module is configured in at the time that Sleep mode is invoked.

Idle Mode

When the device enters Idle mode, the device clock is operational, but the CPU and selected peripherals are shut down.

The SPI module can continue to operate in Idle mode by calling PLIB_SPI_StopInIdleDisable, or can stop operation in Idle mode by calling PLIB_SPI_StopInIdleEnable.

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet to determine availability.

SPI Receive-only Operation

Calling PLIB_SPI_PinDisable (data in pin) disables the transmission at the SDO pin. This allows the SPI module to be configured for a receive-only mode of operation. This function is applicable to all SPI operating modes.

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

SPI Error Handling

If a new data word has been shifted and the previous buffer contents have not been read, the status can be read by calling PLIB_SPI_ReceiverHasOverflowed. Any received data is not transferred, and further data reception is disabled until the buffer is cleared by calling PLIB_SPI_ReceiverOverflowClear.

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

SPI Master Mode Clock Frequency

In Master mode, the PBCLK is divided and then used as the serial clock. The division is based on the settings in the SPIxBRG register. The serial clock is output via the SCKx pin to slave devices.

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Interrupts

The SPI module has the ability to generate interrupts reflecting the events that occur during the data communication. Interrupts can be enabled or disabled using PLIB_SPI_ErrorInterruptEnable/PLIB_SPI_ErrorInterruptDisable.

The following types of interrupts can be generated:

- Receive data available interrupts are signalled by SPI receive and transmit flag. This event occurs when there is new data assembled in the SPI receive buffer.
- Transmit buffer empty interrupts are signalled by SPI receive and transmit flag. This event occurs when there is space available in the SPI transmit buffer and new data can be written.
- Error interrupts are signalled by SPI receive and transmit flag. This event occurs when there is an overflow condition for the receive buffer when there is an underrun of the transmit buffer, or when a frame error event occurs.

Note: Not all features are available on all devices. Refer to the **"Serial Peripheral Interface (SPI)"** chapter in the specific device data sheet for availability.

Configuring the Library

The library is configured for the supported SPI modules when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Configuration and Status Functions

	Name	Description
	PLIB_SPI_BaudRateClockSelect	Selects the type of clock is used by the Baud Rate Generator.
	PLIB_SPI_BaudRateSet	Sets the baud rate to the desired value.
	PLIB_SPI_ClockPolaritySelect	Enables clock polarity.
	PLIB_SPI_CommunicationWidthSelect	Selects the data width for the SPI communication.
	PLIB_SPI_Disable	Disables the SPI module.
	PLIB_SPI_Enable	Enables the SPI module.
	PLIB_SPI_ErrorInterruptDisable	Enables SPI error interrupts.

	PLIB_SPI_ErrorInterruptEnable	Enables SPI error interrupts
	PLIB_SPI_FIFOCountGet	Reads the SPI Buffer Element Count bits for either receive or transmit.
	PLIB_SPI_FIFODisable	Disables the SPI enhanced buffer.
	PLIB_SPI_FIFOEnable	Enables the SPI enhanced buffer.
	PLIB_SPI_FIFOInterruptModeSelect	Selects the SPI buffer interrupt mode.
	PLIB_SPI_FIFOShiftRegisterIsEmpty	Returns the current status of the SPI shift register.
	PLIB_SPI_InputSamplePhaseSelect	Selects the SPI data input sample phase.
	PLIB_SPI_IsBusy	Returns the current SPI module activity status.
	PLIB_SPI_MasterEnable	Enables the SPI in Master mode.
	PLIB_SPI_OutputDataPhaseSelect	Selects serial output data change.
	PLIB_SPI_PinDisable	Enables the selected SPI pins.
	PLIB_SPI_PinEnable	Enables the selected SPI pins.
	PLIB_SPI_ReadDataIsSignExtended	Returns the current status of the receive (RX) FIFO sign-extended data.
	PLIB_SPI_SlaveEnable	Enables the SPI in Slave mode.
	PLIB_SPI_SlaveSelectDisable	Disables Master mode slave select.
	PLIB_SPI_SlaveSelectEnable	Enables Master mode slave select.
	PLIB_SPI_StopInIdleDisable	Continues module operation when the device enters Idle mode.
	PLIB_SPI_StopInIdleEnable	Discontinues module operation when the device enters Idle mode.

b) Data Transfer Functions

	Name	Description
	PLIB_SPI_BufferClear	Clears the SPI buffer.
	PLIB_SPI_BufferRead	Returns the SPI buffer value.
	PLIB_SPI_BufferAddressGet	Returns the address of the SPIxBUF (Transmit(SPIxTXB) and Receive (SPIxRXB)) register.
	PLIB_SPI_BufferRead16bit	Returns 16-bit SPI buffer value.
	PLIB_SPI_BufferRead32bit	Returns 32-bit SPI buffer value.
	PLIB_SPI_BufferWrite	Write the data to the SPI buffer.
	PLIB_SPI_BufferWrite16bit	Writes 16-bit data to the SPI buffer.
	PLIB_SPI_BufferWrite32bit	Write 32-bit data to the SPI buffer.

c) Framed Mode Functions

	Name	Description
	PLIB_SPI_FramedCommunicationDisable	Disables framed SPI support.
	PLIB_SPI_FramedCommunicationEnable	Enables framed SPI support.
	PLIB_SPI_FrameErrorStatusGet	Returns the current status of the SPI frame error.
	PLIB_SPI_FrameErrorStatusClear	Clears the SPI frame error flag.
	PLIB_SPI_FrameSyncPulseCounterSelect	Selects at which character the SPI frame sync pulse is generated.
	PLIB_SPI_FrameSyncPulseDirectionSelect	Selects the frame sync pulse direction.
	PLIB_SPI_FrameSyncPulseEdgeSelect	Selects the frame sync pulse edge.
	PLIB_SPI_FrameSyncPulsePolaritySelect	Selects the frame sync pulse polarity.
	PLIB_SPI_FrameSyncPulseWidthSelect	Sets the frame sync pulse width.

d) Audio Mode Functions

	Name	Description
	PLIB_SPI_AudioCommunicationWidthSelect	Selects the data width for the SPI audio communication.
	PLIB_SPI_AudioErrorDisable	Disables the SPI error.
	PLIB_SPI_AudioErrorEnable	Enables the SPI error.
	PLIB_SPI_AudioProtocolDisable	Audio protocol is disabled.
	PLIB_SPI_AudioProtocolEnable	Audio protocol is enabled.
	PLIB_SPI_AudioProtocolModeSelect	Selects the Audio Protocol mode.
	PLIB_SPI_AudioTransmitModeSelect	Selects the transmit audio data format.

e) Transmitter Functions

	Name	Description
	PLIB_SPI_TransmitBufferIsEmpty	Returns the current status of the transmit buffer.

	PLIB_SPI_TransmitBufferIsFull	Returns the current transmit buffer status of the SPI module.
	PLIB_SPI_TransmitUnderRunStatusGet	Returns the current status of the transmit underrun.
	PLIB_SPI_TransmitUnderRunStatusClear	Clears the SPI transmit underrun flag.

f) Receiver Functions

	Name	Description
	PLIB_SPI_ReceiverBufferIsFull	Returns the current status of the SPI receive buffer.
	PLIB_SPI_ReceiverFIFOIsEmpty	Returns the current status of the SPI receive FIFO.
	PLIB_SPI_ReceiverHasOverflowed	Returns the current status of the SPI receiver overflow.
	PLIB_SPI_ReceiverOverflowClear	Clears the SPI receive overflow flag.

g) Feature Existence Functions

	Name	Description
	PLIB_SPI_ExistsAudioCommunicationWidth	Identifies whether the AudioCommunicationWidth feature exists on the SPI module.
	PLIB_SPI_ExistsAudioErrorControl	Identifies whether the AudioErrorControl feature exists on the SPI module.
	PLIB_SPI_ExistsAudioProtocolControl	Identifies whether the AudioProtocolControl feature exists on the SPI module.
	PLIB_SPI_ExistsAudioProtocolMode	Identifies whether the AudioProtocolMode feature exists on the SPI module.
	PLIB_SPI_ExistsAudioTransmitMode	Identifies whether the AudioTransmitMode feature exists on the SPI module.
	PLIB_SPI_ExistsBaudRate	Identifies whether the BaudRate feature exists on the SPI module.
	PLIB_SPI_ExistsBaudRateClock	Identifies whether the BaudRateClock feature exists on the SPI module.
	PLIB_SPI_ExistsBuffer	Identifies whether the Buffer feature exists on the SPI module.
	PLIB_SPI_ExistsBusStatus	Identifies whether the BusStatus feature exists on the SPI module.
	PLIB_SPI_ExistsClockPolarity	Identifies whether the ClockPolarity feature exists on the SPI module.
	PLIB_SPI_ExistsCommunicationWidth	Identifies whether the CommunicationWidth feature exists on the SPI module.
	PLIB_SPI_ExistsEnableControl	Identifies whether the EnableControl feature exists on the SPI module.
	PLIB_SPI_ExistsErrorInterruptControl	Identifies whether the ErrorInterruptControl feature exists on the SPI module.
	PLIB_SPI_ExistsFIFOControl	Identifies whether the FIFOControl feature exists on the SPI module.
	PLIB_SPI_ExistsFIFOCount	Identifies whether the FIFOCount feature exists on the SPI module.
	PLIB_SPI_ExistsFIFOInterruptMode	Identifies whether the FIFOInterruptMode feature exists on the SPI module.
	PLIB_SPI_ExistsFIFOShiftRegisterEmptyStatus	Identifies whether the FIFOShiftRegisterEmptyStatus feature exists on the SPI module.
	PLIB_SPI_ExistsFramedCommunication	Identifies whether the FramedCommunication feature exists on the SPI module.
	PLIB_SPI_ExistsFrameErrorStatus	Identifies whether the FrameErrorStatus feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulseCounter	Identifies whether the FrameSyncPulseCounter feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulseDirection	Identifies whether the FrameSyncPulseDirection feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulseEdge	Identifies whether the FrameSyncPulseEdge feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulsePolarity	Identifies whether the FrameSyncPulsePolarity feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulseWidth	Identifies whether the FrameSyncPulseWidth feature exists on the SPI module.
	PLIB_SPI_ExistsInputSamplePhase	Identifies whether the InputSamplePhase feature exists on the SPI module.
	PLIB_SPI_ExistsMasterControl	Identifies whether the MasterControl feature exists on the SPI module.
	PLIB_SPI_ExistsOutputDataPhase	Identifies whether the OutputDataPhase feature exists on the SPI module.
	PLIB_SPI_ExistsPinControl	Identifies whether the PinControl feature exists on the SPI module.
	PLIB_SPI_ExistsReadDataSignStatus	Identifies whether the ReadDataSignStatus feature exists on the SPI module.
	PLIB_SPI_ExistsReceiveBufferStatus	Identifies whether the ReceiveBufferStatus feature exists on the SPI module.
	PLIB_SPI_ExistsReceiveFIFOStatus	Identifies whether the ReceiveFIFOStatus feature exists on the SPI module.
	PLIB_SPI_ExistsReceiverOverflow	Identifies whether the ReceiverOverflow feature exists on the SPI module.
	PLIB_SPI_ExistsSlaveSelectControl	Identifies whether the SlaveSelectControl feature exists on the SPI module.
	PLIB_SPI_ExistsStopInIdleControl	Identifies whether the StopInIdle feature exists on the SPI module.
	PLIB_SPI_ExistsTransmitBufferEmptyStatus	Identifies whether the TransmitBufferEmptyStatus feature exists on the SPI module.
	PLIB_SPI_ExistsTransmitBufferFullStatus	Identifies whether the TransmitBufferFullStatus feature exists on the SPI module.
	PLIB_SPI_ExistsTransmitUnderRunStatus	Identifies whether the TransmitUnderRunStatus feature exists on the SPI module.
	PLIB_SPI_Exists16bitBuffer	Identifies whether the Buffer16bit feature exists on the SPI module.
	PLIB_SPI_Exists32bitBuffer	Identifies whether the Buffer32bit feature exists on the SPI module.

h) Data Types and Constants

	Name	Description
	SPI_AUDIO_COMMUNICATION_WIDTH	Defines the list of SPI audio communication width.
	SPI_AUDIO_ERROR	Defines the list of SPI audio error.
	SPI_AUDIO_PROTOCOL	Data type defining the audio protocol mode.
	SPI_AUDIO_TRANSMIT_MODE	Defines the list of SPI transmit audio mode format.
	SPI_BAUD_RATE_CLOCK	Defines the list of SPI Baud Rate Generator (BRG).
	SPI_CLOCK_POLARITY	Defines the list of SPI clock polarity.
	SPI_COMMUNICATION_WIDTH	Defines the list of SPI communication width.
	SPI_DATA_TYPE	Data type defining the SPI data size.
	SPI_ERROR_INTERRUPT	Defines the list of SPI error interrupts.
	SPI_FIFO_INTERRUPT	Defines the list of SPI Buffer Interrupt mode.
	SPI_FIFO_TYPE	Defines the list of SPI buffer mode.
	SPI_FRAME_PULSE_DIRECTION	Defines the list of SPI frame sync pulse direction.
	SPI_FRAME_PULSE_EDGE	Defines the list of SPI frame sync pulse edge.
	SPI_FRAME_PULSE_POLARITY	Defines the list of SPI frame sync pulse polarity.
	SPI_FRAME_PULSE_WIDTH	Defines the list of SPI frame sync pulse width.
	SPI_FRAME_SYNC_PULSE	Data type defining the frame sync pulse counter values.
	SPI_INPUT_SAMPLING_PHASE	Defines the list of SPI data input sample phase.
	SPI_MODULE_ID	Identifies the supported SPI modules.
	SPI_OUTPUT_DATA_PHASE	Defines the list of SPI serial output data changes.
	SPI_PIN	Data type defining the SPI pin.

Description

This section describes the Application Programming Interface (API) functions of the SPI Peripheral Library.

Refer to each section for a detailed description.

a) General Configuration and Status Functions

PLIB_SPI_BaudRateClockSelect Function

Selects the type of clock is used by the Baud Rate Generator.

File

plib_spi.h

C

```
void PLIB_SPI_BaudRateClockSelect(SPI_MODULE_ID index, SPI_BAUD_RATE_CLOCK type);
```

Returns

None.

Description

This function selects the type of clock is used by the Baud Rate Generator.

Remarks

This function implements an operation of the baud rate clock control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsBaudRateClock" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_BaudRateClockSelect (MY_SPI_INSTANCE, SPI_BAUD_RATE_MCLK_CLOCK);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
type	One of the SPI_BAUD_RATE_CLOCK enumeration values as the SPI baud clock

Function

void PLIB_SPI_BaudRateClockSelect (SPI_MODULE_ID index,
SPI_BAUD_RATE_CLOCK type)

PLIB_SPI_BaudRateSet Function

Sets the baud rate to the desired value.

File

plib_spi.h

C

```
void PLIB_SPI_BaudRateSet(SPI_MODULE_ID index, uint32_t clockFrequency, uint32_t baudRate);
```

Returns

None.

Description

This function sets the baud rate to the desired value.

Remarks

Setting a new baud rate value causes the baud rate timer to reset. This ensures that the baud rate timer does not have to overflow before outputting the new baud rate.

If the system clock is changed during an active receive operation, a receive error or data loss may result. To avoid this issue, verify that no receptions are in progress before changing the system clock.

This function implements an operation of the baud rate set feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsBaudRate" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
 // Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_BaudRateSet(MY_SPI_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
clockFrequency	Clock frequency
baudrate	Baud rate value

Function

void PLIB_SPI_BaudRateSet(SPI_MODULE_ID index, uint32_t clockFrequency,
uint32_t baudRate)

PLIB_SPI_ClockPolaritySelect Function

Enables clock polarity.

File

plib_spi.h

C

```
void PLIB_SPI_ClockPolaritySelect(SPI_MODULE_ID index, SPI_CLOCK_POLARITY polarity);
```

Returns

None.

Description

This function enables clock polarity.

Remarks

This function implements an operation of the clock polarity feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsClockPolarity" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_ClockPolaritySelect(MY_SPI_INSTANCE, SPI_CLOCK_POLARITY_IDLE_HIGH );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
polarity	One of the SPI_CLOCK_POLARITY enumeration values as the SPI clock polarity

Function

void PLIB_SPI_ClockPolaritySelect(SPI_MODULE_ID index,
SPI_CLOCK_POLARITY polarity)

PLIB_SPI_CommunicationWidthSelect Function

Selects the data width for the SPI communication.

File

plib_spi.h

C

```
void PLIB_SPI_CommunicationWidthSelect(SPI_MODULE_ID index, SPI_COMMUNICATION_WIDTH width);
```

Returns

None.

Description

This function selects the data width for the SPI communication.

Remarks

This function implements an operation of the communication width feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsCommunicationWidth" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_CommunicationWidthSelect(MY_SPI_INSTANCE, SPI_COMMUNICATION_WIDTH_8BITS);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
width	One of the SPI_COMMUNICATION_WIDTH enumeration values as the SPI buffer width

Function

void PLIB_SPI_CommunicationWidthSelect (SPI_MODULE_ID index,
SPI_COMMUNICATION_WIDTH width)

PLIB_SPI_Disable Function

Disables the SPI module.

File

plib_spi.h

C

```
void PLIB_SPI_Disable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function disables the SPI module.

Remarks

This function implements an operation of the enable control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsEnableControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_Disable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_Disable (SPI_MODULE_ID index)

PLIB_SPI_Enable Function

Enables the SPI module.

File

plib_spi.h

C

```
void PLIB_SPI_Enable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function enables the SPI module.

Remarks

The SCKx, SDOx, SDIx and SSx pins must be assigned to available RPn pins before use.

This function implements an operation of the enable control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsEnableControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_Enable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_Enable(SPI_MODULE_ID index)

PLIB_SPI_ErrorInterruptDisable Function

Enables SPI error interrupts.

File

plib_spi.h

C

```
void PLIB_SPI_ErrorInterruptDisable(SPI_MODULE_ID index, SPI_ERROR_INTERRUPT error);
```

Returns

None.

Description

This function enables SPI error interrupts.

Remarks

This function implements an operation of the error interrupt control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsErrorInterruptControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_ErrorInterruptDisable (MY_SPI_INSTANCE, SPI_ERROR_INTERRUPT_FRAME_ERROR_OVERFLOW);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
error	One of the SPI_ERROR_INTERRUPT enumeration values as the SPI interrupt error

Function

void PLIB_SPI_ErrorInterruptDisable (SPI_MODULE_ID index,
SPI_ERROR_INTERRUPT error)

PLIB_SPI_ErrorInterruptEnable Function

Enables SPI error interrupts

File

plib_spi.h

C

```
void PLIB_SPI_ErrorInterruptEnable(SPI_MODULE_ID index, SPI_ERROR_INTERRUPT error);
```

Returns

None.

Description

This function enables SPI error interrupts.

Remarks

This function implements an operation of the error interrupt control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsErrorInterruptControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_ErrorInterruptEnable (MY_SPI_INSTANCE, SPI_ERROR_INTERRUPT_FRAME_ERROR_OVERFLOW);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
type	One of the SPI_ERROR_INTERRUPT enumeration values as the SPI interrupt error

Function

void PLIB_SPI_ErrorInterruptEnable (SPI_MODULE_ID index,
SPI_ERROR_INTERRUPT error)

PLIB_SPI_FIFOCountGet Function

Reads the SPI Buffer Element Count bits for either receive or transmit.

File

plib_spi.h

C

```
uint8_t PLIB_SPI_FIFOCountGet(SPI_MODULE_ID index, SPI_FIFO_TYPE type);
```

Returns

CountValue - Buffer element count bits

Description

This function reads the number of SPI transfers pending for Master mode and the number of unread SPI transfers for Slave mode.

Remarks

Valid in Enhanced Buffer mode.

This function implements an operation of the FIFO control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFIFOCount" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
uint8_t count = PLIB_SPI_FIFOCountGet(MY_SPI_INSTANCE,SPI_FIFO_TYPE_TRANSMIT);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
type	One of the SPI_FIFO_TYPE enumeration values

Function

uint8_t PLIB_SPI_FIFOCountGet (SPI_MODULE_ID index, SPI_FIFO_TYPE type)

PLIB_SPI_FIFODisable Function

Disables the SPI enhanced buffer.

File

plib_spi.h

C

```
void PLIB_SPI_FIFODisable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function disables the SPI enhanced buffer.

Remarks

Enables the legacy standard single buffer mode.

This function implements an operation of the FIFO control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFIFOControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FIFODisable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_FIFODisable (SPI_MODULE_ID index)

PLIB_SPI_FIFOEnable Function

Enables the SPI enhanced buffer.

File

plib_spi.h

C

```
void PLIB_SPI_FIFOEnable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function enables the SPI enhanced buffer.

Remarks

This enables the enhanced buffer mode.

This function implements an operation of the FIFO control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFIFOControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FIFOEnable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_FIFOEnable (SPI_MODULE_ID index)

PLIB_SPI_FIFOInterruptModeSelect Function

Selects the SPI buffer interrupt mode.

File

plib_spi.h

C

```
void PLIB_SPI_FIFOInterruptModeSelect(SPI_MODULE_ID index, SPI_FIFO_INTERRUPT mode);
```

Returns

None.

Description

This function selects the SPI buffer interrupt mode from SPI_FIFO_INTERRUPT.

Remarks

Valid in Enhanced Buffer mode.

This function implements an operation of the FIFO interrupt feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFIFOInterruptMode" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FIFOInterruptModeSelect(MY_SPI_INSTANCE,
                SPI_FIFO_INTERRUPT_WHEN_TRANSMIT_BUFFER_IS_NOT_FULL);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	One of the SPI_FIFO_INTERRUPT enumeration values as the SPI buffer interrupt mode

Function

void PLIB_SPI_FIFOInterruptModeSelect (SPI_MODULE_ID index,
SPI_FIFO_INTERRUPT mode)

PLIB_SPI_FIFOShiftRegisterIsEmpty Function

Returns the current status of the SPI shift register.

File

plib_spi.h

C

```
bool PLIB_SPI_FIFOShiftRegisterIsEmpty(SPI_MODULE_ID index);
```

Returns

- true - SPI shift register is empty and ready to send or receive
- false - SPI shift register is not empty

Description

This function returns the current status of the SPI shift register.

Remarks

Valid in Enhanced Buffer mode.

This function implements an operation of the FIFO status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFIFOShiftRegisterEmptyStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool Status = PLIB_SPI_FIFOShiftRegisterIsEmpty(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_FIFOShiftRegisterIsEmpty (SPI_MODULE_ID index)

PLIB_SPI_InputSamplePhaseSelect Function

Selects the SPI data input sample phase.

File

plib_spi.h

C

```
void PLIB_SPI_InputSamplePhaseSelect(SPI_MODULE_ID index, SPI_INPUT_SAMPLING_PHASE phase);
```

Returns

None.

Description

This function selects the input sampling phase in Master mode.

Remarks

This function implements an operation of the input sample phase feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsInputSamplePhase" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_InputSamplePhaseSelect(MY_SPI_INSTANCE, SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
phase	One of the SPI_INPUT_SAMPLING_PHASE as the SPI input sampling phase

Function

void PLIB_SPI_InputSamplePhaseSelect(SPI_MODULE_ID index,
SPI_INPUT_SAMPLING_PHASE phase)

PLIB_SPI_IsBusy Function

Returns the current SPI module activity status.

File

plib_spi.h

C

```
bool PLIB_SPI_IsBusy(SPI_MODULE_ID index);
```

Returns

- true - SPI module is currently busy with some transactions
- false - SPI module is currently idle

Description

This function returns the current SPI module activity status.

Remarks

This function implements an operation of the bus status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsBusStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool status = PLIB_SPI_IsBusy(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_IsBusy (SPI_MODULE_ID index)

PLIB_SPI_MasterEnable Function

Enables the SPI in Master mode.

File

plib_spi.h

C

```
void PLIB_SPI_MasterEnable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function enables the SPI in Master mode.

Remarks

This function implements an operation of the master enable control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsMasterControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_MasterEnable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_MasterEnable(SPI_MODULE_ID index)

PLIB_SPI_OutputDataPhaseSelect Function

Selects serial output data change.

File

plib_spi.h

C

```
void PLIB_SPI_OutputDataPhaseSelect(SPI_MODULE_ID index, SPI_OUTPUT_DATA_PHASE phase);
```

Returns

None.

Description

This function selects serial output data change.

Remarks

This function implements an operation of the output data phase feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsOutputDataPhase" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_OutputDataPhaseSelect(MY_SPI_INSTANCE, SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	One of the SPI_OUTPUT_DATA_PHASE enumeration values as the SPI serial output data change

Function

void PLIB_SPI_OutputDataPhaseSelect (SPI_MODULE_ID index,
SPI_OUTPUT_DATA_PHASE data)

PLIB_SPI_PinDisable Function

Enables the selected SPI pins.

File

plib_spi.h

C

```
void PLIB_SPI_PinDisable(SPI_MODULE_ID index, SPI_PIN pin);
```

Returns

None.

Description

This function enables the selected SPI pins.

Remarks

This function implements an operation of the pin control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsPinControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_PinDisable(MY_SPI_INSTANCE, SPI_PIN_SLAVE_SELECT);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pin	One of the SPI_PIN enumeration values as the SPI pin

Function

void PLIB_SPI_PinDisable (SPI_MODULE_ID index, SPI_PIN pin)

PLIB_SPI_PinEnable Function

Enables the selected SPI pins.

File

plib_spi.h

C

```
void PLIB_SPI_PinEnable(SPI_MODULE_ID index, SPI_PIN pin);
```

Returns

None.

Description

This function enables the selected SPI pins.

Remarks

This function implements an operation of the pin control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsPinControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_PinEnable(MY_SPI_INSTANCE, SPI_PIN_SLAVE_SELECT);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pin	One of the SPI_PIN enumeration values as the SPI pin

Function

void PLIB_SPI_PinEnable (SPI_MODULE_ID index,SPI_PIN pin)

PLIB_SPI_ReadDataIsSignExtended Function

Returns the current status of the receive (RX) FIFO sign-extended data.

File

plib_spi.h

C

```
bool PLIB_SPI_ReadDataIsSignExtended(SPI_MODULE_ID index);
```

Returns

- true - Data from RX FIFO is sign-extended
- false - Data from RX FIFO is not sign-extended

Description

This function returns the current status of the receive (RX) FIFO sign-extended data.

Remarks

This function implements an operation of the data sign feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsReadDataSignStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool Status = PLIB_SPI_ReadDataIsSignExtended(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_ReadDataIsSignExtended(SPI_MODULE_ID index)

PLIB_SPI_SlaveEnable Function

Enables the SPI in Slave mode.

File

plib_spi.h

C

```
void PLIB_SPI_SlaveEnable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function enables the SPI in Slave mode.

Remarks

This function implements an operation of the master enable control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsMasterControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_SlaveEnable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_SlaveEnable(SPI_MODULE_ID index)

PLIB_SPI_SlaveSelectDisable Function

Disables Master mode slave select.

File

plib_spi.h

C

```
void PLIB_SPI_SlaveSelectDisable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function disables Master mode slave select.

Remarks

This feature does not support Framed SPI mode.

This function implements an operation of the slave select feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsSlaveSelectControl" in your application to automatically determine whether this feature is available.

To disable Slave mode slave select pin (SSEN), PLIB_SPI_PinDisable API can be used.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_SlaveSelectDisable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_SlaveSelectDisable(SPI_MODULE_ID index)

PLIB_SPI_SlaveSelectEnable Function

Enables Master mode slave select.

File

plib_spi.h

C

```
void PLIB_SPI_SlaveSelectEnable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function enables Master mode slave select.

Remarks

This feature does not support Framed SPI mode.

This function implements an operation of the Master mode slave select feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsSlaveSelectControl" in your application to automatically determine whether this feature is available.

To enable Slave mode slave select pin (SSEN), PLIB_SPI_PinEnable API can be used.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_SlaveSelectEnable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_SlaveSelectEnable(SPI_MODULE_ID index)

PLIB_SPI_StopInIdleDisable Function

Continues module operation when the device enters Idle mode.

File

plib_spi.h

C

```
void PLIB_SPI_StopInIdleDisable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function sets up the SPI module such that module operation is continued when the device enters Idle mode.

Remarks

This function implements an operation of the stop in idle control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsStopInIdleControl" in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_StopInIdleDisable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_StopInIdleDisable (SPI_MODULE_ID index)

PLIB_SPI_StopInIdleEnable Function

Discontinues module operation when the device enters Idle mode.

File

plib_spi.h

C

```
void PLIB_SPI_StopInIdleEnable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function sets up the SPI module such that module operation is disabled when the device enters Idle mode.

Remarks

This function implements an operation of the stop in idle control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsStopInIdleControl" in your application to automatically determine if this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_StopInIdleEnable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_StopInIdleEnable (SPI_MODULE_ID index)

b) Data Transfer Functions

PLIB_SPI_BufferClear Function

Clears the SPI buffer.

File

plib_spi.h

C

```
void PLIB_SPI_BufferClear(SPI_MODULE_ID index);
```

Returns

None.

Description

This function clears the SPI buffer.

Remarks

This function implements an operation of the buffer control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsBuffer" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
 // Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_BufferClear(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_BufferClear (SPI_MODULE_ID index)

PLIB_SPI_BufferRead Function

Returns the SPI buffer value.

File

plib_spi.h

C

```
uint8_t PLIB_SPI_BufferRead(SPI_MODULE_ID index);
```

Returns

Reads the SPI buffer.

Description

This function returns the SPI buffer value.

Remarks

This function implements an operation of the buffer control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsBuffer" in your application to automatically determine whether this feature is

available.

Preconditions

None.

Example

```
 // Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
uint8_t bufferValue = PLIB_SPI_BufferRead(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SPI_BufferRead (SPI_MODULE_ID index)

PLIB_SPI_BufferAddressGet Function

Returns the address of the SPIxBUF (Transmit(SPIxTXB) and Receive (SPIxRXB)) register.

File

plib_spi.h

C

```
void* PLIB_SPI_BufferAddressGet(SPI_MODULE_ID index);
```

Returns

The address of the SPIxBUF register

Description

This function returns the address of the SPIxBUF (Transmit(SPIxTXB) and Receive (SPIxRXB)) register.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_BufferAddressGet(SPI_MODULE_ID index)

PLIB_SPI_BufferRead16bit Function

Returns 16-bit SPI buffer value.

File

plib_spi.h

C

```
uint16_t PLIB_SPI_BufferRead16bit(SPI_MODULE_ID index);
```

Returns

Returns the SPI 16-bit buffer value.

Description

This function returns 16-bit SPI buffer value.

Remarks

This function implements an operation of the buffer control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_Exists16bitBuffer" in your application to automatically determine whether this feature is available.

Preconditions

SPI 16-bit wide communication must be selected using PLIB_SPI_CommunicationWidthSelect.

Example

```
#define MY_SPI_INSTANCE SPI_ID_1

uint16_t bufferValue = PLIB_SPI_BufferRead16bit( MY_SPI_INSTANCE );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint16_t PLIB_SPI_BufferRead16bit (SPI_MODULE_ID index)

PLIB_SPI_BufferRead32bit Function

Returns 32-bit SPI buffer value.

File

plib_spi.h

C

```
uint32_t PLIB_SPI_BufferRead32bit(SPI_MODULE_ID index);
```

Returns

Returns the SPI 32-bit buffer value.

Description

This function returns 32-bit SPI buffer value.

Remarks

This function implements an operation of the buffer control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_Exists32bitBuffer" in your application to automatically determine whether this feature is available.

Preconditions

SPI 32-bit wide communication must be selected using PLIB_SPI_CommunicationWidthSelect.

Example

```
#define MY_SPI_INSTANCE SPI_ID_1

uint32_t bufferValue = PLIB_SPI_BufferRead32bit( MY_SPI_INSTANCE );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_SPI_BufferRead32bit (SPI_MODULE_ID index)

PLIB_SPI_BufferWrite Function

Write the data to the SPI buffer.

File

plib_spi.h

C

```
void PLIB_SPI_BufferWrite(SPI_MODULE_ID index, uint8_t data);
```

Returns

None.

Description

This function writes data to the SPI buffer.

Remarks

This function implements an operation of the buffer control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsBuffer" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_BufferWrite ( MY_SPI_INSTANCE, 0xFF );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Data to written to the SPI buffer

Function

void PLIB_SPI_BufferWrite (SPI_MODULE_ID index , uint8_t data)

PLIB_SPI_BufferWrite16bit Function

Writes 16-bit data to the SPI buffer.

File

plib_spi.h

C

```
void PLIB_SPI_BufferWrite16bit(SPI_MODULE_ID index, uint16_t data);
```

Returns

None.

Description

This function writes 16-bit data to the SPI buffer.

Remarks

This function implements an operation of the buffer control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_Exists16bitBuffer" in your application to automatically determine whether this feature is available.

Preconditions

SPI 16-bit wide communication must be selected using PLIB_SPI_CommunicationWidthSelect.

Example

```
#define MY_SPI_INSTANCE SPI_ID_1

PLIB_SPI_BufferWrite16bit ( MY_SPI_INSTANCE, 0x55AA );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	16-bit data to be written to the SPI buffer

Function

void PLIB_SPI_BufferWrite16bit (SPI_MODULE_ID index , uint16_t data)

PLIB_SPI_BufferWrite32bit Function

Write 32-bit data to the SPI buffer.

File

plib_spi.h

C

```
void PLIB_SPI_BufferWrite32bit(SPI_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

This function writes 32-bit data to the SPI buffer.

Remarks

This function implements an operation of the buffer control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_Exists32bitBuffer" in your application to automatically determine whether this feature is available.

Preconditions

SPI 32-bit wide communication must be selected using PLIB_SPI_CommunicationWidthSelect.

Example

```
#define MY_SPI_INSTANCE SPI_ID_1

PLIB_SPI_BufferWrite ( MY_SPI_INSTANCE, 0x55AA55AA );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	32-bit data to be written to the SPI buffer

Function

void PLIB_SPI_BufferWrite32bit (SPI_MODULE_ID index , uint32_t data)

c) Framed Mode Functions

PLIB_SPI_FramedCommunicationDisable Function

Disables framed SPI support.

File

plib_spi.h

C

```
void PLIB_SPI_FramedCommunicationDisable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function disables framed SPI support.

Remarks

This function implements an operation of the framed communication feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFramedCommunication" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FramedCommunicationDisable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_FramedCommunicationDisable (SPI_MODULE_ID index)

PLIB_SPI_FramedCommunicationEnable Function

Enables framed SPI support.

File

plib_spi.h

C

```
void PLIB_SPI_FramedCommunicationEnable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function enables framed SPI support.

Remarks

This function implements an operation of the framed communication feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFramedCommunication" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FramedCommunicationEnable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_FramedCommunicationEnable (SPI_MODULE_ID index)

PLIB_SPI_FrameErrorStatusGet Function

Returns the current status of the SPI frame error.

File

plib_spi.h

C

```
bool PLIB_SPI_FrameErrorStatusGet(SPI_MODULE_ID index);
```

Returns

- true - Frame error detected
- false - No frame error detected

Description

This function returns the current status of the SPI frame error.

Remarks

Valid only if Frame mode is enabled.

This function implements an operation of the framed communication feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFrameErrorStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool status = PLIB_SPI_FrameErrorStatusGet(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_FrameErrorStatusGet (SPI_MODULE_ID index)

PLIB_SPI_FrameErrorStatusClear Function

Clears the SPI frame error flag.

File

plib_spi.h

C

```
void PLIB_SPI_FrameErrorStatusClear(SPI_MODULE_ID index);
```

Returns

None.

Description

This function clears the SPI frame error flag.

Remarks

This function implements an operation of the frame error status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "ExistsFrameErrorStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FrameErrorStatusClear(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_FrameErrorStatusClear(SPI_MODULE_ID index)

PLIB_SPI_FrameSyncPulseCounterSelect Function

Selects at which character the SPI frame sync pulse is generated.

File

plib_spi.h

C

```
void PLIB_SPI_FrameSyncPulseCounterSelect(SPI_MODULE_ID index, SPI_FRAME_SYNC_PULSE pulse);
```

Returns

None.

Description

This function selects at which character the SPI frame sync pulse is generated.

Remarks

This is valid only when PLIB_SPI_FramedCommunicationEnable is enabled.

This function implements an operation of the framed communication feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFrameSyncPulseCounter" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FrameSyncPulseCounterSelect(MY_SPI_INSTANCE,
                                     SPI_FRAME_SYNC_PULSE_ON_EVERY_32_DATA_CHARACTER );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pulse	One of the SPI_FRAME_SYNC_PULSE enumeration values as the SPI frame sync pulse count

Function

void PLIB_SPI_FrameSyncPulseCounterSelect (SPI_MODULE_ID index,
SPI_FRAME_SYNC_PULSE pulse)

PLIB_SPI_FrameSyncPulseDirectionSelect Function

Selects the frame sync pulse direction.

File

plib_spi.h

C

```
void PLIB_SPI_FrameSyncPulseDirectionSelect(SPI_MODULE_ID index, SPI_FRAME_PULSE_DIRECTION direction);
```

Returns

None.

Description

This function selects the frame sync pulse direction.

Remarks

This function implements an operation of the framed communication feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFrameSyncPulseDirection" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FrameSyncPulseDirectionSelect(MY_SPI_INSTANCE, SPI_FRAME_PULSE_DIRECTION_INPUT );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
direction	One of the SPI_FRAME_PULSE_DIRECTION enumeration values as the SPI frame sync pulse polarity

Function

void PLIB_SPI_FrameSyncPulseDirectionSelect (SPI_MODULE_ID index,
SPI_FRAME_PULSE_DIRECTION direction)

PLIB_SPI_FrameSyncPulseEdgeSelect Function

Selects the frame sync pulse edge.

File

plib_spi.h

C

```
void PLIB_SPI_FrameSyncPulseEdgeSelect(SPI_MODULE_ID index, SPI_FRAME_PULSE_EDGE edge);
```

Returns

None.

Description

This function selects the frame sync pulse edge.

Remarks

This function implements an operation of the framed communication feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFrameSyncPulseEdge" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FrameSyncPulseEdgeSelect(MY_SPI_INSTANCE,
                SPI_FRAME_PULSE_EDGE_COINCIDES_FIRST_BIT_CLOCK);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
edge	One of the SPI_FRAME_PULSE_EDGE enumeration values as the SPI frame sync pulse edge

Function

void PLIB_SPI_FrameSyncPulseEdgeSelect (SPI_MODULE_ID index,
SPI_FRAME_PULSE_EDGE edge)

PLIB_SPI_FrameSyncPulsePolaritySelect Function

Selects the frame sync pulse polarity.

File

plib_spi.h

C

```
void PLIB_SPI_FrameSyncPulsePolaritySelect(SPI_MODULE_ID index, SPI_FRAME_PULSE_POLARITY polarity);
```

Returns

None.

Description

This function selects the frame sync pulse polarity.

Remarks

Available only for Frame mode.

This function implements an operation of the framed communication feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFrameSyncPulsePolarity" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FrameSyncPulsePolaritySelect(MY_SPI_INSTANCE, SPI_FRAME_PULSE_POLARITY_ACTIVE_HIGH );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
polarity	One of the SPI_FRAME_PULSE_POLARITY enumeration values as the SPI frame sync pulse polarity

Function

void PLIB_SPI_FrameSyncPulsePolaritySelect (SPI_MODULE_ID index,
SPI_FRAME_PULSE_POLARITY polarity)

PLIB_SPI_FrameSyncPulseWidthSelect Function

Sets the frame sync pulse width.

File

plib_spi.h

C

```
void PLIB_SPI_FrameSyncPulseWidthSelect(SPI_MODULE_ID index, SPI_FRAME_PULSE_WIDTH width);
```

Returns

None.

Description

This function sets the frame sync pulse width.

Remarks

Length of the word is dependent on the communication mode.

This function implements an operation of the framed communication feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsFrameSyncPulseWidth" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_FrameSyncPulseWidthSelect (MY_SPI_INSTANCE,SPI_FRAME_PULSE_WIDTH_ONE_WORD_LENGTH);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
edge	One of the SPI_FRAME_PULSE_WIDTH enumeration values as the SPI frame sync pulse width.

Function

void PLIB_SPI_FrameSyncPulseWidthSelect (SPI_MODULE_ID index,
SPI_FRAME_PULSE_WIDTH width)

d) Audio Mode Functions

PLIB_SPI_AudioCommunicationWidthSelect Function

Selects the data width for the SPI audio communication.

File

plib_spi.h

C

```
void PLIB_SPI_AudioCommunicationWidthSelect(SPI_MODULE_ID index, SPI_AUDIO_COMMUNICATION_WIDTH mode);
```

Returns

None.

Description

This function selects the data width for the SPI audio communication.

Remarks

This mode is available only when PLIB_SPI_AudioProtocolEnable is enabled.

This function implements an operation of the audio communication width feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsAudioCommunicationWidth" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
```

```
PLIB_SPI_AudioCommunicationWidthSelect(MY_SPI_INSTANCE,
                        SPI_AUDIO_COMMUNICATION_32DATA_32FIFO_32CHANNEL);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
width	One of the SPI_AUDIO_COMMUNICATION_WIDTH enumeration values as the SPI buffer width

Function

void PLIB_SPI_AudioCommunicationWidthSelect (SPI_MODULE_ID index,
SPI_AUDIO_COMMUNICATION_WIDTH width)

PLIB_SPI_AudioErrorDisable Function

Disables the SPI error.

File

plib_spi.h

C

```
void PLIB_SPI_AudioErrorDisable(SPI_MODULE_ID index, SPI_AUDIO_ERROR error);
```

Returns

None.

Description

This function disables the SPI error.

Remarks

This function implements an operation of the audio error control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsAudioErrorControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_AudioErrorDisable (MY_SPI_INSTANCE, SPI_AUDIO_ERROR_RECEIVE_OVERFLOW);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
error	One of the SPI_AUDIO_ERROR enumeration values as the SPI error

Function

void PLIB_SPI_AudioErrorDisable (SPI_MODULE_ID index, SPI_AUDIO_ERROR error)

PLIB_SPI_AudioErrorEnable Function

Enables the SPI error.

File

plib_spi.h

C

```
void PLIB_SPI_AudioErrorEnable(SPI_MODULE_ID index, SPI_AUDIO_ERROR error);
```

Returns

None.

Description

This function enables the SPI error.

Remarks

This function implements an operation of the audio error control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsAudioErrorControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_AudioErrorEnable (MY_SPI_INSTANCE, SPI_AUDIO_ERROR_RECEIVE_OVERFLOW);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
error	One of the SPI_AUDIO_ERROR enumeration values as the SPI error

Function

void PLIB_SPI_AudioErrorEnable (SPI_MODULE_ID index, SPI_Audio_ERROR error)

PLIB_SPI_AudioProtocolDisable Function

Audio protocol is disabled.

File

plib_spi.h

C

```
void PLIB_SPI_AudioProtocolDisable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function disables the audio protocol.

Remarks

This function implements an operation of the audio protocol control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsAudioProtocolControl" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_AudioProtocolDisable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_AudioProtocolDisable (SPI_MODULE_ID index)

PLIB_SPI_AudioProtocolEnable Function

Audio protocol is enabled.

File

plib_spi.h

C

```
void PLIB_SPI_AudioProtocolEnable(SPI_MODULE_ID index);
```

Returns

None.

Description

This function enables the audio protocol.

Remarks

This function implements an operation of the audio protocol control feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsAudioProtocolControl" in your application to automatically determine whether this feature is available.

Preconditions

Disable the SPI module by calling PLIB_SPI_Disable.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_AudioProtocolEnable(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_AudioProtocolEnable (SPI_MODULE_ID index)

PLIB_SPI_AudioProtocolModeSelect Function

Selects the Audio Protocol mode.

File

plib_spi.h

C

```
void PLIB_SPI_AudioProtocolModeSelect(SPI_MODULE_ID index, SPI_AUDIO_PROTOCOL mode);
```

Returns

None.

Description

This function selects the Audio Protocol mode.

Remarks

This function implements an operation of the audio protocol mode feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsAudioProtocolMode" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_AudioProtocolModeSelect(MY_SPI_INSTANCE,SPI_AUDIO_PROTOCOL_RIGHT_JUSTIFIED );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	One of the SPI_AUDIO_PROTOCOL enumeration values as the audio protocol

Function

void PLIB_SPI_AudioProtocolModeSelect(SPI_MODULE_ID index,
SPI_AUDIO_PROTOCOL mode)

PLIB_SPI_AudioTransmitModeSelect Function

Selects the transmit audio data format.

File

plib_spi.h

C

```
void PLIB_SPI_AudioTransmitModeSelect(SPI_MODULE_ID index, SPI_AUDIO_TRANSMIT_MODE mode);
```

Returns

None.

Description

This function selects the transmit audio data format.

Remarks

This function implements an operation of the audio transmit mode feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsAudioTransmitMode" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_AudioTransmitModeSelect (MY_SPI_INSTANCE, SPI_AUDIO_TRANSMIT_MONO);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	One of the SPI_TRANSMIT_AUDIO_MODE enumeration values as the transmit audio format

Function

void PLIB_SPI_AudioTransmitModeSelect (SPI_MODULE_ID index,
SPI_AUDIO_TRANSMIT_MODE mode)

e) Transmitter Functions

PLIB_SPI_TransmitBufferIsEmpty Function

Returns the current status of the transmit buffer.

File

plib_spi.h

C

```
bool PLIB_SPI_TransmitBufferIsEmpty(SPI_MODULE_ID index);
```

Returns

- true - Transmit buffer is empty
- false - Transmit buffer is not empty

Description

This function returns the current status of the transmit buffer.

Remarks

This function implements an operation of the transmit buffer empty status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsTransmitBufferEmptyStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool Status = PLIB_SPI_TransmitBufferIsEmpty(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_TransmitBufferIsEmpty (SPI_MODULE_ID index)

PLIB_SPI_TransmitBufferIsFull Function

Returns the current transmit buffer status of the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_TransmitBufferIsFull(SPI_MODULE_ID index);
```

Returns

- true - Transmit not yet started, transmit buffer is full
- false - Transmit started, transmit buffer is empty/not full

Description

This function returns the current transmit buffer status of the SPI module.

Remarks

In Standard Buffer mode - automatically set in hardware when SPI buffer writes occur, loading the transmit buffer. Automatically cleared in hardware when the SPI module transfers data from the transmit buffer to the shift register.

In Enhanced Buffer mode - automatically set in hardware when SPI buffer writes occur, loading the last available buffer. Automatically cleared in hardware when the buffer is available for writing.

This function implements an operation of the transmit buffer status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsTransmitBufferFullStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool buffullstate = PLIB_SPI_TransmitBufferIsFull (MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_TransmitBufferIsFull (SPI_MODULE_ID index)

PLIB_SPI_TransmitUnderRunStatusGet Function

Returns the current status of the transmit underrun.

File

plib_spi.h

C

```
bool PLIB_SPI_TransmitUnderRunStatusGet(SPI_MODULE_ID index);
```

Returns

- true - Transmit buffer has encountered an underrun condition
- false - Transmit buffer run has not encountered an underrun condition

Description

This function returns the current status of the transmit underrun.

Remarks

Valid in Framed Sync mode.

This function implements an operation of the transmit underrun status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsTransmitUnderRunStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool Status = PLIB_SPI_TransmitUnderRunStatusGet(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_TransmitUnderRunStatusGet(SPI_MODULE_ID index)

PLIB_SPI_TransmitUnderRunStatusClear Function

Clears the SPI transmit underrun flag.

File

plib_spi.h

C

```
void PLIB_SPI_TransmitUnderRunStatusClear(SPI_MODULE_ID index);
```

Returns

None.

Description

This function clears the SPI transmit underrun flag.

Remarks

This function implements an operation of the transmit underrun status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "ExistsTransmitUnderRunStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_TransmitUnderRunStatusClear(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_TransmitUnderRunStatusClear(SPI_MODULE_ID index)

f) Receiver Functions

PLIB_SPI_ReceiverBufferIsFull Function

Returns the current status of the SPI receive buffer.

File

plib_spi.h

C

```
bool PLIB_SPI_ReceiverBufferIsFull(SPI_MODULE_ID index);
```

Returns

Receiver Buffer Full Status:

- true - Receive complete, receive buffer is full
- false - Receive is not complete, receive buffer is empty

Description

This function returns the current status of the SPI receive buffer.

Remarks

In Standard Buffer mode - automatically set in hardware when the SPI module transfers data from the shift register to the receive buffer. Automatically cleared in hardware when the core reads the SPI buffer, read in the receive buffer.

In Enhanced Buffer mode - automatically set in hardware when the SPI module transfers data from the shift register to the receive buffer, filling the last unread buffer. Automatically cleared in hardware when a buffer is available for a transfer from the shift register.

This function implements an operation of the receiver buffer status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsReceiveBufferStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
```

```
// application developer.
bool receivefullstate = PLIB_SPI_ReceiverBufferIsFull (MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_ReceiverBufferIsFull (SPI_MODULE_ID index)

PLIB_SPI_ReceiverFIFOIsEmpty Function

Returns the current status of the SPI receive FIFO.

File

plib_spi.h

C

```
bool PLIB_SPI_ReceiverFIFOIsEmpty(SPI_MODULE_ID index);
```

Returns

- true - Receive FIFO is empty
- false - Receive FIFO is not empty

Description

This function returns the current status of the SPI receive FIFO.

Remarks

Valid in Enhanced Buffer mode.

This function implements an operation of the FIFO status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsReceiveFIFOStatus" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool fifostate = PLIB_SPI_ReceiverFIFOIsEmpty (MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_ReceiverFIFOIsEmpty (SPI_MODULE_ID index)

PLIB_SPI_ReceiverHasOverflowed Function

Returns the current status of the SPI receiver overflow.

File

plib_spi.h

C

```
bool PLIB_SPI_ReceiverHasOverflowed(SPI_MODULE_ID index);
```

Returns

SPI receiver overflow status:

- true - A new byte/word is completely received and discarded. The user software has not read the previous data in the SPI buffer register.
- false - No Overflow has occurred

Description

This function returns the current status of the SPI receiver overflow.

Remarks

This function implements an operation of the receiver overflow status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsReceiverOverflow" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
bool overflowstate = PLIB_SPI_ReceiverHasOverflowed(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SPI_ReceiverHasOverflowed (SPI_MODULE_ID index)

PLIB_SPI_ReceiverOverflowClear Function

Clears the SPI receive overflow flag.

File

plib_spi.h

C

```
void PLIB_SPI_ReceiverOverflowClear(SPI_MODULE_ID index);
```

Returns

None.

Description

This function clears the SPI receive overflow flag.

Remarks

This function implements an operation of the receiver overflow status feature. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use "PLIB_SPI_ExistsReceiverOverflow" in your application to automatically determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_SPI_INSTANCE, is the SPI instance selected for use by the
// application developer.
PLIB_SPI_ReceiverOverflowClear(MY_SPI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SPI_ReceiverOverflowClear(SPI_MODULE_ID index)

g) Feature Existence Functions

PLIB_SPI_ExistsAudioCommunicationWidth Function

Identifies whether the AudioCommunicationWidth feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsAudioCommunicationWidth(SPI_MODULE_ID index);
```

Returns

- true - The AudioCommunicationWidth feature is supported on the device
- false - The AudioCommunicationWidth feature is not supported on the device

Description

This function identifies whether the AudioCommunicationWidth feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_AudioCommunicationWidthSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsAudioCommunicationWidth(SPI_MODULE_ID index)

PLIB_SPI_ExistsAudioErrorControl Function

Identifies whether the AudioErrorControl feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsAudioErrorControl(SPI_MODULE_ID index);
```

Returns

- true - The AudioErrorControl feature is supported on the device
- false - The AudioErrorControl feature is not supported on the device

Description

This function identifies whether the AudioErrorControl feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_AudioErrorEnable
- PLIB_SPI_AudioErrorDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsAudioErrorControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsAudioProtocolControl Function

Identifies whether the AudioProtocolControl feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsAudioProtocolControl(SPI_MODULE_ID index);
```

Returns

- true - The AudioProtocolControl feature is supported on the device
- false - The AudioProtocolControl feature is not supported on the device

Description

This function identifies whether the AudioProtocolControl feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_AudioProtocolEnable
- PLIB_SPI_AudioProtocolDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsAudioProtocolControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsAudioProtocolMode Function

Identifies whether the AudioProtocolMode feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsAudioProtocolMode(SPI_MODULE_ID index);
```

Returns

- true - The AudioProtocolMode feature is supported on the device
- false - The AudioProtocolMode feature is not supported on the device

Description

This function identifies whether the AudioProtocolMode feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_AudioProtocolModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsAudioProtocolMode(SPI_MODULE_ID index)

PLIB_SPI_ExistsAudioTransmitMode Function

Identifies whether the AudioTransmitMode feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsAudioTransmitMode(SPI_MODULE_ID index);
```

Returns

- true - The AudioTransmitMode feature is supported on the device
- false - The AudioTransmitMode feature is not supported on the device

Description

This function identifies whether the AudioTransmitMode feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_AudioTransmitModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsAudioTransmitMode(SPI_MODULE_ID index)

PLIB_SPI_ExistsBaudRate Function

Identifies whether the BaudRate feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsBaudRate(SPI_MODULE_ID index);
```

Returns

- true - The BaudRate feature is supported on the device
- false - The BaudRate feature is not supported on the device

Description

This function identifies whether the BaudRate feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_BaudRateSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsBaudRate(SPI_MODULE_ID index)

PLIB_SPI_ExistsBaudRateClock Function

Identifies whether the BaudRateClock feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsBaudRateClock(SPI_MODULE_ID index);
```

Returns

- true - The BaudRateClock feature is supported on the device
- false - The BaudRateClock feature is not supported on the device

Description

This function identifies whether the BaudRateClock feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_BaudRateClockSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsBaudRateClock(SPI_MODULE_ID index)

PLIB_SPI_ExistsBuffer Function

Identifies whether the Buffer feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsBuffer(SPI_MODULE_ID index);
```

Returns

- true - The Buffer feature is supported on the device
- false - The Buffer feature is not supported on the device

Description

This function identifies whether the Buffer feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_BufferClear
- PLIB_SPI_BufferRead
- PLIB_SPI_BufferWrite
- PLIB_SPI_BufferAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsBuffer(SPI_MODULE_ID index)

PLIB_SPI_ExistsBusStatus Function

Identifies whether the BusStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsBusStatus(SPI_MODULE_ID index);
```

Returns

- true - The BusStatus feature is supported on the device
- false - The BusStatus feature is not supported on the device

Description

This function identifies whether the BusStatus feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_IsBusy

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsBusStatus(SPI_MODULE_ID index)

PLIB_SPI_ExistsClockPolarity Function

Identifies whether the ClockPolarity feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsClockPolarity(SPI_MODULE_ID index);
```

Returns

- true - The ClockPolarity feature is supported on the device
- false - The ClockPolarity feature is not supported on the device

Description

This function identifies whether the ClockPolarity feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_ClockPolaritySelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsClockPolarity(SPI_MODULE_ID index)

PLIB_SPI_ExistsCommunicationWidth Function

Identifies whether the CommunicationWidth feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsCommunicationWidth(SPI_MODULE_ID index);
```

Returns

- true - The CommunicationWidth feature is supported on the device
- false - The CommunicationWidth feature is not supported on the device

Description

This function identifies whether the CommunicationWidth feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_CommunicationWidthSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsCommunicationWidth(SPI_MODULE_ID index)

PLIB_SPI_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsEnableControl(SPI_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_Enable
- PLIB_SPI_Disable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsEnableControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsErrorInterruptControl Function

Identifies whether the ErrorInterruptControl feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsErrorInterruptControl(SPI_MODULE_ID index);
```

Returns

- true - The ErrorInterruptControl feature is supported on the device
- false - The ErrorInterruptControl feature is not supported on the device

Description

This function identifies whether the ErrorInterruptControl feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_ErrorInterruptEnable
- PLIB_SPI_ErrorInterruptDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsErrorInterruptControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsFIFOControl Function

Identifies whether the FIFOControl feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFIFOControl(SPI_MODULE_ID index);
```

Returns

- true - The FIFOControl feature is supported on the device
- false - The FIFOControl feature is not supported on the device

Description

This function identifies whether the FIFOControl feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_FIFOEnable
- PLIB_SPI_FIFODisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFIFOControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsFIFOCount Function

Identifies whether the FIFOCount feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFIFOCount(SPI_MODULE_ID index);
```

Returns

- true - The FIFOCount feature is supported on the device
- false - The FIFOCount feature is not supported on the device

Description

This function identifies whether the FIFOCount feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_FIFOCountGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFIFOCount(SPI_MODULE_ID index)

PLIB_SPI_ExistsFIFOInterruptMode Function

Identifies whether the FIFOInterruptMode feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFIFOInterruptMode(SPI_MODULE_ID index);
```

Returns

- true - The FIFOInterruptMode feature is supported on the device
- false - The FIFOInterruptMode feature is not supported on the device

Description

This function identifies whether the FIFOInterruptMode feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_FIFOInterruptModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFIFOInterruptMode(SPI_MODULE_ID index)

PLIB_SPI_ExistsFIFOShiftRegisterEmptyStatus Function

Identifies whether the FIFOShiftRegisterEmptyStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFIFOShiftRegisterEmptyStatus(SPI_MODULE_ID index);
```

Returns

- true - The FIFOShiftRegisterEmptyStatus feature is supported on the device
- false - The FIFOShiftRegisterEmptyStatus feature is not supported on the device

Description

This function identifies whether the FIFOShiftRegisterEmptyStatus feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_FIFOShiftRegisterIsEmpty

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFIFOShiftRegisterEmptyStatus(SPI_MODULE_ID index)

PLIB_SPI_ExistsFramedCommunication Function

Identifies whether the FramedCommunication feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFramedCommunication(SPI_MODULE_ID index);
```

Returns

- true - The FramedCommunication feature is supported on the device
- false - The FramedCommunication feature is not supported on the device

Description

This function identifies whether the FramedCommunication feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_FramedCommunicationEnable
- PLIB_SPI_FramedCommunicationDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFramedCommunication(SPI_MODULE_ID index)

PLIB_SPI_ExistsFrameErrorStatus Function

Identifies whether the FrameErrorStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFrameErrorStatus(SPI_MODULE_ID index);
```

Returns

- true - The FrameErrorStatus feature is supported on the device
- false - The FrameErrorStatus feature is not supported on the device

Description

This function identifies whether the FrameErrorStatus feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_FrameErrorStatusGet
- PLIB_SPI_FrameErrorStatusClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFrameErrorStatus(SPI_MODULE_ID index)

PLIB_SPI_ExistsFrameSyncPulseCounter Function

Identifies whether the FrameSyncPulseCounter feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFrameSyncPulseCounter(SPI_MODULE_ID index);
```

Returns

- true - The FrameSyncPulseCounter feature is supported on the device
- false - The FrameSyncPulseCounter feature is not supported on the device

Description

This function identifies whether the FrameSyncPulseCounter feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_FrameSyncPulseCounterSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFrameSyncPulseCounter(SPI_MODULE_ID index)

PLIB_SPI_ExistsFrameSyncPulseDirection Function

Identifies whether the FrameSyncPulseDirection feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFrameSyncPulseDirection(SPI_MODULE_ID index);
```

Returns

- true - The FrameSyncPulseDirection feature is supported on the device
- false - The FrameSyncPulseDirection feature is not supported on the device

Description

This function identifies whether the FrameSyncPulseDirection feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_FrameSyncPulseDirectionSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFrameSyncPulseDirection(SPI_MODULE_ID index)

PLIB_SPI_ExistsFrameSyncPulseEdge Function

Identifies whether the FrameSyncPulseEdge feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFrameSyncPulseEdge(SPI_MODULE_ID index);
```

Returns

- true - The FrameSyncPulseEdge feature is supported on the device
- false - The FrameSyncPulseEdge feature is not supported on the device

Description

This function identifies whether the FrameSyncPulseEdge feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_FrameSyncPulseEdgeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFrameSyncPulseEdge(SPI_MODULE_ID index)

PLIB_SPI_ExistsFrameSyncPulsePolarity Function

Identifies whether the FrameSyncPulsePolarity feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFrameSyncPulsePolarity(SPI_MODULE_ID index);
```

Returns

- true - The FrameSyncPulsePolarity feature is supported on the device
- false - The FrameSyncPulsePolarity feature is not supported on the device

Description

This function identifies whether the FrameSyncPulsePolarity feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_FrameSyncPulsePolaritySelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFrameSyncPulsePolarity(SPI_MODULE_ID index)

PLIB_SPI_ExistsFrameSyncPulseWidth Function

Identifies whether the FrameSyncPulseWidth feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsFrameSyncPulseWidth(SPI_MODULE_ID index);
```

Returns

- true - The FrameSyncPulseWidth feature is supported on the device
- false - The FrameSyncPulseWidth feature is not supported on the device

Description

This function identifies whether the FrameSyncPulseWidth feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_FrameSyncPulseWidthSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsFrameSyncPulseWidth(SPI_MODULE_ID index)

PLIB_SPI_ExistsInputSamplePhase Function

Identifies whether the InputSamplePhase feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsInputSamplePhase(SPI_MODULE_ID index);
```

Returns

- true - The InputSamplePhase feature is supported on the device
- false - The InputSamplePhase feature is not supported on the device

Description

This function identifies whether the InputSamplePhase feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_InputSamplePhaseSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsInputSamplePhase(SPI_MODULE_ID index)

PLIB_SPI_ExistsMasterControl Function

Identifies whether the MasterControl feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsMasterControl(SPI_MODULE_ID index);
```

Returns

- true - The MasterControl feature is supported on the device
- false - The MasterControl feature is not supported on the device

Description

This function identifies whether the MasterControl feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_MasterEnable
- PLIB_SPI_SlaveEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsMasterControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsOutputDataPhase Function

Identifies whether the OutputDataPhase feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsOutputDataPhase(SPI_MODULE_ID index);
```

Returns

- true - The OutputDataPhase feature is supported on the device
- false - The OutputDataPhase feature is not supported on the device

Description

This function identifies whether the OutputDataPhase feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_OutputDataPhaseSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsOutputDataPhase(SPI_MODULE_ID index)

PLIB_SPI_ExistsPinControl Function

Identifies whether the PinControl feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsPinControl(SPI_MODULE_ID index);
```

Returns

- true - The PinControl feature is supported on the device
- false - The PinControl feature is not supported on the device

Description

This function identifies whether the PinControl feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_PinEnable
- PLIB_SPI_PinDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsPinControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsReadDataSignStatus Function

Identifies whether the ReadDataSignStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsReadDataSignStatus(SPI_MODULE_ID index);
```

Returns

- true - The ReadDataSignStatus feature is supported on the device
- false - The ReadDataSignStatus feature is not supported on the device

Description

This function identifies whether the ReadDataSignStatus feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_ReadDataIsSignExtended

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsReadDataSignStatus(SPI_MODULE_ID index)

PLIB_SPI_ExistsReceiveBufferStatus Function

Identifies whether the ReceiveBufferStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsReceiveBufferStatus(SPI_MODULE_ID index);
```

Returns

- true - The ReceiveBufferStatus feature is supported on the device
- false - The ReceiveBufferStatus feature is not supported on the device

Description

This function identifies whether the ReceiveBufferStatus feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_ReceiverBufferIsFull

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsReceiveBufferStatus(SPI_MODULE_ID index)

PLIB_SPI_ExistsReceiveFIFOStatus Function

Identifies whether the ReceiveFIFOStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsReceiveFIFOStatus(SPI_MODULE_ID index);
```

Returns

- true - The ReceiveFIFOStatus feature is supported on the device
- false - The ReceiveFIFOStatus feature is not supported on the device

Description

This function identifies whether the ReceiveFIFOStatus feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_ReceiverFIFOIsEmpty

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsReceiveFIFOStatus(SPI_MODULE_ID index)

PLIB_SPI_ExistsReceiverOverflow Function

Identifies whether the ReceiverOverflow feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsReceiverOverflow(SPI_MODULE_ID index);
```

Returns

- true - The ReceiverOverflow feature is supported on the device
- false - The ReceiverOverflow feature is not supported on the device

Description

This function identifies whether the ReceiverOverflow feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_ReceiverHasOverflowed
- PLIB_SPI_ReceiverOverflowClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsReceiverOverflow(SPI_MODULE_ID index)

PLIB_SPI_ExistsSlaveSelectControl Function

Identifies whether the SlaveSelectControl feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsSlaveSelectControl(SPI_MODULE_ID index);
```

Returns

- true - The SlaveSelectControl feature is supported on the device
- false - The SlaveSelectControl feature is not supported on the device

Description

This function identifies whether the SlaveSelectControl feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_SlaveSelectEnable
- PLIB_SPI_SlaveSelectDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsSlaveSelectControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsStopInIdleControl Function

Identifies whether the StopInIdle feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsStopInIdleControl(SPI_MODULE_ID index);
```

Returns

- true - The StopInIdle feature is supported on the device
- false - The StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_StopInIdleEnable
- PLIB_SPI_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsStopInIdleControl(SPI_MODULE_ID index)

PLIB_SPI_ExistsTransmitBufferEmptyStatus Function

Identifies whether the TransmitBufferEmptyStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsTransmitBufferEmptyStatus(SPI_MODULE_ID index);
```

Returns

- true - The TransmitBufferEmptyStatus feature is supported on the device
- false - The TransmitBufferEmptyStatus feature is not supported on the device

Description

This function identifies whether the TransmitBufferEmptyStatus feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_TransmitBufferIsEmpty

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsTransmitBufferEmptyStatus(SPI_MODULE_ID index)

PLIB_SPI_ExistsTransmitBufferFullStatus Function

Identifies whether the TransmitBufferFullStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsTransmitBufferFullStatus(SPI_MODULE_ID index);
```

Returns

- true - The TransmitBufferFullStatus feature is supported on the device
- false - The TransmitBufferFullStatus feature is not supported on the device

Description

This function identifies whether the TransmitBufferFullStatus feature is available on the SPI module. When this function returns true, this function is supported on the device:

- PLIB_SPI_TransmitBufferIsFull

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsTransmitBufferFullStatus(SPI_MODULE_ID index)

PLIB_SPI_ExistsTransmitUnderRunStatus Function

Identifies whether the TransmitUnderRunStatus feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_ExistsTransmitUnderRunStatus(SPI_MODULE_ID index);
```

Returns

- true - The TransmitUnderRunStatus feature is supported on the device
- false - The TransmitUnderRunStatus feature is not supported on the device

Description

This function identifies whether the TransmitUnderRunStatus feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_TransmitUnderRunStatusGet
- PLIB_SPI_TransmitUnderRunStatusClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_ExistsTransmitUnderRunStatus(SPI_MODULE_ID index)

PLIB_SPI_Exists16bitBuffer Function

Identifies whether the Buffer16bit feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_Exists16bitBuffer(SPI_MODULE_ID index);
```

Returns

- true - The Buffer16bit feature is supported on the device
- false - The Buffer16bit feature is not supported on the device

Description

This function identifies whether the Buffer16bit feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_BufferRead16bit
- PLIB_SPI_BufferWrite16bit

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_Exists16bitBuffer(SPI_MODULE_ID index)

PLIB_SPI_Exists32bitBuffer Function

Identifies whether the Buffer32bit feature exists on the SPI module.

File

plib_spi.h

C

```
bool PLIB_SPI_Exists32bitBuffer(SPI_MODULE_ID index);
```

Returns

- true - The Buffer32bit feature is supported on the device
- false - The Buffer32bit feature is not supported on the device

Description

This function identifies whether the Buffer32bit feature is available on the SPI module. When this function returns true, these functions are supported on the device:

- PLIB_SPI_BufferRead32bit
- PLIB_SPI_BufferWrite32bit

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SPI_Exists32bitBuffer(SPI_MODULE_ID index)

h) Data Types and Constants

SPI_AUDIO_COMMUNICATION_WIDTH Enumeration

Defines the list of SPI audio communication width.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_AUDIO_COMMUNICATION_24DATA_32FIFO_32CHANNEL,
  SPI_AUDIO_COMMUNICATION_32DATA_32FIFO_32CHANNEL,
  SPI_AUDIO_COMMUNICATION_16DATA_16FIFO_32CHANNEL,
  SPI_AUDIO_COMMUNICATION_16DATA_16FIFO_16CHANNEL
} SPI_AUDIO_COMMUNICATION_WIDTH;
```

Members

Members	Description
SPI_AUDIO_COMMUNICATION_24DATA_32FIFO_32CHANNEL	Communication is 24-bit Data,32-bit FIFO,32-bit Channel/64-bit Frame
SPI_AUDIO_COMMUNICATION_32DATA_32FIFO_32CHANNEL	Communication is 32-bit Data,32-bit FIFO,32-bit Channel/64-bit Frame
SPI_AUDIO_COMMUNICATION_16DATA_16FIFO_32CHANNEL	Communication is 16-bit Data,16-bit FIFO,32-bit Channel/64-bit Frame
SPI_AUDIO_COMMUNICATION_16DATA_16FIFO_16CHANNEL	Communication is 16-bit Data,16-bit FIFO,16-bit Channel/64-bit Frame

Description

SPI Audio Communication Width

This macro defines the list of SPI audio communication width.

SPI_AUDIO_ERROR Enumeration

Defines the list of SPI audio error.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_AUDIO_ERROR_RECEIVE_OVERFLOW,
  SPI_AUDIO_ERROR_TRANSMIT_UNDERRUN
} SPI_AUDIO_ERROR;
```

Members

Members	Description
SPI_AUDIO_ERROR_RECEIVE_OVERFLOW	SPI error for receive overflow
SPI_AUDIO_ERROR_TRANSMIT_UNDERRUN	SPI error for transmit underrun

Description

SPI Audio Error

This macro defines the list of SPI audio error.

SPI_AUDIO_PROTOCOL Enumeration

Data type defining the audio protocol mode.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_AUDIO_PROTOCOL_PCM_DSP,
  SPI_AUDIO_PROTOCOL_RIGHT_JUSTIFIED,
  SPI_AUDIO_PROTOCOL_LEFT_JUSTIFIED,
  SPI_AUDIO_PROTOCOL_I2S
} SPI_AUDIO_PROTOCOL;
```

Members

Members	Description
SPI_AUDIO_PROTOCOL_PCM_DSP	Audio protocol set to PCM/DSP mode
SPI_AUDIO_PROTOCOL_RIGHT_JUSTIFIED	Audio protocol set to Right-Justified mode
SPI_AUDIO_PROTOCOL_LEFT_JUSTIFIED	Audio protocol set to Left-Justified mode
SPI_AUDIO_PROTOCOL_I2S	Audio protocol set to I2C mode

Description

Audio Protocol Mode enumeration

This data type defining the audio protocol mode.

Remarks

This enumeration is processor specific.

SPI_AUDIO_TRANSMIT_MODE Enumeration

Defines the list of SPI transmit audio mode format.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_AUDIO_TRANSMIT_MONO,
  SPI_AUDIO_TRANSMIT_STEREO
} SPI_AUDIO_TRANSMIT_MODE;
```

Members

Members	Description
SPI_AUDIO_TRANSMIT_MONO	SPI Transmit Audio Data Format is Mono
SPI_AUDIO_TRANSMIT_STEREO	SPI Transmit Audio Data Format is Stereo

Description

Audio Transmit mode format

This macro defines the list of SPI transmit audio mode format.

SPI_BAUD_RATE_CLOCK Enumeration

Defines the list of SPI Baud Rate Generator (BRG).

File

help_plib_spi.h

C

```
typedef enum {
  SPI_BAUD_RATE_MCLK_CLOCK,
  SPI_BAUD_RATE_PBCLK_CLOCK
} SPI_BAUD_RATE_CLOCK;
```

Members

Members	Description
SPI_BAUD_RATE_MCLK_CLOCK	MCLK is used by the Baud Rate Generator
SPI_BAUD_RATE_PBCLK_CLOCK	Peripheral bus clock is used by the Baud Rate Generator

Description

SPI Baud Rate Generator

This macro defines the list of the SPI Baud Rate Generator.

SPI_CLOCK_POLARITY Enumeration

Defines the list of SPI clock polarity.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_CLOCK_POLARITY_IDLE_HIGH,
  SPI_CLOCK_POLARITY_IDLE_LOW
} SPI_CLOCK_POLARITY;
```

Members

Members	Description
SPI_CLOCK_POLARITY_IDLE_HIGH	Idle state for clock is a high level;active state is a low level
SPI_CLOCK_POLARITY_IDLE_LOW	Idle state for clock is a low level;active state is a high level

Description

SPI Clock polarity

This macro defines the list of SPI clock polarity.

SPI_COMMUNICATION_WIDTH Enumeration

Defines the list of SPI communication width.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_COMMUNICATION_WIDTH_32BITS,
  SPI_COMMUNICATION_WIDTH_16BITS,
  SPI_COMMUNICATION_WIDTH_8BITS
} SPI_COMMUNICATION_WIDTH;
```

Members

Members	Description
SPI_COMMUNICATION_WIDTH_32BITS	Communication is 32-bit-wide
SPI_COMMUNICATION_WIDTH_16BITS	Communication is word-wide
SPI_COMMUNICATION_WIDTH_8BITS	Communication is byte-wide

Description

SPI Communication Width

This macro defines the list of SPI communication width.

SPI_DATA_TYPE Type

Data type defining the SPI data size.

File

help_plib_spi.h

C

```
typedef uint16_t SPI_DATA_TYPE;
```

Description

SPI Data Type definition

This data type defines the SPI data size.

SPI_ERROR_INTERRUPT Enumeration

Defines the list of SPI error interrupts.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_ERROR_INTERRUPT_FRAME_ERROR_OVERFLOW,
  SPI_ERROR_INTERRUPT_RECEIVE_OVERFLOW,
  SPI_ERROR_INTERRUPT_TRANSMIT_UNDERRUN
} SPI_ERROR_INTERRUPT;
```

Members

Members	Description
SPI_ERROR_INTERRUPT_FRAME_ERROR_OVERFLOW	SPI interrupt for frame error
SPI_ERROR_INTERRUPT_RECEIVE_OVERFLOW	SPI interrupt for receive overflow error
SPI_ERROR_INTERRUPT_TRANSMIT_UNDERRUN	SPI interrupt for transmit underrun error

Description

SPI Error Interrupt

This macro defines the list of SPI error interrupts.

SPI_FIFO_INTERRUPT Enumeration

Defines the list of SPI Buffer Interrupt mode.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_FIFO_INTERRUPT_WHEN_TRANSMIT_BUFFER_IS_NOT_FULL,
  SPI_FIFO_INTERRUPT_WHEN_TRANSMIT_BUFFER_IS_1HALF_EMPTY_OR_MORE,
  SPI_FIFO_INTERRUPT_WHEN_TRANSMIT_BUFFER_IS_COMPLETELY_EMPTY,
  SPI_FIFO_INTERRUPT_WHEN_TRANSMISSION_IS_COMPLETE,
  SPI_FIFO_INTERRUPT_WHEN_RECEIVE_BUFFER_IS_FULL,
  SPI_FIFO_INTERRUPT_WHEN_RECEIVE_BUFFER_IS_1HALF_FULL_OR_MORE,
  SPI_FIFO_INTERRUPT_WHEN_RECEIVE_BUFFER_IS_NOT_EMPTY,
  SPI_FIFO_INTERRUPT_WHEN_BUFFER_IS_EMPTY
} SPI_FIFO_INTERRUPT;
```

Members

Members	Description
SPI_FIFO_INTERRUPT_WHEN_TRANSMIT_BUFFER_IS_NOT_FULL	Interrupt when the transmit buffer is not full
SPI_FIFO_INTERRUPT_WHEN_TRANSMIT_BUFFER_IS_1HALF_EMPTY_OR_MORE	Interrupt when the transmit buffer is half empty
SPI_FIFO_INTERRUPT_WHEN_TRANSMIT_BUFFER_IS_COMPLETELY_EMPTY	Interrupt when the transmit buffer is empty
SPI_FIFO_INTERRUPT_WHEN_TRANSMISSION_IS_COMPLETE	Interrupt when transmission is complete
SPI_FIFO_INTERRUPT_WHEN_RECEIVE_BUFFER_IS_FULL	Interrupt when receive buffer is full
SPI_FIFO_INTERRUPT_WHEN_RECEIVE_BUFFER_IS_1HALF_FULL_OR_MORE	Interrupt when the receive buffer half full or more
SPI_FIFO_INTERRUPT_WHEN_RECEIVE_BUFFER_IS_NOT_EMPTY	Interrupt when the receive buffer is not empty
SPI_FIFO_INTERRUPT_WHEN_BUFFER_IS_EMPTY	Interrupt when the receive buffer is empty

Description

SPI Buffer Interrupt Mode

This macro defines the list of SPI Buffer Interrupt mode.

SPI_FIFO_TYPE Enumeration

Defines the list of SPI buffer mode.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_FIFO_TYPE_TRNSMIT,
  SPI_FIFO_TYPE_RECEIVE
} SPI_FIFO_TYPE;
```

Members

Members	Description
SPI_FIFO_TYPE_TRNSMIT	Buffer type is transmit
SPI_FIFO_TYPE_RECEIVE	Buffer type is receive

Description

SPI Buffer Mode

This macro defines the list of SPI buffer mode.

SPI_FRAME_PULSE_DIRECTION Enumeration

Defines the list of SPI frame sync pulse direction.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_FRAME_PULSE_DIRECTION_OUTPUT,
  SPI_FRAME_PULSE_DIRECTION_INPUT
} SPI_FRAME_PULSE_DIRECTION;
```

Members

Members	Description
SPI_FRAME_PULSE_DIRECTION_OUTPUT	Frame sync pulse direction is output
SPI_FRAME_PULSE_DIRECTION_INPUT	Frame sync pulse direction is input

Description

SPI Frame sync pulse direction

This macro defines the list of SPI frame sync pulse direction.

SPI_FRAME_PULSE_EDGE Enumeration

Defines the list of SPI frame sync pulse edge.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_FRAME_PULSE_EDGE_COINCIDES_FIRST_BIT_CLOCK,
  SPI_FRAME_PULSE_EDGE_PRECEDES_FIRST_BIT_CLOCK
} SPI_FRAME_PULSE_EDGE;
```

Members

Members	Description
SPI_FRAME_PULSE_EDGE_COINCIDES_FIRST_BIT_CLOCK	Frame sync pulse coincides with first bit clock
SPI_FRAME_PULSE_EDGE_PRECEDES_FIRST_BIT_CLOCK	Frame sync pulse precedes first bit clock

Description

SPI Frame sync pulse edge

This macro defines the list of SPI frame sync pulse edge.

SPI_FRAME_PULSE_POLARITY Enumeration

Defines the list of SPI frame sync pulse polarity.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_FRAME_PULSE_POLARITY_ACTIVE_HIGH,
  SPI_FRAME_PULSE_POLARITY_ACTIVE_LOW
} SPI_FRAME_PULSE_POLARITY;
```

Members

Members	Description
SPI_FRAME_PULSE_POLARITY_ACTIVE_HIGH	Frame sync pulse is active high
SPI_FRAME_PULSE_POLARITY_ACTIVE_LOW	Frame sync pulse is active low

Description

SPI Frame sync pulse polarity

This macro defines the list of SPI frame sync pulse polarity.

SPI_FRAME_PULSE_WIDTH Enumeration

Defines the list of SPI frame sync pulse width.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_FRAME_PULSE_WIDTH_ONE_WORD_LENGTH,
  SPI_FRAME_PULSE_WIDTH_ONE_CLOCK_WIDE
} SPI_FRAME_PULSE_WIDTH;
```

Members

Members	Description
SPI_FRAME_PULSE_WIDTH_ONE_WORD_LENGTH	Frame sync Pulse width as one word length wide
SPI_FRAME_PULSE_WIDTH_ONE_CLOCK_WIDE	Frame sync Pulse width as one clock wide

Description

SPI Frame sync pulse width

This macro defines the list of SPI frame sync pulse width.

SPI_FRAME_SYNC_PULSE Enumeration

Data type defining the frame sync pulse counter values.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_FRAME_SYNC_PULSE_ON_EVERY_32_DATA_CHARACTER,
  SPI_FRAME_SYNC_PULSE_ON_EVERY_16_DATA_CHARACTER,
  SPI_FRAME_SYNC_PULSE_ON_EVERY_8_DATA_CHARACTER,
  SPI_FRAME_SYNC_PULSE_ON_EVERY_4_DATA_CHARACTER,
  SPI_FRAME_SYNC_PULSE_ON_EVERY_2_DATA_CHARACTER,
  SPI_FRAME_SYNC_PULSE_ON_EVERY_DATA_CHARACTER
} SPI_FRAME_SYNC_PULSE;
```

Members

Members	Description
SPI_FRAME_SYNC_PULSE_ON_EVERY_32_DATA_CHARACTER	Generate a frame sync pulse on every 32 data character
SPI_FRAME_SYNC_PULSE_ON_EVERY_16_DATA_CHARACTER	Generate a frame sync pulse on every 16 data character
SPI_FRAME_SYNC_PULSE_ON_EVERY_8_DATA_CHARACTER	Generate a frame sync pulse on every 8 data character
SPI_FRAME_SYNC_PULSE_ON_EVERY_4_DATA_CHARACTER	Generate a frame sync pulse on every 4 data character
SPI_FRAME_SYNC_PULSE_ON_EVERY_2_DATA_CHARACTER	Generate a frame sync pulse on every 2 data character
SPI_FRAME_SYNC_PULSE_ON_EVERY_DATA_CHARACTER	Generate a frame sync pulse on every data character

Description

Frame Sync Pulse Counter enumeration

This data type defining the frame sync pulse counter values.

SPI_INPUT_SAMPLING_PHASE Enumeration

Defines the list of SPI data input sample phase.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE,
  SPI_INPUT_SAMPLING_PHASE_AT_END
} SPI_INPUT_SAMPLING_PHASE;
```

Members

Members	Description
SPI_INPUT_SAMPLING_PHASE_IN_MIDDLE	SPI Data Input Sample phase in middle
SPI_INPUT_SAMPLING_PHASE_AT_END	SPI Data Input Sample phase at end

Description

SPI Data Input Sample Phase

This macro defines the list of SPI data input sample phase.

SPI_MODULE_ID Enumeration

Identifies the supported SPI modules.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_ID_1,
  SPI_ID_2,
  SPI_ID_3,
  SPI_ID_4,
  SPI_NUMBER_OF_MODULES
} SPI_MODULE_ID;
```

Members

Members	Description
SPI_ID_1	SPI Module 1 ID
SPI_ID_2	SPI Module 2 ID
SPI_ID_3	SPI Module 3 ID
SPI_ID_4	SPI Module 4 ID
SPI_NUMBER_OF_MODULES	Number of available SPI modules.

Description

SPI Module ID

This enumeration identifies the SPI modules that are available on a microcontroller. This is the superset of all the possible instances that might be available on Microchip microcontrollers.

Remarks

The caller should not rely on the specific numbers assigned to any of these values as they may change from one processor to the next.

Not all modules will be available on all microcontrollers. Refer to the data sheet for the specific controller in use to determine which modules are supported. The numbers used in the enumeration values will match the numbers provided in the data sheet.

SPI_OUTPUT_DATA_PHASE Enumeration

Defines the list of SPI serial output data changes.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK,
  SPI_OUTPUT_DATA_PHASE_ON_IDLE_TO_ACTIVE_CLOCK
} SPI_OUTPUT_DATA_PHASE;
```

Members

Members	Description
SPI_OUTPUT_DATA_PHASE_ON_ACTIVE_TO_IDLE_CLOCK	Serial output data changes on transition from active clock state to idle clock state
SPI_OUTPUT_DATA_PHASE_ON_IDLE_TO_ACTIVE_CLOCK	Serial output data changes on transition from idle clock state to active clock state.

Description

SPI Output Data Phase

This macro defines the list of SPI serial output data changes.

SPI_PIN Enumeration

Data type defining the SPI pin.

File

help_plib_spi.h

C

```
typedef enum {
  SPI_PIN_DATA_OUT,
  SPI_PIN_DATA_IN,
  SPI_PIN_SLAVE_SELECT
} SPI_PIN;
```

Members

Members	Description
SPI_PIN_DATA_OUT	SPI data output pin
SPI_PIN_DATA_IN	SPI data input pin
SPI_PIN_SLAVE_SELECT	SPI slave select pin

Description

SPI pin

This data type defining the SPI pin.

Remarks

This enumeration is processor specific.

Files

Files

Name	Description
plib_spi.h	SPI Peripheral Library Interface Header for common definitions.
help_plib_spi.h	Identifies the various enumerations in SPI modules supported

Description

This section lists the source and header files used by the library.

plib_spi.h

SPI Peripheral Library Interface Header for common definitions.

Functions

	Name	Description
	PLIB_SPI_AudioCommunicationWidthSelect	Selects the data width for the SPI audio communication.
	PLIB_SPI_AudioErrorDisable	Disables the SPI error.
	PLIB_SPI_AudioErrorEnable	Enables the SPI error.
	PLIB_SPI_AudioProtocolDisable	Audio protocol is disabled.
	PLIB_SPI_AudioProtocolEnable	Audio protocol is enabled.
	PLIB_SPI_AudioProtocolModeSelect	Selects the Audio Protocol mode.
	PLIB_SPI_AudioTransmitModeSelect	Selects the transmit audio data format.
	PLIB_SPI_BaudRateClockSelect	Selects the type of clock is used by the Baud Rate Generator.
	PLIB_SPI_BaudRateSet	Sets the baud rate to the desired value.
	PLIB_SPI_BufferAddressGet	Returns the address of the SPIxBUF (Transmit(SPIxTXB) and Receive (SPIxRXB)) register.
	PLIB_SPI_BufferClear	Clears the SPI buffer.
	PLIB_SPI_BufferRead	Returns the SPI buffer value.
	PLIB_SPI_BufferRead16bit	Returns 16-bit SPI buffer value.
	PLIB_SPI_BufferRead32bit	Returns 32-bit SPI buffer value.
	PLIB_SPI_BufferWrite	Write the data to the SPI buffer.
	PLIB_SPI_BufferWrite16bit	Writes 16-bit data to the SPI buffer.
	PLIB_SPI_BufferWrite32bit	Write 32-bit data to the SPI buffer.
	PLIB_SPI_ClockPolaritySelect	Enables clock polarity.
	PLIB_SPI_CommunicationWidthSelect	Selects the data width for the SPI communication.
	PLIB_SPI_Disable	Disables the SPI module.

	PLIB_SPI_Enable	Enables the SPI module.
	PLIB_SPI_ErrorInterruptDisable	Enables SPI error interrupts.
	PLIB_SPI_ErrorInterruptEnable	Enables SPI error interrupts
	PLIB_SPI_Exists16bitBuffer	Identifies whether the Buffer16bit feature exists on the SPI module.
	PLIB_SPI_Exists32bitBuffer	Identifies whether the Buffer32bit feature exists on the SPI module.
	PLIB_SPI_ExistsAudioCommunicationWidth	Identifies whether the AudioCommunicationWidth feature exists on the SPI module.
	PLIB_SPI_ExistsAudioErrorControl	Identifies whether the AudioErrorControl feature exists on the SPI module.
	PLIB_SPI_ExistsAudioProtocolControl	Identifies whether the AudioProtocolControl feature exists on the SPI module.
	PLIB_SPI_ExistsAudioProtocolMode	Identifies whether the AudioProtocolMode feature exists on the SPI module.
	PLIB_SPI_ExistsAudioTransmitMode	Identifies whether the AudioTransmitMode feature exists on the SPI module.
	PLIB_SPI_ExistsBaudRate	Identifies whether the BaudRate feature exists on the SPI module.
	PLIB_SPI_ExistsBaudRateClock	Identifies whether the BaudRateClock feature exists on the SPI module.
	PLIB_SPI_ExistsBuffer	Identifies whether the Buffer feature exists on the SPI module.
	PLIB_SPI_ExistsBusStatus	Identifies whether the BusStatus feature exists on the SPI module.
	PLIB_SPI_ExistsClockPolarity	Identifies whether the ClockPolarity feature exists on the SPI module.
	PLIB_SPI_ExistsCommunicationWidth	Identifies whether the CommunicationWidth feature exists on the SPI module.
	PLIB_SPI_ExistsEnableControl	Identifies whether the EnableControl feature exists on the SPI module.
	PLIB_SPI_ExistsErrorInterruptControl	Identifies whether the ErrorInterruptControl feature exists on the SPI module.
	PLIB_SPI_ExistsFIFOControl	Identifies whether the FIFOControl feature exists on the SPI module.
	PLIB_SPI_ExistsFIFOCount	Identifies whether the FIFOCount feature exists on the SPI module.
	PLIB_SPI_ExistsFIFOInterruptMode	Identifies whether the FIFOInterruptMode feature exists on the SPI module.
	PLIB_SPI_ExistsFIFOShiftRegisterEmptyStatus	Identifies whether the FIFOShiftRegisterEmptyStatus feature exists on the SPI module.
	PLIB_SPI_ExistsFramedCommunication	Identifies whether the FramedCommunication feature exists on the SPI module.
	PLIB_SPI_ExistsFrameErrorStatus	Identifies whether the FrameErrorStatus feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulseCounter	Identifies whether the FrameSyncPulseCounter feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulseDirection	Identifies whether the FrameSyncPulseDirection feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulseEdge	Identifies whether the FrameSyncPulseEdge feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulsePolarity	Identifies whether the FrameSyncPulsePolarity feature exists on the SPI module.
	PLIB_SPI_ExistsFrameSyncPulseWidth	Identifies whether the FrameSyncPulseWidth feature exists on the SPI module.
	PLIB_SPI_ExistsInputSamplePhase	Identifies whether the InputSamplePhase feature exists on the SPI module.
	PLIB_SPI_ExistsMasterControl	Identifies whether the MasterControl feature exists on the SPI module.
	PLIB_SPI_ExistsOutputDataPhase	Identifies whether the OutputDataPhase feature exists on the SPI module.
	PLIB_SPI_ExistsPinControl	Identifies whether the PinControl feature exists on the SPI module.
	PLIB_SPI_ExistsReadDataSignStatus	Identifies whether the ReadDataSignStatus feature exists on the SPI module.
	PLIB_SPI_ExistsReceiveBufferStatus	Identifies whether the ReceiveBufferStatus feature exists on the SPI module.
	PLIB_SPI_ExistsReceiveFIFOStatus	Identifies whether the ReceiveFIFOStatus feature exists on the SPI module.
	PLIB_SPI_ExistsReceiverOverflow	Identifies whether the ReceiverOverflow feature exists on the SPI module.
	PLIB_SPI_ExistsSlaveSelectControl	Identifies whether the SlaveSelectControl feature exists on the SPI module.
	PLIB_SPI_ExistsStopInIdleControl	Identifies whether the StopInIdle feature exists on the SPI module.
	PLIB_SPI_ExistsTransmitBufferEmptyStatus	Identifies whether the TransmitBufferEmptyStatus feature exists on the SPI module.
	PLIB_SPI_ExistsTransmitBufferFullStatus	Identifies whether the TransmitBufferFullStatus feature exists on the SPI module.
	PLIB_SPI_ExistsTransmitUnderRunStatus	Identifies whether the TransmitUnderRunStatus feature exists on the SPI module.
	PLIB_SPI_FIFOCountGet	Reads the SPI Buffer Element Count bits for either receive or transmit.
	PLIB_SPI_FIFODisable	Disables the SPI enhanced buffer.
	PLIB_SPI_FIFOEnable	Enables the SPI enhanced buffer.
	PLIB_SPI_FIFOInterruptModeSelect	Selects the SPI buffer interrupt mode.
	PLIB_SPI_FIFOShiftRegisterIsEmpty	Returns the current status of the SPI shift register.
	PLIB_SPI_FramedCommunicationDisable	Disables framed SPI support.
	PLIB_SPI_FramedCommunicationEnable	Enables framed SPI support.
	PLIB_SPI_FrameErrorStatusClear	Clears the SPI frame error flag.
	PLIB_SPI_FrameErrorStatusGet	Returns the current status of the SPI frame error.
	PLIB_SPI_FrameSyncPulseCounterSelect	Selects at which character the SPI frame sync pulse is generated.
	PLIB_SPI_FrameSyncPulseDirectionSelect	Selects the frame sync pulse direction.

	PLIB_SPI_FrameSyncPulseEdgeSelect	Selects the frame sync pulse edge.
	PLIB_SPI_FrameSyncPulsePolaritySelect	Selects the frame sync pulse polarity.
	PLIB_SPI_FrameSyncPulseWidthSelect	Sets the frame sync pulse width.
	PLIB_SPI_InputSamplePhaseSelect	Selects the SPI data input sample phase.
	PLIB_SPI_IsBusy	Returns the current SPI module activity status.
	PLIB_SPI_MasterEnable	Enables the SPI in Master mode.
	PLIB_SPI_OutputDataPhaseSelect	Selects serial output data change.
	PLIB_SPI_PinDisable	Enables the selected SPI pins.
	PLIB_SPI_PinEnable	Enables the selected SPI pins.
	PLIB_SPI_ReadDataIsSignExtended	Returns the current status of the receive (RX) FIFO sign-extended data.
	PLIB_SPI_ReceiverBufferIsFull	Returns the current status of the SPI receive buffer.
	PLIB_SPI_ReceiverFIFOIsEmpty	Returns the current status of the SPI receive FIFO.
	PLIB_SPI_ReceiverHasOverflowed	Returns the current status of the SPI receiver overflow.
	PLIB_SPI_ReceiverOverflowClear	Clears the SPI receive overflow flag.
	PLIB_SPI_SlaveEnable	Enables the SPI in Slave mode.
	PLIB_SPI_SlaveSelectDisable	Disables Master mode slave select.
	PLIB_SPI_SlaveSelectEnable	Enables Master mode slave select.
	PLIB_SPI_StopInIdleDisable	Continues module operation when the device enters Idle mode.
	PLIB_SPI_StopInIdleEnable	Discontinues module operation when the device enters Idle mode.
	PLIB_SPI_TransmitBufferIsEmpty	Returns the current status of the transmit buffer.
	PLIB_SPI_TransmitBufferIsFull	Returns the current transmit buffer status of the SPI module.
	PLIB_SPI_TransmitUnderRunStatusClear	Clears the SPI transmit underrun flag.
	PLIB_SPI_TransmitUnderRunStatusGet	Returns the current status of the transmit underrun.

Description

SPI Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the SPI PLIB.

Identifies the various enumerations in SPI modules supported

Enumerations

	Name	Description
	SPI_AUDIO_COMMUNICATION_WIDTH	Defines the list of SPI audio communication width.
	SPI_AUDIO_ERROR	Defines the list of SPI audio error.
	SPI_AUDIO_PROTOCOL	Data type defining the audio protocol mode.
	SPI_AUDIO_TRANSMIT_MODE	Defines the list of SPI transmit audio mode format.
	SPI_BAUD_RATE_CLOCK	Defines the list of SPI Baud Rate Generator (BRG).
	SPI_CLOCK_POLARITY	Defines the list of SPI clock polarity.
	SPI_COMMUNICATION_WIDTH	Defines the list of SPI communication width.
	SPI_ERROR_INTERRUPT	Defines the list of SPI error interrupts.
	SPI_FIFO_INTERRUPT	Defines the list of SPI Buffer Interrupt mode.
	SPI_FIFO_TYPE	Defines the list of SPI buffer mode.
	SPI_FRAME_PULSE_DIRECTION	Defines the list of SPI frame sync pulse direction.
	SPI_FRAME_PULSE_EDGE	Defines the list of SPI frame sync pulse edge.
	SPI_FRAME_PULSE_POLARITY	Defines the list of SPI frame sync pulse polarity.
	SPI_FRAME_PULSE_WIDTH	Defines the list of SPI frame sync pulse width.
	SPI_FRAME_SYNC_PULSE	Data type defining the frame sync pulse counter values.
	SPI_INPUT_SAMPLING_PHASE	Defines the list of SPI data input sample phase.

	SPI_MODULE_ID	Identifies the supported SPI modules.
	SPI_OUTPUT_DATA_PHASE	Defines the list of SPI serial output data changes.
	SPI_PIN	Data type defining the SPI pin.

Types

	Name	Description
	SPI_DATA_TYPE	Data type defining the SPI data size.

Description

This enumeration identifies the SPI modules that are available on a microcontroller. This is the superset of all the possible instances that might be available on Microchip microcontrollers.

SQI Peripheral Library

This section describes the Serial Quad Interface (SQI) Peripheral Library.

Introduction

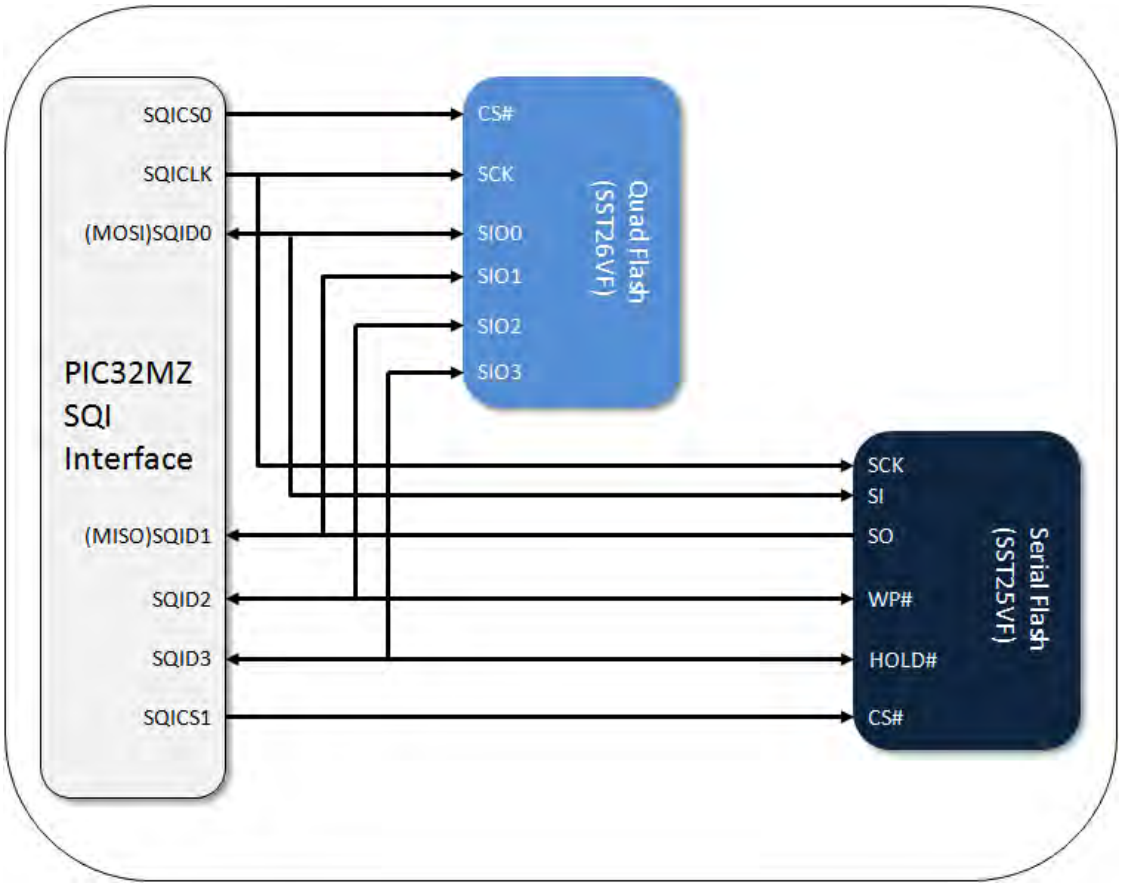
This library provides a low-level abstraction of the Serial Quad Interface (SQI) Peripheral that is available on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the SQI module without the necessity of interacting directly with the module's registers, there by hiding differences from one microcontroller variant to another.

Description

The SQI module is a synchronous serial interface that provides access to serial Flash memories and other serial devices. The SQI bus interface consists of four data lines (SQID3-SQID0), a clock line (SQICLK), two select lines (SQICS0 and SQICS1) and the module supports single Lane (identical to SPI), dual Lane, and quad Lane interface modes. SQI operates in only master mode. The SQI module has configurable transmit and receive buffers, programmable baud rates through the internal clock divider, clock phase, and clock polarity control for efficient data operations. Transmit and receive buffers can be accessed through SQITXDATA and SQIRXDATA registers. Similarly, the control buffer can be accessed through the SQI1CON register and is mainly used to pipeline the operations.

The SQI module operates in three transfer modes: DMA, PIO, and XIP using three data flow modes:SPI Mode 0 and Mode 3, and a high-speed Serial Flash mode . All three modes use the control buffer to pipeline the command/data sequences on the SQI bus. Following diagrams describe typical SQI hardware interface and software flow. Figure 1 shows the typical hardware interface of SQI module.

Figure 1: Hardware Interface Diagram



Refer to **Section 46. "Serial Quad Interface (SQI)"** (DS60001244), which is available on the Microchip website for additional details on control register information and operation.

Using the Library

This topic describes the basic architecture of the SQI Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_sqi.h`

The interface to the SQI peripheral library is defined in the `plib_sqi.h` header file, which is included by the peripheral library header file,

`peripheral.h`. Any C language source (`.c`) file that uses the SQI peripheral library must include `peripheral.h`.

Library File:

The SQI peripheral library archive (`.a`) file is installed with MPLAB Harmony.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Hardware Abstraction Model

This library provides the low-level abstraction of the SQI module on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in the software and introduces the library interface.

Description

Before jumping into the software abstraction, it is important to understand the SQI hardware a little more in detail.

Figure 2 provides a glimpse of SQI hardware block diagram. As shown the diagram the features of SQI are divided into multiple logic blocks and the SQI peripheral library provides APIs to configure the various logic block thus the features.

The control and status SFRs block contains all the registers that are used to configure the SQI in a specific mode of operation. The PIO mode of operation of SQI requires a set of registers to be configured by the Host processor and writing to/ reading from the TXDATA and RXDATA registers. The XIP logic facilitates the SQI modules eXecute-In-Place mode of operation, where Host processor programs the set of registers that configure the XIP mode and the engine automatically reads the external Flash and the read data gets mapped into a direct memory region. Where as DMA mode requires the Host processor to program a set of buffer descriptors and instructs SQI to point to the address of those buffer descriptors for the reads and writes. As mentioned earlier there are 3 buffers; transmit, receive and control that are accessed through SQIxTXDATA, SQIxRXDATA, and SQIxCON registers, respectively.

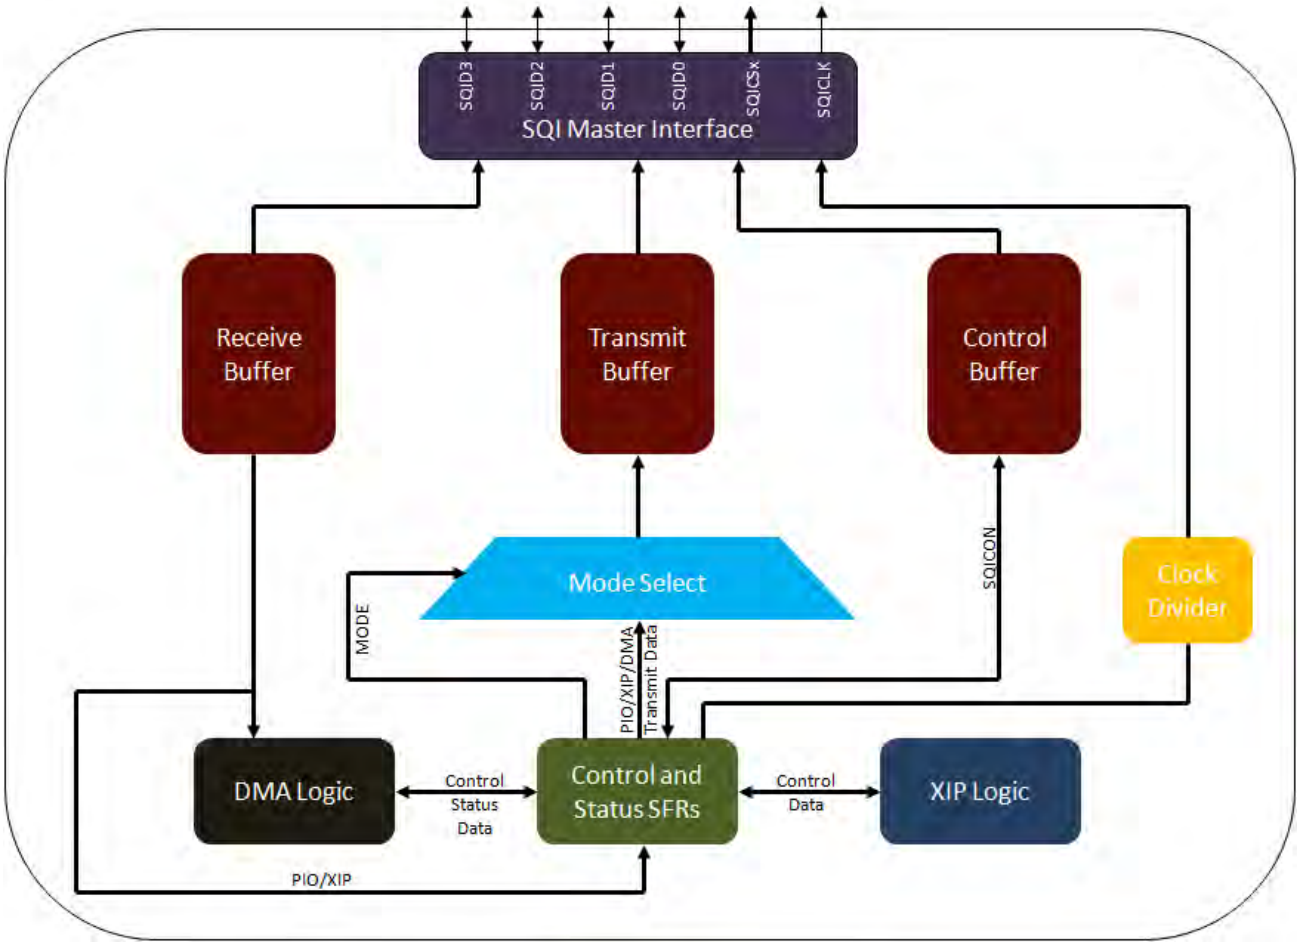


Figure 2: SQI Hardware Block Diagram

The SQI Peripheral Library takes requests from application software or the SQI device driver and controls the SQI hardware as per the inputs passed to the Library Interface. Figure 3 provides the SQI peripheral library software abstraction layer diagram.

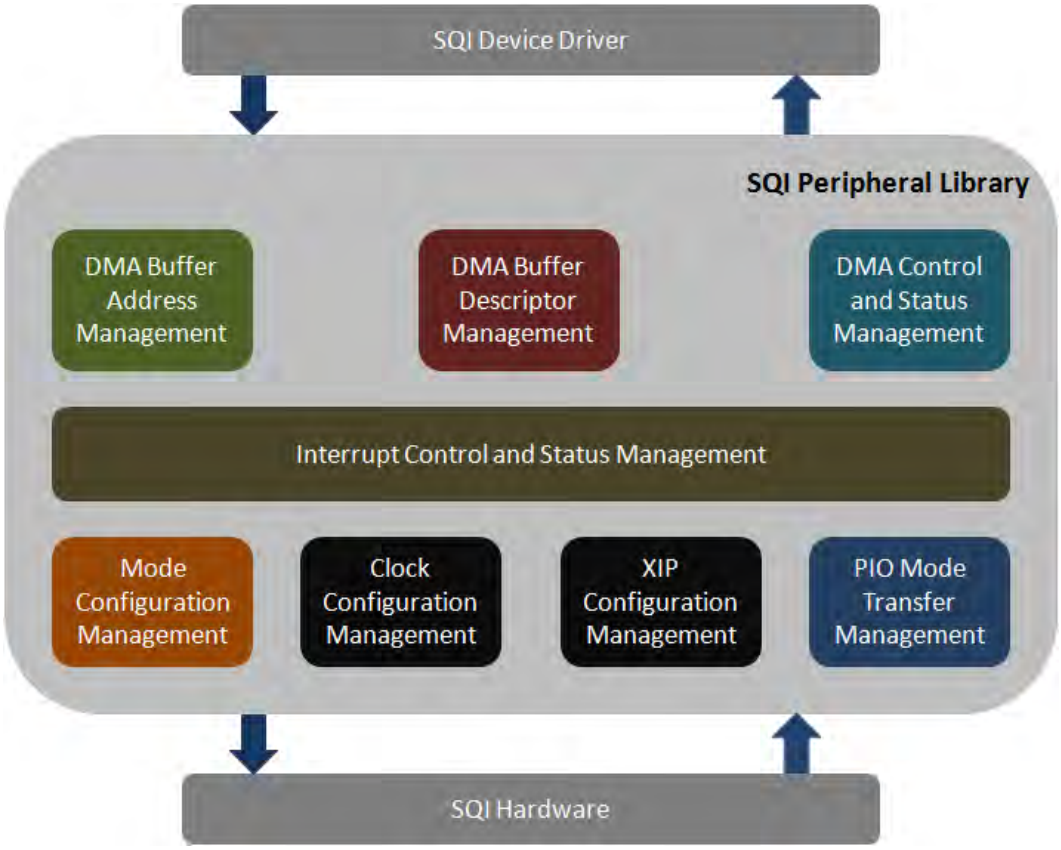

Figure 3: SQI Software Abstraction Model

The major components are SQI Peripheral Library are:

- Configuration Management
- Interrupt Control and Status Management
- DMA Mode Management

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the SQI module.

Library Interface Section	Description
Mode Configuration Management Functions	These functions are used to set up transfer mode (DMA/XIP/PIO), data mode (SPI Mode 0/Mode 3/Serial Flash), lane mode (single/dual/quad) and XIP control registers.
Clock Configuration Management Functions	These functions are used to enable the clock, set up a clock divider and check the status of the clock to see if it is stable.
XIP Configuration Management Functions	These functions are used to set up parameters for XIP mode of operation.
PIO Mode Transfer Management Functions	These functions are used to set up TXDATA, RXDATA registers and status checks.
Interrupt Control and Status Management Functions	These functions are used to control the interrupts. SQI supports only status type of interrupts (no error interrupts).
DMA Buffer Address Management Functions	These functions are used to set up the address of the base descriptor, check the address of the current descriptor
DMA Buffer Descriptor Management Functions	These functions are used to set up and control 4 words (BD_CTRL, BD_STATUS (reserved), BD_BUF_ADDR and BD_NEXT_PTR)
DMA Control and Status Management Functions	These functions are used to control the buffer descriptor fetch process and check the status during the buffer descriptor fetches.

How the Library Works

Note: Not all features are available on all devices. Refer to the **"Serial Quad Interface (SQI)"** chapter in the specific device data sheet for availability.

Core Functionality

SQI modules core functionality is to transfer data between the serial device (mostly quad Flash) attached and the PIC microcontroller. To achieve this, SQI module uses 3 transfer modes: DMA, PIO and XIP. Each transfer mode can be configured to use any of the 3 available data flow modes (Mode 0, Mode 3 and Serial Flash Mode) to achieve the transfers. DMA and PIO modes are typically used to transfer data and XIP mode is used for code execution.

Each mode of operation requires setting-up the clock, selecting data flow mode and selecting lane mode and other parameters as required by the device driver or application. SQI peripheral library includes complete set of API necessary to perform these operations.

The following sections describe the SQI core functionality in each mode of operation.

XIP Mode

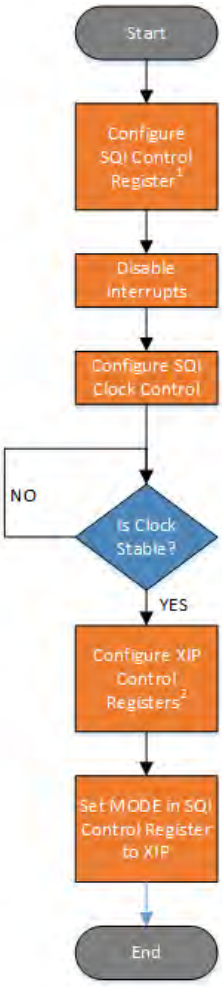
Describes XIP mode.

Description

XIP (eXecute-In-Place) mode is mostly used to execute the code out of the attached serial Flash device. However, this mode can also be used to transfer data as deemed necessary. In order for SQI to operate in XIP mode, host processor would have to set up the two SFRs dedicated to the XIP mode in addition to SQI configuration and clock control SFRs. Please refer to the specific data sheet and family reference manual for the configuration details.

Please note that all the XIP configuration values depend on the parameters of the interfaced serial Flash memory device. In XIP mode, reading values of any other SFRs return the contents of the serial Flash device, the way it is mapped.

The following figure shows the XIP mode software flow.



Notes:
1. This step configures the SQI configuration fields, SQIEN, CSEN, and DATAEN, with the exception of MODE<1:0>.
2. There are two XIP control registers: SQI1XCON1 and SQI1XCON2.

Example:

```
// Example is written to access SST26VF032 Flash device
```

```
// Example assumes the Flash Device is connected to Chip Select 0

//Global defines
#define SST26VF_HS_READ    0x0B
#define SST26VF_MODE_CODE  0x0
#define SST26VF_MODE_BYTES 0x0

// Set up SQI Configuration Bits
PLIB_SQI_Enable(SQI_ID_1);
PLIB_SQI_CSOutputEnableSelect(SQI_ID_1, SQI_CS_OEN_0);
PLIB_SQI_DataOutputEnableSelect(SQI_ID_1, SQI_DATA_OEN_QUAD);

// Disable All Interrupts
PLIB_SQI_InterruptDisable(SQI_ID_1, SQI_ALL_INT);
PLIB_SQI_InterruptSignalDisable(SQI_ID_1, SQI_ALL_INT);

// Set up SQI Transfer Clock
PLIB_SQI_ClockDividerSet(SQI_ID_1,CLK_DIV_1);
PLIB_SQI_ClockEnable(SQI_ID_1);
while (!PLIB_SQI_ClockIsStable(SQI_ID_1));

// Configure XIP Control 1 SFR
PLIB_SQI_XIPControlWord1Set (SQI_ID_1,
                             SQI_LANE_QUAD,
                             SQI_LANE_QUAD,
                             SQI_LANE_QUAD,
                             SQI_LANE_QUAD,
                             SQI_LANE_QUAD,
                             SST26VF_HS_READ,
                             ADDR_BYTES_3,
                             DUMMY_BYTES_2
                            );

// Configure XIP Control 2 SFR
PLIB_SQI_XIPControlWord2Set (SQI_ID_1,
                             SST26VF_MODE_CODE,
                             MODE_BYTES_0,
                             SQI_CS_0
                            );

// Set Transfer Mode to XIP
PLIB_SQI_TransferModeSet(SQI_ID_1, SQI_XFER_MODE_XIP);

// The SQI is now in XIP mode and should start fetching the code
```

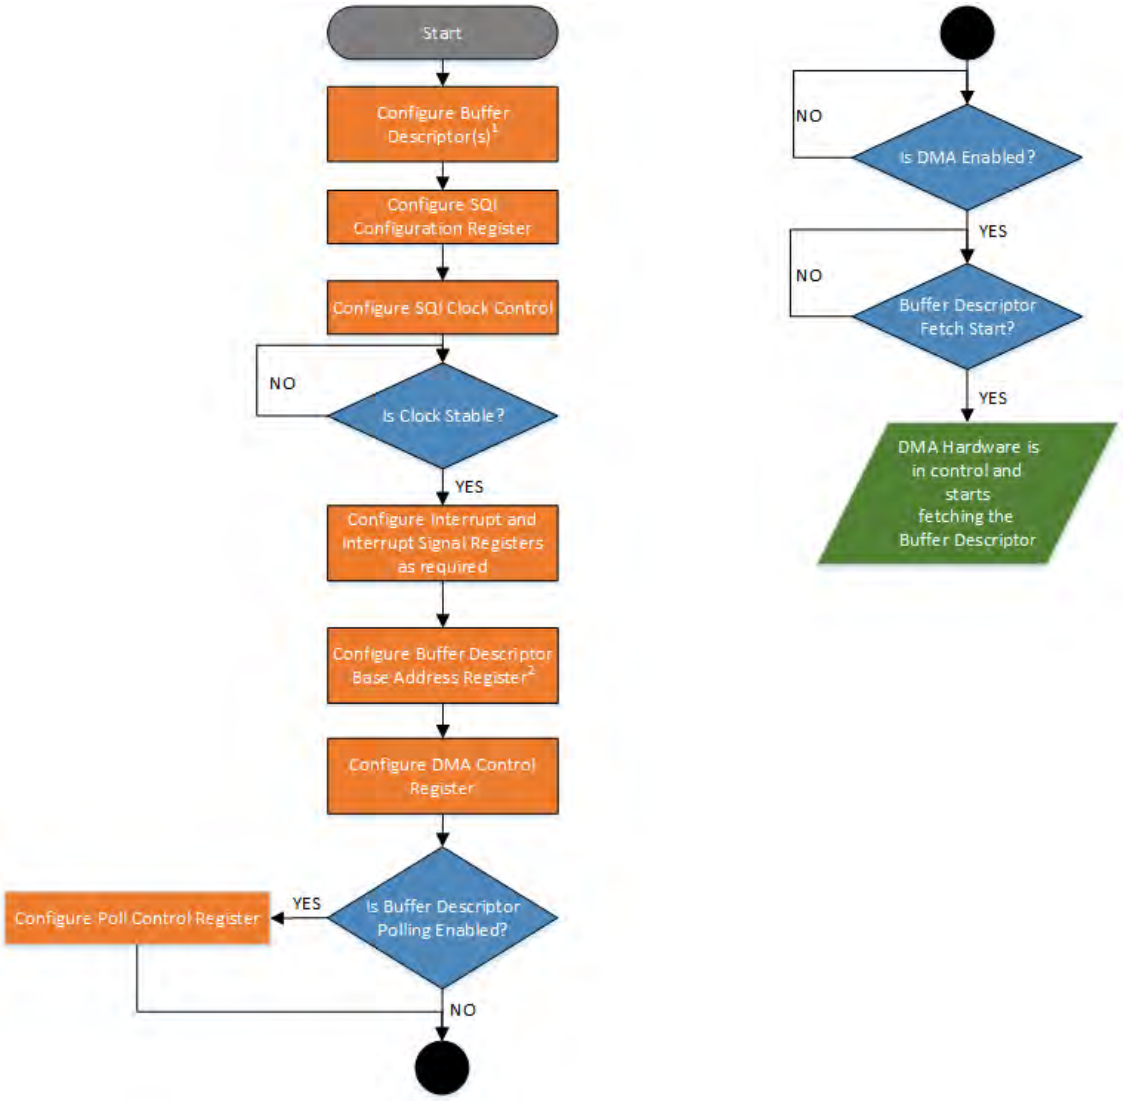
DMA Mode

Describes DMA mode.

Description

DMA mode is used for higher throughput data transfers. In DMA mode, the SQI DMA engine controls the data transfers off-loading the host processor. However, the host processor would have to configure the buffer descriptor and some SQI control SFRs to initiate the DMA process. Once the transactions are in progress, the DMA will be in control and the host processor can get the control through the interrupts or by disabling the DMA.

The following figure shows the DMA mode software flow.



Notes:

1. Buffer descriptor is a data structure in memory containing 4 words (BD_CTRL, BD_STAT, BD_BUFADDR and BD_NXTPTR).
2. Base address register points to first buffer descriptor in the chain.

Example:

```
// Example is written to access SST26VF032 Flash device
// Example assumes the Flash Device is connected to Chip Select 0

//Global defines
#define SST26VF_EQIO       0x38
#define SST26VF_HS_READ    0x0B
#define SST26VF_MODE_CODE  0x0
#define SST26VF_MODE_BYTES 0x0
#define NUMBER_OF_BDs      5
#define POLL_CON_VALUE     10

{

// Set up the Buffer Descriptors
for ( i=0; i <(NUMBER_OF_BDs-1); i++)
{
// Set up Buffer Descriptors. Handle structures as application
// needs.

// Configure SQI Control Fields
PLIB_SQI_Enable(SQI_ID_1);
PLIB_SQI_CSOutputEnableSelect(SQI_ID_1,SQI_CS_OEN_0);
PLIB_SQI_DataOutputEnableSelect(SQI_ID_1,SQI_DATA_OEN_2);
```

```
PLIB_SQI_BurstEnable(SQI_ID_1);
PLIB_SQI_SerialModeSet(SQI_ID_1);
PLIB_SQI_TransferModeSet(SQI_ID_1,SQI_XFER_MODE_PIO);

// Configure the SQI Transfer Clock
PLIB_SQI_ClockDividerSet(SQI_ID_1,CLK_DIV_4);
PLIB_SQI_ClockEnable(SQI_ID_1);
while (!PLIB_SQI_ClockIsStable(SQI_ID_1));

//Enable Buffer Descriptor Done and Packet Done Interrupts
PLIB_SQI_InterruptEnable(SQI_ID_1,BDDONE);
PLIB_SQI_InterruptSignalEnable(SQI_ID_1,BDDONE);
PLIB_SQI_InterruptEnable(SQI_ID_1,PKTCOMP);
PLIB_SQI_InterruptSignalEnable(SQI_ID_1,PKTCOMP);

// Send EQIO(0x38) Command to SST26VF032 to Enable Quad Lane Mode
// Note: These steps are not in the flow as these are specific to
// one Flash Device (SST26VF032)
PLIB_SQI_ChipSelectSet(SQI_ID_1,SQI_CS_0);
PLIB_SQI_LaneModeSet(SQI_ID_1,SQI_SINGLE_LANE);
PLIB_SQI_TransferCommandSet(SQI_ID_1,SQI_CMD_TRANSMIT);
// Transfers 1 Command Byte, No Address/Dummy Bytes
PLIB_SQI_TransferCountSet(SQI_ID_1, 0x1);
PLIB_SQI_TransmitterDataSend(SQI_ID_1, SST26VF_EQIO);

// Set the SQI in DMA Mode
PLIB_SQI_TransferModeSet(SQI_ID_1,SQI_XFER_MODE_DMA);

// Set up the Base Buffer Descriptor Address
if (!PLIB_SQI_DMAIsActive(SQI_ID_1))
    PLIB_SQI_DMABDBaseAddressSet(SQI_ID_1, (void *) (&MY_BASE_BD_STRUCT));

//Set up DMA Control Register
PLIB_SQI_DMABDEnable(SQI_ID_1);
PLIB_SQI_DMABDPollEnable(SQI_ID_1);

// Set up DMA Polling
If (PLIB_SQI_DMABDPollIsEnabled(SQI_ID_1))
   // Poll DMA every 10 cycles
   PLIB_SQI_PollControlSet(SQI_ID_1, MY_POLL_CONTROL_VALUE);

// Start the DMA Process - DMA Engine is now in Control
If (PLIB_SQI_DMAIsEnabled(SQI_ID_1))
{
   if (!PLIB_SQI_DMAIsActive(MY_SQI_INSTANCE))
      PLIB_SQI_DMABDFetchStart(SQI_ID_1);

}

}
```

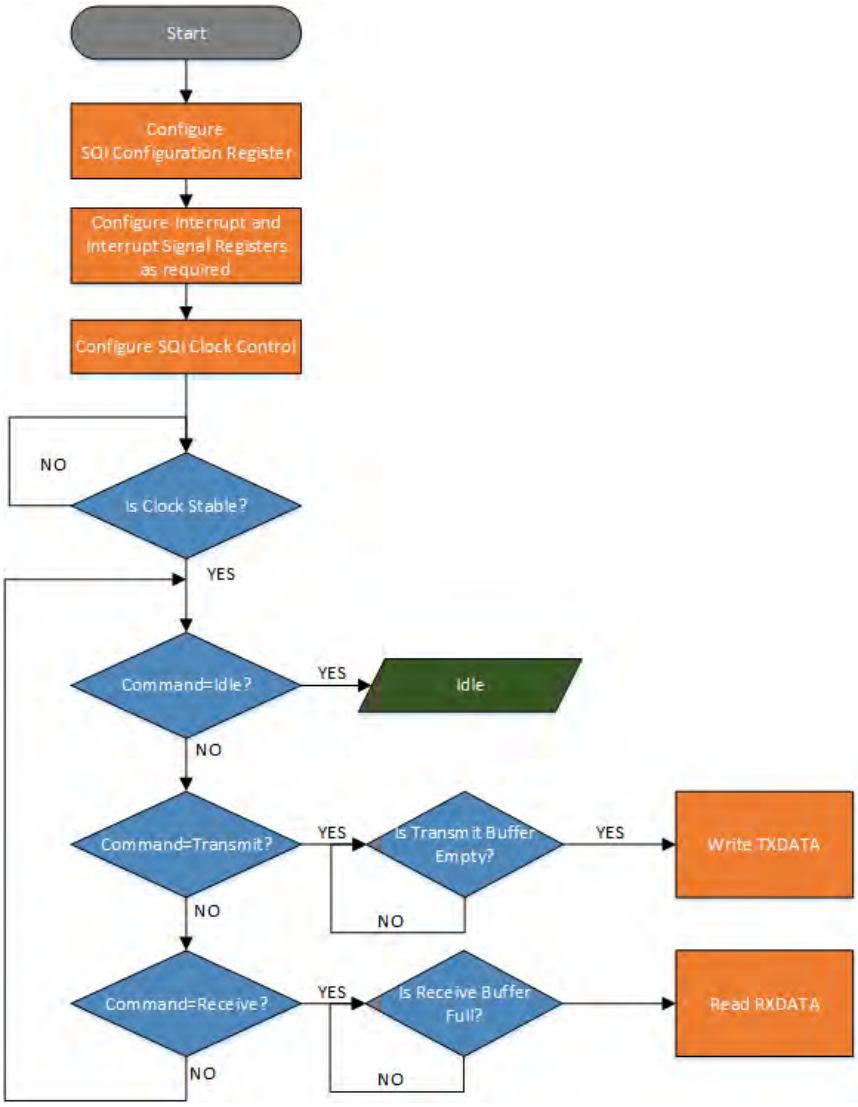
PIO Mode

Describes PIO mode.

Description

PIO mode is mostly used for data transfers. In PIO mode, the SQI module is entirely under the control of host processor. For the SQI module to operate in PIO mode, the host processor would have to set up the configuration, control, and clock control SFRs. Once the transactions are in progress, the host processor can use interrupts and status flags to control the operation. Please refer to the specific device data sheet and family reference manual for the configuration details.

The following figure shows the PIO mode software flow.



Example:

```
// Example is written to access SST26VF032 Flash device
// Example assumes the Flash Device is connected to Chip Select 0
// Example reads the device ID of the SST26VF032

//Global defines
#define FALSE                0
#define TRUE                 1
#define SST26VF_EQIO         0x38
#define SST26VF_HS_READ      0x0B
#define SST26VF_QJEDID_READ  0x9F
#define SST26VF_JEDEC_ID     0xBF2602

{
int32_t jedecID;

// Set up SQI Configuration (SQI1CFG) Register
PLIB_SQI_ConfigWordSet(MY_SQI_INSTANCE,
                       1,
                       SQI_CS_OEN_0,
                       SQI_DATA_OEN_QUAD,
                       0,
                       1,
                       0,
                       0,
                       0,
                       SQI_DATA_FORMAT_MSBF,
                       SQI_DATA_MODE_3,
```

```
                        SQI_XFER_MODE_PIO
                        );

```

Configuring the Library

The library is configured for the supported SQI module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) Mode Configuration Management Functions

	Name	Description
	PLIB_SQI_BurstEnable	Sets the burst enable (BURSTEN) function for higher throughput. This function is an artifact of the System Bus architecture.
	PLIB_SQI_ClockDisable	Disables the SQI transfer clock.
	PLIB_SQI_ControlBufferThresholdGet	Returns the transmit buffer space in bytes.
	PLIB_SQI_ControlBufferThresholdSet	Sets the control buffer threshold value.
	PLIB_SQI_ControlWordGet	Get the SQI Control Word.
	PLIB_SQI_ControlWordSet	Sets the SQI Control Word.
	PLIB_SQI_CSOutputEnableSelect	Selects the output enables on SQI Chip Select pins.
	PLIB_SQI_DataFormatGet	Returns the data format.
	PLIB_SQI_DataFormatSet	Sets the data format to Least Significant Bit First (LSBF)..
	PLIB_SQI_DataModeSet	Sets the SQI data mode of operation.
	PLIB_SQI_DataOutputEnableSelect	Selects the output enables on SQI data outputs.
	PLIB_SQI_Disable	Disables the SQI module.
	PLIB_SQI_Enable	Enables the SQI module.
	PLIB_SQI_HoldClear	Clears the hold function to be disabled on SQID3 in single and dual lane modes.
	PLIB_SQI_HoldGet	Gets the status of HOLD function on SQID3 pin.
	PLIB_SQI_HoldSet	Sets the hold function to be enabled on SQID3 in single or dual lane modes.
	PLIB_SQI_LaneModeGet	Returns the lane mode (single/dual/quad).
	PLIB_SQI_LaneModeSet	Sets the data lane mode (single/dual/quad).
	PLIB_SQI_NumberOfReceiveBufferReads	Returns the number of receive buffer reads.
	PLIB_SQI_ReceiveData	Reads the data from the receive buffer.
	PLIB_SQI_ReceiveLatchDisable	Disables the receive latch so receive data is discarded when in transmit mode.
	PLIB_SQI_ReceiveLatchEnable	Enables the receive latch so receive data is latched during transmit mode.
	PLIB_SQI_ReceiveLatchGet	Returns the receive latch status in transmit mode.
	PLIB_SQI_SoftReset	Issues a soft reset to the SQI module.
	PLIB_SQI_TransferModeGet	Returns the SQI transfer mode of operation.
	PLIB_SQI_TransferModeSet	Sets the SQI transfer mode of operation.
	PLIB_SQI_TransmitData	Writes data into the SQI transmit buffer.
	PLIB_SQI_WriteProtectClear	Clears the Write-Protect function to be disabled on SQID2 in single or dual lane modes.
	PLIB_SQI_WriteProtectGet	Gets the state of the write-protect feature on SQID2.
	PLIB_SQI_WriteProtectSet	Sets the write-protect feature to be enabled on SQID2 in single or dual lane modes only.
	PLIB_SQI_ConBufferSoftReset	Issues a soft reset to the SQI control buffer.
	PLIB_SQI_RxBufferSoftReset	Issues a soft reset to the SQI receive buffer.
	PLIB_SQI_TxBufferSoftReset	Issues a soft reset to the SQI transmit buffer.
	PLIB_SQI_TapDelaySet	Sets the tap delays.
	PLIB_SQI_DDRModeGet	Return the SQI data rate mode (single/double) value.
	PLIB_SQI_DDRModeSet	Sets SQI communication to DDR mode.

b) Clock Configuration Management Functions

	Name	Description
	PLIB_SQI_ClockDividerSet	Sets the SQI clock (that drives the SQI protocol) divider value. Divides the base clock to generate the SQI clock.
	PLIB_SQI_ClockEnable	Enables the SQI transfer clock.
	PLIB_SQI_ClockIsStable	Returns SQI transfer clock state.

c) XIP Configuration Management Functions

	Name	Description
	PLIB_SQI_XIPAddressBytesGet	Returns the number of address bytes.
	PLIB_SQI_XIPAddressBytesSet	Sets the number of address bytes.
	PLIB_SQI_XIPChipSelectGet	Returns the current active Chip Select.

	PLIB_SQI_XIPChipSelectSet	Activates the Chip Select in XIP mode.
	PLIB_SQI_XIPControlWord1Get	Get the XIP mode Control Word 1.
	PLIB_SQI_XIPControlWord1Set	Sets the XIP mode Control Word 1.
	PLIB_SQI_XIPControlWord2Get	Gets the XIP mode Control Word 2.
	PLIB_SQI_XIPControlWord2Set	Sets the XIP mode Control Word 2.
	PLIB_SQI_XIPDummyBytesGet	Sets the number of dummy bytes.
	PLIB_SQI_XIPDummyBytesSet	Sets the number of dummy bytes.
	PLIB_SQI_XIPLaneModeSet	Selects the lane (Single/Dual/Quad) mode for different transaction in XIP mode.
	PLIB_SQI_XIPModeBytesGet	Returns the number of bytes used for mode code command.
	PLIB_SQI_XIPModeBytesSet	Allocates the bytes for mode code command.
	PLIB_SQI_XIPModeCodeGet	Returns the mode code op-code.
	PLIB_SQI_XIPModeCodeSet	Sets the mode code command.
	PLIB_SQI_XIPReadOpcodeGet	Returns the read op code in XIP mode.
	PLIB_SQI_XIPReadOpcodeSet	Sets the read op code in XIP mode.
	PLIB_SQI_XIPControlWord3Get	Gets the XIP mode Control Word 3.
	PLIB_SQI_XIPControlWord3Set	Sets the XIP mode Control Word 3.
	PLIB_SQI_XIPControlWord4Get	Gets the XIP mode Control Word 4.
	PLIB_SQI_XIPDDRModeSet	Selects the rate mode (SDR/DDR) for different transactions in XIP mode.
	PLIB_SQI_XIPSDRCommandDDRDataGet	Returns the SQI command in SDR mode and Data in DDR mode bit value.
	PLIB_SQI_XIPSDRCommandDDRDataSet	Sets the SQI command in SDR mode.
	PLIB_SQI_XIPControlWord4Set	Sets the XIP mode Control Word 4.

d) PIO Mode Transfer Management Functions

	Name	Description
	PLIB_SQI_ByteCountGet	Returns the current transmit/receive count.
	PLIB_SQI_ByteCountSet	Sets the transmit/receive count.
	PLIB_SQI_ChipSelectDeassertDisable	Clears the Chip Select deassert.
	PLIB_SQI_ChipSelectDeassertEnable	Sets the Chip Select deassert.
	PLIB_SQI_ChipSelectGet	Returns the Chip Select that is currently active.
	PLIB_SQI_ChipSelectSet	Activates the Chip Select.
	PLIB_SQI_ConfigWordGet	Gets the SQI Configuration Word.
	PLIB_SQI_ConfigWordSet	Sets SQI Configuration Word.
	PLIB_SQI_ReceiveBufferIsUnderrun	Returns the status of receive buffer.
	PLIB_SQI_RxBufferThresholdGet	Returns the receive command threshold.
	PLIB_SQI_RxBufferThresholdIntGet	Sets the receive buffer threshold interrupt.
	PLIB_SQI_RxBufferThresholdIntSet	Sets the receive buffer threshold for interrupt.
	PLIB_SQI_RxBufferThresholdSet	Sets the receive command threshold.
	PLIB_SQI_TransferDirectionGet	Returns the transfer command.
	PLIB_SQI_TransferDirectionSet	Sets the transfer command.
	PLIB_SQI_TransmitBufferFreeSpaceGet	Returns the number of transmit buffer words available.
	PLIB_SQI_TransmitBufferHasOverflowed	Returns the current status of the transmit buffer.
	PLIB_SQI_TxBufferThresholdGet	Returns the transmit command threshold value.
	PLIB_SQI_TxBufferThresholdIntGet	Returns the value to trigger the transmit buffer threshold interrupt.
	PLIB_SQI_TxBufferThresholdIntSet	Sets the value to trigger the transmit buffer threshold interrupt.
	PLIB_SQI_TxBufferThresholdSet	Sets the transmit command threshold.

e) Interrupt Control and Status Management Functions

	Name	Description
	PLIB_SQI_InterruptDisable	Disables the interrupt source.
	PLIB_SQI_InterruptEnable	Enables the passed interrupt source.
	PLIB_SQI_InterruptFlagGet	Return SQI Interrupt flag status.
	PLIB_SQI_InterruptIsEnabled	Returns the interrupt state.
	PLIB_SQI_InterruptSignalDisable	Disables the interrupt signal source.
	PLIB_SQI_InterruptSignalEnable	Enables the passed interrupt signal source.
	PLIB_SQI_InterruptSignalIsEnabled	Returns the interrupt signal state.

	PLIB_SQI_DataLineStatus	Returns the logical status of the SQI data lines.
	PLIB_SQI_CommandStatusGet	Returns the SQI command (transmit/receive/idle).
	PLIB_SQI_ConBufWordsAvailable	Returns the number of control buffer words available.

f) DMA Buffer Address Management Functions

	Name	Description
	PLIB_SQI_DMABDBaseAddressGet	Returns the address of the base buffer descriptor.
	PLIB_SQI_DMABDBaseAddressSet	Sets the address of the base buffer descriptor.
	PLIB_SQI_DMABDCurrentAddressGet	Returns the address of the current buffer descriptor in process.

g) DMA Buffer Descriptor Management Functions

	Name	Description
	PLIB_SQI_DMABDControlWordGet	Returns Current Buffer Descriptor Control Word Information.
	PLIB_SQI_DMABDReceiveBufferCountGet	Returns the receive buffer space in bytes.
	PLIB_SQI_DMABDReceiveBufferLengthGet	Returns the receive length in bytes.
	PLIB_SQI_DMABDReceiveStateGet	Returns the current state of the buffer descriptor in progress.
	PLIB_SQI_DMABDTransmitBufferCountGet	Returns the transmit buffer space in bytes.
	PLIB_SQI_DMABDTransmitBufferLengthGet	Returns the transmit length in bytes.
	PLIB_SQI_DMABDTransmitStateGet	Returns the current state of the buffer descriptor in progress.
	PLIB_SQI_DMABDFetchStop	Stops the DMA buffer descriptor fetch process.

h) DMA Control and Status Management Functions

	Name	Description
	PLIB_SQI_DMABDFetchStart	Starts the DMA buffer descriptor fetch process.
	PLIB_SQI_DMABDIsBusy	Returns whether or not the DMA Buffer Descriptor is busy.
	PLIB_SQI_DMABDPollCounterSet	Sets the poll counter value.
	PLIB_SQI_DMABDPollDisable	Disables the buffer descriptor polling.
	PLIB_SQI_DMABDPollEnable	Enables the buffer descriptor polling.
	PLIB_SQI_DMABDPollIsEnabled	Returns whether or not the DMA buffer descriptor poll is enabled.
	PLIB_SQI_DMABDStateGet	Returns the current state of the buffer descriptor in progress.
	PLIB_SQI_DMADisable	Disables the built-in DMA logic.
	PLIB_SQI_DMAEnable	Enables the built-in DMA logic.
	PLIB_SQI_DMAHasStarted	Returns whether or no the DMA process has started.
	PLIB_SQI_DMAIsEnabled	Returns whether or not DMA is enabled.

i) Other Functions

	Name	Description
	PLIB_SQI_StatusCheckSet	Sets the Flash status check related control bits.

j) Feature Existence Functions

	Name	Description
	PLIB_SQI_ExistsBDBaseAddress	Identifies whether the BDBaseAddress feature exists on the SQI module.
	PLIB_SQI_ExistsBDControlWord	Identifies whether the BDControlWord feature exists on the SQI module.
	PLIB_SQI_ExistsBDCurrentAddress	Identifies whether the BDCurrentAddress feature exists on the SQI module.
	PLIB_SQI_ExistsBDPollCount	Identifies whether the BDPollCount feature exists on the SQI module.
	PLIB_SQI_ExistsBDPollingEnable	Identifies whether the BDPollingEnable feature exists on the SQI module.
	PLIB_SQI_ExistsBDProcessState	Identifies whether the BDProcessState feature exists on the SQI module.
	PLIB_SQI_ExistsBDRxBufCount	Identifies whether the BDRxBufCount feature exists on the SQI module.
	PLIB_SQI_ExistsBDRxLength	Identifies whether the BDRxLength feature exists on the SQI module.
	PLIB_SQI_ExistsBDRxState	Identifies whether the BDRxState feature exists on the SQI module.
	PLIB_SQI_ExistsBDTxBufCount	Identifies whether the BDTxBufCount feature exists on the SQI module.
	PLIB_SQI_ExistsBDTxLength	Identifies whether the BDTxLength feature exists on the SQI module.
	PLIB_SQI_ExistsBDTxState	Identifies whether the BDTxState feature exists on the SQI module.
	PLIB_SQI_ExistsBurstControl	Identifies whether the BurstControl feature exists on the SQI module.
	PLIB_SQI_ExistsChipSelect	Identifies whether the ChipSelect feature exists on the SQI module.

	PLIB_SQI_ExistsClockControl	Identifies whether the ClockControl feature exists on the SQI module.
	PLIB_SQI_ExistsClockDivider	Identifies whether the ClockDivider feature exists on the SQI module.
	PLIB_SQI_ExistsClockReady	Identifies whether the ClockReady feature exists on the SQI module.
	PLIB_SQI_ExistsConBufThreshold	Identifies whether the ConBufThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsConfigWord	Identifies whether the ConfigWord feature exists on the SQI module.
	PLIB_SQI_ExistsControlWord	Identifies whether the ControlWord feature exists on the SQI module.
	PLIB_SQI_ExistsCSDeassert	Identifies whether the CSDeassert feature exists on the SQI module.
	PLIB_SQI_ExistsCSOutputEnable	Identifies whether the CSOutputEnable feature exists on the SQI module.
	PLIB_SQI_ExistsDataFormat	Identifies whether the DataFormat feature exists on the SQI module.
	PLIB_SQI_ExistsDataModeControl	Identifies whether the DataModeControl feature exists on the SQI module.
	PLIB_SQI_ExistsDataOutputEnable	Identifies whether the DataOutputEnable feature exists on the SQI module.
	PLIB_SQI_ExistsDataPinStatus	Identifies whether the DataPinStatus feature exists on the SQI module.
	PLIB_SQI_ExistsDmaEnable	Identifies whether the DMAEnable feature exists on the SQI module.
	PLIB_SQI_ExistsDMAEngineBusy	Identifies whether the DMAEngineBusy feature exists on the SQI module.
	PLIB_SQI_ExistsDMAProcessInProgress	Identifies whether the DMAProcessInProgress feature exists on the SQI module.
	PLIB_SQI_ExistsEnableControl	Identifies whether the EnableControl feature exists on the SQI module.
	PLIB_SQI_ExistsHoldPinControl	Identifies whether the HoldPinControl feature exists on the SQI module.
	PLIB_SQI_ExistsInterruptControl	Identifies whether the InterruptControl feature exists on the SQI module.
	PLIB_SQI_ExistsInterruptSignalControl	Identifies whether the InterruptSignalControl feature exists on the SQI module.
	PLIB_SQI_ExistsInterruptStatus	Identifies whether the InterruptStatus feature exists on the SQI module.
	PLIB_SQI_ExistsLaneMode	Identifies whether the LaneMode feature exists on the SQI module.
	PLIB_SQI_ExistsReceiveLatch	Identifies whether the ReceiveLatch feature exists on the SQI module.
	PLIB_SQI_ExistsRxBufferCount	Identifies whether the RxBufferCount feature exists on the SQI module.
	PLIB_SQI_ExistsRxBufIntThreshold	Identifies whether the RxBufIntThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsRxBufThreshold	Identifies whether the RxBufThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsRxData	Identifies whether the RxData feature exists on the SQI module.
	PLIB_SQI_ExistsRxUnderRun	Identifies whether the RxUnderRun feature exists on the SQI module.
	PLIB_SQI_ExistsSoftReset	Identifies whether the SoftReset feature exists on the SQI module.
	PLIB_SQI_ExistsTransferCommand	Identifies whether the TransferCommand feature exists on the SQI module.
	PLIB_SQI_ExistsTransferCount	Identifies whether the TransferCount feature exists on the SQI module.
	PLIB_SQI_ExistsTransferModeControl	Identifies whether the TransferModeControl feature exists on the SQI module.
	PLIB_SQI_ExistsTxBufferFree	Identifies whether the TxBufferFree feature exists on the SQI module.
	PLIB_SQI_ExistsTxBufIntThreshold	Identifies whether the TxBufIntThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsTxBufThreshold	Identifies whether the TxBufThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsTxData	Identifies whether the TxData feature exists on the SQI module.
	PLIB_SQI_ExistsTxOverFlow	Identifies whether the TxOverFlow feature exists on the SQI module.
	PLIB_SQI_ExistsWPPinControl	Identifies whether the WPPinControl feature exists on the SQI module.
	PLIB_SQI_ExistsXIPChipSelect	Identifies whether the XIPChipSelect feature exists on the SQI module.
	PLIB_SQI_ExistsXIPControlWord1	Identifies whether the XIPControlWord1 feature exists on the SQI module.
	PLIB_SQI_ExistsXIPControlWord2	Identifies whether the XIPControlWord2 feature exists on the SQI module.
	PLIB_SQI_ExistsXIPLaneMode	Identifies whether the XIPLaneMode feature exists on the SQI module.
	PLIB_SQI_ExistsXIPModeBytes	Identifies whether the XIPModeBytes feature exists on the SQI module.
	PLIB_SQI_ExistsXIPModeCode	Identifies whether the XIPModeCode feature exists on the SQI module.
	PLIB_SQI_ExistsXIPNumberOfAddressBytes	Identifies whether the XIPNumberOfAddressBytes feature exists on the SQI module.
	PLIB_SQI_ExistsXIPNumberOfDummyBytes	Identifies whether the XIPNumberOfDummyBytes feature exists on the SQI module.
	PLIB_SQI_ExistsXIPReadOpCode	Identifies whether the XIPReadOpCode feature exists on the SQI module.
	PLIB_SQI_ExistsCommandStatus	Identifies whether the CommandStatus feature exists on the SQI module.
	PLIB_SQI_ExistsConBufAvailable	Identifies whether the ConBufWordsAvailable feature exists on the SQI module.
	PLIB_SQI_ExistsConBufferSoftReset	Identifies whether the control buffer soft reset feature exists on the SQI module.
	PLIB_SQI_ExistsDDRMode	Identifies whether the DDRMode feature exists on the SQI module.
	PLIB_SQI_ExistsDMABDFetch	Identifies whether the DMABDFetch feature exists on the SQI module.
	PLIB_SQI_ExistsRxBufferSoftReset	Identifies whether the receive buffer soft reset feature exists on the SQI module.
	PLIB_SQI_ExistsStatusCheck	Identifies whether the StatusCheckSet feature exists on the SQI module.
	PLIB_SQI_ExistsTapDelay	Identifies whether the TapDelay feature exists on the SQI module.
	PLIB_SQI_ExistsTxBufferSoftReset	Identifies whether the transmit buffer soft reset feature exists on the SQI module.

	PLIB_SQI_ExistsXIPControlWord3	Identifies whether the XIPControlWord3 feature exists on the SQI module.
	PLIB_SQI_ExistsXIPControlWord4	Identifies whether the XIPControlWord4 feature exists on the SQI module.
	PLIB_SQI_ExistsXIPDDRMode	Identifies whether the XIPDDRMode feature exists on the SQI module.
	PLIB_SQI_ExistsXIPSDRCommandDDRData	Identifies whether the XIPSDRCommandDDRData feature exists on the SQI module.

k) Data Types and Constants

	Name	Description
	SQI_ADDR_BYTES	Defines the list of SQI address bytes.
	SQI_BD_CTRL_WORD	Defines the list of SQI Buffer Descriptor control word.
	SQI_BD_STATE	Defines the list of SQI Buffer Descriptor states.
	SQI_CLK_DIV	Defines the list of SQI Clock Divider values.
	SQI_CS_NUM	Defines the list of SQI Chip Selects.
	SQI_CS_OEN	Defines the list of SQI Chip Selects on which output is enable.
	SQI_DATA_FORMAT	Defines the Data Format Options available (LSBF/MSBF).
	SQI_DATA_MODE	Defines the list of SQI Data modes.
	SQI_DATA_OEN	Defines the list of SQI Data pins on which output is enabled.
	SQI_DATA_TYPE	Data type defining the SQI Data size.
	SQI_DUMMY_BYTES	Defines the list of SQI dummy bytes.
	SQI_INTERRUPTS	Defines the list of SQI interrupts.
	SQI_LANE_MODE	Defines the list of SQI Lane modes (single/dual/quad).
	SQI_MODE_BYTES	Defines the list of SQI mode bytes.
	SQI_MODULE_ID	Identifies the supported SQI modules.
	SQI_XFER_CMD	Defines the list of SQI transfer commands.
	SQI_XFER_MODE	Defines the list of SQI Transfer modes.

Description

This section describes the Application Programming Interface (API) functions of the SQI Peripheral Library.

Refer to each section for a detailed description.

a) Mode Configuration Management Functions

PLIB_SQI_BurstEnable Function

Sets the burst enable (BURSTEN) function for higher throughput. This function is an artifact of the System Bus architecture.

File

plib_sqi.h

C

```
void PLIB_SQI_BurstEnable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function enables burst mode for higher throughput. Burst mode should always be enabled.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_BurstEnable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_BurstEnable (SQI_MODULE_ID index)

PLIB_SQI_ClockDisable Function

Disables the SQI transfer clock.

File

plib_sqi.h

C

```
void PLIB_SQI_ClockDisable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function disables the SQI transfer clock (divided clock).

Remarks

SQICLK is disabled.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ClockDisable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_ClockDisable (SQI_MODULE_ID index)

PLIB_SQI_ControlBufferThresholdGet Function

Returns the transmit buffer space in bytes.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_ControlBufferThresholdGet(SQI_MODULE_ID index);
```

Returns

Control buffer threshold space.

Description

This function returns the threshold value for the control buffer in bytes.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t conBufThres = PLIB_SQI_ControlBufferThresholdGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_ControlBufferThresholdGet(SQI_MODULE_ID index)

PLIB_SQI_ControlBufferThresholdSet Function

Sets the control buffer threshold value.

File

plib_sqi.h

C

```
void PLIB_SQI_ControlBufferThresholdSet(SQI_MODULE_ID index, uint8_t threshold);
```

Returns

None.

Description

This function sets the control buffer threshold value in bytes, that is used to signal control buffer threshold interrupts.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and MY_CONBUF_THRESHOLD is the threshold value.
PLIB_SQI_ControlBufferThresholdSet(MY_SQI_INSTANCE, MY_CONBUF_THRESHOLD);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
threshold	Control buffer threshold

Function

void PLIB_SQI_ControlBufferThresholdSet(SQI_MODULE_ID index, uint8_t threshold)

PLIB_SQI_ControlWordGet Function

Get the SQI Control Word.

File

plib_sqi.h

C

```
uint32_t PLIB_SQI_ControlWordGet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the SQI Control Word.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint32_t sqiCon = PLIB_SQI_ControlWordGet (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_SQI_ControlWordGet (SQI_MODULE_ID index)

PLIB_SQI_ControlWordSet Function

Sets the SQI Control Word.

File

plib_sqi.h

C

```
void PLIB_SQI_ControlWordSet(SQI_MODULE_ID index, bool csDeassert, SQI_CS_NUM csNum, SQI_LANE_MODE
laneMode, SQI_XFER_CMD command, uint16_t xferCount);
```

Returns

None.

Description

This function sets the SQI Control Word. This function is a combination of several functions in case the driver plans to write the complete Control Word. In PIO mode, the Control word is before each transfer

Remarks

Chip select is not actually asserted, only enabled to be asserted.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ControlWordSet(MY_SQI_INSTANCE,
                        1,
                        SQI_CS_1,
                        SQI_LANE_QUAD,
                        SQI_CMD_TRANSMIT,
                        5
                        );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

csDeassert	Chip select deassert after transfer
csNum	Active Chip Select number (0/1)
laneMode	SQI lane mode (QUAL/DUAL/SINGLE)
command	Transfer command (TRANSMIT/RECIEVE/IDLE)
xferCount	Number of bytes to be transmitted/received

Function

void PLIB_SQI_ControlWordSet(SQI_MODULE_ID index,
bool csDeassert,
SQI_CS_NUM csNum,
SQI_LANE_MODE laneMode,
SQI_XFER_CMD command,
uint16_t xferCount
)

PLIB_SQI_CSOutputEnableSelect Function

Selects the output enables on SQI Chip Select pins.

File

plib_sqi.h

C

```
void PLIB_SQI_CSOutputEnableSelect(SQI_MODULE_ID index, SQI_CS_OEN csPins);
```

Returns

None.

Description

This function enables the selected SQI chip selects as outputs.

Remarks

Chip select is not actually asserted, only enabled to be asserted.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_CSOutputEnableSelect(MY_SQI_INSTANCE, SQI_CS_OEN_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
csPins	Chip select pins for which outputs are enabled

Function

void PLIB_SQI_CSOutputEnableSelect(SQI_MODULE_ID index, SQI_CS_OEN csPins)

PLIB_SQI_DataFormatGet Function

Returns the data format.

File

plib_sqi.h

C

```
SQI_DATA_FORMAT PLIB_SQI_DataFormatGet(SQI_MODULE_ID index);
```

Returns

- true - Data Format is LSBF (i.e., LITTLE-ENDIAN)
- false - Data Format is MSBF

Description

This function returns the SQI data format (LSBF or MSBF).

Remarks

Typical data format in most of systems is LITTLE-ENDIAN.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
SQI_DATA_FORMAT dataFormat = PLIB_SQI_DataFormatGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_DATA_FORMAT PLIB_SQI_DataFormatGet(SQI_MODULE_ID index)

PLIB_SQI_DataFormatSet Function

Sets the data format to Least Significant Bit First (LSBF)..

File

plib_sqi.h

C

```
void PLIB_SQI_DataFormatSet(SQI_MODULE_ID index, SQI_DATA_FORMAT dataformat);
```

Returns

None.

Description

This function sets the SQI data format to LSBF (i.e., LITTLE-ENDIAN).

Remarks

Typical data format in most of the Systems is LITTLE ENDIAN.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DataFormatSet(MY_SQI_INSTANCE, SQI_DATA_FORMAT_LSBF);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_DataFormatSet(SQI_MODULE_ID index, SQI_DATA_FORMAT dataformat)

PLIB_SQI_DataModeSet Function

Sets the SQI data mode of operation.

File

plib_sqi.h

C

```
void PLIB_SQI_DataModeSet(SQI_MODULE_ID index, SQI_DATA_MODE mode);
```

Returns

None.

Description

This function sets the data mode to be SPI Mode 0, SPI Mode 3, or Serial Flash.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and SQI_DATA_MODE_3 is an enum element.
PLIB_SQI_DataModeSet(MY_SQI_INSTANCE, SQI_DATA_MODE_SF);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	Data mode (Mode 0/Mode 3)

Function

void PLIB_SQI_DataModeSet(SQI_MODULE_ID index, SQI_DATA_MODE mode)

PLIB_SQI_DataOutputEnableSelect Function

Selects the output enables on SQI data outputs.

File

plib_sqi.h

C

```
void PLIB_SQI_DataOutputEnableSelect(SQI_MODULE_ID index, SQI_DATA_OEN dataPins);
```

Returns

None.

Description

This function enables the selected SQI data lines as outputs.

Remarks

Chip select is not actually asserted, only enabled to be asserted.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DataOutputEnableSelect(MY_SQI_INSTANCE, SQI_DATA_OEN_DUAL);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
dataPins	Data pins for which outputs are enabled

Function

void PLIB_SQI_DataOutputEnableSelect (SQI_MODULE_ID index, SQI_DATA_OEN dataPins)

PLIB_SQI_Disable Function

Disables the SQI module.

File

plib_sqi.h

C

```
void PLIB_SQI_Disable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function disables the SQI module.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_Disable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_Disable (SQI_MODULE_ID index)

PLIB_SQI_Enable Function

Enables the SQI module.

File

plib_sqi.h

C

```
void PLIB_SQI_Enable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function enables the SQI module.

Remarks

The SQICLK, SQICSx, SQID0, SQID1, SQID2, and SQID3 pins must be assigned to available RPn pins before use.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_Enable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_Enable(SQI_MODULE_ID index)

PLIB_SQI_HoldClear Function

Clears the hold function to be disabled on SQID3 in single and dual lane modes.

File

plib_sqi.h

C

```
void PLIB_SQI_HoldClear(SQI_MODULE_ID index);
```

Returns

None.

Description

This function sets SQID3 to be controlled by SQI for normal data operation.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_HoldClear(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_HoldClear (SQI_MODULE_ID index)

PLIB_SQI_HoldGet Function

Gets the status of HOLD function on SQID3 pin.

File

plib_sqi.h

C

```
bool PLIB_SQI_HoldGet(SQI_MODULE_ID index);
```

Returns

SQID3 as HOLD pin value.

Description

This function gets the status of HOLD function on SQID3 pin.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool holdStatus = PLIB_SQI_HoldGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_HoldGet (SQI_MODULE_ID index)

PLIB_SQI_HoldSet Function

Sets the hold function to be enabled on SQID3 in single or dual lane modes.

File

plib_sqi.h

C

```
void PLIB_SQI_HoldSet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function sets the SQID3 pin to HIGH/LOW to be be used for hold function in single and dual lane modes for supported Flash memories.

Remarks

This function should be used only when SQI is in single/dual lane modes.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_HoldSet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_HoldSet (SQI_MODULE_ID index)

PLIB_SQI_LaneModeGet Function

Returns the lane mode (single/dual/quad).

File

plib_sqi.h

C

```
SQI_LANE_MODE PLIB_SQI_LaneModeGet(SQI_MODULE_ID index);
```

Returns

Lane mode (single/dual/quad).

Description

This function returns the number of lanes (single/dual/quad) used for transfers.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
SQI_LANE_MODE laneMode = PLIB_SQI_LaneModeGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_LANE_MODE PLIB_SQI_LaneModeGet (SQI_MODULE_ID index)

PLIB_SQI_LaneModeSet Function

Sets the data lane mode (single/dual/quad).

File

plib_sqi.h

C

```
void PLIB_SQI_LaneModeSet(SQI_MODULE_ID index, SQI_LANE_MODE mode);
```

Returns

None.

Description

This function sets the number of lanes (single/dual/quad) used for transfers.

Remarks

None.

Preconditions

Make sure the output enable is selected on the data lines using PLIB_SQI_DataOutputEnableSelect. The device needs to be programmed to the same mode that the SQI controller is set to (may require special commands).

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_LaneModeSet(MY_SQI_INSTANCE, SQI_LANE_QUAD);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	Lane mode (single/dual/quad)

Function

void PLIB_SQI_LaneModeSet (SQI_MODULE_ID index, SQI_LANE_MODE mode)

PLIB_SQI_NumberOfReceiveBufferReads Function

Returns the number of receive buffer reads.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_NumberOfReceiveBufferReads(SQI_MODULE_ID index);
```

Returns

Number of Receive Buffer Reads.

Description

This function returns the number of receive buffer reads for debug purpose.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t rxBufReads = PLIB_SQI_ReceiveBufferReadsGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_ReceiveBufferReadsGet(SQI_MODULE_ID index)

PLIB_SQI_ReceiveData Function

Reads the data from the receive buffer.

File

plib_sqi.h

C

```
uint32_t PLIB_SQI_ReceiveData(SQI_MODULE_ID index);
```

Returns

None.

Description

This function reads the data from the SQI receive buffer.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
```

```
// application developer.
uint32_t receivedData= PLIB_SQI_ReceiveData(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_SQI_ReceiveData (SQI_MODULE_ID index)

PLIB_SQI_ReceiveLatchDisable Function

Disables the receive latch so receive data is discarded when in transmit mode.

File

plib_sqi.h

C

```
void PLIB_SQI_ReceiveLatchDisable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function disables the receive latch, which disables the receive data to be latched in transmit mode.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ReceiveLatchDisable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_ReceiveLatchDisable (SQI_MODULE_ID index)

PLIB_SQI_ReceiveLatchEnable Function

Enables the receive latch so receive data is latched during transmit mode.

File

plib_sqi.h

C

```
void PLIB_SQI_ReceiveLatchEnable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function enables the receive latch, which latches receive data in transmit mode. Otherwise, receive data in transmit mode is discarded.

Remarks

As most of the SQI communication is half-duplex, enable this function only when it is absolutely required.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ReceiveLatchEnable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_ReceiveLatchEnable (SQI_MODULE_ID index)

PLIB_SQI_ReceiveLatchGet Function

Returns the receive latch status in transmit mode.

File

plib_sqi.h

C

```
bool PLIB_SQI_ReceiveLatchGet(SQI_MODULE_ID index);
```

Returns

- true - Receive latch is set
- false - Receive latch is not set

Description

This function returns the receive latch status in transmit mode. Returns true, if latch is set (enabling latching of receive buffer data), false if latch is not set (disabling the latching of the receive buffer data).

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool rxLatch = PLIB_SQI_ReceiveLatchGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_ReceiveLatchGet (SQI_MODULE_ID index)

PLIB_SQI_SoftReset Function

Issues a soft reset to the SQI module.

File

plib_sqi.h

C

```
void PLIB_SQI_SoftReset(SQI_MODULE_ID index);
```

Returns

None.

Description

This function issues a software reset to the SQI module clearing all the read/write register, internal state machines and data buffers.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_SoftReset(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_SoftReset (SQI_MODULE_ID index)

PLIB_SQI_TransferModeGet Function

Returns the SQI transfer mode of operation.

File

plib_sqi.h

C

```
SQI_XFER_MODE PLIB_SQI_TransferModeGet(SQI_MODULE_ID index);
```

Returns

Transfer mode (PIO/DMA/XIP).

Description

This function returns the SQI transfer mode of operation: PIO, DMA, or XIP.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
SQI_XFER_MODE xferMode = PLIB_SQI_TransferModeGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured.

Function

SQI_XFER_MODE PLIB_SQI_TransferModeGet (SQI_MODULE_ID index)

PLIB_SQI_TransferModeSet Function

Sets the SQI transfer mode of operation.

File

plib_sqi.h

C

```
void PLIB_SQI_TransferModeSet(SQI_MODULE_ID index, SQI_XFER_MODE mode);
```

Returns

None.

Description

This function sets the SQI transfer mode of operation, (PIO, DMA, or XIP.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and SQI_XFER_MODE_DMA is an enum element.
PLIB_SQI_TransferModeSet(MY_SQI_INSTANCE, SQI_XFER_MODE_DMA);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	Transfer mode (PIO/DMA/XIP)

Function

void PLIB_SQI_TransferModeSet (SQI_MODULE_ID index, SQI_XFER_MODE mode)

PLIB_SQI_TransmitData Function

Writes data into the SQI transmit buffer.

File

plib_sqi.h

C

```
void PLIB_SQI_TransmitData(SQI_MODULE_ID index, uint32_t data);
```

Returns

None.

Description

This function writes the data into the SQI transmit buffer, which will be eventually sent out on SQI bus.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and MY_TRANSMIT_DATA is the data to be sent.
PLIB_SQI_TransmitData(MY_SQI_INSTANCE, MY_TRANSMIT_DATA);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

data	Data to be transmitted

Function

void PLIB_SQI_TransmitData (SQI_MODULE_ID index, uint32_t data)

PLIB_SQI_WriteProtectClear Function

Clears the Write-Protect function to be disabled on SQID2 in single or dual lane modes.

File

plib_sqi.h

C

```
void PLIB_SQI_WriteProtectClear(SQI_MODULE_ID index);
```

Returns

None.

Description

This function disables the SQID2 pin to be used for write-protect.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_WriteProtectClear(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_WriteProtectClear (SQI_MODULE_ID index)

PLIB_SQI_WriteProtectGet Function

Gets the state of the write-protect feature on SQID2.

File

plib_sqi.h

C

```
bool PLIB_SQI_WriteProtectGet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the write-protect feature status on the SQID2 pin.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool wpStatus = PLIB_SQI_WriteProtectGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_WriteProtectGet (SQI_MODULE_ID index)

PLIB_SQI_WriteProtectSet Function

Sets the write-protect feature to be enabled on SQID2 in single or dual lane modes only.

File

plib_sqi.h

C

```
void PLIB_SQI_WriteProtectSet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function enables the SQID2 pin to be used for write-protect in single and dual lane modes for supported Flash memories.

Remarks

This function should be used only when SQI is in single/dual lane modes.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_WriteProtectSet (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_WriteProtectSet (SQI_MODULE_ID index)

PLIB_SQI_ConBufferSoftReset Function

Issues a soft reset to the SQI control buffer.

File

plib_sqi.h

C

```
void PLIB_SQI_ConBufferSoftReset(SQI_MODULE_ID index);
```

Returns

None.

Description

This function issues a soft reset to the SQI control buffer clearing all the data in the buffer and addresses.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ConBufferSoftReset(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_ConBufferSoftReset (SQI_MODULE_ID index)

PLIB_SQI_RxBufferSoftReset Function

Issues a soft reset to the SQI receive buffer.

File

plib_sqi.h

C

```
void PLIB_SQI_RxBufferSoftReset(SQI_MODULE_ID index);
```

Returns

None.

Description

This function issues a soft reset to the SQI receive buffer clearing all the data in the buffer and addresses.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_RxBufferSoftReset(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_RxBufferSoftReset (SQI_MODULE_ID index)

PLIB_SQI_TxBufferSoftReset Function

Issues a soft reset to the SQI transmit buffer.

File

plib_sqi.h

C

```
void PLIB_SQI_TxBufferSoftReset(SQI_MODULE_ID index);
```

Returns

None.

Description

This function issues a soft reset to the SQI transmit buffer clearing all the data in the buffer and addresses.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_TxBufferSoftReset(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_TxBufferSoftReset (SQI_MODULE_ID index)

PLIB_SQI_TapDelaySet Function

Sets the tap delays.

File

plib_sqi.h

C

```
void PLIB_SQI_TapDelaySet(SQI_MODULE_ID index, uint8_t sdrClkInDly, uint8_t dataOutDly, uint8_t clkOutDly);
```

Returns

SQI command (transmit/receive/idle) that is currently being executed.

Description

Sets the tap delays that might be required at the higher interface speeds to handle data set-up and hold delays.

Remarks

This function should be used only when the SQI returns failures at maximum frequency.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
void PLIB_SQI_TapDelaySet(SQI_MODULE_ID index,
                          8,
                          0,
                          2
                          );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_TapDelaySet(SQI_MODULE_ID index,

uint8_t sdrClkInDly,
uint8_t dataOutDly,
uint8_t clkOutDly
);

PLIB_SQI_DDRModeGet Function

Return the SQI data rate mode (single/double) value.

File

plib_sqi.h

C

```
bool PLIB_SQI_DDRModeGet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the SQI communication mode value.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool pioDDRMode = PLIB_SQI_DDRModeGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_DDRModeGet(SQI_MODULE_ID index)

PLIB_SQI_DDRModeSet Function

Sets SQI communication to DDR mode.

File

plib_sqi.h

C

```
void PLIB_SQI_DDRModeSet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function sets SQI communication to DDR mode.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DDRModeSet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_DDRModeSet(SQI_MODULE_ID index)

b) Clock Configuration Management Functions

PLIB_SQI_ClockDividerSet Function

Sets the SQI clock (that drives the SQI protocol) divider value. Divides the base clock to generate the SQI clock.

File

plib_sqi.h

C

```
void PLIB_SQI_ClockDividerSet(SQI_MODULE_ID index, SQI_CLK_DIV clkDivider);
```

Returns

None.

Description

This function sets the SQI clock divider value.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ClockDividerSet(MY_SQI_INSTANCE, CLK_DIV_1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
clkDivider	Clock divider value

Function

void PLIB_SQI_ClockDividerSet (SQI_MODULE_ID index, SQI_CLK_DIV clkDivider)

PLIB_SQI_ClockEnable Function

Enables the SQI transfer clock.

File

plib_sqi.h

C

```
void PLIB_SQI_ClockEnable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function enables the SQI transfer clock (divided clock).

Remarks

SQICLK is enabled.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ClockEnable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_ClockEnable (SQI_MODULE_ID index)

PLIB_SQI_ClockIsStable Function

Returns SQI transfer clock state.

File

plib_sqi.h

C

```
bool PLIB_SQI_ClockIsStable(SQI_MODULE_ID index);
```

Returns

True if clock is stable and false if it is not.

Description

This function returns the SQI transfer clock state.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool clockState = PLIB_SQI_ClockIsStable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_ClockIsStable (SQI_MODULE_ID index)

c) XIP Configuration Management Functions

PLIB_SQI_XIPAddressBytesGet Function

Returns the number of address bytes.

File

plib_sqi.h

C

```
SQI_ADDR_BYTES PLIB_SQI_XIPAddressBytesGet(SQI_MODULE_ID index);
```

Returns

Number of Address Bytes.

Description

This function returns the number of address bytes to be sent to the flash.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t addressBytes = PLIB_SQI_XIPAddressBytesGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_ADDR_BYTES PLIB_SQI_XIPAddressBytesGet (SQI_MODULE_ID index)

PLIB_SQI_XIPAddressBytesSet Function

Sets the number of address bytes.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPAddressBytesSet(SQI_MODULE_ID index, SQI_ADDR_BYTES bytes);
```

Returns

None.

Description

This function sets the number of address bytes to be sent to the flash. Typical flash address bytes are 3 (24-bit address).

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPAddressBytesSet(MY_SQI_INSTANCE, ADDR_BYTES_3);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
bytes	Number of address bytes

Function

void PLIB_SQI_XIPAddressBytesSet (SQI_MODULE_ID index, SQI_ADDR_BYTES bytes)

PLIB_SQI_XIPChipSelectGet Function

Returns the current active Chip Select.

File

plib_sqi.h

C

```
SQI_CS_NUM PLIB_SQI_XIPChipSelectGet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the active Chip Select in XIP mode.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
SQI_CS_NUM xipCSActive = (PLIB_SQI_XIPChipSelectGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_CS_NUM PLIB_SQI_XIPChipSelectGet (SQI_MODULE_ID index)

PLIB_SQI_XIPChipSelectSet Function

Activates the Chip Select in XIP mode.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPChipSelectSet(SQI_MODULE_ID index, SQI_CS_NUM csNum);
```

Returns

None.

Description

This function sets the Chip Select that is active in XIP mode.

Remarks

None.

Preconditions

Make sure the Chip Select output enable is selected on the CS lines (PLIB_SQI_CSOutputEnableSelect).

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPChipSelectSet(MY_SQI_INSTANCE, SQI_CS_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
csNum	Chip select number

Function

void PLIB_SQI_XIPChipSelectSet (SQI_MODULE_ID index, SQI_CS_NUM csNum)

PLIB_SQI_XIPControlWord1Get Function

Get the XIP mode Control Word 1.

File

plib_sqi.h

C

```
uint32_t PLIB_SQI_XIPControlWord1Get(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the XIP mode Control Word 1.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint32_t xipCon1 = PLIB_SQI_XIPControlWord1Set (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_SQI_XIPControlWord1Get (SQI_MODULE_ID index)

PLIB_SQI_XIPControlWord1Set Function

Sets the XIP mode Control Word 1.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPControlWord1Set(SQI_MODULE_ID index, SQI_DUMMY_BYTES dummyBytes, SQI_ADDR_BYTES
addressBytes, uint8_t readOpcode, SQI_LANE_MODE dataLaneMode, SQI_LANE_MODE dummyLaneMode, SQI_LANE_MODE
modeCodeLaneMode, SQI_LANE_MODE addressLaneMode, SQI_LANE_MODE cmdLaneMode);
```

Returns

None.

Description

This function sets XIP mode Control Word 1. This function combines work of multiple PLIB APIs and can be used by the driver where complete XIP Control Word 1 is being modified.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPControlWord1Set (MY_SQI_INSTANCE,
                             DUMMY_BYTES_2,
                             ADDR_BYTES_3,
                             0x0B,
                             SQI_LANE_QUAD,
                             SQI_LANE_QUAD,
                             SQI_LANE_QUAD,
                             SQI_LANE_QUAD,
                             SQI_LANE_QUAD,
                            );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
dummyBytes	Number of dummy bytes (0-7)
addressBytes	Number of address bytes (0-4)
readOpcode	Quad flash read opcode (ex: 0x0B)
dataLaneMode	Number of SQI data lanes used for sending data bytes
dummyLaneMode	Number of SQI data lanes used for sending dummy bytes
modeCodeLaneMode	Number of SQI data lanes used for sending mode code
addressLaneMode	Number of SQI data lanes used for sending address
cmdLaneMode	Number of SQI data lanes used for sending command

Function

```
void PLIB_SQI_XIPControlWord1Set (  SQI_MODULE_ID   index,
                                   SQI_DUMMY_BYTES dummyBytes,
                                   SQI_ADDR_BYTES  addressBytes,
uint8_t        readOpcode,
                                   SQI_LANE_MODE   dataLaneMode,
                                   SQI_LANE_MODE   dummyLaneMode,
                                   SQI_LANE_MODE   modeCodeLaneMode,
                                   SQI_LANE_MODE   addressLaneMode,
                                   SQI_LANE_MODE   cmdLaneMode
)
```

PLIB_SQI_XIPControlWord2Get Function

Gets the XIP mode Control Word 2.

File

plib_sqi.h

C

```
uint32_t PLIB_SQI_XIPControlWord2Get(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the XIP mode Control Word 2.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint32_t xipCon2 = PLIB_SQI_XIPControlWord2Get (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_SQI_XIPControlWord2Get (SQI_MODULE_ID index)

PLIB_SQI_XIPControlWord2Set Function

Sets the XIP mode Control Word 2.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPControlWord2Set(SQI_MODULE_ID index, SQI_CS_NUM devSelect, SQI_MODE_BYTES modeBytes,
uint8_t modeCode);
```

Returns

None.

Description

This function sets XIP mode Control Word 2. This function combines work of multiple PLIB APIs and can be used by the driver where complete XIP Control Word 2 is being modified.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPControlWord2Set (MY_SQI_INSTANCE,
                             SQI_CS_0,
                             MODE_BYTES_0,
                             0x0
                            );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
modeCode	Mode code used for supported flash devices

modeBytes	Number of mode code bytes
devSelect	Chip select for XIP mode

Function

void PLIB_SQI_XIPControlWord2Set (SQI_MODULE_ID index,
SQI_CS_NUM devSelect,
SQI_MODE_BYTES modeBytes,
uint8_t modeCode
)

PLIB_SQI_XIPDummyBytesGet Function

Sets the number of dummy bytes.

File

plib_sqi.h

C

```
SQI_DUMMY_BYTES PLIB_SQI_XIPDummyBytesGet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the number of dummy bytes to be sent to the flash after the address bytes, i.e., before doing a fast read.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t dummyBytes = PLIB_SQI_XIPDummyBytesGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_DUMMY_BYTES PLIB_SQI_XIPDummyBytesGet (SQI_MODULE_ID index)

PLIB_SQI_XIPDummyBytesSet Function

Sets the number of dummy bytes.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPDummyBytesSet(SQI_MODULE_ID index, SQI_DUMMY_BYTES bytes);
```

Returns

None.

Description

This function sets the number of dummy bytes to be sent to the flash after the address bytes, i.e., before doing a fast read.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPDummyBytesSet(MY_SQI_INSTANCE, DUMMY_BYTE_1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
bytes	Number of dummy bytes

Function

void PLIB_SQI_XIPDummyBytesSet (SQI_MODULE_ID index, SQI_DUMMY_BYTES bytes)

PLIB_SQI_XIPLaneModeSet Function

Selects the lane (Single/Dual/Quad) mode for different transaction in XIP mode.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPLaneModeSet(SQI_MODULE_ID index, SQI_LANE_MODE dataLanes, SQI_LANE_MODE dummyLanes,
SQI_LANE_MODE modeLanes, SQI_LANE_MODE addrLanes, SQI_LANE_MODE cmdLanes);
```

Returns

None.

Description

This function selects the lane (Single/Dual/Quad) mode for different transaction in XIP mode.

Remarks

This function can't be called when in XIP mode.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPLaneModeSet(MY_SQI_INSTANCE,
                        SQI_QUAD_SINGLE,
                        SQI_QUAD_SINGLE,
                        SQI_QUAD_SINGLE,
                        SQI_QUAD_SINGLE,
                        SQI_QUAD_SINGLE
                       );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
dataLanes	Data lane mode (single/dual/quad)
dummyLanes	Dummy lane mode (single/dual/quad)
modeLanes	Mode lane mode (single/dual/quad)
addrLanes	Address lane mode (single/dual/quad)
cmdLanes	Command lane mode (single/dual/quad)

Function

void PLIB_SQI_XIPLaneModeSet (SQI_MODULE_ID index,
SQI_LANE_MODE dataLanes,
SQI_LANE_MODE dummyLanes,
SQI_LANE_MODE modeLanes,
SQI_LANE_MODE addrLanes,
SQI_LANE_MODE cmdLanes
)

PLIB_SQI_XIPModeBytesGet Function

Returns the number of bytes used for mode code command.

File

plib_sqi.h

C

```
SQI_MODE_BYTES PLIB_SQI_XIPModeBytesGet(SQI_MODULE_ID index);
```

Returns

Number of Bytes used for Mode Code Command.

Description

This function returns the number of bytes for the mode code command in XIP mode.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
SQI_MODE_BYTES modeCodeBytes = PLIB_SQI_XIPModeBytesGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_MODE_BYTES PLIB_SQI_XIPModeBytesGet (SQI_MODULE_ID index)

PLIB_SQI_XIPModeBytesSet Function

Allocates the bytes for mode code command.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPModeBytesSet(SQI_MODULE_ID index, SQI_MODE_BYTES bytes);
```

Returns

None.

Description

This function sets the number of bytes for the mode code command in XIP mode.

Remarks

Refer to serial device data sheet for the details on this command.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPModeBytesSet(MY_SQI_INSTANCE, MODE_BYTES_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
bytes	Number of bytes of Mode code

Function

void PLIB_SQI_XIPModeBytesSet (SQI_MODULE_ID index, SQI_MODE_BYTES bytes)

PLIB_SQI_XIPModeCodeGet Function

Returns the mode code op-code.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_XIPModeCodeGet(SQI_MODULE_ID index);
```

Returns

Mode Code Opcode.

Description

This function returns the mode code command (opcode) in XIP mode for the devices that support it.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t modeCode = PLIB_SQI_XIPModeCodeGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_XIPModeCodeGet (SQI_MODULE_ID index)

PLIB_SQI_XIPModeCodeSet Function

Sets the mode code command.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPModeCodeSet(SQI_MODULE_ID index, uint8_t code);
```

Returns

None.

Description

This function sets the mode code command in XIP mode for the supported flash devices.

Remarks

Some of the devices seems to support this command, refer to specific serial device data sheet for op-code and sequence details.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPModeCodeSet(MY_SQI_INSTANCE, MY_MODE_CODE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
code	Mode code (byte)

Function

void PLIB_SQI_XIPModeCodeSet (SQI_MODULE_ID index, uint8_t code)

PLIB_SQI_XIPReadOpcodeGet Function

Returns the read op code in XIP mode.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_XIPReadOpcodeGet(SQI_MODULE_ID index);
```

Returns

Read Opcode.

Description

This function returns the read op code used in XIP mode.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t readOpcode = PLIB_SQI_XIPReadOpcodeGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_XIPReadOpcodeGet (SQI_MODULE_ID index)

PLIB_SQI_XIPReadOpcodeSet Function

Sets the read op code in XIP mode.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPReadOpcodeSet(SQI_MODULE_ID index, uint8_t opCode);
```

Returns

None.

Description

This function sets the flash read opcode in XIP mode. Value of read op code depends on the Flash device attached.

Remarks

Refer to the Flash device data sheet for supported read op codes.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and MY_READ_OPCODE is the op code dependent on
// attached serial device.
PLIB_SQI_XIPReadOpcodeSet(MY_SQI_INSTANCE, MY_READ_OPCODE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
opCode	Flash read op code

Function

void PLIB_SQI_XIPReadOpcodeSet (SQI_MODULE_ID index, uint8_t opCode)

PLIB_SQI_XIPControlWord3Get Function

Gets the XIP mode Control Word 3.

File

plib_sqi.h

C

```
uint32_t PLIB_SQI_XIPControlWord3Get(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the XIP mode Control Word 3.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
```

```
uint32_t xipCon3 = PLIB_SQI_XIPControlWord3Get (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_SQI_XIPControlWord3Get (SQI_MODULE_ID index)

PLIB_SQI_XIPControlWord3Set Function

Sets the XIP mode Control Word 3.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPControlWord3Set(SQI_MODULE_ID index, bool initStatCheck, uint8_t initCmdCount,
SQI_LANE_MODE initCmdType, uint8_t initCmd3, uint8_t initCmd2, uint8_t initCmd1);
```

Returns

None.

Description

This function sets XIP mode Control Word 3. This function is used to set multiple commands in XIP mode.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPControlWord2Set (MY_SQI_INSTANCE,
                             0,
                             3,
                             SQI_LANE_QUAD,
                             0x06,              //WEN
                             0x99,              //RST
                             0x66               //RSTEN
                            );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
initStatCheck	Flash status check at the end of initialization commands
initCmdCount	Number of mode code bytes
initCmdType	Chip select for XIP mode
initCmd3	Command 3
initCmd2	Command 2
initCmd1	Command 1

Function

void PLIB_SQI_XIPControlWord3Set (SQI_MODULE_ID index,
bool initStatCheck,
uint8_t initCmdCount,
SQI_LANE_MODE initCmdType,
uint8_t initCmd3,
uint8_t initCmd2,

uint8_t initCmd1
)

PLIB_SQI_XIPControlWord4Get Function

Gets the XIP mode Control Word 4.

File

plib_sqi.h

C

```
uint32_t PLIB_SQI_XIPControlWord4Get(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the XIP mode Control Word 4.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint32_t xipCon4 = PLIB_SQI_XIPControlWord4Get (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_SQI_XIPControlWord4Get (SQI_MODULE_ID index)

PLIB_SQI_XIPDDRModeSet Function

Selects the rate mode (SDR/DDR) for different transactions in XIP mode.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPDDRModeSet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function selects the double data rate mode for different transactions (command, address, dummy and data etc.,) in XIP mode of operation

Remarks

This function can't be called when in XIP mode. The device is set in SDR mode if this function is not invoked.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
```

```
PLIB_SQI_XIPDDRModeSet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_XIPDDRModeSet (SQI_MODULE_ID index)

PLIB_SQI_XIPSDRCommandDDRDataGet Function

Returns the SQI command in SDR mode and Data in DDR mode bit value.

File

plib_sqi.h

C

```
bool PLIB_SQI_XIPSDRCommandDDRDataGet(SQI_MODULE_ID index);
```

Returns

Returns true if the bit is set and false if it's cleared.

Description

This function returns the command to be transferred in SDR mode and data in DDR mode bit value. Some serial flash devices require the sequence to send command in SDR mode and the rest of the data (including address bytes) in DDR mode

Remarks

This function can't be called when in XIP mode.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool cmdsdrValue = PLIB_SQI_XIPSDRCommandDDRDataGet (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_XIPSDRCommandDDRDataGet (SQI_MODULE_ID index)

PLIB_SQI_XIPSDRCommandDDRDataSet Function

Sets the SQI command in SDR mode.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPSDRCommandDDRDataSet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function sets the command to be transferred in SDR mode and data in DDR mode. Some serial flash devices require the sequence to send command in SDR mode and the rest of the data (including address bytes) in DDR mode

Remarks

This function can't be called when in XIP mode. This function has no affect if the set-up is working in single lane mode.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPSDRCommandDDRDataSet (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_XIPSDRCommandDDRDataSet (SQI_MODULE_ID index)

PLIB_SQI_XIPControlWord4Set Function

Sets the XIP mode Control Word 4.

File

plib_sqi.h

C

```
void PLIB_SQI_XIPControlWord4Set(SQI_MODULE_ID index, bool initStatCheck, uint8_t initCmdCount,
SQI_LANE_MODE initCmdType, uint8_t initCmd3, uint8_t initCmd2, uint8_t initCmd1);
```

Returns

None.

Description

This function sets XIP mode Control Word 4. This function is used to set multiple commands in XIP mode.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_XIPControlWord4Set (MY_SQI_INSTANCE,
                             0,
                             1,
                             SQI_LANE_QUAD,
                             0x00,
                             0x00,
                             0xC7              //Chip Erase
                            );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
initStatCheck	Flash status check at the end of initialization commands
initCmdCount	Number of mode code bytes
initCmdType	Chip select for XIP mode
initCmd3	Command 3
initCmd2	Command 2

initCmd1	Command 1

Function

void PLIB_SQI_XIPControlWord4Set (SQI_MODULE_ID index,
bool initStatCheck,
uint8_t initCmdCount,
SQI_LANE_MODE initCmdType,
uint8_t initCmd3,
uint8_t initCmd2,
uint8_t initCmd1
)

d) PIO Mode Transfer Management Functions

PLIB_SQI_ByteCountGet Function

Returns the current transmit/receive count.

File

plib_sqi.h

C

```
uint16_t PLIB_SQI_ByteCountGet(SQI_MODULE_ID index);
```

Returns

Transfer Count.

Description

This function returns the transmit/receive count, which is set by software and is actively controlled and maintained by hardware.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint16_t xferCount = PLIB_SQI_ByteCountGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
count	Transmit/Receive count

Function

uint16_t PLIB_SQI_ByteCountGet (SQI_MODULE_ID index)

PLIB_SQI_ByteCountSet Function

Sets the transmit/receive count.

File

plib_sqi.h

C

```
void PLIB_SQI_ByteCountSet(SQI_MODULE_ID index, uint16_t xferCount);
```

Returns

None.

Description

This function sets the number of bytes to transmit or receive, which is set by software and is actively controlled and maintained by hardware.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and MY_XFER_COUNT is the transfer count.
PLIB_SQI_ByteCountSet(MY_SQI_INSTANCE, MY_XFER_COUNT);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
count	Transmit/Receive count

Function

void PLIB_SQI_ByteCountSet (SQI_MODULE_ID index, uint16_t xferCount)

PLIB_SQI_ChipSelectDeassertDisable Function

Clears the Chip Select deassert.

File

plib_sqi.h

C

```
void PLIB_SQI_ChipSelectDeassertDisable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function disables the Chip Select deassert. Chip Select stays asserted after transmission or reception of specified number of bytes.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ChipSelectDeassertDisable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_ChipSelectDeassertDisable(SQI_MODULE_ID index)

PLIB_SQI_ChipSelectDeassertEnable Function

Sets the Chip Select deassert.

File

plib_sqi.h

C

```
void PLIB_SQI_ChipSelectDeassertEnable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function enables Chip Select deassert. Chip Select is deasserted after transmission or reception of the specified number of bytes.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ChipSelectDeassertEnable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_ChipSelectDeassertEnable (SQI_MODULE_ID index)

PLIB_SQI_ChipSelectGet Function

Returns the Chip Select that is currently active.

File

plib_sqi.h

C

```
SQI_CS_NUM PLIB_SQI_ChipSelectGet(SQI_MODULE_ID index);
```

Returns

Chip Select (2-bit) - Current Chip Select active (0/1).

Description

This function returns the Chip Select that is currently active.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
SQI_CS_NUM csNum = PLIB_SQI_ChipSelectGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_CS_NUM PLIB_SQI_ChipSelectGet(SQI_MODULE_ID index)

PLIB_SQI_ChipSelectSet Function

Activates the Chip Select.

File

plib_sqi.h

C

```
void PLIB_SQI_ChipSelectSet(SQI_MODULE_ID index, SQI_CS_NUM csNum);
```

Returns

None.

Description

This function sets the Chip Select to be activated on the next transaction.

Remarks

None.

Preconditions

Make sure the Chip Select output enable is selected on the CS lines (PLIB_SQI_CSOutputEnableSelect).

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and SQI_CS_NUM_0 is the enum element.
PLIB_SQI_ChipSelectSet(MY_SQI_INSTANCE, SQI_CS_NUM_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
csNum	Chip select number

Function

void PLIB_SQI_ChipSelectSet (SQI_MODULE_ID index, SQI_CS_NUM csNum)

PLIB_SQI_ConfigWordGet Function

Gets the SQI Configuration Word.

File

plib_sqi.h

C

```
uint32_t PLIB_SQI_ConfigWordGet(SQI_MODULE_ID index);
```

Returns

None.

Description

This function returns the SQI Configuration Word.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint32_t sqiCfg = PLIB_SQI_ConfigWordGet (MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_SQI_ConfigWordGet (SQI_MODULE_ID index)

PLIB_SQI_ConfigWordSet Function

Sets SQI Configuration Word.

File

plib_sqi.h

C

```
void PLIB_SQI_ConfigWordSet(SQI_MODULE_ID index, bool sqiEnable, SQI_CS_OEN csPins, SQI_DATA_OEN dataPins,
bool reset, bool burstEn, bool hold, bool writeProtect, bool rxLatch, SQI_DATA_FORMAT lsbf, SQI_DATA_MODE
dataMode, SQI_XFER_MODE xferMode);
```

Returns

None.

Description

This function sets the SQI Configuration Word. This function is a combination of several function in case the driver plans to write the complete Configuration Word.

Remarks

Chip select is not actually asserted, only enabled to be asserted.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_ConfigWordSet(MY_SQI_INSTANCE,
                       1,
                       SQI_CS_OEN_0,
                       SQI_DATA_OEN_QUAD,
                       0,
                       1,
                       0,
                       0,
                       0,
                       SQI_DATA_FORMAT_LSBF,
                       SQI_DATA_MODE_3,
                       SQI_XFER_MODE_PIO
                       );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
sqiEnable	Enables/Disables the SQI module
csPins	Chip Select Output Enable

dataPins	Data Output Enable
reset	Resets control, transmit, receive buffers and state machines
burstEn	Burst Enable (always set to '1')
hold	SQID2 to act as HOLD# signal in single and dual lane modes
writeProtect	SQID3 to act as WP# signal in single and dual lane modes
rxLatch	Activates receive latch in transmit mode
lsbf	Sets data endian mode to least significant bit first (LSBF)
dataMode	Sets data mode to mode 0/mode 1/Serial Flash mode
xferMode	Sets transfer mode to XIP/DMA/PIO mode

Function

void PLIB_SQI_ConfigWordSet(SQI_MODULE_ID index,
bool sqiEnable,
SQI_CS_OEN csPins,
SQI_DATA_OEN dataPins,
bool reset,
bool burstEn,
bool hold,
bool writeProtect,
bool rxLatch,
SQI_DATA_FORMAT lsbf,
SQI_DATA_MODE dataMode,
SQI_XFER_MODE xferMode
)

PLIB_SQI_ReceiveBufferIsUnderrun Function

Returns the status of receive buffer.

File

plib_sqi.h

C

```
bool PLIB_SQI_ReceiveBufferIsUnderrun(SQI_MODULE_ID index);
```

Returns

- true - Receive Buffer is underrun
- false - Receive Buffer is not underrun

Description

This function returns the status of the receive buffer.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool rxun = PLIB_SQI_ReceiveBufferIsUnderrun(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_ReceiveBufferIsUnderrun (SQI_MODULE_ID index)

PLIB_SQI_RxBufferThresholdGet Function

Returns the receive command threshold.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_RxBufferThresholdGet(SQI_MODULE_ID index);
```

Returns

Receive Buffer Threshold value.

Description

This function returns the receive command threshold that is used to monitor receives based on the receive buffer space availability.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t rxBufThres = PLIB_SQI_RxCommandThresholdGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_RxBufferThresholdGet (SQI_MODULE_ID index)

PLIB_SQI_RxBufferThresholdIntGet Function

Sets the receive buffer threshold interrupt.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_RxBufferThresholdIntGet(SQI_MODULE_ID index);
```

Returns

Receive Buffer Threshold value (used to trigger an interrupt).

Description

This function returns the receive buffer threshold used to set an interrupt.

Remarks

This is a 5-bit field and bits 7, 6, and 5 are ignored in the char.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t rxBufIntThres = PLIB_SQI_RxBufferThresholdIntGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
threshold	Receive interrupt (buffer) threshold

Function

uint8_t PLIB_SQI_RxBufferThresholdIntGet (SQI_MODULE_ID index)

PLIB_SQI_RxBufferThresholdIntSet Function

Sets the receive buffer threshold for interrupt.

File

plib_sqi.h

C

```
void PLIB_SQI_RxBufferThresholdIntSet(SQI_MODULE_ID index, uint8_t threshold);
```

Returns

None.

Description

This function sets the receive buffer threshold used to trigger an interrupt. Sets an interrupt condition when receive buffer count is larger than or equal to the receive interrupt threshold bytes.

Remarks

This is a 5-bit field and bits 7,6,5 are ignored in the char.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and MY_RX_INT_THRESHOLD is the threshold value.
PLIB_SQI_RxBufferThresholdIntSet(MY_SQI_INSTANCE, MY_RX_INT_THRESHOLD);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
threshold	Receive buffer threshold for interrupt

Function

void PLIB_SQI_RxBufferThresholdIntSet (SQI_MODULE_ID index, uint8_t threshold)

PLIB_SQI_RxBufferThresholdSet Function

Sets the receive command threshold.

File

plib_sqi.h

C

```
void PLIB_SQI_RxBufferThresholdSet(SQI_MODULE_ID index, uint8_t threshold);
```

Returns

None.

Description

This function sets the receive command threshold that is used to monitor receives based on the receive buffer space availability.

Remarks

Valid threshold values are 0-31.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and MY_RECEIVE_THRESHOLD is the receive threshold value.
PLIB_SQI_RxCommandThresholdSet(MY_SQI_INSTANCE, MY_RECEIVE_THRESHOLD);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
threshold	Receive command (buffer) threshold

Function

void PLIB_SQI_RxBufferThresholdSet (SQI_MODULE_ID index, uint8_t threshold)

PLIB_SQI_TransferDirectionGet Function

Returns the transfer command.

File

plib_sqi.h

C

```
SQI_XFER_CMD PLIB_SQI_TransferDirectionGet(SQI_MODULE_ID index);
```

Returns

Transfer Command (Idle/Receive/Transmit).

Description

This function returns the transfer command that is active currently.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
SQI_XFER_CMD xferDirection = PLIB_SQI_TransferDirectionGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_XFER_CMD PLIB_SQI_TransferDirectionGet (SQI_MODULE_ID index)

PLIB_SQI_TransferDirectionSet Function

Sets the transfer command.

File

plib_sqi.h

C

```
void PLIB_SQI_TransferDirectionSet(SQI_MODULE_ID index, SQI_XFER_CMD command);
```

Returns

None.

Description

This function sets the transfer command to Idle/Transmit/Receive.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and SQI_CMD_TRANSMIT is an enum element.
PLIB_SQI_TransferDirectionSet(MY_SQI_INSTANCE, SQI_CMD_TRANSMIT);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
command	Transfer command

Function

void PLIB_SQI_TransferDirectionSet (SQI_MODULE_ID index, SQI_XFER_CMD command)

PLIB_SQI_TransmitBufferFreeSpaceGet Function

Returns the number of transmit buffer words available.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_TransmitBufferFreeSpaceGet(SQI_MODULE_ID index);
```

Returns

Amount of transmit buffer space free in bytes.

Description

This function returns the number of transmit buffer bytes available.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t txBufFreeSpace = PLIB_SQI_TransmitBufferFreeSpaceGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_TransmitBufferFreeSpaceGet(SQI_MODULE_ID index)

PLIB_SQI_TransmitBufferHasOverflowed Function

Returns the current status of the transmit buffer.

File

plib_sqi.h

C

```
bool PLIB_SQI_TransmitBufferHasOverflowed(SQI_MODULE_ID index);
```

Returns

- true - Transmit Buffer has overflowed
- false - Transmit Buffer has not overflowed

Description

This function returns the current state of the transmit buffer.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool txOv = PLIB_SQI_TransmitBufferHasOverflowed(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_TransmitBufferHasOverflowed (SQI_MODULE_ID index)

PLIB_SQI_TxBufferThresholdGet Function

Returns the transmit command threshold value.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_TxBufferThresholdGet(SQI_MODULE_ID index);
```

Returns

Transmit buffer threshold value.

Description

This function returns the transmit command threshold value that is used to monitor transmits based on the transmit buffer space availability.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t txThreshold = PLIB_SQI_TxBufferThresholdGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_TxBufferThresholdGet(SQI_MODULE_ID index)

PLIB_SQI_TxBufferThresholdIntGet Function

Returns the value to trigger the transmit buffer threshold interrupt.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_TxBufferThresholdIntGet(SQI_MODULE_ID index);
```

Returns

Transmit buffer threshold for interrupt.

Description

This function returns the transmit buffer threshold used to set an interrupt. When enabled, interrupt is triggered when transmit buffer has more space than the transmit interrupt threshold bytes.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t txBufIntThres = PLIB_SQI_TxBufferThresholdIntGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_TxBufferThresholdIntGet (SQI_MODULE_ID index)

PLIB_SQI_TxBufferThresholdIntSet Function

Sets the value to trigger the transmit buffer threshold interrupt.

File

plib_sqi.h

C

```
void PLIB_SQI_TxBufferThresholdIntSet(SQI_MODULE_ID index, uint8_t threshold);
```

Returns

None.

Description

This function sets the transmit buffer threshold used for an interrupt. When enabled, interrupt is triggered when transmit buffer has more space than the transmit interrupt threshold bytes.

Remarks

This is a 5-bit field and bits 7,6,5 are ignored in the char.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and MY_TX_INT_THRESHOLD is the threshold value.
PLIB_SQI_TxBufferThresholdIntSet(MY_SQI_INSTANCE, MY_TX_INT_THRESHOLD);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
threshold	Transmit interrupt (buffer) threshold

Function

void PLIB_SQI_TxBufferThresholdIntSet (SQI_MODULE_ID index, uint8_t threshold)

PLIB_SQI_TxBufferThresholdSet Function

Sets the transmit command threshold.

File

plib_sqi.h

C

```
void PLIB_SQI_TxBufferThresholdSet(SQI_MODULE_ID index, uint8_t threshold);
```

Returns

None.

Description

This function sets the transmit command threshold, which is used to control transmits based on the transmit buffer space availability.

Remarks

Valid threshold values are 0-31.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and MY_TRANSMIT_THRESHOLD is the threshold value.
PLIB_SQI_TxBufferThresholdSet(MY_SQI_INSTANCE, MY_TRANSMIT_THRESHOLD);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
threshold	Transmit command (buffer) threshold

Function

void PLIB_SQI_TxBufferThresholdSet(SQI_MODULE_ID index, uint8_t threshold)

e) Interrupt Control and Status Management Functions

PLIB_SQI_InterruptDisable Function

Disables the interrupt source.

File

plib_sqi.h

C

```
void PLIB_SQI_InterruptDisable(SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function disables the interrupt source passed into the function.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer and TXFULL is an enum element.
PLIB_SQI_InterruptDisable(MY_SQI_INSTANCE, SQI_TXFULL);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
interruptFlag	Interrupt to be disabled

Function

void PLIB_SQI_InterruptDisable (SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag)

PLIB_SQI_InterruptEnable Function

Enables the passed interrupt source.

File

plib_sqi.h

C

```
void PLIB_SQI_InterruptEnable(SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function enables the interrupt source passed into the function.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_InterruptEnable(MY_SQI_INSTANCE, SQI_TXFULL);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
interruptFlag	Interrupt to be enabled

Function

void PLIB_SQI_InterruptEnable (SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag)

PLIB_SQI_InterruptFlagGet Function

Return SQI Interrupt flag status.

File

plib_sqi.h

C

```
bool PLIB_SQI_InterruptFlagGet(SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag);
```

Returns

Interrupt status.

Description

This function returns the SQI interrupt source flag status (set/cleared).

Remarks

None.

Preconditions

None.

Example

```
if ( PLIB_SQI_InterruptFlagGet(MY_SQI_INSTANCE,SQI_INT_ANY) )
    if ( PLIB_SQI_InterruptFlagGet(MY_SQI_INSTANCE,SQI_TXFULL) )
    {
       ...
    }
    if ( PLIB_SQI_InterruptFlagGet(MY_SQI_INSTANCE,SQI_RXFULL) )
    {
        ...
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt flag of interest

Function

bool PLIB_SQI_InterruptFlagGet(SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag)

PLIB_SQI_InterruptIsEnabled Function

Returns the interrupt state.

File

plib_sqi.h

C

```
bool PLIB_SQI_InterruptIsEnabled(SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag);
```

Returns

- true - Interrupt is enabled
- false - Interrupt is disabled

Description

This function returns whether or not the interrupt state is enabled or disabled.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
if (PLIB_SQI_InterruptIsEnabled(MY_SQI_INSTANCE, SQI_TXFULL))
{
    ..
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
interruptFlag	Interrupt under check

Function

bool PLIB_SQI_InterruptIsEnabled (SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag)

PLIB_SQI_InterruptSignalDisable Function

Disables the interrupt signal source.

File

plib_sqi.h

C

```
void PLIB_SQI_InterruptSignalDisable(SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function disables the interrupt signals source passed into the function, thus prohibiting it from reaching to the external interrupt controller.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_InterruptSignalDisable(MY_SQI_INSTANCE, SQI_TXFULL);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
interruptFlag	Interrupt to be disabled

Function

void PLIB_SQI_InterruptSignalDisable (SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag)

PLIB_SQI_InterruptSignalEnable Function

Enables the passed interrupt signal source.

File

plib_sqi.h

C

```
void PLIB_SQI_InterruptSignalEnable(SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function enables the interrupt signal source to be passed into the function, which allows it to go out to the external Interrupt Controller.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_InterruptSignalEnable(MY_SQI_INSTANCE, SQI_TXFULL);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
interruptFlag	Interrupt to be enabled

Function

void PLIB_SQI_InterruptSignalEnable (SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag)

PLIB_SQI_InterruptSignalIsEnabled Function

Returns the interrupt signal state.

File

plib_sqi.h

C

```
bool PLIB_SQI_InterruptSignalIsEnabled(SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag);
```

Returns

- true - Interrupt signal is enabled
- false - Interrupt signal is disabled

Description

This function returns whether the interrupt signal state is enabled or disabled.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
```

```
if (PLIB_SQI_InterruptSignalIsEnabled(MY_SQI_INSTANCE, SQI_TXFULL))
{
    ..
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
interruptFlag	Interrupt signal under check

Function

bool PLIB_SQI_InterruptSignalIsEnabled (SQI_MODULE_ID index, SQI_INTERRUPTS interruptFlag)

PLIB_SQI_DataLineStatus Function

Returns the logical status of the SQI data lines.

File

plib_sqi.h

C

```
bool PLIB_SQI_DataLineStatus(SQI_MODULE_ID index, uint8_t dataPin);
```

Returns

SQIDx Status (High/Low).

Description

This function returns the logical status of the data lines (0/1).

Remarks

Parsing values other than 0/1/2/3 returns SQID0 pin status.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool sqiDataLineStatus = PLIB_SQI_DataLineStatus(MY_SQI_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
dataPin	Data pin for which status will be returned (0/1/2/3)

Function

bool PLIB_SQI_DataLineStatus(SQI_MODULE_ID index, uint8_t dataPin)

PLIB_SQI_CommandStatusGet Function

Returns the SQI command (transmit/receive/idle).

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_CommandStatusGet(SQI_MODULE_ID index);
```

Returns

SQI command (transmit/receive/idle) that is currently being executed.

Description

This function returns the SQI command (transmit/receive/idle) that is currently being executed.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t cmdStat = PLIB_SQI_CommandStatusGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_CommandStatusGet(SQI_MODULE_ID index)

PLIB_SQI_ConBufWordsAvailable Function

Returns the number of control buffer words available.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_ConBufWordsAvailable(SQI_MODULE_ID index);
```

Returns

Number of words available.

Description

This function returns the number of control buffer words available.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t numConBuf = PLIB_SQI_ConBufWordsAvailable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_ConBufWordsAvailable(SQI_MODULE_ID index)

f) DMA Buffer Address Management Functions

PLIB_SQI_DMABDBaseAddressGet Function

Returns the address of the base buffer descriptor.

File

plib_sqi.h

C

```
void* PLIB_SQI_DMABDBaseAddressGet(SQI_MODULE_ID index);
```

Returns

Base Buffer Descriptor address.

Description

This function returns the address of the base DMA buffer descriptor.

Remarks

Check to make sure if DMA Buffer Descriptor fetch is in progress.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
void *baseBDAddress;

If (!PLIB_SQI_DMAIsActive(MY_SQI_INSTANCE))
{
   baseBDAddress = PLIB_SQI_DMABDBaseAddressGet(MY_SQI_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void * PLIB_SQI_DMABDBaseAddressGet(SQI_MODULE_ID index)

PLIB_SQI_DMABDBaseAddressSet Function

Sets the address of the base buffer descriptor.

File

plib_sqi.h

C

```
void PLIB_SQI_DMABDBaseAddressSet(SQI_MODULE_ID index, void * baseBDAddress);
```

Returns

None.

Description

This function writes the address of the base (first/only) buffer descriptor into the buffer descriptor base address register.

Remarks

Check to make sure if DMA Buffer Descriptor fetch is in progress.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
if (!PLIB_SQI_DMAIsActive(MY_SQI_INSTANCE))
    PLIB_SQI_DMABDBaseAddressSet(MY_SQI_INSTANCE, (void *) (&MY_BD_STRUCT));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
baseBDAddress	Base buffer descriptor address

Function

void PLIB_SQI_DMABDBaseAddressSet (SQI_MODULE_ID index, void *baseBDAddress)

PLIB_SQI_DMABDCurrentAddressGet Function

Returns the address of the current buffer descriptor in process.

File

plib_sqi.h

C

```
void* PLIB_SQI_DMABDCurrentAddressGet(SQI_MODULE_ID index);
```

Returns

Current Buffer Descriptor Address.

Description

This function returns the address of the DMA buffer descriptor that is currently in progress.

Remarks

Check to make sure if DMA Buffer Descriptor fetch is in progress.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint32_t currentBDAddress;

If (PLIB_SQI_DMAIsActive(MY_SQI_INSTANCE))
{
   void* currentBDAddress = PLIB_SQI_DMABDCurrentAddressGet(MY_SQI_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void* PLIB_SQI_DMABDCurrentAddressGet (SQI_MODULE_ID index)

g) DMA Buffer Descriptor Management Functions

PLIB_SQI_DMABDControlWordGet Function

Returns Current Buffer Descriptor Control Word Information.

File

plib_sqi.h

C

```
uint16_t PLIB_SQI_DMABDControlWordGet(SQI_MODULE_ID index);
```

Returns

Control Word - DMA Buffer Descriptor Control Word

Description

This function returns current buffer descriptor Control Word information excluding buffer length. This information is returned in transmit and receive status functions.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint16_t dmabdconword;

dmabdconword =  PLIB_SQI_DMABDControlWordGet(MY_SQI_INSTANCE);

switch (dmabdconword)
{
    case BD_ENABLED: ...;
    case BD_DISABLED: ...;
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint16_t PLIB_SQI_DMABDControlWordGet (SQI_MODULE_ID index)

PLIB_SQI_DMABDReceiveBufferCountGet Function

Returns the receive buffer space in bytes.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_DMABDReceiveBufferCountGet(SQI_MODULE_ID index);
```

Returns

Receive buffer space in bytes.

Description

This function returns the current receive buffer space in bytes.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t bdRxBufCount = PLIB_SQI_DMABDReceiveBufferCountGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_DMABDReceiveBufferCountGet(SQI_MODULE_ID index)

PLIB_SQI_DMABDReceiveBufferLengthGet Function

Returns the receive length in bytes.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_DMABDReceiveBufferLengthGet(SQI_MODULE_ID index);
```

Returns

Receive buffer space in bytes.

Description

This function returns the current receive length in bytes.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t bdRxBufLength = PLIB_SQI_DMABDReceiveBufferLengthGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_DMABDReceiveBufferLengthGet(SQI_MODULE_ID index)

PLIB_SQI_DMABDReceiveStateGet Function

Returns the current state of the buffer descriptor in progress.

File

plib_sqi.h

C

```
SQI_BD_STATE PLIB_SQI_DMABDReceiveStateGet(SQI_MODULE_ID index);
```

Returns

Status - DMA Buffer Descriptor State

Description

This function returns the current state of the buffer descriptor in progress.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t bdrxState = PLIB_SQI_DMABDReceiveStateGet(MY_SQI_INSTANCE);

switch (bdRxState)
{
   case BD_IDLE: ...;
   case BD_STATE_FETCH_REQ_PENDING: ...;
   .
   .
   .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_BD_STATE uint8_t PLIB_SQI_DMABDReceiveStateGet(SQI_MODULE_ID index)

PLIB_SQI_DMABDTransmitBufferCountGet Function

Returns the transmit buffer space in bytes.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_DMABDTransmitBufferCountGet(SQI_MODULE_ID index);
```

Returns

Transmit buffer space in bytes.

Description

This function returns the current transmit buffer space in bytes.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t bdTxBufCount = PLIB_SQI_DMABDTransmitBufferCountGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_DMABDTransmitBufferCountGet(SQI_MODULE_ID index)

PLIB_SQI_DMABDTransmitBufferLengthGet Function

Returns the transmit length in bytes.

File

plib_sqi.h

C

```
uint8_t PLIB_SQI_DMABDTransmitBufferLengthGet(SQI_MODULE_ID index);
```

Returns

Transmit buffer space in bytes.

Description

This function returns the current transmit length in bytes.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t bdTxBufLength = PLIB_SQI_DMABDTransmitBufferLengthGet(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_SQI_DMABDTransmitBufferLengthGet(SQI_MODULE_ID index)

PLIB_SQI_DMABDTransmitStateGet Function

Returns the current state of the buffer descriptor in progress.

File

plib_sqi.h

C

```
SQI_BD_STATE PLIB_SQI_DMABDTransmitStateGet(SQI_MODULE_ID index);
```

Returns

Status - DMA Buffer Descriptor State

Description

This function returns the current state of the buffer descriptor in progress.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
```

```
// application developer.
uint8_t bdTxState = PLIB_SQI_DMABDTransmitStateGet(MY_SQI_INSTANCE);

switch (bdTxState)
{
   case BD_IDLE: ...;
   case BD_FETCH_REQ_PENDING: ...;
   .
   .
   .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_BD_STATE PLIB_SQI_DMABDTransmitStateGet(SQI_MODULE_ID index)

PLIB_SQI_DMABDFetchStop Function

Stops the DMA buffer descriptor fetch process.

File

plib_sqi.h

C

```
void PLIB_SQI_DMABDFetchStop(SQI_MODULE_ID index);
```

Returns

None.

Description

This function stops the DMA buffer descriptor fetch process.

Remarks

None.

Preconditions

PLIB_SQI_DMABDFetchStart is called.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DMABDFetchStop(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_DMABDFetchStop (SQI_MODULE_ID index)

h) DMA Control and Status Management Functions

PLIB_SQI_DMABDFetchStart Function

Starts the DMA buffer descriptor fetch process.

File

plib_sqi.h

C

```
void PLIB_SQI_DMABDFetchStart(SQI_MODULE_ID index);
```

Returns

None.

Description

This function starts the DMA buffer descriptor fetch process.

Remarks

None.

Preconditions

Make sure the buffer descriptors are set up and the buffer descriptor base address register is pointing to the first/only buffer descriptor. Also ensure any previous buffer descriptor processing is fixed.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DMABDFetchStart(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_DMABDFetchStart (SQI_MODULE_ID index)

PLIB_SQI_DMABDIsBusy Function

Returns whether or not the DMA Buffer Descriptor is busy.

File

plib_sqi.h

C

```
bool PLIB_SQI_DMABDIsBusy(SQI_MODULE_ID index);
```

Returns

- true - DMA Buffer Descriptor is busy
- false - DMA Buffer Descriptor is not busy

Description

This function returns whether or not the DMA buffer descriptor process is busy.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool bdBusy =  PLIB_SQI_DMABDIsBusy(MY_SQI_INSTANCE)
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_DMABDIsBusy (SQI_MODULE_ID index)

PLIB_SQI_DMABDPollCounterSet Function

Sets the poll counter value.

File

plib_sqi.h

C

```
void PLIB_SQI_DMABDPollCounterSet(SQI_MODULE_ID index, uint16_t pollCount);
```

Returns

None.

Description

This function sets the poll counter value that indicates the number of cycles the DMA would wait before fetching the next descriptor word, if the current descriptor fetched was disabled.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
if (PLIB_SQI_DMABDPollIsEnabled(MY_SQI_INSTANCE)
{
    PLIB_SQI_DMABDPollCounterSet(MY_SQI_INSTANCE, MY_POLL_VALUE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
pollControl	Polling value

Function

void PLIB_SQI_DMABDPollCounterSet(SQI_MODULE_ID index, uint16_t pollCount)

PLIB_SQI_DMABDPollDisable Function

Disables the buffer descriptor polling.

File

plib_sqi.h

C

```
void PLIB_SQI_DMABDPollDisable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function disables the buffer descriptor polling.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DMABDPollDisable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_DMABDPollDisable (SQI_MODULE_ID index)

PLIB_SQI_DMABDPollEnable Function

Enables the buffer descriptor polling.

File

plib_sqi.h

C

```
void PLIB_SQI_DMABDPollEnable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function enables the buffer descriptor polling and works in tandem with poll control register.

Remarks

Enable this control bit only when you are planning to have dead descriptors in the linked list.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DMABDPollEnable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_DMABDPollEnable (SQI_MODULE_ID index)

PLIB_SQI_DMABDPollIsEnabled Function

Returns whether or not the DMA buffer descriptor poll is enabled.

File

plib_sqi.h

C

```
bool PLIB_SQI_DMABDPollIsEnabled(SQI_MODULE_ID index);
```

Returns

- true - The DMA Poll Control is enabled

- false - The DMA Poll Control is disabled

Description

This function returns whether or not the DMA buffer descriptor poll is enabled or disabled.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
If (PLIB_SQI_DMABDPollIsEnabled(MY_SQI_INSTANCE))
{
   PLIB_SQI_PollControlSet(MY_SQI_INSTANCE, MY_POLL_CONTROL_VALUE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_DMABDPollIsEnabled (SQI_MODULE_ID index)

PLIB_SQI_DMABDStateGet Function

Returns the current state of the buffer descriptor in progress.

File

plib_sqi.h

C

```
SQI_BD_STATE PLIB_SQI_DMABDStateGet(SQI_MODULE_ID index);
```

Returns

Status - DMA Buffer Descriptor State

Description

This function returns the current state of the buffer descriptor in progress.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
uint8_t bdState = PLIB_SQI_DMABDStateGet(MY_SQI_INSTANCE);

switch (bdState)
{
   case BD_IDLE: ...;
   case BD_FETCH_REQ_PENDING: ...;
   .
   .
   .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

SQI_BD_STATE PLIB_SQI_DMABDStateGet(SQI_MODULE_ID index)

PLIB_SQI_DMADisable Function

Disables the built-in DMA logic.

File

plib_sqi.h

C

```
void PLIB_SQI_DMADisable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function disables the built-in DMA logic for data transfer.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DMADisable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_DMADisable (SQI_MODULE_ID index)

PLIB_SQI_DMAEnable Function

Enables the built-in DMA logic.

File

plib_sqi.h

C

```
void PLIB_SQI_DMAEnable(SQI_MODULE_ID index);
```

Returns

None.

Description

This function enables the built-in DMA logic for data transfer.

Remarks

None.

Preconditions

DMA buffer descriptors need to be setup before enabling the DMA.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DMAEnable(MY_SQI_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_SQI_DMAEnable (SQI_MODULE_ID index)

PLIB_SQI_DMAHasStarted Function

Returns whether or no the DMA process has started.

File

plib_sqi.h

C

```
bool PLIB_SQI_DMAHasStarted(SQI_MODULE_ID index);
```

Returns

- true - The DMA process has started
- false - The DMA process has not started

Description

This function returns whether or not the DMA process has started.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
bool dmaStarted =  PLIB_SQI_DMAHasStarted (MY_SQI_INSTANCE)
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_DMAHasStarted (SQI_MODULE_ID index)

PLIB_SQI_DMAIsEnabled Function

Returns whether or not DMA is enabled.

File

plib_sqi.h

C

```
bool PLIB_SQI_DMAIsEnabled(SQI_MODULE_ID index);
```

Returns

- true - DMA is enabled
- false - DMA is disabled

Description

This function returns whether or not the DMA is enabled or disabled.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
If (PLIB_SQI_DMAIsEnabled(MY_SQI_INSTANCE))
{
   ...
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_SQI_DMAIsEnabled (SQI_MODULE_ID index)

i) Other Functions

PLIB_SQI_StatusCheckSet Function

Sets the Flash status check related control bits.

File

plib_sqi.h

C

```
void PLIB_SQI_StatusCheckSet(SQI_MODULE_ID index, uint16_t statCheckCmd, uint8_t numStatBytes,
SQI_LANE_MODE statCmdType, bool statBitPos);
```

Returns

None.

Description

This function sets the Flash status check related control bits and enables the status check for PIO mode.

Remarks

None.

Preconditions

None.

Example

```
// Where MY_SQI_INSTANCE, is the SQI instance selected for use by the
// application developer.
PLIB_SQI_DDRModeSet(MY_SQI_INSTANCE,
                    0x05,
                    1,
                    SQI_LANE_QUAD,
                    0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
statCheckCmd	Status check command to be sent to the Flash
numStatBytes	Number of status command bytes
statCmdType	Lane mode (Single/Dual/Quad) for status command

Function

void PLIB_SQI_StatusCheckSet(SQI_MODULE_ID index,
uint16_t statCheckCmd,
uint8_t numStatBytes,
SQI_LANE_MODE statCmdType,
bool statBitPos
)

j) Feature Existence Functions

PLIB_SQI_ExistsBDBaseAddress Function

Identifies whether the BDBaseAddress feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDBaseAddress(SQI_MODULE_ID index);
```

Returns

- true - The BDBaseAddress feature is supported on the device
- false - The BDBaseAddress feature is not supported on the device

Description

This function identifies whether the BDBaseAddress feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_DMABDBaseAddressSet
- PLIB_SQI_DMABDBaseAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDBaseAddress(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDControlWord Function

Identifies whether the BDControlWord feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDControlWord(SQI_MODULE_ID index);
```

Returns

- true - The BDControlWord feature is supported on the device
- false - The BDControlWord feature is not supported on the device

Description

This function identifies whether the BDControlWord feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDControlWordGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDControlWord(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDCurrentAddress Function

Identifies whether the BDCurrentAddress feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDCurrentAddress(SQI_MODULE_ID index);
```

Returns

- true - The BDCurrentAddress feature is supported on the device
- false - The BDCurrentAddress feature is not supported on the device

Description

This function identifies whether the BDCurrentAddress feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDCurrentAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDCurrentAddress(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDPollCount Function

Identifies whether the BDPollCount feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDPollCount(SQI_MODULE_ID index);
```

Returns

- true - The BDPollCount feature is supported on the device
- false - The BDPollCount feature is not supported on the device

Description

This function identifies whether the BDPollCount feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDPollCounterSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDPollCount(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDPollingEnable Function

Identifies whether the BDPollingEnable feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDPollingEnable(SQI_MODULE_ID index);
```

Returns

- true - The BDPollingEnable feature is supported on the device
- false - The BDPollingEnable feature is not supported on the device

Description

This function identifies whether the BDPollingEnable feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_DMABDPollEnable
- PLIB_SQI_DMABDPollDisable
- PLIB_SQI_DMABDPollIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDPollingEnable(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDProcessState Function

Identifies whether the BDProcessState feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDProcessState(SQI_MODULE_ID index);
```

Returns

- true - The BDProcessState feature is supported on the device
- false - The BDProcessState feature is not supported on the device

Description

This function identifies whether the BDProcessState feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDStateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDProcessState(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDRxBufCount Function

Identifies whether the BDRxBufCount feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDRxBufCount(SQI_MODULE_ID index);
```

Returns

- true - The BDRxBufCount feature is supported on the device
- false - The BDRxBufCount feature is not supported on the device

Description

This function identifies whether the BDRxBufCount feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDReceiveBufferCountGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDRxBufCount(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDRxLength Function

Identifies whether the BDRxLength feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDRxLength(SQI_MODULE_ID index);
```

Returns

- true - The BDRxLength feature is supported on the device
- false - The BDRxLength feature is not supported on the device

Description

This function identifies whether the BDRxLength feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDReceiveBufferLengthGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDRxLength(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDRxState Function

Identifies whether the BDRxState feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDRxState(SQI_MODULE_ID index);
```

Returns

- true - The BDRxState feature is supported on the device
- false - The BDRxState feature is not supported on the device

Description

This function identifies whether the BDRxState feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDReceiveStateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDRxState(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDTxBufCount Function

Identifies whether the BDTxBufCount feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDTxBufCount(SQI_MODULE_ID index);
```

Returns

- true - The BDTxBufCount feature is supported on the device
- false - The BDTxBufCount feature is not supported on the device

Description

This function identifies whether the BDTxBufCount feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDTransmitBufferCountGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDTxBufCount(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDTxLength Function

Identifies whether the BDTxLength feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDTxLength(SQI_MODULE_ID index);
```

Returns

- true - The BDTxLength feature is supported on the device
- false - The BDTxLength feature is not supported on the device

Description

This function identifies whether the BDTxLength feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDTransmitBufferLengthGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDTxLength(SQI_MODULE_ID index)

PLIB_SQI_ExistsBDTxState Function

Identifies whether the BDTxState feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBDTxState(SQI_MODULE_ID index);
```

Returns

- true - The BDTxState feature is supported on the device
- false - The BDTxState feature is not supported on the device

Description

This function identifies whether the BDTxState feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDTransmitStateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBDTxState(SQI_MODULE_ID index)

PLIB_SQI_ExistsBurstControl Function

Identifies whether the BurstControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsBurstControl(SQI_MODULE_ID index);
```

Returns

- true - The BurstControl feature is supported on the device
- false - The BurstControl feature is not supported on the device

Description

This function identifies whether the BurstControl feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_BurstEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsBurstControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsChipSelect Function

Identifies whether the ChipSelect feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsChipSelect(SQI_MODULE_ID index);
```

Returns

- true - The ChipSelect feature is supported on the device
- false - The ChipSelect feature is not supported on the device

Description

This function identifies whether the ChipSelect feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_ChipSelectSet
- PLIB_SQI_ChipSelectGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsChipSelect(SQI_MODULE_ID index)

PLIB_SQI_ExistsClockControl Function

Identifies whether the ClockControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsClockControl(SQI_MODULE_ID index);
```

Returns

- true - The ClockControl feature is supported on the device
- false - The ClockControl feature is not supported on the device

Description

This function identifies whether the ClockControl feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_ClockEnable
- PLIB_SQI_ClockDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsClockControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsClockDivider Function

Identifies whether the ClockDivider feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsClockDivider(SQI_MODULE_ID index);
```

Returns

- true - The ClockDivider feature is supported on the device
- false - The ClockDivider feature is not supported on the device

Description

This function identifies whether the ClockDivider feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_ClockDividerSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsClockDivider(SQI_MODULE_ID index)

PLIB_SQI_ExistsClockReady Function

Identifies whether the ClockReady feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsClockReady(SQI_MODULE_ID index);
```

Returns

- true - The ClockReady feature is supported on the device
- false - The ClockReady feature is not supported on the device

Description

This function identifies whether the ClockReady feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_ClockIsStable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsClockReady(SQI_MODULE_ID index)

PLIB_SQI_ExistsConBufThreshold Function

Identifies whether the ConBufThreshold feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsConBufThreshold(SQI_MODULE_ID index);
```

Returns

- true - The ConBufThreshold feature is supported on the device
- false - The ConBufThreshold feature is not supported on the device

Description

This function identifies whether the ConBufThreshold feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_ControlBufferThresholdSet
- PLIB_SQI_ControlBufferThresholdGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsConBufThreshold(SQI_MODULE_ID index)

PLIB_SQI_ExistsConfigWord Function

Identifies whether the ConfigWord feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsConfigWord(SQI_MODULE_ID index);
```

Returns

- true - The ConfigWord feature is supported on the device
- false - The ConfigWord feature is not supported on the device

Description

This function identifies whether the ConfigWord feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_ConfigWordSet
- PLIB_SQI_ConfigWordGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsConfigWord(SQI_MODULE_ID index)

PLIB_SQI_ExistsControlWord Function

Identifies whether the ControlWord feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsControlWord(SQI_MODULE_ID index);
```

Returns

- true - The ControlWord feature is supported on the device
- false - The ControlWord feature is not supported on the device

Description

This function identifies whether the ControlWord feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_ControlWordSet
- PLIB_SQI_ControlWordGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsControlWord(SQI_MODULE_ID index)

PLIB_SQI_ExistsCSDeassert Function

Identifies whether the CSDeassert feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsCSDeassert(SQI_MODULE_ID index);
```

Returns

- true - The CSDeassert feature is supported on the device
- false - The CSDeassert feature is not supported on the device

Description

This function identifies whether the CSDeassert feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_ChipSelectDeassertEnable
- PLIB_SQI_ChipSelectDeassertDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsCSDeassert(SQI_MODULE_ID index)

PLIB_SQI_ExistsCSOutputEnable Function

Identifies whether the CSOutputEnable feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsCSOutputEnable(SQI_MODULE_ID index);
```

Returns

- true - The CSOutputEnable feature is supported on the device
- false - The CSOutputEnable feature is not supported on the device

Description

This function identifies whether the CSOutputEnable feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_CSOutputEnableSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsCSOutputEnable(SQI_MODULE_ID index)

PLIB_SQI_ExistsDataFormat Function

Identifies whether the DataFormat feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDataFormat(SQI_MODULE_ID index);
```

Returns

- true - The DataFormat feature is supported on the device
- false - The DataFormat feature is not supported on the device

Description

This function identifies whether the DataFormat feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_DataFormatSet
- PLIB_SQI_DataFormatGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDataFormat(SQI_MODULE_ID index)

PLIB_SQI_ExistsDataModeControl Function

Identifies whether the DataModeControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDataModeControl(SQI_MODULE_ID index);
```

Returns

- true - The DataModeControl feature is supported on the device
- false - The DataModeControl feature is not supported on the device

Description

This function identifies whether the DataModeControl feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DataModeSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDataModeControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsDataOutputEnable Function

Identifies whether the DataOutputEnable feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDataOutputEnable(SQI_MODULE_ID index);
```

Returns

- true - The DataOutputEnable feature is supported on the device
- false - The DataOutputEnable feature is not supported on the device

Description

This function identifies whether the DataOutputEnable feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DataOutputEnableSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDataOutputEnable(SQI_MODULE_ID index)

PLIB_SQI_ExistsDataPinStatus Function

Identifies whether the DataPinStatus feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDataPinStatus(SQI_MODULE_ID index);
```

Returns

- true - The DataPinStatus feature is supported on the device
- false - The DataPinStatus feature is not supported on the device

Description

This function identifies whether the DataPinStatus feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DataLineStatus

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDataPinStatus(SQI_MODULE_ID index)

PLIB_SQI_ExistsDmaEnable Function

Identifies whether the DMAEnable feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDmaEnable(SQI_MODULE_ID index);
```

Returns

- true - The DMAEnable feature is supported on the device
- false - The DMAEnable feature is not supported on the device

Description

This function identifies whether the DMAEnable feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_DMAEnable
- PLIB_SQI_DMADisable
- PLIB_SQI_DMAIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDmaEnable(SQI_MODULE_ID index)

PLIB_SQI_ExistsDMAEngineBusy Function

Identifies whether the DMAEngineBusy feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDMAEngineBusy(SQI_MODULE_ID index);
```

Returns

- true - The DMAEngineBusy feature is supported on the device
- false - The DMAEngineBusy feature is not supported on the device

Description

This function identifies whether the DMAEngineBusy feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMABDIsBusy

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDMAEngineBusy(SQI_MODULE_ID index)

PLIB_SQI_ExistsDMAProcessInProgress Function

Identifies whether the DMAProcessInProgress feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDMAProcessInProgress(SQI_MODULE_ID index);
```

Returns

- true - The DMAProcessInProgress feature is supported on the device
- false - The DMAProcessInProgress feature is not supported on the device

Description

This function identifies whether the DMAProcessInProgress feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_DMAHasStarted

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDMAProcessInProgress(SQI_MODULE_ID index)

PLIB_SQI_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsEnableControl(SQI_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_Enable
- PLIB_SQI_Disable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsEnableControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsHoldPinControl Function

Identifies whether the HoldPinControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsHoldPinControl(SQI_MODULE_ID index);
```

Returns

- true - The HoldPinControl feature is supported on the device
- false - The HoldPinControl feature is not supported on the device

Description

This function identifies whether the HoldPinControl feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_HoldSet
- PLIB_SQI_HoldClear
- PLIB_SQI_HoldGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsHoldPinControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsInterruptControl Function

Identifies whether the InterruptControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsInterruptControl(SQI_MODULE_ID index);
```

Returns

- true - The InterruptControl feature is supported on the device
- false - The InterruptControl feature is not supported on the device

Description

This function identifies whether the InterruptControl feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_InterruptEnable
- PLIB_SQI_InterruptDisable
- PLIB_SQI_InterruptIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsInterruptControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsInterruptSignalControl Function

Identifies whether the InterruptSignalControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsInterruptSignalControl(SQI_MODULE_ID index);
```

Returns

- true - The InterruptSignalControl feature is supported on the device
- false - The InterruptSignalControl feature is not supported on the device

Description

This function identifies whether the InterruptSignalControl feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_InterruptSignalEnable
- PLIB_SQI_InterruptSignalDisable
- PLIB_SQI_InterruptSignalIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsInterruptSignalControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsInterruptStatus Function

Identifies whether the InterruptStatus feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsInterruptStatus(SQI_MODULE_ID index);
```

Returns

- true - The InterruptStatus feature is supported on the device
- false - The InterruptStatus feature is not supported on the device

Description

This function identifies whether the InterruptStatus feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_InterruptFlagGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsInterruptStatus(SQI_MODULE_ID index)

PLIB_SQI_ExistsLaneMode Function

Identifies whether the LaneMode feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsLaneMode(SQI_MODULE_ID index);
```

Returns

- true - The LaneMode feature is supported on the device
- false - The LaneMode feature is not supported on the device

Description

This function identifies whether the LaneMode feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_LaneModeSet

- PLIB_SQI_LaneModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsLaneMode(SQI_MODULE_ID index)

PLIB_SQI_ExistsReceiveLatch Function

Identifies whether the ReceiveLatch feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsReceiveLatch(SQI_MODULE_ID index);
```

Returns

- true - The ReceiveLatch feature is supported on the device
- false - The ReceiveLatch feature is not supported on the device

Description

This function identifies whether the ReceiveLatch feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_ReceiveLatchEnable
- PLIB_SQI_ReceiveLatchDisable
- PLIB_SQI_ReceiveLatchGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsReceiveLatch(SQI_MODULE_ID index)

PLIB_SQI_ExistsRxBufferCount Function

Identifies whether the RxBufferCount feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsRxBufferCount(SQI_MODULE_ID index);
```

Returns

- true - The RxBufferCount feature is supported on the device

- false - The RxBufferCount feature is not supported on the device

Description

This function identifies whether the RxBufferCount feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_NumberOfReceiveBufferReads

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsRxBufferCount(SQI_MODULE_ID index)

PLIB_SQI_ExistsRxBufIntThreshold Function

Identifies whether the RxBufIntThreshold feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsRxBufIntThreshold(SQI_MODULE_ID index);
```

Returns

- true - The RxBufIntThreshold feature is supported on the device
- false - The RxBufIntThreshold feature is not supported on the device

Description

This function identifies whether the RxBufIntThreshold feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_RxBufferThresholdIntSet
- PLIB_SQI_RxBufferThresholdIntGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsRxBufIntThreshold(SQI_MODULE_ID index)

PLIB_SQI_ExistsRxBufThreshold Function

Identifies whether the RxBufThreshold feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsRxBufThreshold(SQI_MODULE_ID index);
```

Returns

- true - The RxBufThreshold feature is supported on the device
- false - The RxBufThreshold feature is not supported on the device

Description

This function identifies whether the RxBufThreshold feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_RxBufferThresholdSet
- PLIB_SQI_RxBufferThresholdGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsRxBufThreshold(SQI_MODULE_ID index)

PLIB_SQI_ExistsRxData Function

Identifies whether the RxData feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsRxData(SQI_MODULE_ID index);
```

Returns

- true - The RxData feature is supported on the device
- false - The RxData feature is not supported on the device

Description

This function identifies whether the RxData feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_ReceiveData

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsRxData(SQI_MODULE_ID index)

PLIB_SQI_ExistsRxUnderRun Function

Identifies whether the RxUnderRun feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsRxUnderRun(SQI_MODULE_ID index);
```

Returns

- true - The RxUnderRun feature is supported on the device
- false - The RxUnderRun feature is not supported on the device

Description

This function identifies whether the RxUnderRun feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_ReceiveBufferIsUnderrun

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsRxUnderRun(SQI_MODULE_ID index)

PLIB_SQI_ExistsSoftReset Function

Identifies whether the SoftReset feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsSoftReset(SQI_MODULE_ID index);
```

Returns

- true - The SoftReset feature is supported on the device
- false - The SoftReset feature is not supported on the device

Description

This function identifies whether the SoftReset feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_SoftReset

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsSoftReset(SQI_MODULE_ID index)

PLIB_SQI_ExistsTransferCommand Function

Identifies whether the TransferCommand feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTransferCommand(SQI_MODULE_ID index);
```

Returns

- true - The TransferCommand feature is supported on the device
- false - The TransferCommand feature is not supported on the device

Description

This function identifies whether the TransferCommand feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_TransferDirectionSet
- PLIB_SQI_TransferDirectionGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTransferCommand(SQI_MODULE_ID index)

PLIB_SQI_ExistsTransferCount Function

Identifies whether the TransferCount feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTransferCount(SQI_MODULE_ID index);
```

Returns

- true - The TransferCount feature is supported on the device
- false - The TransferCount feature is not supported on the device

Description

This function identifies whether the TransferCount feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_ByteCountSet
- PLIB_SQI_ByteCountGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTransferCount(SQI_MODULE_ID index)

PLIB_SQI_ExistsTransferModeControl Function

Identifies whether the TransferModeControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTransferModeControl(SQI_MODULE_ID index);
```

Returns

- true - The TransferModeControl feature is supported on the device
- false - The TransferModeControl feature is not supported on the device

Description

This function identifies whether the TransferModeControl feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_TransferModeSet
- PLIB_SQI_TransferModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTransferModeControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsTxBufferFree Function

Identifies whether the TxBufferFree feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTxBufferFree(SQI_MODULE_ID index);
```

Returns

- true - The TxBufferFree feature is supported on the device
- false - The TxBufferFree feature is not supported on the device

Description

This function identifies whether the TxBufferFree feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_TransmitBufferFreeSpaceGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTxBufferFree(SQI_MODULE_ID index)

PLIB_SQI_ExistsTxBufIntThreshold Function

Identifies whether the TxBufIntThreshold feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTxBufIntThreshold(SQI_MODULE_ID index);
```

Returns

- true - The TxBufIntThreshold feature is supported on the device
- false - The TxBufIntThreshold feature is not supported on the device

Description

This function identifies whether the TxBufIntThreshold feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_TxBufferThresholdIntSet
- PLIB_SQI_TxBufferThresholdIntGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTxBufIntThreshold(SQI_MODULE_ID index)

PLIB_SQI_ExistsTxBufThreshold Function

Identifies whether the TxBufThreshold feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTxBufThreshold(SQI_MODULE_ID index);
```

Returns

- true - The TxBufThreshold feature is supported on the device
- false - The TxBufThreshold feature is not supported on the device

Description

This function identifies whether the TxBufThreshold feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_TxBufferThresholdSet
- PLIB_SQI_TxBufferThresholdGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTxBufThreshold(SQI_MODULE_ID index)

PLIB_SQI_ExistsTxData Function

Identifies whether the TxData feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTxData(SQI_MODULE_ID index);
```

Returns

- true - The TxData feature is supported on the device
- false - The TxData feature is not supported on the device

Description

This function identifies whether the TxData feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_TransmitData

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTxData(SQI_MODULE_ID index)

PLIB_SQI_ExistsTxOverFlow Function

Identifies whether the TxOverFlow feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTxOverFlow(SQI_MODULE_ID index);
```

Returns

- true - The TxOverFlow feature is supported on the device
- false - The TxOverFlow feature is not supported on the device

Description

This function identifies whether the TxOverFlow feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_TransmitBufferHasOverflowed

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTxOverFlow(SQI_MODULE_ID index)

PLIB_SQI_ExistsWPPinControl Function

Identifies whether the WPPinControl feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsWPPinControl(SQI_MODULE_ID index);
```

Returns

- true - The WPPinControl feature is supported on the device
- false - The WPPinControl feature is not supported on the device

Description

This function identifies whether the WPPinControl feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_WriteProtectSet
- PLIB_SQI_WriteProtectClear
- PLIB_SQI_WriteProtectGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsWPPinControl(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPChipSelect Function

Identifies whether the XIPChipSelect feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPChipSelect(SQI_MODULE_ID index);
```

Returns

- true - The XIPChipSelect feature is supported on the device
- false - The XIPChipSelect feature is not supported on the device

Description

This function identifies whether the XIPChipSelect feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPChipSelectSet
- PLIB_SQI_XIPChipSelectGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPChipSelect(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPControlWord1 Function

Identifies whether the XIPControlWord1 feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPControlWord1(SQI_MODULE_ID index);
```

Returns

- true - The XIPControlWord1 feature is supported on the device
- false - The XIPControlWord1 feature is not supported on the device

Description

This function identifies whether the XIPControlWord1 feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPControlWord1Set
- PLIB_SQI_XIPControlWord1Get

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPControlWord1(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPControlWord2 Function

Identifies whether the XIPControlWord2 feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPControlWord2(SQI_MODULE_ID index);
```

Returns

- true - The XIPControlWord2 feature is supported on the device
- false - The XIPControlWord2 feature is not supported on the device

Description

This function identifies whether the XIPControlWord2 feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPControlWord2Set
- PLIB_SQI_XIPControlWord2Get

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPControlWord2(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPLaneMode Function

Identifies whether the XIPLaneMode feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPLaneMode(SQI_MODULE_ID index);
```

Returns

- true - The XIPLaneMode feature is supported on the device
- false - The XIPLaneMode feature is not supported on the device

Description

This function identifies whether the XIPLaneMode feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_XIPLaneModeSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPLaneMode(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPModeBytes Function

Identifies whether the XIPModeBytes feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPModeBytes(SQI_MODULE_ID index);
```

Returns

- true - The XIPModeBytes feature is supported on the device
- false - The XIPModeBytes feature is not supported on the device

Description

This function identifies whether the XIPModeBytes feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPModeBytesSet
- PLIB_SQI_XIPModeBytesGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPModeBytes(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPModeCode Function

Identifies whether the XIPModeCode feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPModeCode(SQI_MODULE_ID index);
```

Returns

- true - The XIPModeCode feature is supported on the device
- false - The XIPModeCode feature is not supported on the device

Description

This function identifies whether the XIPModeCode feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPModeCodeSet
- PLIB_SQI_XIPModeCodeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPModeCode(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPNumberOfAddressBytes Function

Identifies whether the XIPNumberOfAddressBytes feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPNumberOfAddressBytes(SQI_MODULE_ID index);
```

Returns

- true - The XIPNumberOfAddressBytes feature is supported on the device
- false - The XIPNumberOfAddressBytes feature is not supported on the device

Description

This function identifies whether the XIPNumberOfAddressBytes feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPAddressBytesSet
- PLIB_SQI_XIPAddressBytesGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPNumberOfAddressBytes(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPNumberOfDummyBytes Function

Identifies whether the XIPNumberOfDummyBytes feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPNumberOfDummyBytes(SQI_MODULE_ID index);
```

Returns

- true - The XIPNumberOfDummyBytes feature is supported on the device
- false - The XIPNumberOfDummyBytes feature is not supported on the device

Description

This function identifies whether the XIPNumberOfDummyBytes feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPDummyBytesSet
- PLIB_SQI_XIPDummyBytesGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPNumberOfDummyBytes(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPReadOpCode Function

Identifies whether the XIPReadOpCode feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPReadOpCode(SQI_MODULE_ID index);
```

Returns

- true - The XIPReadOpCode feature is supported on the device
- false - The XIPReadOpCode feature is not supported on the device

Description

This function identifies whether the XIPReadOpCode feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPReadOpcodeSet
- PLIB_SQI_XIPReadOpcodeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPReadOpCode(SQI_MODULE_ID index)

PLIB_SQI_ExistsCommandStatus Function

Identifies whether the CommandStatus feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsCommandStatus(SQI_MODULE_ID index);
```

Returns

- true - The CommandStatus feature is supported on the device
- false - The CommandStatus feature is not supported on the device

Description

This function identifies whether the CommandStatus feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_CommandStatusGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsCommandStatus(SQI_MODULE_ID index)

PLIB_SQI_ExistsConBufAvailable Function

Identifies whether the ConBufWordsAvailable feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsConBufAvailable(SQI_MODULE_ID index);
```

Returns

- true - The ConBufWordsAvailable feature is supported on the device
- false - The ConBufWordsAvailable feature is not supported on the device

Description

This function identifies whether the ConBufWordsAvailable feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_ConBufWordsAvailable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsConBufAvailable(SQI_MODULE_ID index)

PLIB_SQI_ExistsConBufferSoftReset Function

Identifies whether the control buffer soft reset feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsConBufferSoftReset(SQI_MODULE_ID index);
```

Returns

- true - The control buffer soft reset feature is supported on the device
- false - The control buffer soft reset feature is not supported on the device

Description

This function identifies whether the control buffer soft reset feature is available on the SQI module. When this function returns true, the following function is supported on the device:

- PLIB_SQI_ConBufferSoftReset

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsConBufferSoftReset(SQI_MODULE_ID index)

PLIB_SQI_ExistsDDRMode Function

Identifies whether the DDRMode feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDDRMode(SQI_MODULE_ID index);
```

Returns

- true - The DDRModeSet and DDRModeGet feature is supported on the device
- false - The DDRModeSet and DDRModeGet feature is not supported on the device

Description

This function identifies whether the DDRModeSet feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_DDRModeSet
- PLIB_SQI_DDRModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDDRMode(SQI_MODULE_ID index)

PLIB_SQI_ExistsDMABDFetch Function

Identifies whether the DMABDFetch feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsDMABDFetch(SQI_MODULE_ID index);
```

Returns

- true - The DMABDFetch feature is supported on the device
- false - The DMABDFetch feature is not supported on the device

Description

This function identifies whether the DMABDFetch feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_DMABDFetchStart
- PLIB_SQI_DMABDFetchStop

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsDMABDFetch(SQI_MODULE_ID index)

PLIB_SQI_ExistsRxBufferSoftReset Function

Identifies whether the receive buffer soft reset feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsRxBufferSoftReset(SQI_MODULE_ID index);
```

Returns

- true - The receive buffer soft reset feature is supported on the device
- false - The receive buffer soft reset feature is not supported on the device

Description

This function identifies whether the receive buffer soft reset feature is available on the SQI module. When this function returns true, the following function is supported on the device:

- PLIB_SQI_RxBufferSoftReset

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsRxBufferSoftReset(SQI_MODULE_ID index)

PLIB_SQI_ExistsStatusCheck Function

Identifies whether the StatusCheckSet feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsStatusCheck(SQI_MODULE_ID index);
```

Returns

- true - The StatusCheckSet feature is supported on the device
- false - The StatusCheckSet feature is not supported on the device

Description

This function identifies whether the StatusCheck feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_StatusCheckSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsStatusCheck(SQI_MODULE_ID index)

PLIB_SQI_ExistsTapDelay Function

Identifies whether the TapDelay feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTapDelay(SQI_MODULE_ID index);
```

Returns

- true - The TapDelaySet feature is supported on the device
- false - The TapDelaySet feature is not supported on the device

Description

This function identifies whether the TapDelay feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_TapDelaySet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTapDelay(SQI_MODULE_ID index)

PLIB_SQI_ExistsTxBufferSoftReset Function

Identifies whether the transmit buffer soft reset feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsTxBufferSoftReset(SQI_MODULE_ID index);
```

Returns

- true - The transmit buffer soft reset feature is supported on the device
- false - The transmit buffer soft reset feature is not supported on the device

Description

This function identifies whether the transmit buffer soft reset feature is available on the SQI module. When this function returns true, the following function is supported on the device:

- PLIB_SQI_TxBufferSoftReset

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsTxBufferSoftReset(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPControlWord3 Function

Identifies whether the XIPControlWord3 feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPControlWord3(SQI_MODULE_ID index);
```

Returns

- true - The XIPControlWord3Set and XIPControlWord3Get feature is supported on the device
- false - The XIPControlWord3Set and XIPControlWord3Get feature is not supported on the device

Description

This function identifies whether the XIPControlWord3 feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPControlWord3Set

- PLIB_SQI_XIPControlWord3Get

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPControlWord3(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPControlWord4 Function

Identifies whether the XIPControlWord4 feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPControlWord4(SQI_MODULE_ID index);
```

Returns

- true - The XIPControlWord4Set and XIPControlWord4Get feature is supported on the device
- false - The XIPControlWord4Set and XIPControlWord4Get feature is not supported on the device

Description

This function identifies whether the XIPControlWord4 feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPControlWord4Set
- PLIB_SQI_XIPControlWord4Get

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPControlWord4(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPDDRMode Function

Identifies whether the XIPDDRMode feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPDDRMode(SQI_MODULE_ID index);
```

Returns

- true - The XIPDDRModeSet feature is supported on the device
- false - The XIPDDRModeSet feature is not supported on the device

Description

This function identifies whether the XIPDDRMode feature is available on the SQI module. When this function returns true, this function is supported on the device:

- PLIB_SQI_XIPDDRModeSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPDDRMode(SQI_MODULE_ID index)

PLIB_SQI_ExistsXIPSDRCommandDDRData Function

Identifies whether the XIPSDRCommandDDRData feature exists on the SQI module.

File

plib_sqi.h

C

```
bool PLIB_SQI_ExistsXIPSDRCommandDDRData(SQI_MODULE_ID index);
```

Returns

- true - The XIPSDRCommandDDRDataSet and XIPSDRCommandDDRDataSetfeatureGet is supported on the device
- false - The XIPSDRCommandDDRDataSet and XIPSDRCommandDDRDataGet not supported on the device

Description

This function identifies whether the XIPSDRCommandDDRData feature is available on the SQI module. When this function returns true, these functions are supported on the device:

- PLIB_SQI_XIPSDRCommandDDRDataSet
- PLIB_SQI_XIPSDRCommandDDRDataGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_SQI_ExistsXIPSDRCommandDDRData(SQI_MODULE_ID index)

k) Data Types and Constants

SQI_ADDR_BYTES Enumeration

Defines the list of SQI address bytes.

File

help_plib_sqi.h

C

```
typedef enum {
  ADDR_BYTES_4,
  ADDR_BYTES_3,
  ADDR_BYTES_2,
  ADDR_BYTES_1,
  ADDR_BYTES_0
} SQI_ADDR_BYTES;
```

Members

Members	Description
ADDR_BYTES_4	SQI is set to Transmit 4 Address Bytes
ADDR_BYTES_3	SQI is set to Transmit 3 Address Bytes
ADDR_BYTES_2	SQI is set to Transmit 2 Address Bytes
ADDR_BYTES_1	SQI is set to Transmit 1 Address Bytes
ADDR_BYTES_0	SQI is set to Transmit No Address Bytes

Description

SQI Number of Address Bytes

This macro defines the list of SQI address bytes.

SQI_BD_CTRL_WORD Enumeration

Defines the list of SQI Buffer Descriptor control word.

File

help_plib_sqi.h

C

```
typedef enum {
  BD_ENABLE,
  BD_DISABLE,
  CS_1_ACTIVE,
  CS_0_ACTIVE,
  FLASH_SC_ENABLE,
  FLASH_SC_DISABLE,
  SET_LSBF,
  SET_MSBF,
  DMA_LANE_QUAD,
  DMA_LANE_DUAL,
  DMA_LANE_SINGLE,
  DMA_IN_TRANSMIT,
  DMA_IN_RECEIVE,
  LAST_BD,
  NOT_LAST_BD,
  LAST_PKT,
  NOT_LAST_PKT,
  PKT_INT_ENABLE,
  PKT_INT_DISABLE,
  BD_DONE_INT_ENABLE,
  BD_DONE_INT_DISABLE,
  BD_BUF_LENGTH
} SQI_BD_CTRL_WORD;
```

Members

Members	Description
BD_ENABLE	Current Buffer Descriptor is Enabled
BD_DISABLE	Current Buffer Descriptor is Disabled
CS_1_ACTIVE	Chip Select 1 is Active
CS_0_ACTIVE	Chip Select 0 is Active
FLASH_SC_ENABLE	Automatic Status Check Enabled
FLASH_SC_DISABLE	Automatic Status Check Disabled
SET_LSBF	Least Significant Bit First
SET_MSBF	Most Significant Bit First

DMA_LANE_QUAD	DMA writes/reads in Quad Lane Mode
DMA_LANE_DUAL	DMA writes/reads in Dual Lane Mode
DMA_LANE_SINGLE	DMA writes/reads in Single Lane Mode
DMA_IN_TRANSMIT	DMA is Transmitting
DMA_IN_RECEIVE	DMA is Receiving
LAST_BD	Indicates Last Buffer Descriptor in the List
NOT_LAST_BD	Indicates Non Last Buffer Descriptor in the List
LAST_PKT	Indicates Last Packet of the Data Chunk
NOT_LAST_PKT	Indicates Non Last Packet of the Data Chunk
PKT_INT_ENABLE	Indicates Packet Interrupt is Enabled
PKT_INT_DISABLE	Indicates Packet Interrupt is Disabled
BD_DONE_INT_ENABLE	Indicates Buffer Descriptor Done Interrupt is Enabled
BD_DONE_INT_DISABLE	Indicates Buffer Descriptor Done Interrupt is Disabled
BD_BUF_LENGTH	Indicates Buffer Length

Description

SQI Buffer Descriptor Control Words

This macro defines the list of SQI Buffer Descriptor control word.

SQI_BD_STATE Enumeration

Defines the list of SQI Buffer Descriptor states.

File

help_plib_sqi.h

C

```
typedef enum {
  BD_STATE_DISABLED,
  BD_STATE_DONE,
  BD_STATE_PROCESSING_DATA,
  BD_STATE_BEING_FETCHED,
  BD_STATE_FETCH_REQ_PENDING,
  BD_STATE_IDLE
} SQI_BD_STATE;
```

Members

Members	Description
BD_STATE_DISABLED	Fetched Buffer Descriptor is Disabled
BD_STATE_DONE	Fetched Buffer Descriptor Processed
BD_STATE_PROCESSING_DATA	Fetched Buffer Descriptor is in Data transfer phase
BD_STATE_BEING_FETCHED	In the process of Fetching the Buffer Descriptor
BD_STATE_FETCH_REQ_PENDING	Buffer Descriptor Fetch Request Pending
BD_STATE_IDLE	Buffer Descriptor process is idle

Description

SQI Buffer Descriptor (BD) State

This macro defines the list of SQI Buffer Descriptor states.

SQI_CLK_DIV Enumeration

Defines the list of SQI Clock Divider values.

File

help_plib_sqi.h

C

```
typedef enum {
  CLK_DIV_256,
  CLK_DIV_128,
```

```
  CLK_DIV_64,
  CLK_DIV_32,
  CLK_DIV_16,
  CLK_DIV_8,
  CLK_DIV_4,
  CLK_DIV_2,
  CLK_DIV_1
} SQI_CLK_DIV;
```

Members

Members	Description
CLK_DIV_256	SQI Clock is divided by 256
CLK_DIV_128	SQI Clock is divided by 128
CLK_DIV_64	SQI Clock is divided by 64
CLK_DIV_32	SQI Clock is divided by 32
CLK_DIV_16	SQI Clock is divided by 16
CLK_DIV_8	SQI Clock is divided by 8
CLK_DIV_4	SQI Clock is divided by 4
CLK_DIV_2	SQI Clock is divided by 2
CLK_DIV_1	SQI Clock is not divided

Description

SQI Clock Divider

This macro defines the list of SQI Clock Divider values.

SQI_CS_NUM Enumeration

Defines the list of SQI Chip Selects.

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_CS_1,
  SQI_CS_0
} SQI_CS_NUM;
```

Members

Members	Description
SQI_CS_1	SQI Chip Select 1
SQI_CS_0	SQI Chip Select 0

Description

SQI Device Select or Chip Select

This macro defines the list of SQI Chip Selects.

SQI_CS_OEN Enumeration

Defines the list of SQI Chip Selects on which output is enable.

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_CS_OEN_BOTH,
  SQI_CS_OEN_1,
  SQI_CS_OEN_0,
  SQI_CS_OEN_NONE
} SQI_CS_OEN;
```

Members

Members	Description
SQI_CS_OEN_BOTH	SQI chip select 0 and 1 are enabled
SQI_CS_OEN_1	SQI chip select 1 is enabled but chip select 0 is disabled
SQI_CS_OEN_0	SQI chip select 0 is enabled but chip select 1 is disabled
SQI_CS_OEN_NONE	SQI chip select 0 and 1 are disabled

Description

SQI Chip Select Output Enable

This macro defines the list of SQI Chip Selects on which output is enabled.

SQI_DATA_FORMAT Enumeration

Defines the Data Format Options available (LSBF/MSBF).

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_DATA_FORMAT_LSBF,
  SQI_DATA_FORMAT_MSBF
} SQI_DATA_FORMAT;
```

Members

Members	Description
SQI_DATA_FORMAT_LSBF	SQI Data is Least Significant Bit First Formatted
SQI_DATA_FORMAT_MSBF	SQI Data is Most Significant Bit First Formatted

Description

SQI Data Mode

This macro defines the Data Formats (LSBF/MSBF).

SQI_DATA_MODE Enumeration

Defines the list of SQI Data modes.

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_DATA_MODE_3,
  SQI_DATA_MODE_0
} SQI_DATA_MODE;
```

Members

Members	Description
SQI_DATA_MODE_3	SQI is in SPI mode 3
SQI_DATA_MODE_0	SQI is in SPI mode 0

Description

SQI Data Mode

This macro defines the list of SQI Data modes.

SQI_DATA_OEN Enumeration

Defines the list of SQI Data pins on which output is enabled.

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_DATA_OEN_QUAD,
  SQI_DATA_OEN_DUAL,
  SQI_DATA_OEN_SINGLE
} SQI_DATA_OEN;
```

Members

Members	Description
SQI_DATA_OEN_QUAD	SQI data outputs 3 to 0 are enabled (quad lane mode)
SQI_DATA_OEN_DUAL	SQI data outputs 1 and 0 are enabled (dual lane mode)
SQI_DATA_OEN_SINGLE	SQI data output 0 is enabled (single lane mode)

Description

SQI Data Output Enable

This macro defines the list of SQI Data Output pins on which output is enabled.

SQI_DATA_TYPE Type

Data type defining the SQI Data size.

File

help_plib_sqi.h

C

```
typedef uint32_t SQI_DATA_TYPE;
```

Description

SQI Data Type definition

This data type defines the SQI Data size

SQI_DUMMY_BYTES Enumeration

Defines the list of SQI dummy bytes.

File

help_plib_sqi.h

C

```
typedef enum {
  DUMMY_BYTES_7,
  DUMMY_BYTES_6,
  DUMMY_BYTES_5,
  DUMMY_BYTES_4,
  DUMMY_BYTES_3,
  DUMMY_BYTES_2,
  DUMMY_BYTE_1,
  DUMMY_BYTES_0
} SQI_DUMMY_BYTES;
```

Members

Members	Description
DUMMY_BYTES_7	SQI is set to Transmit 7 Dummy Bytes
DUMMY_BYTES_6	SQI is set to Transmit 6 Dummy Bytes
DUMMY_BYTES_5	SQI is set to Transmit 5 Dummy Bytes
DUMMY_BYTES_4	SQI is set to Transmit 4 Dummy Bytes
DUMMY_BYTES_3	SQI is set to Transmit 3 Dummy Bytes
DUMMY_BYTES_2	SQI is set to Transmit 2 Dummy Bytes

DUMMY_BYTE_1	SQI is set to Transmit 1 Dummy Bytes
DUMMY_BYTES_0	SQI is set to Transmit No Dummy Bytes

Description

SQI Number of Dummy Bytes

This macro defines the list of SQI dummy bytes after address bytes.

SQI_INTERRUPTS Enumeration

Defines the list of SQI interrupts.

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_PKTCOMP,
  SQI_BDDONE,
  SQI_CONTHR,
  SQI_CONEMPTY,
  SQI_CONFULL,
  SQI_RXTHR,
  SQI_RXFULL,
  SQI_RXEMPTY,
  SQI_TXTHR,
  SQI_TXFULL,
  SQI_TXEMPTY
} SQI_INTERRUPTS;
```

Members

Members	Description
SQI_PKTCOMP	SQI Packet Complete Interrupt (used in DMA mode)
SQI_BDDONE	SQI Buffer Descriptor Done Interrupt (used in DMA mode)
SQI_CONTHR	SQI Control Buffer Threshold Interrupt
SQI_CONEMPTY	SQI Control Buffer Empty Interrupt
SQI_CONFULL	SQI Control Buffer Full Interrupt
SQI_RXTHR	SQI Receive Buffer Threshold Interrupt
SQI_RXFULL	SQI Receive Buffer Empty Interrupt
SQI_RXEMPTY	SQI Receive Buffer Full Interrupt
SQI_TXTHR	SQI Transmit Buffer Threshold Interrupt
SQI_TXFULL	SQI Transmit Buffer Empty Interrupt
SQI_TXEMPTY	SQI Transmit Buffer Full Interrupt

Description

SQI Interrupt List

This macro defines the list of SQI interrupts.

SQI_LANE_MODE Enumeration

Defines the list of SQI Lane modes (single/dual/quad).

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_LANE_QUAD,
  SQI_LANE_DUAL,
  SQI_LANE_SINGLE
} SQI_LANE_MODE;
```

Members

Members	Description
SQI_LANE_QUAD	SQI is set into Quad Lane Mode
SQI_LANE_DUAL	SQI is set into Dual Lane Mode
SQI_LANE_SINGLE	SQI is set into Single Lane Mode

Description

SQI Lane Mode

This macro defines the list of SQI Lane modes.

SQI_MODE_BYTES Enumeration

Defines the list of SQI mode bytes.

File

help_plib_sqi.h

C

```
typedef enum {
  MODE_BYTES_3,
  MODE_BYTES_2,
  MODE_BYTES_1,
  MODE_BYTES_0
} SQI_MODE_BYTES;
```

Members

Members	Description
MODE_BYTES_3	SQI is set to Transmit 3 Mode Bytes
MODE_BYTES_2	SQI is set to Transmit 2 Mode Bytes
MODE_BYTES_1	SQI is set to Transmit 1 Mode Bytes
MODE_BYTES_0	SQI is set to Transmit No Mode Bytes

Description

SQI Number of Mode Bytes

This macro defines the list of SQI mode bytes allocated for mode code.

SQI_MODULE_ID Enumeration

Identifies the supported SQI modules.

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_ID_1,
  SQI_NUMBER_OF_MODULES
} SQI_MODULE_ID;
```

Members

Members	Description
SQI_ID_1	SQI Module 1 ID
SQI_NUMBER_OF_MODULES	Number of available SQI modules

Description

SQI Module ID

This enumeration identifies the SQI modules that are available on the microcontroller. This is the super set of all the possible instances that might be available on the Microchip microcontrollers.

Remarks

The caller should not rely on the specific numbers assigned to any of these values as they may change from one processor to the next.

Not all modules will be available on all microcontrollers. Refer to the data sheet for the specific controller in use to determine which modules are supported. The numbers used in the enumeration values will match the numbers provided in the data sheet.

SQI_XFER_CMD Enumeration

Defines the list of SQI transfer commands.

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_CMD_RECEIVE,
  SQI_CMD_TRANSMIT,
  SQI_CMD_IDLE
} SQI_XFER_CMD;
```

Members

Members	Description
SQI_CMD_RECEIVE	SQI issues a Receive Command
SQI_CMD_TRANSMIT	SQI issues a Transmit Command
SQI_CMD_IDLE	SQI is Idle

Description

SQI Transfer Command

This macro defines the list of SQI transfer commands.

SQI_XFER_MODE Enumeration

Defines the list of SQI Transfer modes.

File

help_plib_sqi.h

C

```
typedef enum {
  SQI_XFER_MODE_XIP,
  SQI_XFER_MODE_DMA,
  SQI_XFER_MODE_PIO
} SQI_XFER_MODE;
```

Members

Members	Description
SQI_XFER_MODE_XIP	SQI is in XIP mode
SQI_XFER_MODE_DMA	SQI is in DMA mode
SQI_XFER_MODE_PIO	SQI is in PIO mode

Description

SQI Transfer Mode

This macro defines the list of SQI Transfer modes.

SQI Peripheral Library Interface Header for common definitions.

Functions

	Name	Description
	PLIB_SQI_BurstEnable	Sets the burst enable (BURSTEN) function for higher throughput. This function is an artifact of the System Bus architecture.
	PLIB_SQI_ByteCountGet	Returns the current transmit/receive count.
	PLIB_SQI_ByteCountSet	Sets the transmit/receive count.
	PLIB_SQI_ChipSelectDeassertDisable	Clears the Chip Select deassert.
	PLIB_SQI_ChipSelectDeassertEnable	Sets the Chip Select deassert.
	PLIB_SQI_ChipSelectGet	Returns the Chip Select that is currently active.
	PLIB_SQI_ChipSelectSet	Activates the Chip Select.
	PLIB_SQI_ClockDisable	Disables the SQI transfer clock.
	PLIB_SQI_ClockDividerSet	Sets the SQI clock (that drives the SQI protocol) divider value. Divides the base clock to generate the SQI clock.
	PLIB_SQI_ClockEnable	Enables the SQI transfer clock.
	PLIB_SQI_ClockIsStable	Returns SQI transfer clock state.
	PLIB_SQI_CommandStatusGet	Returns the SQI command (transmit/receive/idle).
	PLIB_SQI_ConBufferSoftReset	Issues a soft reset to the SQI control buffer.
	PLIB_SQI_ConBufWordsAvailable	Returns the number of control buffer words available.
	PLIB_SQI_ConfigWordGet	Gets the SQI Configuration Word.
	PLIB_SQI_ConfigWordSet	Sets SQI Configuration Word.
	PLIB_SQI_ControlBufferThresholdGet	Returns the transmit buffer space in bytes.
	PLIB_SQI_ControlBufferThresholdSet	Sets the control buffer threshold value.
	PLIB_SQI_ControlWordGet	Get the SQI Control Word.
	PLIB_SQI_ControlWordSet	Sets the SQI Control Word.
	PLIB_SQI_CSOutputEnableSelect	Selects the output enables on SQI Chip Select pins.
	PLIB_SQI_DataFormatGet	Returns the data format.
	PLIB_SQI_DataFormatSet	Sets the data format to Least Significant Bit First (LSBF)..
	PLIB_SQI_DataLineStatus	Returns the logical status of the SQI data lines.
	PLIB_SQI_DataModeSet	Sets the SQI data mode of operation.
	PLIB_SQI_DataOutputEnableSelect	Selects the output enables on SQI data outputs.
	PLIB_SQI_DDRModeGet	Return the SQI data rate mode (single/double) value.
	PLIB_SQI_DDRModeSet	Sets SQI communication to DDR mode.
	PLIB_SQI_Disable	Disables the SQI module.
	PLIB_SQI_DMABDBaseAddressGet	Returns the address of the base buffer descriptor.
	PLIB_SQI_DMABDBaseAddressSet	Sets the address of the base buffer descriptor.
	PLIB_SQI_DMABDControlWordGet	Returns Current Buffer Descriptor Control Word Information.
	PLIB_SQI_DMABDCurrentAddressGet	Returns the address of the current buffer descriptor in process.
	PLIB_SQI_DMABDFetchStart	Starts the DMA buffer descriptor fetch process.
	PLIB_SQI_DMABDFetchStop	Stops the DMA buffer descriptor fetch process.
	PLIB_SQI_DMABDIsBusy	Returns whether or not the DMA Buffer Descriptor is busy.
	PLIB_SQI_DMABDPollCounterSet	Sets the poll counter value.
	PLIB_SQI_DMABDPollDisable	Disables the buffer descriptor polling.
	PLIB_SQI_DMABDPollEnable	Enables the buffer descriptor polling.
	PLIB_SQI_DMABDPollIsEnabled	Returns whether or not the DMA buffer descriptor poll is enabled.
	PLIB_SQI_DMABDReceiveBufferCountGet	Returns the receive buffer space in bytes.
	PLIB_SQI_DMABDReceiveBufferLengthGet	Returns the receive length in bytes.
	PLIB_SQI_DMABDReceiveStateGet	Returns the current state of the buffer descriptor in progress.
	PLIB_SQI_DMABDStateGet	Returns the current state of the buffer descriptor in progress.

	PLIB_SQI_DMABDTransmitBufferCountGet	Returns the transmit buffer space in bytes.
	PLIB_SQI_DMABDTransmitBufferLengthGet	Returns the transmit length in bytes.
	PLIB_SQI_DMABDTransmitStateGet	Returns the current state of the buffer descriptor in progress.
	PLIB_SQI_DMADisable	Disables the built-in DMA logic.
	PLIB_SQI_DMAEnable	Enables the built-in DMA logic.
	PLIB_SQI_DMAHasStarted	Returns whether or no the DMA process has started.
	PLIB_SQI_DMAIsEnabled	Returns whether or not DMA is enabled.
	PLIB_SQI_Enable	Enables the SQI module.
	PLIB_SQI_ExistsBDBaseAddress	Identifies whether the BDBaseAddress feature exists on the SQI module.
	PLIB_SQI_ExistsBDControlWord	Identifies whether the BDControlWord feature exists on the SQI module.
	PLIB_SQI_ExistsBDCurrentAddress	Identifies whether the BDCurrentAddress feature exists on the SQI module.
	PLIB_SQI_ExistsBDPollCount	Identifies whether the BDPollCount feature exists on the SQI module.
	PLIB_SQI_ExistsBDPollingEnable	Identifies whether the BDPollingEnable feature exists on the SQI module.
	PLIB_SQI_ExistsBDProcessState	Identifies whether the BDProcessState feature exists on the SQI module.
	PLIB_SQI_ExistsBDRxBufCount	Identifies whether the BDRxBufCount feature exists on the SQI module.
	PLIB_SQI_ExistsBDRxLength	Identifies whether the BDRxLength feature exists on the SQI module.
	PLIB_SQI_ExistsBDRxState	Identifies whether the BDRxState feature exists on the SQI module.
	PLIB_SQI_ExistsBDTxBufCount	Identifies whether the BDTxBufCount feature exists on the SQI module.
	PLIB_SQI_ExistsBDTxLength	Identifies whether the BDTxLength feature exists on the SQI module.
	PLIB_SQI_ExistsBDTxState	Identifies whether the BDTxState feature exists on the SQI module.
	PLIB_SQI_ExistsBurstControl	Identifies whether the BurstControl feature exists on the SQI module.
	PLIB_SQI_ExistsChipSelect	Identifies whether the ChipSelect feature exists on the SQI module.
	PLIB_SQI_ExistsClockControl	Identifies whether the ClockControl feature exists on the SQI module.
	PLIB_SQI_ExistsClockDivider	Identifies whether the ClockDivider feature exists on the SQI module.
	PLIB_SQI_ExistsClockReady	Identifies whether the ClockReady feature exists on the SQI module.
	PLIB_SQI_ExistsCommandStatus	Identifies whether the CommandStatus feature exists on the SQI module.
	PLIB_SQI_ExistsConBufAvailable	Identifies whether the ConBufWordsAvailable feature exists on the SQI module.
	PLIB_SQI_ExistsConBufferSoftReset	Identifies whether the control buffer soft reset feature exists on the SQI module.
	PLIB_SQI_ExistsConBufThreshold	Identifies whether the ConBufThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsConfigWord	Identifies whether the ConfigWord feature exists on the SQI module.
	PLIB_SQI_ExistsControlWord	Identifies whether the ControlWord feature exists on the SQI module.
	PLIB_SQI_ExistsCSDeassert	Identifies whether the CSDeassert feature exists on the SQI module.
	PLIB_SQI_ExistsCSOutputEnable	Identifies whether the CSOutputEnable feature exists on the SQI module.
	PLIB_SQI_ExistsDataFormat	Identifies whether the DataFormat feature exists on the SQI module.
	PLIB_SQI_ExistsDataModeControl	Identifies whether the DataModeControl feature exists on the SQI module.
	PLIB_SQI_ExistsDataOutputEnable	Identifies whether the DataOutputEnable feature exists on the SQI module.
	PLIB_SQI_ExistsDataPinStatus	Identifies whether the DataPinStatus feature exists on the SQI module.
	PLIB_SQI_ExistsDDRMode	Identifies whether the DDRMode feature exists on the SQI module.
	PLIB_SQI_ExistsDMABDFetch	Identifies whether the DMABDFetch feature exists on the SQI module.
	PLIB_SQI_ExistsDmaEnable	Identifies whether the DMAEnable feature exists on the SQI module.
	PLIB_SQI_ExistsDMAEngineBusy	Identifies whether the DMAEngineBusy feature exists on the SQI module.
	PLIB_SQI_ExistsDMAProcessInProgress	Identifies whether the DMAProcessInProgress feature exists on the SQI module.
	PLIB_SQI_ExistsEnableControl	Identifies whether the EnableControl feature exists on the SQI module.
	PLIB_SQI_ExistsHoldPinControl	Identifies whether the HoldPinControl feature exists on the SQI module.
	PLIB_SQI_ExistsInterruptControl	Identifies whether the InterruptControl feature exists on the SQI module.
	PLIB_SQI_ExistsInterruptSignalControl	Identifies whether the InterruptSignalControl feature exists on the SQI module.
	PLIB_SQI_ExistsInterruptStatus	Identifies whether the InterruptStatus feature exists on the SQI module.
	PLIB_SQI_ExistsLaneMode	Identifies whether the LaneMode feature exists on the SQI module.
	PLIB_SQI_ExistsReceiveLatch	Identifies whether the ReceiveLatch feature exists on the SQI module.
	PLIB_SQI_ExistsRxBufferCount	Identifies whether the RxBufferCount feature exists on the SQI module.
	PLIB_SQI_ExistsRxBufferSoftReset	Identifies whether the receive buffer soft reset feature exists on the SQI module.
	PLIB_SQI_ExistsRxBufIntThreshold	Identifies whether the RxBufIntThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsRxBufThreshold	Identifies whether the RxBufThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsRxData	Identifies whether the RxData feature exists on the SQI module.
	PLIB_SQI_ExistsRxUnderRun	Identifies whether the RxUnderRun feature exists on the SQI module.

	PLIB_SQI_ExistsSoftReset	Identifies whether the SoftReset feature exists on the SQI module.
	PLIB_SQI_ExistsStatusCheck	Identifies whether the StatusCheckSet feature exists on the SQI module.
	PLIB_SQI_ExistsTapDelay	Identifies whether the TapDelay feature exists on the SQI module.
	PLIB_SQI_ExistsTransferCommand	Identifies whether the TransferCommand feature exists on the SQI module.
	PLIB_SQI_ExistsTransferCount	Identifies whether the TransferCount feature exists on the SQI module.
	PLIB_SQI_ExistsTransferModeControl	Identifies whether the TransferModeControl feature exists on the SQI module.
	PLIB_SQI_ExistsTxBufferFree	Identifies whether the TxBufferFree feature exists on the SQI module.
	PLIB_SQI_ExistsTxBufferSoftReset	Identifies whether the transmit buffer soft reset feature exists on the SQI module.
	PLIB_SQI_ExistsTxBufIntThreshold	Identifies whether the TxBufIntThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsTxBufThreshold	Identifies whether the TxBufThreshold feature exists on the SQI module.
	PLIB_SQI_ExistsTxData	Identifies whether the TxData feature exists on the SQI module.
	PLIB_SQI_ExistsTxOverFlow	Identifies whether the TxOverFlow feature exists on the SQI module.
	PLIB_SQI_ExistsWPPinControl	Identifies whether the WPPinControl feature exists on the SQI module.
	PLIB_SQI_ExistsXIPChipSelect	Identifies whether the XIPChipSelect feature exists on the SQI module.
	PLIB_SQI_ExistsXIPControlWord1	Identifies whether the XIPControlWord1 feature exists on the SQI module.
	PLIB_SQI_ExistsXIPControlWord2	Identifies whether the XIPControlWord2 feature exists on the SQI module.
	PLIB_SQI_ExistsXIPControlWord3	Identifies whether the XIPControlWord3 feature exists on the SQI module.
	PLIB_SQI_ExistsXIPControlWord4	Identifies whether the XIPControlWord4 feature exists on the SQI module.
	PLIB_SQI_ExistsXIPDDRMode	Identifies whether the XIPDDRMode feature exists on the SQI module.
	PLIB_SQI_ExistsXIPLaneMode	Identifies whether the XIPLaneMode feature exists on the SQI module.
	PLIB_SQI_ExistsXIPModeBytes	Identifies whether the XIPModeBytes feature exists on the SQI module.
	PLIB_SQI_ExistsXIPModeCode	Identifies whether the XIPModeCode feature exists on the SQI module.
	PLIB_SQI_ExistsXIPNumberOfAddressBytes	Identifies whether the XIPNumberOfAddressBytes feature exists on the SQI module.
	PLIB_SQI_ExistsXIPNumberOfDummyBytes	Identifies whether the XIPNumberOfDummyBytes feature exists on the SQI module.
	PLIB_SQI_ExistsXIPReadOpCode	Identifies whether the XIPReadOpCode feature exists on the SQI module.
	PLIB_SQI_ExistsXIPSDRCommandDDRData	Identifies whether the XIPSDRCommandDDRData feature exists on the SQI module.
	PLIB_SQI_HoldClear	Clears the hold function to be disabled on SQID3 in single and dual lane modes.
	PLIB_SQI_HoldGet	Gets the status of HOLD function on SQID3 pin.
	PLIB_SQI_HoldSet	Sets the hold function to be enabled on SQID3 in single or dual lane modes.
	PLIB_SQI_InterruptDisable	Disables the interrupt source.
	PLIB_SQI_InterruptEnable	Enables the passed interrupt source.
	PLIB_SQI_InterruptFlagGet	Return SQI Interrupt flag status.
	PLIB_SQI_InterruptIsEnabled	Returns the interrupt state.
	PLIB_SQI_InterruptSignalDisable	Disables the interrupt signal source.
	PLIB_SQI_InterruptSignalEnable	Enables the passed interrupt signal source.
	PLIB_SQI_InterruptSignalIsEnabled	Returns the interrupt signal state.
	PLIB_SQI_LaneModeGet	Returns the lane mode (single/dual/quad).
	PLIB_SQI_LaneModeSet	Sets the data lane mode (single/dual/quad).
	PLIB_SQI_NumberOfReceiveBufferReads	Returns the number of receive buffer reads.
	PLIB_SQI_ReceiveBufferIsUnderrun	Returns the status of receive buffer.
	PLIB_SQI_ReceiveData	Reads the data from the receive buffer.
	PLIB_SQI_ReceiveLatchDisable	Disables the receive latch so receive data is discarded when in transmit mode.
	PLIB_SQI_ReceiveLatchEnable	Enables the receive latch so receive data is latched during transmit mode.
	PLIB_SQI_ReceiveLatchGet	Returns the receive latch status in transmit mode.
	PLIB_SQI_RxBufferSoftReset	Issues a soft reset to the SQI receive buffer.
	PLIB_SQI_RxBufferThresholdGet	Returns the receive command threshold.
	PLIB_SQI_RxBufferThresholdIntGet	Sets the receive buffer threshold interrupt.
	PLIB_SQI_RxBufferThresholdIntSet	Sets the receive buffer threshold for interrupt.
	PLIB_SQI_RxBufferThresholdSet	Sets the receive command threshold.
	PLIB_SQI_SoftReset	Issues a soft reset to the SQI module.
	PLIB_SQI_StatusCheckSet	Sets the Flash status check related control bits.
	PLIB_SQI_TapDelaySet	Sets the tap delays.
	PLIB_SQI_TransferDirectionGet	Returns the transfer command.
	PLIB_SQI_TransferDirectionSet	Sets the transfer command.

	PLIB_SQI_TransferModeGet	Returns the SQI transfer mode of operation.
	PLIB_SQI_TransferModeSet	Sets the SQI transfer mode of operation.
	PLIB_SQI_TransmitBufferFreeSpaceGet	Returns the number of transmit buffer words available.
	PLIB_SQI_TransmitBufferHasOverflowed	Returns the current status of the transmit buffer.
	PLIB_SQI_TransmitData	Writes data into the SQI transmit buffer.
	PLIB_SQI_TxBufferSoftReset	Issues a soft reset to the SQI transmit buffer.
	PLIB_SQI_TxBufferThresholdGet	Returns the transmit command threshold value.
	PLIB_SQI_TxBufferThresholdIntGet	Returns the value to trigger the transmit buffer threshold interrupt.
	PLIB_SQI_TxBufferThresholdIntSet	Sets the value to trigger the transmit buffer threshold interrupt.
	PLIB_SQI_TxBufferThresholdSet	Sets the transmit command threshold.
	PLIB_SQI_WriteProtectClear	Clears the Write-Protect function to be disabled on SQID2 in single or dual lane modes.
	PLIB_SQI_WriteProtectGet	Gets the state of the write-protect feature on SQID2.
	PLIB_SQI_WriteProtectSet	Sets the write-protect feature to be enabled on SQID2 in single or dual lane modes only.
	PLIB_SQI_XIPAddressBytesGet	Returns the number of address bytes.
	PLIB_SQI_XIPAddressBytesSet	Sets the number of address bytes.
	PLIB_SQI_XIPChipSelectGet	Returns the current active Chip Select.
	PLIB_SQI_XIPChipSelectSet	Activates the Chip Select in XIP mode.
	PLIB_SQI_XIPControlWord1Get	Get the XIP mode Control Word 1.
	PLIB_SQI_XIPControlWord1Set	Sets the XIP mode Control Word 1.
	PLIB_SQI_XIPControlWord2Get	Gets the XIP mode Control Word 2.
	PLIB_SQI_XIPControlWord2Set	Sets the XIP mode Control Word 2.
	PLIB_SQI_XIPControlWord3Get	Gets the XIP mode Control Word 3.
	PLIB_SQI_XIPControlWord3Set	Sets the XIP mode Control Word 3.
	PLIB_SQI_XIPControlWord4Get	Gets the XIP mode Control Word 4.
	PLIB_SQI_XIPControlWord4Set	Sets the XIP mode Control Word 4.
	PLIB_SQI_XIPDDRModeSet	Selects the rate mode (SDR/DDR) for different transactions in XIP mode.
	PLIB_SQI_XIPDummyBytesGet	Sets the number of dummy bytes.
	PLIB_SQI_XIPDummyBytesSet	Sets the number of dummy bytes.
	PLIB_SQI_XIPLaneModeSet	Selects the lane (Single/Dual/Quad) mode for different transaction in XIP mode.
	PLIB_SQI_XIPModeBytesGet	Returns the number of bytes used for mode code command.
	PLIB_SQI_XIPModeBytesSet	Allocates the bytes for mode code command.
	PLIB_SQI_XIPModeCodeGet	Returns the mode code op-code.
	PLIB_SQI_XIPModeCodeSet	Sets the mode code command.
	PLIB_SQI_XIPReadOpcodeGet	Returns the read op code in XIP mode.
	PLIB_SQI_XIPReadOpcodeSet	Sets the read op code in XIP mode.
	PLIB_SQI_XIPSDRCommandDDRDataGet	Returns the SQI command in SDR mode and Data in DDR mode bit value.
	PLIB_SQI_XIPSDRCommandDDRDataSet	Sets the SQI command in SDR mode.

Description

Serial Quad Interface (SQI) Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the SQI Peripheral Library.

File Name

plib_sqi.h

Company

Microchip Technology Inc.

help_plib_sqi.h

Identifies the various enumerations in SQI modules supported.

Enumerations

	Name	Description
	SQI_ADDR_BYTES	Defines the list of SQI address bytes.
	SQI_BD_CTRL_WORD	Defines the list of SQI Buffer Descriptor control word.
	SQI_BD_STATE	Defines the list of SQI Buffer Descriptor states.
	SQI_CLK_DIV	Defines the list of SQI Clock Divider values.
	SQI_CS_NUM	Defines the list of SQI Chip Selects.
	SQI_CS_OEN	Defines the list of SQI Chip Selects on which output is enable.
	SQI_DATA_FORMAT	Defines the Data Format Options available (LSBF/MSBF).
	SQI_DATA_MODE	Defines the list of SQI Data modes.
	SQI_DATA_OEN	Defines the list of SQI Data pins on which output is enabled.
	SQI_DUMMY_BYTES	Defines the list of SQI dummy bytes.
	SQI_INTERRUPTS	Defines the list of SQI interrupts.
	SQI_LANE_MODE	Defines the list of SQI Lane modes (single/dual/quad).
	SQI_MODE_BYTES	Defines the list of SQI mode bytes.
	SQI_MODULE_ID	Identifies the supported SQI modules.
	SQI_XFER_CMD	Defines the list of SQI transfer commands.
	SQI_XFER_MODE	Defines the list of SQI Transfer modes.

Types

	Name	Description
	SQI_DATA_TYPE	Data type defining the SQI Data size.

Description

This enumeration identifies the SQI modules which are available on the microcontroller. This is the super set of all the possible instances that might be available on the Microchip microcontrollers.

Timer Peripheral Library

This section describes the Timer Peripheral Library.

Introduction

This library provides a low-level abstraction of the Timer module on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thereby hiding differences from one microcontroller variant to another.

Description

The timer function is one of the basic features of a microcontroller. Timers are useful for generating accurate time-based periodic interrupts for software application or real-time operating systems. Other uses include counting external pulses or accurate timing measurement of external events using the timer's gate functions or producing precise time delays. Some timers can also be used to control timing of other peripherals.

Using the Library

This topic describes the basic architecture of the Timer Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_tmr.h`

The interface to the Timer Peripheral Library is defined in the `plib_tmr.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the Timer Peripheral Library must include `peripheral.h`.

Library File:

The Timer Peripheral Library is part of the processor-specific peripheral library archive (`.a`) file installed with the compiler. Libraries in this archive are automatically available to the linker (in the default search path) for any project built using the Microchip compiler.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Hardware Abstraction Model

This library provides the low-level abstraction of the Timer module on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in the software and introduces the library interface.

Note: The interface provided is a superset of all the functionality of the available timers on the device. Refer to the **"Timer"** chapters in the specific device data sheet or the family reference manual section specified in that chapter to determine the set of functions that are supported for each Timer module on your device.

Description

Microchip timers can be classified as:

- Overflow-based
- Period match-based

These timers are essentially counters of a specific size (8-, 16-, or 32-bits wide) that increment based on the clock cycle and the timer prescaler. An application can monitor these counters to determine how much time has elapsed.

The prescaler determines the timer granularity (resolution). It is a mechanism for generating the clock for the timer by the CPU clock. Every CPU has a clock source and the frequency of this source decides the rate at which instructions are executed by the processor. Most of the timers have the option of providing input clock prescalers, while some have the optional postscalers. The prescaler is used to divide the clock frequency of the Timer module and produce a clock for the timer.

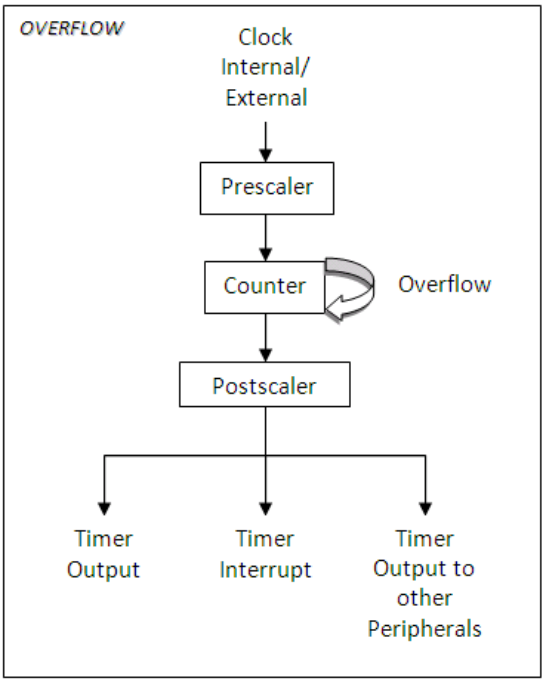
Each timer can be configured with a different source (internal or external) meaning, the source of the timer's input clock is selectable. Both internal and external sources are available, depending on the part in use, with some timers providing a clock synchronization mechanisms with reference to external source.

On some timers the clock edge, either the rising or the falling edge, on which the increment occurs, is selectable.

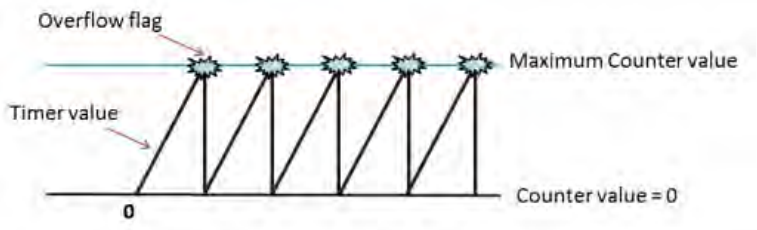
Overflow-based Timers

Overflow-based timers provide timer outputs or generate interrupts after a rollover from the maximum possible timer count.

Overflow Timer Abstraction Diagram



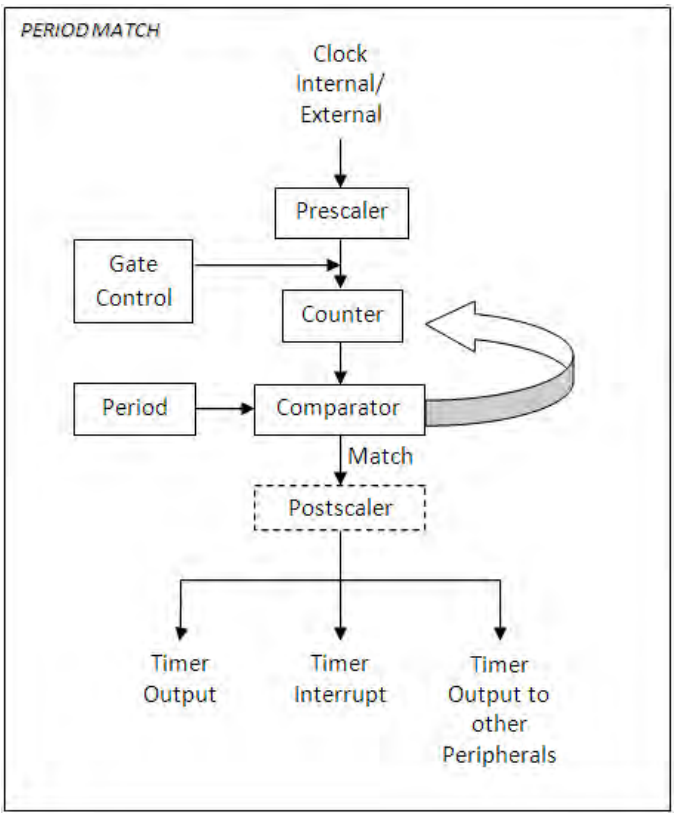
An overflow interrupt is triggered whenever the timer register overflows (i.e., reaches its maximum value based on its size as depicted by the following diagram).

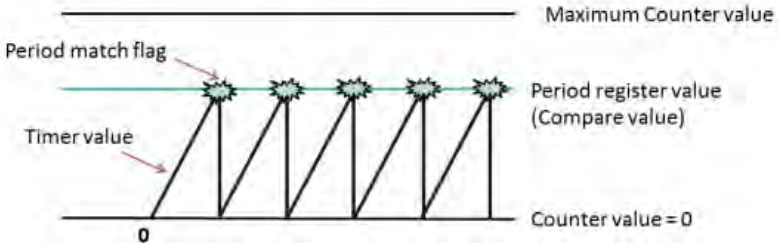


Period Match-based Timers

Period match-based timers provide the timer outputs or generate interrupts upon a match between the counter's count value against the preprogrammed period.

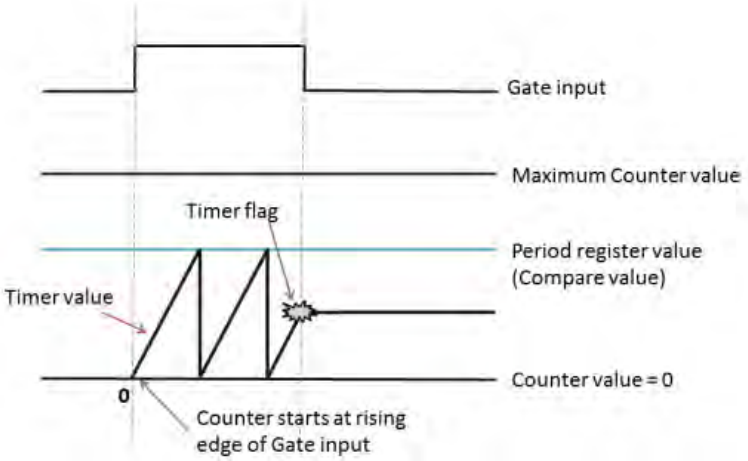
Period Match Timer Abstraction Diagram





Gated Time Accumulation/Gated Control Mode

The Gated Time Accumulation/Gate control mode allows the internal timer to increment based upon the duration of the high time applied to the timer input pin. In the Gated Time Accumulation mode, the timer clock source is derived from the internal system clock. When the input clock pin state is high, the timer will count up until a period match has occurred, or the input pin state is changed to a low state. A pin state transition from high-to-low will trigger an interrupt.



Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the Timer module.

Library Interface Section	Description
General Setup Functions	This section provides a set of functions that are used for: • Starting and stopping the timer • Setting up Single-shot or Continuous mode of operation • Timer oscillator control • Selecting if the external event can reset the counter • Timer assignment to various modules as the clock source • Setting up the counter resolution
Power Control Functions	This section provides functions that are required for controlling the timer operation in power-saving modes such as Idle and Sleep.
Clock Source Control Functions	This section provides a set of functions that are used for: • Selecting the input clock source • Setting up external clock synchronization • Selecting the source edge to increment the counter • Getting the source edge information
Gate Control Functions	This section provides a set of functions for controlling the gating logic of the timers.
Preprocessing Functions	This section provides a set of functions that are used for prescaler setup.
Period Control Functions	This section provides a set of functions for reading and writing the period.
Counter Control Functions	This section provides a set of functions for: • Reading and writing the counter values • Asynchronous write control
Post-processing Functions	This section provides a set of functions for controlling how the Timer module operates with other peripherals. This section only covers the peripherals that can be controlled from inside of the Timer module. For peripherals that have a dedicated timer, or the control lies within the peripheral, refer to that peripheral for the interface into the timers. This section can also provide a postscaling option, if available, on the microcontroller.
Miscellaneous Functions	This section provides a set of functions that are required to read status information.

How the Library Works

Timer modules can operate in the following modes:

- Synchronous Clock Counter
- Synchronous External Clock Counter
- Asynchronous External Clock Counter
- Gated Timer

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine availability.

Synchronous Internal Clock Counter

This section provides information and examples for setting up Synchronous Internal Clock Counter operation.

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine availability.

Description

Synchronous Clock Counter operation provides the following capabilities:

- Elapsed time measurements
- Time delays
- Periodic timer interrupts

Setup

Use the following steps for synchronous internal clock counter setup:

1. Some timer modules support multiple resolutions, which can be selected using PLIB_TMR_Mode16BitEnable or PLIB_TMR_Mode32BitEnable.
2. Set the start value of the timer using PLIB_TMR_Counter16BitSet or PLIB_TMR_Counter32BitSet.
3. The period register value can be set using PLIB_TMR_Period8BitSet, PLIB_TMR_Period16BitSet or PLIB_TMR_Period32BitSet. Use the appropriate function based on the resolution of the timer.
4. Clear the timer register using PLIB_TMR_Counter16BitClear or PLIB_TMR_Counter32BitClear.
5. In this mode, the input clock source for the timer is the internal clock, and is selected using PLIB_TMR_ClockSourceSelect, depending on which clock is used as the internal clock in the timer module of the device.
6. The prescaler for the clock can be selected using PLIB_TMR_PrescaleSelect. Pass in the desired prescaler into the function from the enumeration TMR_PRESCALE.
7. Start the timer once the setup is complete using PLIB_TMR_Start. The timer operation can be stopped using PLIB_TMR_Stop.

Example: Synchronous Counter (Internal Clock) Setup

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the application
// developer.

// Stop the timer
PLIB_TMR_Stop(MY_TIMER_INSTANCE);

// Set the prescaler, and set the clock source as internal
PLIB_TMR_PrescaleSelect(MY_TIMER_INSTANCE, TMR_PRESCALE_TMRX_VALUE_1);
PLIB_TMR_ClockSourceSelect(MY_TIMER_INSTANCE, TMR_CLOCK_SOURCE_PERIPHERAL_CLOCK);

// Clear the timer
PLIB_TMR_Counter16BitClear(MY_TIMER_INSTANCE);

// Load the period register
PLIB_TMR_Period16BitSet(MY_TIMER_INSTANCE, 0xFFFF);

// Start the timer
PLIB_TMR_Start(MY_TIMER_INSTANCE);
```

Timer interrupt is generated if enabled, when the timer count matches the period value if available, or when the counter overflows.

Example: Changing Counter Value During Timer Operation

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the application
// developer.
uint16_t timer_value;

// Clear the timer
timer_value = PLIB_TMR_Counter16BitGet(MY_TIMER_INSTANCE);

if(timer_value > 0x0ff0)
{
   PLIB_TMR_Counter16BitSet(MY_TIMER_INSTANCE, 0x000a);
}
```

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine availability.

Synchronous External Clock Counter

This section provides information and examples for Synchronous External Clock Counter operation.

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine availability.

Description

Synchronous external clock counter operation provides the following capabilities:

- Counting periodic or non-periodic pulses
- Use external clock as time base for timers

Setup

Use the following steps for synchronous external clock counter setup:

1. Some timer modules support multiple resolutions, which can be selected using PLIB_TMR_Mode16BitEnable or PLIB_TMR_Mode32BitEnable.

2. The period register value can be set using PLIB_TMR_Period16BitSet or PLIB_TMR_Period32BitSet. Use the appropriate function based on the resolution of the timer.
3. Set the start value of the timer using PLIB_TMR_Counter16BitSet or PLIB_TMR_Counter32BitSet.
4. Some timer modules, can select an external clock as its input source. Use PLIB_TMR_ClockSourceSelect to select the external clock source.
5. The clock source is synchronized with the internal clock for synchronous operation. Use PLIB_TMR_ClockSourceExternalSyncEnable to synchronize the external clock source.
6. The prescaler for the clock can be selected using PLIB_TMR_PrescaleSelect. Pass in the desired prescaler into the function from the enumeration TMR_PRESCALE.
7. Clear the timer register using PLIB_TMR_Counter16BitClear or PLIB_TMR_Counter32BitClear.
8. Start the timer once the setup is complete using PLIB_TMR_Start. The timer operation can be stopped using PLIB_TMR_Stop.

Example: Synchronous Counter (External Clock) Setup

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the application
// developer.

// Stop the timer
PLIB_TMR_Stop(MY_TIMER_INSTANCE);

// Set the prescaler, and set the clock source as external and enable synchronization
PLIB_TMR_PrescaleSelect(MY_TIMER_INSTANCE, TMR_PRESCALE_VALUE_256);
PLIB_TMR_ClockSourceSelect(MY_TIMER_INSTANCE, TMR_CLOCK_SOURCE_EXTERNAL_INPUT_PIN);
PLIB_TMR_ClockSourceExternalSyncEnable(MY_TIMER_INSTANCE);

// Clear the timer
PLIB_TMR_Counter16BitClear(MY_TIMER_INSTANCE);

// Load the period register
PLIB_TMR_Period16BitSet(MY_TIMER_INSTANCE, 0xFFFF);

// Start the timer
PLIB_TMR_Start(MY_TIMER_INSTANCE);
```

A timer interrupt is generated if enabled, when the timer count matches the period value if available, or when the counter overflows.

Example: Changing Counter Value During Timer Operation

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the application
// developer.
uint16_t timer_value;

// read the current timer value
timer_value = PLIB_TMR_Counter16BitGet(MY_TIMER_INSTANCE);

if(timer_value > 0x0ff0)
{
   PLIB_TMR_Counter16BitSet(MY_TIMER_INSTANCE, 0x000a);
}
```

Note: Not all modes are available on all devices. Please refer to the specific device data sheet to determine availability.

Asynchronous Counter

This section provides information and examples for setting up Asynchronous Counter operation.

Note: Not all features are available on all devices. Refer to the **"Timer"** chapters in the specific device data sheet for availability.

Description

Asynchronous Counter operation provides the following capabilities:

- The timer can operate in Sleep mode and can generate an interrupt on a period match
- The processor can wake up from Sleep on the timer interrupt
- The timer can be clocked from the Secondary Oscillator for real-time clock applications

Setup

Use the following steps for Asynchronous Counter setup:

1. Some timer modules support multiple resolutions, which can be selected using PLIB_TMR_Mode16BitEnable or PLIB_TMR_Mode32BitEnable.
2. The period register value can be set using PLIB_TMR_Period16BitSet or PLIB_TMR_Period32BitSet. Use the appropriate function based on the resolution of the timer.
3. Set the start value of the timer using PLIB_TMR_Counter16BitSet and PLIB_TMR_Counter32BitSet.

4. Some timer modules can select an external clock as its input source. Use PLIB_TMR_ClockSourceSelect to select the external clock source.
5. For Asynchronous mode operation, the clock source is not synchronized with the internal clock. Use PLIB_TMR_ClockSourceExternalSyncDisable to disable the synchronization of the external clock source.
6. The prescaler for the clock can be selected using PLIB_TMR_PrescaleSelect. Pass in the desired prescaler into the function from the enumeration TMR_PRESCALE.
7. Clear the timer register using PLIB_TMR_Counter16BitClear or PLIB_TMR_Counter32BitClear.
8. Start the timer once the setup is complete using PLIB_TMR_Start. The timer operation can be stopped using PLIB_TMR_Stop.

Example: Asynchronous Counter Setup

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the application
// developer.

// Stop the timer
PLIB_TMR_Stop(MY_TIMER_INSTANCE);

// Set the prescaler, and set the clock source as external and disable synchronization
PLIB_TMR_PrescaleSelect(MY_TIMER_INSTANCE, TMR_PRESCALE_VALUE_64);
PLIB_TMR_ClockSourceSelect(MY_TIMER_INSTANCE, TMR_CLOCK_SOURCE_EXTERNAL_INPUT_PIN);
PLIB_TMR_ClockSourceExternalSyncDisable(MY_TIMER_INSTANCE);

// Clear the timer
PLIB_TMR_Counter16BitClear(MY_TIMER_INSTANCE);

// Load the period register
PLIB_TMR_Period16BitSet(MY_TIMER_INSTANCE, 0x7F);

// Start the timer
PLIB_TMR_Start(MY_TIMER_INSTANCE);
```

A timer interrupt is generated if enabled, when the timer count matches the period value if available, or when the counter overflows.

Note: Not all features are available on all devices. Refer to the **"Timer"** chapters in the specific device data sheet for availability.

Gated Timer

This section provides information and examples for setting up Gated Timer operation.

Note: Not all features are available on all devices. Refer to the **"Timer"** chapters in the specific device data sheet for availability.

Description

Gated Timer operation can be used to allow measurement of an external signal.

Setup

Use the following steps for Gated Timer setup:

1. Some timer modules support multiple resolutions, which can be selected using PLIB_TMR_Mode16BitEnable or PLIB_TMR_Mode32BitEnable.
2. The period register value can be set using PLIB_TMR_Period16BitSet or PLIB_TMR_Period32BitSet. Use the appropriate function based on the resolution of the timer.
3. Set the start value of the timer using PLIB_TMR_Counter16BitSet and PLIB_TMR_Counter32BitSet.
4. In this mode, the input clock source for the timer is the internal clock, and is selected using PLIB_TMR_ClockSourceSelect, depending on which clock is used as the internal clock in the timer module of the device.
5. The prescaler for the clock can be selected using PLIB_TMR_PrescaleSelect. Pass in the desired pre scaler into the function from the enumeration TMR_PRESCALE.
6. Clear the timer register using PLIB_TMR_Counter16BitClear or PLIB_TMR_Counter32BitClear.
7. Gated operation can be enabled using the function PLIB_TMR_GateEnable.
8. Start the timer once the setup is complete using PLIB_TMR_Start. The timer operation can be stopped using PLIB_TMR_Stop.

Example: Gated Timer Setup

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the application
// developer.

// Stop the timer
PLIB_TMR_Stop(MY_TIMER_INSTANCE);

// Set the prescaler, and set the clock source as external and disable synchronization
PLIB_TMR_PrescaleSelect(MY_TIMER_INSTANCE, TMR_PRESCALE_VALUE_64);
PLIB_TMR_ClockSourceSelect(MY_TIMER_INSTANCE, TMR_CLOCK_SOURCE_EXTERNAL_INPUT_PIN);
```

```
PLIB_TMR_ClockSourceExternalSyncDisable(MY_TIMER_INSTANCE);

// Clear the timer
PLIB_TMR_Counter16BitClear(MY_TIMER_INSTANCE);

// Load the period register
PLIB_TMR_Period16BitSet(MY_TIMER_INSTANCE, 0x7F00);

// Enable the gate timer
PLIB_TMR_GateEnable(MY_TIMER_INSTANCE);

// Start the timer
PLIB_TMR_Start(MY_TIMER_INSTANCE);
```

A timer interrupt is generated if enabled, on the falling edge of the gate signal.

Note: Not all features are available on all devices. Refer to the **"Timer"** chapters in the specific device data sheet for availability.

Other Features

This section provides information on additional features.

Description

Each of the following modes can additionally support some or all of the features listed. Please refer to the specific device data sheet or family reference manual for details.

Operation During Sleep Mode

When the Timer module is configured to operate in Asynchronous mode (with an external clock source), it will continue to increment each timer clock (or prescale multiple of clocks) during Sleep mode.

Operation During Idle Mode

A Timer module can continue to operate in Idle mode by calling PLIB_TMR_StopInIdleDisable, or can stop operation in Idle mode by calling PLIB_TMR_StopInIdleEnable.

Timer Mode Control

- PLIB_TMR_Mode16BitEnable: This interface enables 16-bit mode and disables 32-bit mode
- PLIB_TMR_Mode32BitEnable: This interface enables 32-bit mode and disables 16-bit mode

Timer Usage Mode

Some timers operate in either Period Match mode or Overflow mode. The mode state can be retrieved from the Timer Peripheral Library using PLI_TMR_IsPeriodMatchBased. This function returns 'true' Period Match mode and 'false' for Overflow mode.

Timer Prescaler Information

Prescaler divisor information associated with the respective prescaler value selected through TMR_PRESCALE can be retrieved through PLIB_TMR_PrescaleDivisorGet.

The true prescaler value can be obtained by using PLIB_TMR_PrescaleGet.

Configuring the Library

The library is configured for the supported Timer modules when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Setup Functions

	Name	Description
	PLIB_TMR_Mode16BitEnable	Enables the Timer module for 16-bit operation and disables all other modes.
	PLIB_TMR_Mode32BitEnable	Enables 32-bit operation on the Timer module combination.
	PLIB_TMR_Start	Starts/enables the indexed timer.
	PLIB_TMR_Stop	Stops/disables the indexed timer.

b) Power Control Functions

	Name	Description
	PLIB_TMR_StopInIdleDisable	Continue module operation when the device enters Idle mode.
	PLIB_TMR_StopInIdleEnable	Discontinues module operation when the device enters Idle mode.

c) Clock Source Control Functions

	Name	Description
	PLIB_TMR_ClockSourceExternalSyncDisable	Disables the clock synchronization of the external input.
	PLIB_TMR_ClockSourceExternalSyncEnable	Enables the clock synchronization of the external input.
	PLIB_TMR_ClockSourceSelect	Selects the clock source.

d) Gate Control Functions

	Name	Description
	PLIB_TMR_GateDisable	Enables counting regardless of the corresponding timer gate function.
	PLIB_TMR_GateEnable	Enables counting controlled by the corresponding gate function.

e) Preprocessing Functions

	Name	Description
	PLIB_TMR_PrescaleDivisorGet	Gets the prescaler divisor information.
	PLIB_TMR_PrescaleGet	Gets the prescaler divisor value.
	PLIB_TMR_PrescaleSelect	Selects the clock prescaler.

f) Period Control Functions

	Name	Description
	PLIB_TMR_Period16BitGet	Gets the 16-bit period value.
	PLIB_TMR_Period16BitSet	Sets the 16-bit period value.
	PLIB_TMR_Period32BitGet	Gets the 32-bit period value.
	PLIB_TMR_Period32BitSet	Sets the 32-bit period value.

g) Counter Control Functions

	Name	Description
	PLIB_TMR_Counter16BitClear	Clears the 16-bit timer value.
	PLIB_TMR_Counter16BitGet	Gets the 16-bit timer value.
	PLIB_TMR_Counter16BitSet	Sets the 16-bit timer value.
	PLIB_TMR_Counter32BitClear	Clears the 32-bit timer value.
	PLIB_TMR_Counter32BitGet	Gets the 32-bit timer value.
	PLIB_TMR_Counter32BitSet	Sets the 32-bit timer value.
	PLIB_TMR_CounterAsyncWriteDisable	Disables the writes to the counter register until the pending write operation completes.
	PLIB_TMR_CounterAsyncWriteEnable	Enables back-to-back writes with legacy asynchronous timer functionality.
	PLIB_TMR_CounterAsyncWriteInProgress	Returns the status of the counter write in Asynchronous mode.

i) Miscellaneous Functions

	Name	Description
	PLIB_TMR_IsPeriodMatchBased	Gets the operating mode state of the Timer module based on Period Match or Overflow mode.

j) Feature Existence Functions

	Name	Description
	PLIB_TMR_ExistsClockSource	Identifies whether the ClockSource feature exists on the Timer module.
	PLIB_TMR_ExistsClockSourceSync	Identifies whether the ClockSourceSync feature exists on the Timer module.
	PLIB_TMR_ExistsCounter16Bit	Identifies whether the Counter16Bit feature exists on the Timer module.
	PLIB_TMR_ExistsCounter32Bit	Identifies whether the Counter32Bit feature exists on the Timer module.
	PLIB_TMR_ExistsCounterAsyncWriteControl	Identifies whether the CounterAsyncWriteControl feature exists on the Timer module.
	PLIB_TMR_ExistsCounterAsyncWriteInProgress	Identifies whether the CounterAsyncWriteInProgress feature exists on the Timer module.
	PLIB_TMR_ExistsEnableControl	Identifies whether the EnableControl feature exists on the Timer module.

	PLIB_TMR_ExistsGatedTimeAccumulation	Identifies whether the GatedTimeAccumulation feature exists on the Timer module.
	PLIB_TMR_ExistsMode16Bit	Identifies whether the Mode16Bit feature exists on the Timer module.
	PLIB_TMR_ExistsMode32Bit	Identifies whether the Mode32Bit feature exists on the Timer module.
	PLIB_TMR_ExistsPeriod16Bit	Identifies whether the Period16Bit feature exists on the Timer module.
	PLIB_TMR_ExistsPeriod32Bit	Identifies whether the Period32Bit feature exists on the Timer module.
	PLIB_TMR_ExistsPrescale	Identifies whether the Prescale feature exists on the Timer module.
	PLIB_TMR_ExistsStopInIdleControl	Identifies whether the StopInIdle feature exists on the Timer module.
	PLIB_TMR_ExistsTimerOperationMode	Identifies whether the TimerOperationMode feature exists on the Timer module.

k) Data Types and Constants

	Name	Description
	TMR_CLOCK_SOURCE	Data type defining the different clock sources.
	TMR_MODULE_ID	Identifies the supported Timer modules.
	TMR_PRESCALE	Defines the list of possible prescaler values.

Description

This section describes the Application Programming Interface (API) functions of the Timer Peripheral Library.

Refer to each section for a detailed description.

a) General Setup Functions

PLIB_TMR_Mode16BitEnable Function

Enables the Timer module for 16-bit operation and disables all other modes.

File

plib_tmr.h

C

```
void PLIB_TMR_Mode16BitEnable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function enables the Timer module for 16-bit operation and disables all other modes.

Remarks

Calling this function disables the operation of the Timer module 8-bit mode.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsMode16Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_Mode16BitEnable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_Mode16BitEnable(TMR_MODULE_ID index)

PLIB_TMR_Mode32BitEnable Function

Enables 32-bit operation on the Timer module combination.

File

plib_tmr.h

C

```
void PLIB_TMR_Mode32BitEnable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function enables the Timer module and the index +1 Timer module to act as one 32-bit timer module and disables all other modes.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsMode32Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_Mode32BitEnable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_Mode32BitEnable(TMR_MODULE_ID index)

PLIB_TMR_Start Function

Starts/enables the indexed timer.

File

plib_tmr.h

C

```
void PLIB_TMR_Start(TMR_MODULE_ID index);
```

Returns

None.

Description

This function starts/enables the indexed timer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
```

```
PLIB_TMR_Start(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_Start(TMR_MODULE_ID index)

PLIB_TMR_Stop Function

Stops/disables the indexed timer.

File

plib_tmr.h

C

```
void PLIB_TMR_Stop(TMR_MODULE_ID index);
```

Returns

None.

Description

This function stops/disables the indexed timer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_Stop(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_Stop(TMR_MODULE_ID index)

b) Power Control Functions

PLIB_TMR_StopInIdleDisable Function

Continue module operation when the device enters Idle mode.

File

plib_tmr.h

C

```
void PLIB_TMR_StopInIdleDisable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function continues module operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsStopInIdleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_StopInIdleDisable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_StopInIdleDisable(TMR_MODULE_ID index)

PLIB_TMR_StopInIdleEnable Function

Discontinues module operation when the device enters Idle mode.

File

plib_tmr.h

C

```
void PLIB_TMR_StopInIdleEnable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function discontinues module operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsStopInIdleControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_StopInIdleEnable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_StopInIdleEnable(TMR_MODULE_ID index)

c) Clock Source Control Functions

PLIB_TMR_ClockSourceExternalSyncDisable Function

Disables the clock synchronization of the external input.

File

plib_tmr.h

C

```
void PLIB_TMR_ClockSourceExternalSyncDisable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function disables the clock synchronization of the external input.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsClockSourceSync in your application to determine whether this feature is available.

Preconditions

The timer module must be configured to use the external clock using the function PLIB_TMR_ClockSourceSelect with the clock source as TMR_CLOCK_SOURCE_EXTERNAL_INPUT_PIN. If the function PLIB_TMR_ClockSourceSelect configures the clock with some other enumeration, this function will have no effect.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_ClockSourceExternalSyncDisable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_ClockSourceExternalSyncDisable(TMR_MODULE_ID index)

PLIB_TMR_ClockSourceExternalSyncEnable Function

Enables the clock synchronization of the external input.

File

plib_tmr.h

C

```
void PLIB_TMR_ClockSourceExternalSyncEnable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function enables the clock synchronization of the external input.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsClockSourceSync in your application to determine whether this feature is available.

Preconditions

The timer module must be configured to use the external clock using the function PLIB_TMR_ClockSourceSelect with the clock source as TMR_CLOCK_SOURCE_EXTERNAL_INPUT_PIN. If the function PLIB_TMR_ClockSourceSelect configures the clock with some other enumeration, this function will have no effect.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_ClockSourceExternalSyncEnable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_ClockSourceExternalSyncEnable(TMR_MODULE_ID index)

PLIB_TMR_ClockSourceSelect Function

Selects the clock source.

File

plib_tmr.h

C

```
void PLIB_TMR_ClockSourceSelect(TMR_MODULE_ID index, TMR_CLOCK_SOURCE source);
```

Returns

None.

Description

This function selects the clock source.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsClockSource in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_ClockSourceSelect(MY_TMR_INSTANCE, TMR_CLOCK_SOURCE_PERIPHERAL_CLOCK);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
source	One of the possible values of TMR_CLOCK_SOURCE

Function

void PLIB_TMR_ClockSourceSelect(TMR_MODULE_ID index, TMR_CLOCK_SOURCE source)

d) Gate Control Functions

PLIB_TMR_GateDisable Function

Enables counting regardless of the corresponding timer gate function.

File

plib_tmr.h

C

```
void PLIB_TMR_GateDisable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function enables counting regardless of the gate function.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsGatedTimeAccumulation in your application to determine whether this feature is available.

Preconditions

The timer must be enabled for this function to take effect.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_GateDisable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_GateDisable(TMR_MODULE_ID index)

PLIB_TMR_GateEnable Function

Enables counting controlled by the corresponding gate function.

File

plib_tmr.h

C

```
void PLIB_TMR_GateEnable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function enables counting controlled by the gate function.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsGatedTimeAccumulation in your application to determine whether this feature is available.

Preconditions

The timer must be enabled, for this function to take effect.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_GateEnable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_GateEnable(TMR_MODULE_ID index)

e) Preprocessing Functions

PLIB_TMR_PrescaleDivisorGet Function

Gets the prescaler divisor information.

File

plib_tmr.h

C

```
uint16_t PLIB_TMR_PrescaleDivisorGet(TMR_MODULE_ID index, TMR_PRESCALE prescale);
```

Returns

prescale divisor value

Description

This function returns the prescaler divisor information.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsPrescale in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
uint16_t div = PLIB_TMR_PrescaleDivisorGet (MY_TMR_INSTANCE, TMR_PRESCALE_VALUE_1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
prescale	One of the possible values of TMR_PRESCALE

Function

uint16_t PLIB_TMR_PrescaleDivisorGet(TMR_MODULE_ID index, TMR_PRESCALE prescale)

PLIB_TMR_PrescaleGet Function

Gets the prescaler divisor value.

File

plib_tmr.h

C

```
uint16_t PLIB_TMR_PrescaleGet(TMR_MODULE_ID index);
```

Returns

Prescaler divisor value.

Description

This function returns the prescaler divisor value. The value returned will be direct number and not the enum equivalent.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsPrescale in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
```

```
// application developer.
uint16_t prescale;
prescale = PLIB_TMR_PrescaleGet (MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint16_t PLIB_TMR_PrescaleGet (TMR_MODULE_ID index)

PLIB_TMR_PrescaleSelect Function

Selects the clock prescaler.

File

plib_tmr.h

C

```
void PLIB_TMR_PrescaleSelect(TMR_MODULE_ID index, TMR_PRESCALE prescale);
```

Returns

None.

Description

This function selects the clock prescaler.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsPrescale in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_PrescaleSelect(MY_TMR_INSTANCE, TMR_PRESCALE_VALUE_8);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
prescale	One of the possible values of TMR_PRESCALE

Function

void PLIB_TMR_PrescaleSelect(TMR_MODULE_ID index, TMR_PRESCALE prescale)

f) Period Control Functions

PLIB_TMR_Period16BitGet Function

Gets the 16-bit period value.

File

plib_tmr.h

C

```
uint16_t PLIB_TMR_Period16BitGet(TMR_MODULE_ID index);
```

Returns

period - 16-bit period value

Description

This function gets the 16-bit period value.

Remarks

The timer period register may be written at any time before the timer is started or after the timer is stopped. The timer period register can also be written when servicing the interrupt for the timer. When the timer is in operation, it is not recommended to write to the period register.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsPeriod16Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
uint16_t period = PLIB_TMR_Period16BitGet(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint16_t PLIB_TMR_Period16BitGet(TMR_MODULE_ID index)

PLIB_TMR_Period16BitSet Function

Sets the 16-bit period value.

File

plib_tmr.h

C

```
void PLIB_TMR_Period16BitSet(TMR_MODULE_ID index, uint16_t period);
```

Returns

None.

Description

This function sets the 16-bit period value.

Remarks

The timer period register may be written at any time before the timer is started or after the timer is stopped. The timer period register can also be written when servicing the interrupt for the timer. When the timer is in operation, it is not recommended to write to the period register.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsPeriod16Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
// where, MY_PERIOD_VALUE is the 16-bit value which needs to be stored in the
// period register.
PLIB_TMR_Period16BitSet(MY_TMR_INSTANCE, MY_PERIOD_VALUE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
period	16-bit period register value

Function

void PLIB_TMR_Period16BitSet(TMR_MODULE_ID index, uint16_t period)

PLIB_TMR_Period32BitGet Function

Gets the 32-bit period value.

File

plib_tmr.h

C

```
uint32_t PLIB_TMR_Period32BitGet(TMR_MODULE_ID index);
```

Returns

period - 32-bit period value

Description

This function gets the 32-bit period value.

Remarks

The timer period register may be written at any time before the timer is started or after the timer is stopped. The timer period register can also be written when servicing the interrupt for the timer. When the timer is in operation, it is not recommended to write to the period register.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsPeriod32Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
uint32_t period = PLIB_TMR_Period32BitGet(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_TMR_Period32BitGet(TMR_MODULE_ID index)

PLIB_TMR_Period32BitSet Function

Sets the 32-bit period value.

File

plib_tmr.h

C

```
void PLIB_TMR_Period32BitSet(TMR_MODULE_ID index, uint32_t period);
```

Returns

None.

Description

This function sets the 32-bit period value.

Remarks

The timer period register may be written at any time before the timer is started or after the timer is stopped. The timer period register can also be written when servicing the interrupt for the timer. When the timer is in operation, it is not recommended to write to the period register.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsPeriod32Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
// where, MY_PERIOD_VALUE is the 32-bit value which needs to be stored in the
// period register.
PLIB_TMR_Period32BitSet(MY_TMR_INSTANCE, MY_PERIOD_VALUE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
period	32-bit period register value

Function

void PLIB_TMR_Period32BitSet(TMR_MODULE_ID index, uint32_t period)

g) Counter Control Functions

PLIB_TMR_Counter16BitClear Function

Clears the 16-bit timer value.

File

plib_tmr.h

C

```
void PLIB_TMR_Counter16BitClear(TMR_MODULE_ID index);
```

Returns

None.

Description

This function clears the 16-bit timer value.

Remarks

When the timer register is written, the timer increment does not occur for that cycle. Writes to the timer register in the asynchronous counter mode should be avoided.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsCounter16Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_Counter16BitClear(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_TMR_Counter16BitClear(TMR_MODULE_ID index)

PLIB_TMR_Counter16BitGet Function

Gets the 16-bit timer value.

File

plib_tmr.h

C

```
uint16_t PLIB_TMR_Counter16BitGet(TMR_MODULE_ID index);
```

Returns

16-bit timer value.

Description

This function gets the 16-bit timer value.

Remarks

PLIB_TMR_Counter16BitGet does not prevent the timer from incrementing during the same instruction cycle.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsCounter16Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
uint16_t timerValue = PLIB_TMR_Counter16BitGet(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint16_t PLIB_TMR_Counter16BitGet(TMR_MODULE_ID index)

PLIB_TMR_Counter16BitSet Function

Sets the 16-bit timer value.

File

plib_tmr.h

C

```
void PLIB_TMR_Counter16BitSet(TMR_MODULE_ID index, uint16_t value);
```

Returns

None.

Description

This function sets the 16-bit timer value.

Remarks

When the timer register is written to, the timer increment does not occur for that cycle. Writes to the timer register in the asynchronous counter mode should be avoided.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsCounter16Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_Counter16BitSet(MY_TMR_INSTANCE, 0x100);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
value	16-bit value to be set

Function

void PLIB_TMR_Counter16BitSet(TMR_MODULE_ID index, uint16_t value)

PLIB_TMR_Counter32BitClear Function

Clears the 32-bit timer value.

File

plib_tmr.h

C

```
void PLIB_TMR_Counter32BitClear(TMR_MODULE_ID index);
```

Returns

None.

Description

This function clears the 32-bit timer value.

Remarks

When the timer register is written, the timer increment does not occur for that cycle. Writes to the timer register in the asynchronous counter mode should be avoided.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsCounter32Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_Counter32BitClear(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_TMR_Counter32BitClear(TMR_MODULE_ID index)

PLIB_TMR_Counter32BitGet Function

Gets the 32-bit timer value.

File

plib_tmr.h

C

```
uint32_t PLIB_TMR_Counter32BitGet(TMR_MODULE_ID index);
```

Returns

32 bit timer value.

Description

This function gets the 32-bit timer value.

Remarks

PLIB_TMR_Counter32BitGet does not prevent the timer from incrementing during the same instruction cycle.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsCounter32Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
uint32_t timerValue = PLIB_TMR_Counter32BitGet(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint32_t PLIB_TMR_Counter32BitGet(TMR_MODULE_ID index)

PLIB_TMR_Counter32BitSet Function

Sets the 32-bit timer value.

File

plib_tmr.h

C

```
void PLIB_TMR_Counter32BitSet(TMR_MODULE_ID index, uint32_t value);
```

Returns

None.

Description

This function sets the 32-bit timer value.

Remarks

When the timer register is written, the timer increment does not occur for that cycle. Writes to the timer register in the asynchronous counter mode should be avoided.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsCounter32Bit in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_Counter32BitSet(MY_TMR_INSTANCE, 0x1000000);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
value	32-bit value to be set

Function

void PLIB_TMR_Counter32BitSet(TMR_MODULE_ID index, uint32_t value)

PLIB_TMR_CounterAsyncWriteDisable Function

Disables the writes to the counter register until the pending write operation completes.

File

plib_tmr.h

C

```
void PLIB_TMR_CounterAsyncWriteDisable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function disables the writes to the counter register until the pending write operation completes.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsCounterAsyncWriteControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_CounterAsyncWriteDisable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_CounterAsyncWriteDisable(TMR_MODULE_ID index)

PLIB_TMR_CounterAsyncWriteEnable Function

Enables back-to-back writes with legacy asynchronous timer functionality.

File

plib_tmr.h

C

```
void PLIB_TMR_CounterAsyncWriteEnable(TMR_MODULE_ID index);
```

Returns

None.

Description

This function enables back-to-back writes with legacy asynchronous timer functionality.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use

PLIB_TMR_ExistsCounterAsyncWriteControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
PLIB_TMR_CounterAsyncWriteEnable(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_TMR_CounterAsyncWriteEnable(TMR_MODULE_ID index)

PLIB_TMR_CounterAsyncWriteInProgress Function

Returns the status of the counter write in Asynchronous mode.

File

plib_tmr.h

C

```
bool PLIB_TMR_CounterAsyncWriteInProgress(TMR_MODULE_ID index);
```

Returns

- true - Write is in progress
- false - Write is complete

Description

This function returns the status of the counter write in Asynchronous mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsCounterAsyncWriteInProgress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
bool inProgress = PLIB_TMR_CounterAsyncWriteInProgress(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_TMR_CounterAsyncWriteInProgress(TMR_MODULE_ID index)

h) Post-processing Functions

i) Miscellaneous Functions

PLIB_TMR_IsPeriodMatchBased Function

Gets the operating mode state of the Timer module based on Period Match or Overflow mode.

File

plib_tmr.h

C

```
bool PLIB_TMR_IsPeriodMatchBased(TMR_MODULE_ID index);
```

Returns

- true - Operation in Period Match mode
- false - Operation in Overflow mode

Description

This function gets the operating mode state of the Timer module based on Period Match or Overflow mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_TMR_ExistsTimerOperationMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Where MY_TMR_INSTANCE, is the timer instance selected for use by the
// application developer.
bool status = PLIB_TMR_IsPeriodMatchBased(MY_TMR_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_TMR_IsPeriodMatchBased (TMR_MODULE_ID index)

j) Feature Existence Functions

PLIB_TMR_ExistsClockSource Function

Identifies whether the ClockSource feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsClockSource(TMR_MODULE_ID index);
```

Returns

- true - The ClockSource feature is supported on the device
- false - The ClockSource feature is not supported on the device

Description

This function identifies whether the ClockSource feature is available on the Timer module. When this function returns true, this function is supported on the device:

- PLIB_TMR_ClockSourceSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsClockSource(TMR_MODULE_ID index)

PLIB_TMR_ExistsClockSourceSync Function

Identifies whether the ClockSourceSync feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsClockSourceSync(TMR_MODULE_ID index);
```

Returns

- true - The ClockSourceSync feature is supported on the device
- false - The ClockSourceSync feature is not supported on the device

Description

This function identifies whether the ClockSourceSync feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_ClockSourceExternalSyncEnable
- PLIB_TMR_ClockSourceExternalSyncDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsClockSourceSync(TMR_MODULE_ID index)

PLIB_TMR_ExistsCounter16Bit Function

Identifies whether the Counter16Bit feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsCounter16Bit(TMR_MODULE_ID index);
```

Returns

- true - The Counter16Bit feature is supported on the device
- false - The Counter16Bit feature is not supported on the device

Description

This function identifies whether the Counter16Bit feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_Counter16BitSet
- PLIB_TMR_Counter16BitGet
- PLIB_TMR_Counter16BitClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsCounter16Bit(TMR_MODULE_ID index)

PLIB_TMR_ExistsCounter32Bit Function

Identifies whether the Counter32Bit feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsCounter32Bit(TMR_MODULE_ID index);
```

Returns

- true - The Counter32Bit feature is supported on the device
- false - The Counter32Bit feature is not supported on the device

Description

This function identifies whether the Counter32Bit feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_Counter32BitSet
- PLIB_TMR_Counter32BitGet
- PLIB_TMR_Counter32BitClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsCounter32Bit(TMR_MODULE_ID index)

PLIB_TMR_ExistsCounterAsyncWriteControl Function

Identifies whether the CounterAsyncWriteControl feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsCounterAsyncWriteControl(TMR_MODULE_ID index);
```

Returns

- true - The CounterAsyncWriteControl feature is supported on the device
- false - The CounterAsyncWriteControl feature is not supported on the device

Description

This function identifies whether the CounterAsyncWriteControl feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_CounterAsyncWriteEnable
- PLIB_TMR_CounterAsyncWriteDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsCounterAsyncWriteControl(TMR_MODULE_ID index)

PLIB_TMR_ExistsCounterAsyncWriteInProgress Function

Identifies whether the CounterAsyncWriteInProgress feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsCounterAsyncWriteInProgress(TMR_MODULE_ID index);
```

Returns

- true - The CounterAsyncWriteInProgress feature is supported on the device
- false - The CounterAsyncWriteInProgress feature is not supported on the device

Description

This function identifies whether the CounterAsyncWriteInProgress feature is available on the Timer module. When this function returns true, this function is supported on the device:

- PLIB_TMR_CounterAsyncWriteInProgress

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsCounterAsyncWriteInProgress(TMR_MODULE_ID index)

PLIB_TMR_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsEnableControl(TMR_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_Start
- PLIB_TMR_Stop

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsEnableControl(TMR_MODULE_ID index)

PLIB_TMR_ExistsGatedTimeAccumulation Function

Identifies whether the GatedTimeAccumulation feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsGatedTimeAccumulation(TMR_MODULE_ID index);
```

Returns

- true - The GatedTimeAccumulation feature is supported on the device
- false - The GatedTimeAccumulation feature is not supported on the device

Description

This function identifies whether the GatedTimeAccumulation feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_GateEnable
- PLIB_TMR_GateDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsGatedTimeAccumulation(TMR_MODULE_ID index)

PLIB_TMR_ExistsMode16Bit Function

Identifies whether the Mode16Bit feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsMode16Bit(TMR_MODULE_ID index);
```

Returns

- true - The Mode16Bit feature is supported on the device
- false - The Mode16Bit feature is not supported on the device

Description

This function identifies whether the Mode16Bit feature is available on the Timer module. When this function returns true, this function is supported on the device:

- PLIB_TMR_Mode16BitEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsMode16Bit(TMR_MODULE_ID index)

PLIB_TMR_ExistsMode32Bit Function

Identifies whether the Mode32Bit feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsMode32Bit(TMR_MODULE_ID index);
```

Returns

- true - The Mode32Bit feature is supported on the device
- false - The Mode32Bit feature is not supported on the device

Description

This function identifies whether the Mode32Bit feature is available on the Timer module. When this function returns true, this function is supported on the device:

- PLIB_TMR_Mode32BitEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsMode32Bit(TMR_MODULE_ID index)

PLIB_TMR_ExistsPeriod16Bit Function

Identifies whether the Period16Bit feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsPeriod16Bit(TMR_MODULE_ID index);
```

Returns

- true - The Period16Bit feature is supported on the device
- false - The Period16Bit feature is not supported on the device

Description

This function identifies whether the Period16Bit feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_Period16BitSet
- PLIB_TMR_Period16BitGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsPeriod16Bit(TMR_MODULE_ID index)

PLIB_TMR_ExistsPeriod32Bit Function

Identifies whether the Period32Bit feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsPeriod32Bit(TMR_MODULE_ID index);
```

Returns

- true - The Period32Bit feature is supported on the device
- false - The Period32Bit feature is not supported on the device

Description

This function identifies whether the Period32Bit feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_Period32BitSet
- PLIB_TMR_Period32BitGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsPeriod32Bit(TMR_MODULE_ID index)

PLIB_TMR_ExistsPrescale Function

Identifies whether the Prescale feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsPrescale(TMR_MODULE_ID index);
```

Returns

- true - The Prescale feature is supported on the device
- false - The Prescale feature is not supported on the device

Description

This function identifies whether the Prescale feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_PrescaleSelect
- PLIB_TMR_PrescaleGet
- PLIB_TMR_PrescaleDivisorGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsPrescale(TMR_MODULE_ID index)

PLIB_TMR_ExistsStopInIdleControl Function

Identifies whether the StopInIdle feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsStopInIdleControl(TMR_MODULE_ID index);
```

Returns

- true - The StopInIdle feature is supported on the device
- false - The StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the Timer module. When this function returns true, these functions are supported on the device:

- PLIB_TMR_StopInIdleEnable
- PLIB_TMR_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsStopInIdleControl(TMR_MODULE_ID index)

PLIB_TMR_ExistsTimerOperationMode Function

Identifies whether the TimerOperationMode feature exists on the Timer module.

File

plib_tmr.h

C

```
bool PLIB_TMR_ExistsTimerOperationMode(TMR_MODULE_ID index);
```

Returns

- true - The TimerOperationMode feature is supported on the device
- false - The TimerOperationMode feature is not supported on the device

Description

This function identifies whether the TimerOperationMode feature is available on the Timer module. When this function returns true, this function is supported on the device:

- PLIB_TMR_IsPeriodMatchBased

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_TMR_ExistsTimerOperationMode(TMR_MODULE_ID index)

k) Data Types and Constants

TMR_CLOCK_SOURCE Enumeration

Data type defining the different clock sources.

File

help_plib_tmr.h

C

```
typedef enum {
  TMR_CLOCK_SOURCE_PERIPHERAL_CLOCK,
  TMR_CLOCK_SOURCE_EXTERNAL_INPUT_PIN
} TMR_CLOCK_SOURCE;
```

Members

Members	Description
TMR_CLOCK_SOURCE_PERIPHERAL_CLOCK	Clock source is the internal clock = FOSC/n (where n, is processor specific)
TMR_CLOCK_SOURCE_EXTERNAL_INPUT_PIN	Clock source is the external input pin

Description

Clock sources selection enumeration

This data type defines the different clock sources.

TMR_MODULE_ID Enumeration

Identifies the supported Timer modules.

File

help_plib_tmr.h

C

```
typedef enum {
  TMR_ID_0,
  TMR_ID_1,
  TMR_ID_2,
  TMR_ID_3,
  TMR_ID_4,
  TMR_ID_5,
  TMR_ID_6,
  TMR_ID_7,
  TMR_ID_8,
  TMR_ID_9,
  TMR_NUMBER_OF_MODULES
} TMR_MODULE_ID;
```

Members

Members	Description
TMR_ID_0	Timer 0
TMR_ID_1	Timer 1
TMR_ID_2	Timer 2
TMR_ID_3	Timer 3
TMR_ID_4	Timer 4
TMR_ID_5	Timer 5
TMR_ID_6	Timer 6
TMR_ID_7	Timer 7
TMR_ID_8	Timer 8
TMR_ID_9	Timer 9
TMR_NUMBER_OF_MODULES	Max number of timers

Description

TMR Module ID

This enumeration identifies the available Timer modules.

Remarks

The caller should not rely on the specific numbers assigned to any of these values as they may change from one processor to the next.

Not all modules will be available on all microcontrollers. Refer to the data sheet for the specific controller in use to determine which modules are supported. The numbers used in the enumeration values will match the numbers provided in the data sheet.

TMR_PRESCALE Enumeration

Defines the list of possible prescaler values.

File

help_plib_tmr.h

C

```
typedef enum {
  TMR_PRESCALE_VALUE_1,
  TMR_PRESCALE_VALUE_2,
  TMR_PRESCALE_VALUE_4,
  TMR_PRESCALE_VALUE_8,
  TMR_PRESCALE_VALUE_16,
  TMR_PRESCALE_VALUE_32,
  TMR_PRESCALE_VALUE_64,
  TMR_PRESCALE_VALUE_256
} TMR_PRESCALE;
```

Members

Members	Description
TMR_PRESCALE_VALUE_1	Timer Prescaler Value 1:1
TMR_PRESCALE_VALUE_2	Timer Prescaler Value 1:2
TMR_PRESCALE_VALUE_4	Timer Prescaler Value 1:4
TMR_PRESCALE_VALUE_8	Timer Prescaler Value 1:8
TMR_PRESCALE_VALUE_16	Timer Prescaler Value 1:16
TMR_PRESCALE_VALUE_32	Timer Prescaler Value 1:32
TMR_PRESCALE_VALUE_64	Timer Prescaler Value 1:64
TMR_PRESCALE_VALUE_256	Timer Prescaler Value 1:256

Description

Prescaler Values

This macro defines the list of possible prescaler values.

Files

Files

Name	Description
plib_tmr.h	Timer Peripheral Library interface header.
help_plib_tmr.h	This is file help_plib_tmr.h.

Description

This section lists the source and header files used by the library.

plib_tmr.h

Timer Peripheral Library interface header.

Functions

	Name	Description
	PLIB_TMR_ClockSourceExternalSyncDisable	Disables the clock synchronization of the external input.
	PLIB_TMR_ClockSourceExternalSyncEnable	Enables the clock synchronization of the external input.
	PLIB_TMR_ClockSourceSelect	Selects the clock source.
	PLIB_TMR_Counter16BitClear	Clears the 16-bit timer value.
	PLIB_TMR_Counter16BitGet	Gets the 16-bit timer value.
	PLIB_TMR_Counter16BitSet	Sets the 16-bit timer value.
	PLIB_TMR_Counter32BitClear	Clears the 32-bit timer value.
	PLIB_TMR_Counter32BitGet	Gets the 32-bit timer value.
	PLIB_TMR_Counter32BitSet	Sets the 32-bit timer value.
	PLIB_TMR_CounterAsyncWriteDisable	Disables the writes to the counter register until the pending write operation completes.
	PLIB_TMR_CounterAsyncWriteEnable	Enables back-to-back writes with legacy asynchronous timer functionality.
	PLIB_TMR_CounterAsyncWriteInProgress	Returns the status of the counter write in Asynchronous mode.
	PLIB_TMR_ExistsClockSource	Identifies whether the ClockSource feature exists on the Timer module.
	PLIB_TMR_ExistsClockSourceSync	Identifies whether the ClockSourceSync feature exists on the Timer module.

	PLIB_TMR_ExistsCounter16Bit	Identifies whether the Counter16Bit feature exists on the Timer module.
	PLIB_TMR_ExistsCounter32Bit	Identifies whether the Counter32Bit feature exists on the Timer module.
	PLIB_TMR_ExistsCounterAsyncWriteControl	Identifies whether the CounterAsyncWriteControl feature exists on the Timer module.
	PLIB_TMR_ExistsCounterAsyncWriteInProgress	Identifies whether the CounterAsyncWriteInProgress feature exists on the Timer module.
	PLIB_TMR_ExistsEnableControl	Identifies whether the EnableControl feature exists on the Timer module.
	PLIB_TMR_ExistsGatedTimeAccumulation	Identifies whether the GatedTimeAccumulation feature exists on the Timer module.
	PLIB_TMR_ExistsMode16Bit	Identifies whether the Mode16Bit feature exists on the Timer module.
	PLIB_TMR_ExistsMode32Bit	Identifies whether the Mode32Bit feature exists on the Timer module.
	PLIB_TMR_ExistsPeriod16Bit	Identifies whether the Period16Bit feature exists on the Timer module.
	PLIB_TMR_ExistsPeriod32Bit	Identifies whether the Period32Bit feature exists on the Timer module.
	PLIB_TMR_ExistsPrescale	Identifies whether the Prescale feature exists on the Timer module.
	PLIB_TMR_ExistsStopInIdleControl	Identifies whether the StopInIdle feature exists on the Timer module.
	PLIB_TMR_ExistsTimerOperationMode	Identifies whether the TimerOperationMode feature exists on the Timer module.
	PLIB_TMR_GateDisable	Enables counting regardless of the corresponding timer gate function.
	PLIB_TMR_GateEnable	Enables counting controlled by the corresponding gate function.
	PLIB_TMR_IsPeriodMatchBased	Gets the operating mode state of the Timer module based on Period Match or Overflow mode.
	PLIB_TMR_Mode16BitEnable	Enables the Timer module for 16-bit operation and disables all other modes.
	PLIB_TMR_Mode32BitEnable	Enables 32-bit operation on the Timer module combination.
	PLIB_TMR_Period16BitGet	Gets the 16-bit period value.
	PLIB_TMR_Period16BitSet	Sets the 16-bit period value.
	PLIB_TMR_Period32BitGet	Gets the 32-bit period value.
	PLIB_TMR_Period32BitSet	Sets the 32-bit period value.
	PLIB_TMR_PrescaleDivisorGet	Gets the prescaler divisor information.
	PLIB_TMR_PrescaleGet	Gets the prescaler divisor value.
	PLIB_TMR_PrescaleSelect	Selects the clock prescaler.
	PLIB_TMR_Start	Starts/enables the indexed timer.
	PLIB_TMR_Stop	Stops/disables the indexed timer.
	PLIB_TMR_StopInIdleDisable	Continue module operation when the device enters Idle mode.
	PLIB_TMR_StopInIdleEnable	Discontinues module operation when the device enters Idle mode.

Description

Timer Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Timer Peripheral Library.

File Name

plib_tmr.h

Company

Microchip Technology Inc.

help_plib_tmr.h

Enumerations

	Name	Description
	TMR_CLOCK_SOURCE	Data type defining the different clock sources.
	TMR_MODULE_ID	Identifies the supported Timer modules.
	TMR_PRESCALE	Defines the list of possible prescaler values.

Description

This is file help_plib_tmr.h.

USART Peripheral Library

This section describes the USART Peripheral Library.

Introduction

This library provides a low-level abstraction of the USART Peripheral Library on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences from one microcontroller variant to another.

Description

The Universal Synchronous/Asynchronous Receiver/Transmitter (USART) module is the key component of the serial communications sub-system of a computer. The USART takes the data and transmits the individual bits in a sequential fashion. While receiving, the USART reassembles the bits into complete bytes. The data can be **8-bit** or **9-bit**.

There are two primary forms of serial transmission: Asynchronous and Synchronous.

Asynchronous

Asynchronous transmission allows data to be transmitted without the sender having to send a clock signal to the receiver. Instead, the sender and receiver must agree on timing parameters (i.e., baud rate) in advance and special bits are added to each word, which are used to synchronize the sending and receiving units.

When a word is given to the USART for asynchronous transmissions, a bit called the "Start" bit is added to the beginning of each word that is to be transmitted. The Start bit is used to alert the receiver that a word of data is about to be sent. After the Start bit, the individual bits of the word of data are sent, with the Least Significant bit (LSb) being sent first. When the entire data word has been sent, the transmitter may add a Parity bit that the transmitter generates. The Parity bit may be used by the receiver to perform simple error checking. Then, at least one Stop bit is sent by the transmitter.

The Start bit is always a space and the Stop bits are always marks. Each transmitted bit persists for a period of 1/(Baud Rate). An on-chip dedicated Baud Rate Generator (BRG) is used to derive standard baud rate frequencies.

When the receiver has received all of the bits in the data word, it may check for the Parity bits (both sender and receiver must agree on whether a Parity bit is to be used), and then the receiver looks for a Stop bit. If the Stop bit does not appear when it is supposed to, the USART module considers the entire word to be unintelligible and will report a framing error to the host processor when the data word is read.

Note: Please refer to the **"USART"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details.

Synchronous

Synchronous serial transmission requires that the sender and receiver share a clock with one another, or that the sender provide a strobe or other timing signal so that the receiver knows when to "read" the next bit of the data. This mode is not available on all microcontrollers.

It is typically used in systems with a single master and one or more slaves. The master device contains the necessary circuitry for baud rate generation and supplies the clock for all devices in the system.

There are two signal lines a bidirectional data line and a clock line. Since the data line is bidirectional, synchronous operation is only half-duplex.

Start and Stop bits are not used in synchronous transmissions.

Using the Library

This topic describes the basic architecture of the USART Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_usart.h`

The interface to the USART Peripheral library is defined in the `plib_usart.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the USART Peripheral library must include `peripheral.h`.

Library File:

The USART Peripheral library archive (`.a`) file is installed with MPLAB Harmony.

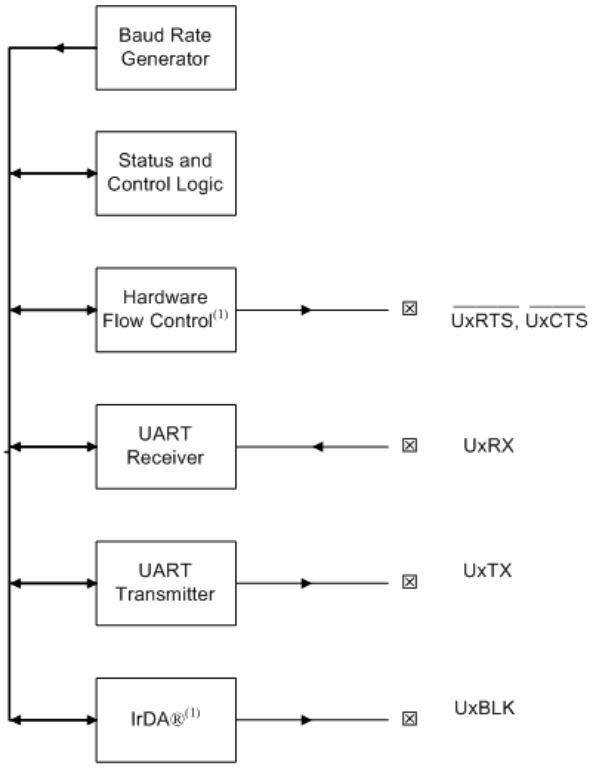
Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Hardware Abstraction Model

This section describes the hardware abstraction model.

Description

Hardware Abstraction Model



Note 1: This feature is not available on all devices. Refer to the **"USART"** chapter in the specific device data sheet to determine availability.

Hardware Abstraction Model

The USART Peripheral Library provides interface routines to interact with the blocks shown in the diagram.

The **Baud Rate Controller** controls the timing in Asynchronous mode, the desired baud rate can be programmed in the baud rate controller or, the baud rate controller can be configured to determine the baud rate of the transmitting device automatically.

The **Transmitter** and **Receiver** are capable of handling 8-bit or 9-bit data, which can be programmed in the control logic. The 9th bit is used to transfer the address or the parity. Enable 9-bit mode if the hardware is to be used for address or parity detection.

The **Status and Control logic**, provide the ability to control different ways the transmitter, receiver, and the baud rate controller can function. It also can provides status about the transmitter, receiver, or the baud rate controller.

The **Hardware Flow Control** uses CTS and the RTS lines to perform handshaking. Flow control is the ability to stop, and then restart the flow without any loss of bytes. Flow control is needed for modems and other hardware to allow a jump in instantaneous flow rates.

The USART module provides two types of infrared USART support: one is the IrDA clock output to support the external IrDA encoder and decoder, and the other is the full implementation of the IrDA encoder and decoder.

Note: These features are not available on all devices. Please refer to the specific device data sheet to determine availability.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the USART module.

Library Interface Section	Description
General Functions	Provides setup and configuration interface routines for • IrDA • Hardware Flow Control • Operation in power saving modes. • and other general setup

Baud Rate Generator Functions	Provides setup and configuration interface routines together with status routines for Baud Rate Generator (BRG).
Transmitter Functions	Provides setup, data transfer, error and the status interface routines for the transmitter.
Receiver Functions	Provides setup, data transfer, error and the status interface routines for the receiver.
Feature Existence Functions	Provides interface routines to determine existence of features.

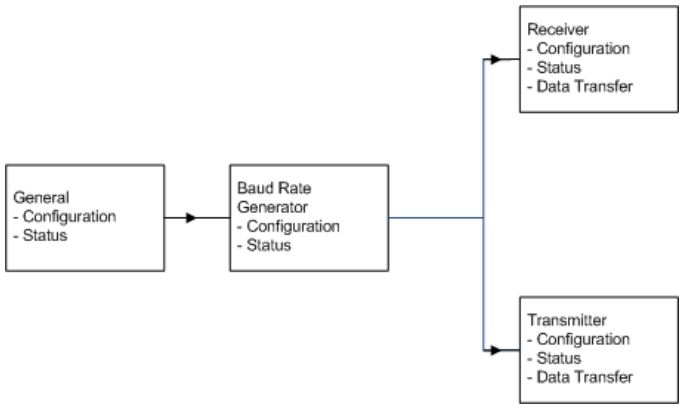
How the Library Works

Provides information on how the library works.

Description

This section provides information on using the peripheral library with the USART module. The usage model for different scenarios is also described.

Usage Model



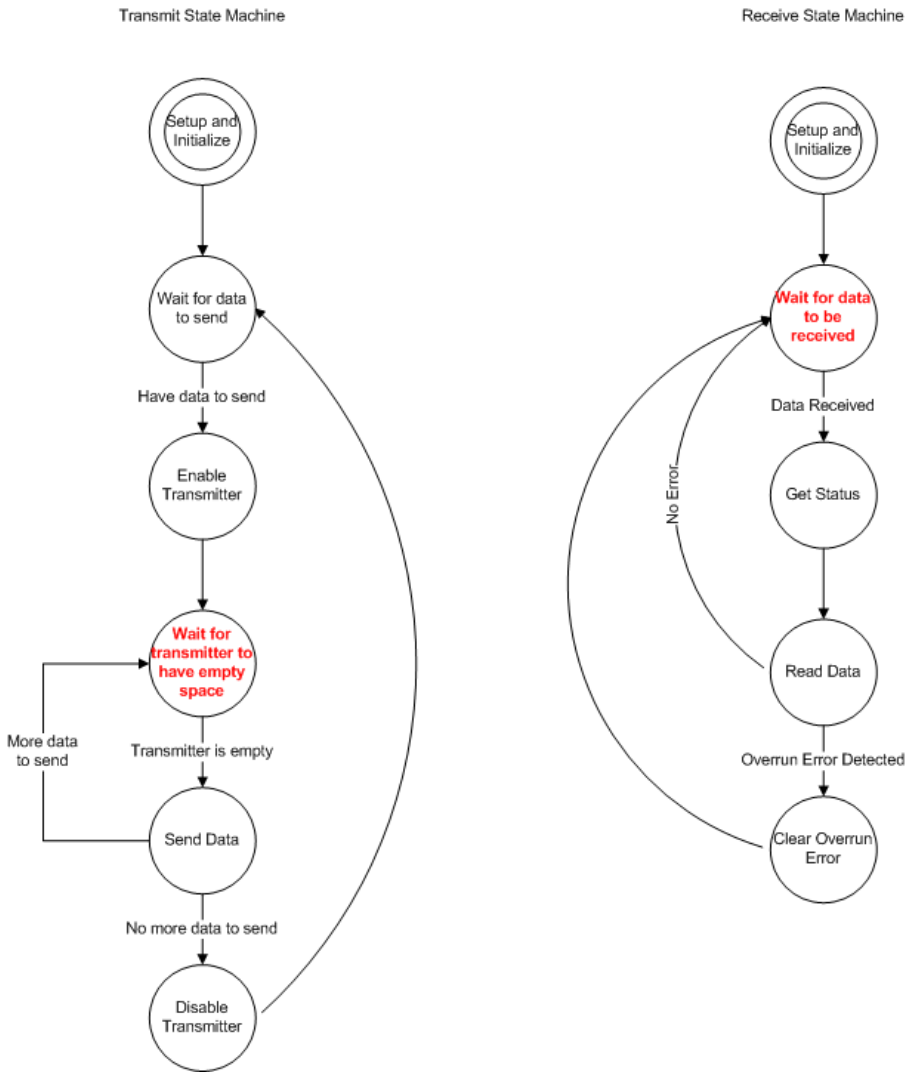
State Machine

This section describes the transmission and reception state machine.

Description

The following state machine is for the transmission and reception during normal operation. This state machine provides a general idea of the usage model of the USART Peripheral Library. Refer to the usage model for more detailed steps for the scenario that is being used.

Transmit and Receive State machine



Notes:

1. The wait states shown in red in the diagram can either be achieved using polled functions or using interrupts.
2. Refer to the specific USART mode in use for the setup and initialization steps.
3. Refer to the following table for the functions that can be used at each state.

State	Associated Function
Setup and initialization	Refer to the specific USART mode for detailed setup instructions.
Wait for data to send	Once the USART module has been appropriately set up and initialized, the state machine waits for the application to issue one of the send data functions.
Wait for data to be received	When the application is using Polled mode, the application can use the function PLIB_USART_ReceiverDataIsAvailable. When the application is using Interrupt mode, the application should wait for a receive interrupt.
Enable transmitter	Use the function PLIB_USART_TransmitterEnable to enable the transmitter
Wait for transmitter to have empty space	When the application is using polled mode, the application can use the function PLIB_USART_TransmitterBufferIsFull. When the application is using Interrupt mode, the application should wait for a transmit interrupt.
Send data	Use the function PLIB_USART_TransmitterByteSend to send data. If an address needs to be transmitted or if a byte needs to be transmitted with a Parity bit use the function PLIB_USART_Transmitter9BitsSend.
Disable transmitter	Use the function PLIB_USART_TransmitterDisable to disable the transmitter.
Get status	To get the status of the hardware module, use the set of functions, PLIB_USART_ReceiverFramingErrorHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred, and PLIB_USART_ReceiverOverrunHasOccurred.

Read data	Use the function PLIB_USART_ReceiverByteReceive to read data.
Clear overrun error	Clear the overrun error using the function PLIB_USART_ReceiverOverrunErrorClear.

Asynchronous USART Mode

This section provides processes for setting up asynchronous transmission and reception.

Description

Asynchronous Transmission

Setup

1. Set the desired baud rate using either PLIB_USART_BaudRateHighSet or PLIB_USART_BaudRateSet.
2. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
3. *If available on the device,* enable the asynchronous serial port using PLIB_USART_SyncModeSelect.
4. Set the number of data bits (8 or 9) and other line control modes using PLIB_USART_LineControlModeSelect.
5. *Optional (if available on the device):* If desired, enable the transmit interrupt.
   - Ensure that the interrupts are enabled for the system and the peripherals
   - Select the interrupt priority
   - Set up the transmit FIFO interrupt mode using PLIB_USART_TransmitterInterruptModeSelect. Refer to USART_TRANSMIT_INTR_MODE for a list of possible values.
6. Enable the USART module using the function PLIB_USART_Enable

Example: Asynchronous Transmission Setup

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently
//being used by the system.
PLIB_USART_BaudRateSet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, baudRate);

// Enable the asynchronous serial port.
// enable asynchronous mode if the part supports it
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_ASYNC_MODE);

/* Select 8 data bits, No parity and one stop bit */
PLIB_USART_LineControlModeSelect(MY_USART_INSTANCE, USART_8N1);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.
```

Enable Transmission

1. Enable the transmission using PLIB_USART_TransmitterEnable.
2. Ensure that the transmit buffer is not full, before attempting to write into the transmit buffer. Either poll using PLIB_USART_TransmitterBufferIsFull or wait for the transmit interrupt.
3. Start the transmission using PLIB_USART_TransmitterByteSend (if transmitting 8-bit data) or PLIB_USART_Transmitter9BitsSend (if transmitting an address or if transmitting a byte with parity).
4. After the transmission is complete, disable the transmitter.

Example: Asynchronous Transmission

```
// Enable the transmission
PLIB_USART_TransmitterEnable(MY_USART_INSTANCE);

// TODO - Either wait for Transmit buffer to be not full or wait for
//an transmit interrupt.

// Transmit the byte when Transmit buffer is empty.
// where, my_byte is the 8 bit data to be transmitted
PLIB_USART_TransmitterByteSend(MY_USART_INSTANCE, my_byte);
```

Asynchronous Transmission of Break Characters

A break characters consists of a **Start Bit** followed by twelve bits of "0" and a **Stop Bit.**

Setup and Transmission

1. Configure the desired mode, using the previous steps described.
2. Enable the transmitter using PLIB_USART_TransmitterEnable.
3. Transmit the break character using PLIB_USART_TransmitterBreakSend function.
4. Check if the break transmission is complete using PLIB_USART_TransmitterBreakSendIsComplete.
5. Transmission of the next bytes can start.

Example: USART Break and Sync Transmission

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently
//being used by the system.
PLIB_USART_BaudRateSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the asynchronous serial port.
// enable asynchronous mode if the part supports it
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_ASYNC_MODE);

/* Select 8 data bits, No parity and one stop bit */
PLIB_USART_LineControlModeSelect(MY_USART_INSTANCE, USART_8N1);

// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Enable the transmission
PLIB_USART_TransmitterEnable(MY_USART_INSTANCE);

// Start the transmission
// Transmit the break character
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);

// Transmit the byte
while(PLIB_USART_TransmitterBreakSendIsComplete(MY_USART_INSTANCE));

PLIB_USART_TransmitterByteSend(MY_USART_INSTANCE, 0x55);
```

Refer to the following steps for setting up asynchronous receptions and how to receive data.

Asynchronous Reception

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateHighSet or PLIB_USART_BaudRateSet.
2. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
3. *If available on the device*, enable the asynchronous serial port using PLIB_USART_SyncModeSelect.
4. Set the number of data bits (8 or 9) and other line control modes using PLIB_USART_LineControlModeSelect.
5. *Optional (if available on the device):* If desired, enable the receive interrupt.
   - Ensure that the interrupts are enabled for the system and the peripherals
   - Select the interrupt priority
   - Set up the receive FIFO interrupt mode using PLIB_USART_ReceiverInterruptModeSelect. Refer to USART_RECEIVE_INTR_MODE for a list of possible values.
6. *Optional:* If inverted receive polarity is desired, use PLIB_USART_ReceiverIdleStateLowEnable.
7. *If available on the device*, enable the reception using PLIB_USART_ReceiverEnable.
8. Enable the USART module using PLIB_USART_Enable.

Example: Asynchronous Reception Setup

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently being
```

```
// used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous slave serial port.
// enable asynchronous mode if the part supports it
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_ASYNC_MODE);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Start the reception
// Enable the continuous reception
PLIB_USART_ReceiverEnable(MY_USART_INSTANCE);
```

Reception

1. Either wait for an interrupt, which will be generated when the reception is completed, or poll using PLIB_USART_ReceiverDataIsAvailable.
2. Read the status of the device using PLIB_USART_ReceiverOverrunHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred, and PLIB_USART_ReceiverFramingErrorHasOccurred.
3. Read the data using PLIB_USART_ReceiverByteReceive.
4. If an overrun error occurred, clear the error using PLIB_USART_ReceiverOverrunErrorClear.

Example: Asynchronous Reception

```
// TODO - Either wait for Receive buffer to have data or wait for
// a receive interrupt.
// read the data
my_byte = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
// where, my_byte is the 8 bit data received

// If overrun error clear the error.
if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Asynchronous Reception with Address Detection Mode

A typical multi-processor communication protocol will differentiate between data bytes and address/control bytes. A common method is to use a 9th data bit to identify whether a data byte is address or data information. If the 9th bit is set, the data is processed as address or control information. If the 9th bit is cleared, the received data word is processed as data associated with the previous address/control byte.

The protocol operates as follows:

- The master device transmits a data word with 9th bit set. The data word contains the address of a slave device.
- All slave devices in the communication chain receive the address word and check the slave address.
- The slave device that was addressed will receive and process subsequent data bytes sent by the master device. All other slave devices will discard subsequent data bytes until a new address word(9th bit set) is received.

This mode will typically be used in RS-485 systems.

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateHighSet or PLIB_USART_BaudRateSet.
2. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
3. *If available on the device*, enable the asynchronous serial port using PLIB_USART_SyncModeSelect.
4. Set the number of data bits (8 or 9) and other line control modes using PLIB_USART_LineControlModeSelect.
5. *Optional (if available on the device):* If desired, enable the receive interrupt.
   - Ensure that the interrupts are enabled for the system and the peripherals. Also select the interrupt priority.
   - Set up the receive FIFO interrupt mode by using the function PLIB_USART_ReceiverInterruptModeSelect. Refer to USART_RECEIVE_INTR_MODE for a list of possible values.
   - For Address Detect mode, configure PLIB_USART_ReceiverInterruptModeSelect with the receive FIFO interrupt mode as USART_RECEIVE_FIFO_ONE_CHAR.
6. *Optional:* If inverted receive polarity is desired, use PLIB_USART_ReceiverIdleStateLowEnable.
7. *If available on the device*, enable the reception using PLIB_USART_ReceiverEnable.
8. Enable address detection using PLIB_USART_ReceiverAddressDetectEnable.
9. Enable the USART module using PLIB_USART_Enable.

Note: This feature is not available on all devices. On devices where automatic address detection is available, configure automatic address detection using PLIB_USART_ReceiverAddressAutoDetectEnable. Skip steps 2-6 in the following Reception section during the reception phase.

Example: Asynchronous Reception Setup (with address detect enable)

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently
// being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous slave serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_ASYNC_MODE);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Set the reception to 9 bits to enable address byte.
PLIB_USART_LineControlModeSelect(MY_USART_INSTANCE, USART_9N1);

// Enable address detection.
PLIB_USART_ReceiverAddressDetectEnable(MY_USART_INSTANCE);

// Start the reception
// Enable the continuous reception
PLIB_USART_ReceiverEnable(MY_USART_INSTANCE);
```

Reception

1. Either wait for an interrupt, which will be generated when the reception is completed or poll using PLIB_USART_ReceiverDataIsAvailable.
2. Read the address using PLIB_USART_ReceiverByteReceive.
3. The application determines if this is the device address. If the device is addressed, disable address detect using PLIB_USART_ReceiverAddressDetectDisable to allow subsequent data bytes to be received; otherwise, discard the received word.
4. Read the status of the device using PLIB_USART_ReceiverOverrunHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred, and PLIB_USART_ReceiverFramingErrorHasOccurred.
5. If an overrun error occurred, clear the error using PLIB_USART_ReceiverOverrunErrorClear.
6. If the device has been addressed, disable the address detection using PLIB_USART_ReceiverAddressDetectDisable, which will allow all received data into the receive buffer and generate interrupts if desired.
7. *Optional (if available on the device):* If a long packet is expected, the receive interrupt mode could be changed to buffer more than one data word between interrupts. Use PLIB_USART_ReceiverInterruptModeSelect with USART_RECEIVE_FIFO_HALF_FULL or USART_RECEIVE_FIFO_3B4FULL.
8. When the last data byte has been received, enable the address detect using PLIB_USART_ReceiverAddressDetectEnable, so that only address bytes will be received.
9. *Optional (if available on the device):* Ensure that the receive interrupt is configured to be triggered after each received word using PLIB_USART_ReceiverInterruptModeSelect with USART_RECEIVE_FIFO_ONE_CHAR.

Example: Asynchronous Reception (with Address Detect)

```
// Either wait for Receive buffer to have data or wait for a receive interrupt.
int8_t my_address;

// Receive the address
if(PLIB_USART_ReceiverDataIsAvailable(MY_USART_INSTANCE))
{
    my_address = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
    // where, my_address is the address received
}

// If overrun error clear the error.
if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}

if(my_address == MY_DEVICE_ADDRESS)
{
    // The device has been addressed.
    PLIB_USART_ReceiverAddressDetectDisable(MY_USART_INSTANCE);
}
```

```
// TODO - Receive the data bytes for the packet. Either wait for RX buffer
//to have data or wait for a receive interrupt.

// When all the bytes for the packet are received.

// Enable address detection mode
PLIB_USART_ReceiverAddressDetectEnable(MY_USART_INSTANCE);
```

Synchronous Master Mode

This section provides processes for setting up synchronous master transmission and reception.

Note: The features described in this section are not available on all devices. Please refer to the **"USART"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details.

Description

Synchronous Master Transmission

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateSet or PLIB_USART_BaudRateHighSet.
2. Enable the synchronous master serial port using PLIB_USART_SyncModeSelect, PLIB_USART_SyncClockSourceSelect, and PLIB_USART_Enable.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. Disable receive using PLIB_USART_ReceiverDisable.
5. *Optional:* If desired set the number of data bits to 9 (to send address byte or to enable parity check) using PLIB_USART_LineControlModeSelect.
6. *Optional:* If desired, enable the transmit interrupt, ensuring that the interrupts are enabled for the system and the peripherals.

Example: Synchronous Master Transmission Setup

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous master serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_ASYNC_MODE);
// enable master clock
PLIB_USART_SyncClockSourceSelect(MY_USART_INSTANCE, USART_SYNC_CLOCK_SOURCE_MASTER);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO Call the appropriate function.
```

Transmission

1. Enable transmission using PLIB_USART_TransmitterEnable.
2. Ensure that the transmit buffer is not full before attempting to write onto the transmit buffer. Either poll using PLIB_USART_TransmitterBufferIsFull or wait for the transmit interrupt.

Note: If using interrupts, make sure that interrupts are also enabled for the system and the peripherals.

3. Start the transmission using PLIB_USART_TransmitterByteSend (if transmitting 8 - bit data) or PLIB_USART_Transmitter9BitsSend (if transmitting address or if transmitting a byte with parity).
4. After the transmission is complete, disable the transmitter.

Example: Synchronous Master Transmission

```
// Enable the transmission
PLIB_USART_TransmitterEnable(MY_USART_INSTANCE);

// TODO Either wait for Transmit buffer to be not full or wait for an transmit interrupt.

// Transmit the byte when Transmit buffer is empty.
// where, my_byte is the 8 bit data to be transmitted
PLIB_USART_TransmitterByteSend(MY_USART_INSTANCE, my_byte);
```

Synchronous Master Reception

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateSet or PLIB_USART_BaudRateHighSet.
2. Enable the synchronous master serial port using PLIB_USART_SyncModeSelect, PLIB_USART_SyncClockSourceSelect, and PLIB_USART_Enable.
3. Set the appropriate IO direction and corresponding to RX and TX I/O pins.
4. *Optional:* If desired, enable the receive interrupt, ensuring that the interrupts are enabled for the system and the peripherals.
5. Start the reception using PLIB_USART_ReceiverDisable.

Example: Synchronous Master Reception Setup

```
uint32_t baudRate = 9600;
// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

PLIB_USART_HandshakeModeSelect(MY_USART_INSTANCE,
                                    USART_HANDSHAKE_MODE_SIMPLEX);
// Enable the synchronous master serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_SYNC_MODE);
// enable master clock
PLIB_USART_SyncClockSourceSelect(MY_USART_INSTANCE, USART_SYNC_CLOCK_SOURCE_MASTER);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Enable receive mode
PLIB_USART_ReceiverEnable(MY_USART_INSTANCE);
```

Reception

1. Either wait for an interrupt, which will be generated when the reception is completed, or poll using PLIB_USART_ReceiverDataIsAvailable.

Note: If using interrupts, make sure that interrupts are also enabled for the system and the peripherals.

2. Read the status of the device using PLIB_USART_ReceiverOverrunHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred and PLIB_USART_ReceiverFramingErrorHasOccurred.
3. Read the data using PLIB_USART_ReceiverByteReceive.
4. If an overrun error occurred, clear the error using the function PLIB_USART_ReceiverOverrunErrorClear.

Example: Synchronous Master Reception

```
// Read the byte
// where, my_byte is the 8 bit data to be transmitted
my_byte = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);

if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Synchronous Slave Mode

This section provides processes for setting up synchronous slave transmission and reception.

Note: This feature is not available on all devices. Please refer to the **"USART"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details.

Description

Synchronous Slave Transmission

Setup

1. Set the desired baud rate using either PLIB_USART_BaudRateHighSet or PLIB_USART_BaudRateSet.
2. Enable the synchronous slave serial port using PLIB_USART_SyncModeSelect, PLIB_USART_SyncClockSourceSelect, and PLIB_USART_Enable.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.

4. Disable receive mode using PLIB_USART_ReceiverDisable.
5. *Optional:* If desired, enable the transmit interrupt,ensuring that the interrupts are enabled for the system and the peripherals.

Example: Synchronous Slave Transmission Setup

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware
//peripheral MY_CLOCK_FREQUENCY - is hardware clock frequency which is
//currently being used by the system.
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous slave serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_SYNC_MODE);
// enable slave clock
PLIB_USART_SyncClockSourceSelect(MY_USART_INSTANCE, USART_SYNC_CLOCK_SOURCE_SLAVE);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Disable receive mode
PLIB_USART_ReceiverDisable(MY_USART_INSTANCE);

// TODO - If using interrupts Enable the transmit interrupt
// TODO - Call the appropriate function for the transmit enable interrupt,
// TODO - Also, make sure that the interrupts are enabled for system and the peripherals.
```

Transmission

1. Enable transmission using PLIB_USART_TransmitterEnable.
2. Ensure that the transmit buffer is not full before attempting to write into the transmit buffer. Either poll using PLIB_USART_TransmitterBufferIsFull or wait for the transmit interrupt.

Note: If using interrupts, ensure that interrupts are also enabled for the system and the peripherals.

3. Start the transmission using PLIB_USART_TransmitterByteSend (if transmitting 8-bit data) or PLIB_USART_Transmitter9BitsSend (if transmitting address if transmitting a byte with parity)
4. After the transmission is complete, disable the transmitter.

Example: Synchronous Slave Transmission

```
// Enable the transmission
PLIB_USART_TransmitterEnable(MY_USART_INSTANCE);

// TODO - Either wait for Transmit buffer to be not full or wait
//for an transmit interrupt.

// Transmit the byte when Transmit buffer is empty.
PLIB_USART_TransmitterByteSend(MY_USART_INSTANCE, my_word);
// where, my_word is the 9 bit data to be transmitted
```

Synchronous Slave Reception

Setup

1. Set the desired baud rate using PLIB_USART_BaudRateHighSet or PLIB_USART_BaudRateSet.
2. Enable the synchronous master serial port using PLIB_USART_SyncModeSelect, PLIB_USART_SyncClockSourceSelect, and PLIB_USART_Enable.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. *Optional:* If desired, enable the receive interrupt, ensuring that the interrupts are enabled for the system and the peripherals.
5. Start the reception using PLIB_USART_ReceiverEnable.

Example: Synchronous Slave Reception Setup

```
// Set the desired baud rate
uint32_t baudRate = 9600;

// where, MY_USART_INSTANCE - is a specific instance of the hardware peripheral.
// where, MY_CLOCK_FREQUENCY - is hardware clock frequency which is currently
//being used by the system.
```

```
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, baudRate, MY_CLOCK_FREQUENCY);

// Enable the synchronous slave serial port.
// enable sync mode
PLIB_USART_SyncModeSelect(MY_USART_INSTANCE, USART_SYNC_MODE);
// enable master clock
PLIB_USART_SyncClockSourceSelect(MY_USART_INSTANCE, USART_SYNC_CLOCK_SOURCE_SLAVE);
// enable USART
PLIB_USART_Enable(MY_USART_INSTANCE);

// Set the appropriate IO direction for USART pins
// TODO - Call the appropriate function.

// Start the reception
// Enable the continuous reception
PLIB_USART_ReceiverDisable(MY_USART_INSTANCE);
```

Reception

1. Either wait for an interrupt, which will be generated when the reception is completed, or poll using PLIB_USART_ReceiverDataIsAvailable.

Note: If using interrupts, ensure that interrupts are also enabled for the system and the peripherals.

2. Read the status of the device using PLIB_USART_ReceiverOverrunHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred, and PLIB_USART_ReceiverFramingErrorHasOccurred.
3. Read the data using PLIB_USART_ReceiverByteReceive.
4. If an overrun error occurred, clear the error using PLIB_USART_ReceiverOverrunErrorClear.

Example: Synchronous Slave Reception

```
// Transmit the data
my_byte = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
// where, my_byte is the 8 bit data received

// If overrun error clear the error.
if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
 PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Other Features

This section describes additional features of the USART Peripheral Library.

Note: The features described in this section are not available on all devices. Please refer to the **"USART"** chapter in the specific device data sheet or the family reference manual section specified in that chapter for details.

Description

IrDA Support

Support for IrDA is available in some microcontrollers.

1. Enable IrDA support using PLIB_USART_IrDAEnable. IrDA support can be disabled using PLIB_USART_IrDADisable.
2. *Optional:* If using the external IrDA encoder and decoder, use the function PLIB_USART_OperationModeSelect with USART_ENABLE_TX_RX_BCLK_USED to output the 16x baud clock.
3. *Optional:* IrDA Transmit Polarity can be inverted using PLIB_USART_TransmitterIdleIsLowEnable.
4. *Optional:* IrDA Receive Polarity can be inverted using PLIB_USART_ReceiverIdleStateLowEnable.
5. Enable the USART using PLIB_USART_Enable.

Loopback Support

This is the mode in which the transmission is internally connected to reception.

1. Set the desired baud rate using PLIB_USART_BaudRateSet or PLIB_USART_BaudRateHighSet.
2. Set up the line control parameters (data bits, stop bits, parity, flow control) using PLIB_USART_LineControlModeSelect. Refer to USART_LINECONTROL_MODE for a list of possible values.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. *Optional:* If desired, enable the transmit interrupt, also make sure that the interrupts are enabled for the system and the peripherals.
5. *Optional:* Also select the interrupt priority.
6. *Optional:* Also, set up the transmit FIFO interrupt mode using PLIB_USART_TransmitterInterruptModeSelect. Refer to USART_TRANSMIT_INTR_MODE for a list of possible values.

7. Enable the USART module using PLIB_USART_Enable and enable the transmission using PLIB_USART_TransmitterEnable.
8. Enable loopback using PLIB_USART_LoopbackEnable. Loopback can be disabled at any time using PLIB_USART_LoopbackDisable
9. Continue with transmission and/or reception using the same steps as for asynchronous transmission/reception.

Auto Baud Support

1. Enable the auto baud detection using the function PLIB_USART_BaudRateAutoDetectEnable, which requires a reception of the Sync character (0x55).
2. *Optional:* Poll PLIB_USART_BaudRateAutoDetectIsComplete to check if the baud rate is detected.
3. *Optional:* Call PLIB_USART_BaudRateGet to get the baud rate that was detected.
4. Clear the receive interrupt.
5. On some microcontrollers, reading the data using PLIB_USART_ReceiverByteReceive may be required.

Flow Control Support

The USART can use Simplex or Flow Control modes:

- Use PLIB_USART_HandshakeModeSelect to enable flow control (USART_HANDSHAKE_MODE_FLOW_CONTROL) or use simplex mode (USART_HANDSHAKE_MODE_SIMPLEX) selected from USART_HANDSHAKE_MODE.
- To configure the USART line control features, use PLIB_USART_LineControlModeSelect selected from USART_LINECONTROL_MODE.
- Additionally, the USART pins may need to be configured using PLIB_USART_OperationModeSelect and the appropriate values from USART_OPERATION_MODE.

Operation During Sleep Mode

When the device enters Sleep mode, all clock sources supplied to the USART modules are shut down. If the device enters Sleep mode in the middle of a USART transmission or reception operation, the operation is aborted and the USART pins are driven to default state.

A Start bit, when detected, can wake up the device.

- The application needs to enable the wake-up on start bit using PLIB_USART_WakeOnStartEnable just before entering Sleep mode, to wake-up the device
- For the device to wake-up from sleep, reception of the Sync character or Wake-up Signal character is required
- *Optional:* If using interrupts, a receive interrupt is generated

Operation During Idle Mode

When the device enters Idle mode, the system clock sources remain functional and the CPU stops code execution.

- USART operation during Idle mode can be stopped using PLIB_USART_StopInIdleEnable. When the device enters Idle mode, the USART module operation is similar to that as in Sleep mode(Refer to Operation in Sleep Mode).
- By default, the USART module continues to operate in Idle mode and provide full functionality

USART Operation With DMA

The DMA module can be used to transfer data between the USART and the CPU, without CPU assistance.

1. Set the desired baud rate using the function PLIB_USART_BaudRateSet or PLIB_USART_BaudRateHighSet.
2. Set up the line control parameters (data bits, stop bits, parity, flow control) using the function PLIB_USART_LineControlModeSelect. Refer to USART_LINECONTROL_MODE for a list of possible values.
3. Set the appropriate I/O direction and corresponding RX and TX I/O pins.
4. Enable the USART module using PLIB_USART_Enable and enable the transmission using PLIB_USART_TransmitterEnable.
5. Enable the Transmit, Receive, and Error interrupts, ensuring that the interrupts are enabled for the system and the peripherals.
6. Select the interrupt priority.
7. Set up the Transmit FIFO Interrupt mode and Receive FIFO Interrupt mode using the PLIB_USART_TransmitterInterruptModeSelect and PLIB_USART_ReceiverInterruptModeSelect functions. To generate interrupts for every character received, use USART_RECEIVE_FIFO_ONE_CHAR from USART_RECEIVE_INTR_MODE.
8. Configure the DMA to be used with the USART receiver and transmitter.

Configuring the Library

The library is configured for the supported USART modules when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Functions

	Name	Description
	PLIB_USART_Disable	Disables the specific USART module
	PLIB_USART_Enable	Enables the specific USART module.

	PLIB_USART_HandshakeModeSelect	Sets the data flow configuration.
	PLIB_USART_IrDADisable	Disables the IrDA encoder and decoder.
	PLIB_USART_IrDAEnable	Enables the IrDA encoder and decoder.
	PLIB_USART_LineControlModeSelect	Sets the data flow configuration.
	PLIB_USART_LoopbackDisable	Disables Loopback mode.
	PLIB_USART_LoopbackEnable	Enables Loopback mode.
	PLIB_USART_OperationModeSelect	Configures the operation mode of the USART module.
	PLIB_USART_StopInIdleDisable	Disables the Stop in Idle mode (the USART module continues operation when the device is in Idle mode).
	PLIB_USART_StopInIdleEnable	Discontinues operation when the device enters Idle mode.
	PLIB_USART_WakeOnStartDisable	Disables the wake-up on start bit detection feature during Sleep mode.
	PLIB_USART_WakeOnStartEnable	Enables the wake-up on start bit detection feature during Sleep mode.
	PLIB_USART_WakeOnStartIsEnabled	Gets the state of the sync break event completion.
	PLIB_USART_ErrorsGet	Return the status of all errors in the specified USART module.
	PLIB_USART_InitializeModeGeneral	Enables or disables general features of the USART module.
	PLIB_USART_InitializeOperation	Configures the Receive and Transmit FIFO interrupt levels and the hardware lines to be used by the module.
	PLIB_USART_AddressGet	Gets the address for the Address Detect mode.
	PLIB_USART_AddressMaskGet	Gets the address mask for the Address Detect mode.
	PLIB_USART_AddressMaskSet	Sets the address mask for the Address Detect mode.
	PLIB_USART_AddressSet	Sets the address for the Address Detect mode.
	PLIB_USART_ModuleIsBusy	Returns the USART module's running status.
	PLIB_USART_RunInOverflowDisable	Disables the Run in overflow condition mode.
	PLIB_USART_RunInOverflowEnable	Enables the USART module to continue to operate when an overflow error condition has occurred.
	PLIB_USART_RunInOverflowIsEnabled	Gets the status of the Run in Overflow condition.
	PLIB_USART_RunInSleepModeDisable	Turns off the USART module's BRG clock during Sleep mode.
	PLIB_USART_RunInSleepModeEnable	Allows the USART module's BRG clock to run when the device enters Sleep mode.
	PLIB_USART_RunInSleepModeIsEnabled	Gets the status of Run in Sleep mode.

b) Baud Rate Generator Functions

	Name	Description
	PLIB_USART_BaudRateAutoDetectEnable	Enables baud rate measurement on the next character, which requires reception of the Sync character.
	PLIB_USART_BaudRateAutoDetectIsComplete	Gets the state of the automatic baud detection.
	PLIB_USART_BaudRateGet	Gets the baud rate current in use.
	PLIB_USART_BaudRateHighDisable	Disables the high baud rate selection.
	PLIB_USART_BaudRateHighEnable	Enables high baud rate selection.
	PLIB_USART_BaudRateHighSet	Sets the baud rate to the desired value.
	PLIB_USART_BaudRateSet	Sets the baud rate to the desired value.
	PLIB_USART_BaudSetAndEnable	Sets the baud rate to the desired value and enables the USART receiver, transmitter and the USART module.
	PLIB_USART_BRGClockSourceGet	Gets the BRG clock source of the USART module.
	PLIB_USART_BRGClockSourceSelect	Configures the BRG clock source of the USART module.

c) Transmitter Functions

	Name	Description
	PLIB_USART_Transmitter9BitsSend	Data to be transmitted in the byte mode with the 9th bit.
	PLIB_USART_TransmitterBreakSend	Transmits the break character.
	PLIB_USART_TransmitterBreakSendIsComplete	Returns the status of the break transmission
	PLIB_USART_TransmitterBufferIsFull	Gets the transmit buffer full status.
	PLIB_USART_TransmitterByteSend	Data to be transmitted in the Byte mode.
	PLIB_USART_TransmitterDisable	Disables the specific USART module transmitter.
	PLIB_USART_TransmitterEnable	Enables the specific USART module transmitter.
	PLIB_USART_TransmitterIdleIsLowDisable	Disables the Transmit Idle Low state.
	PLIB_USART_TransmitterIdleIsLowEnable	Enables the Transmit Idle Low state.

	PLIB_USART_TransmitterInterruptModeSelect	Sets the USART transmitter interrupt mode.
	PLIB_USART_TransmitterIsEmpty	Gets the transmit shift register empty status.
	PLIB_USART_TransmitterAddressGet	Returns the address of the USART TX register

d) Receiver Functions

	Name	Description
	PLIB_USART_ReceiverAddressAutoDetectDisable	Disables the automatic Address Detect mode.
	PLIB_USART_ReceiverAddressAutoDetectEnable	Setup the automatic Address Detect mode.
	PLIB_USART_ReceiverAddressDetectDisable	Enables the Address Detect mode.
	PLIB_USART_ReceiverAddressDetectEnable	Enables the Address Detect mode.
	PLIB_USART_ReceiverAddressIsReceived	Checks and return if the data received is an address.
	PLIB_USART_ReceiverByteReceive	Data to be received in the Byte mode.
	PLIB_USART_ReceiverDataIsAvailable	Identifies if the receive data is available for the specified USART module.
	PLIB_USART_ReceiverDisable	Disables the USART receiver.
	PLIB_USART_ReceiverEnable	Enables the USART receiver.
	PLIB_USART_ReceiverFramingErrorHasOccurred	Gets the framing error status.
	PLIB_USART_ReceiverIdleStateLowDisable	Disables receive polarity inversion.
	PLIB_USART_ReceiverIdleStateLowEnable	Enables receive polarity inversion.
	PLIB_USART_ReceiverInterruptModeSelect	Sets the USART receiver FIFO level.
	PLIB_USART_ReceiverIsIdle	Identifies if the receiver is idle.
	PLIB_USART_ReceiverOverrunErrorClear	Clears a USART vverrun error.
	PLIB_USART_ReceiverOverrunHasOccurred	Identifies if there was a receiver overrun error.
	PLIB_USART_ReceiverParityErrorHasOccurred	Gets the parity error status.
	PLIB_USART_ReceiverAddressGet	Returns the address of the USART RX register
	PLIB_USART_Receiver9BitsReceive	Data to be received in the byte mode with the 9th bit.

e) Feature Existence Functions

	Name	Description
	PLIB_USART_ExistsBaudRate	Identifies whether the BaudRate feature exists on the USART module.
	PLIB_USART_ExistsBaudRateAutoDetect	Identifies whether the BaudRateAutoDetect feature exists on the USART module.
	PLIB_USART_ExistsBaudRateHigh	Identifies whether the BaudRateHigh feature exists on the USART module.
	PLIB_USART_ExistsEnable	Identifies whether the EnableControl feature exists on the USART module.
	PLIB_USART_ExistsHandshakeMode	Identifies whether the HandShakeMode feature exists on the USART module.
	PLIB_USART_ExistsIrDA	Identifies whether the IrDAControl feature exists on the USART module.
	PLIB_USART_ExistsLineControlMode	Identifies whether the LineControlMode feature exists on the USART module.
	PLIB_USART_ExistsLoopback	Identifies whether the Loopback feature exists on the USART module.
	PLIB_USART_ExistsOperationMode	Identifies whether the OperationMode feature exists on the USART module.
	PLIB_USART_ExistsReceiver	Identifies whether the Receiver feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressAutoDetect	Identifies whether the ReceiverAddressAutoDetect feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressDetect	Identifies whether the ReceiverAddressDetect feature exists on the USART module.
	PLIB_USART_ExistsReceiverDataAvailableStatus	Identifies whether the ReceiverDataAvailable feature exists on the USART module
	PLIB_USART_ExistsReceiverEnable	Identifies whether the ReceiverEnableControl feature exists on the USART module.
	PLIB_USART_ExistsReceiverFramingErrorStatus	Identifies whether the ReceiverFramingError feature exists on the USART module.
	PLIB_USART_ExistsReceiverIdleStateLowEnable	Identifies whether the ReceiverPolarityInvert feature exists on the USART module.
	PLIB_USART_ExistsReceiverIdleStatus	Identifies whether the ReceiverIdle feature exists on the USART module.
	PLIB_USART_ExistsReceiverInterruptMode	Identifies whether the ReceiverInterruptMode feature exists on the USART module.
	PLIB_USART_ExistsReceiverOverrunStatus	Identifies whether the ReceiverOverrunError feature exists on the USART module.
	PLIB_USART_ExistsReceiverParityErrorStatus	Identifies whether the ReceiverParityError feature exists on the USART module.

	PLIB_USART_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the USART module.
	PLIB_USART_ExistsTransmitter	Identifies whether the Transmitter feature exists on the USART module.
	PLIB_USART_ExistsTransmitter9BitsSend	Identifies whether the Transmitter9Bits feature exists on the USART module.
	PLIB_USART_ExistsTransmitterBreak	Identifies whether the TransmitterBreak feature exists on the USART module.
	PLIB_USART_ExistsTransmitterBufferFullStatus	Identifies whether the TransmitterBufferFull feature exists on the USART module.
	PLIB_USART_ExistsTransmitterEmptyStatus	Identifies whether the TransmitterEmpty feature exists on the USART module.
	PLIB_USART_ExistsTransmitterEnable	Identifies whether the TransmitterEnableControl feature exists on the USART module
	PLIB_USART_ExistsTransmitterIdleIsLow	Identifies whether the TransmitterIdleIsLow feature exists on the USART module.
	PLIB_USART_ExistsTransmitterInterruptMode	Identifies whether the TransmitterInterruptMode feature exists on the USART module.
	PLIB_USART_ExistsWakeOnStart	Identifies whether the WakeOnStart feature exists on the USART module.
	PLIB_USART_ExistsReceiver9Bits	Identifies whether the 9 Bits Receiver feature exists on the USART module.
	PLIB_USART_ExistsBRGClockSourceSelect	Identifies whether the BRG Clock source select feature exists on the USART module.
	PLIB_USART_ExistsModuleBusyStatus	Identifies whether the module running status feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddress	Identifies whether the Receiver Address feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressMask	Identifies whether the Receiver Address Mask feature exists on the USART module.
	PLIB_USART_ExistsRunInOverflow	Identifies whether the Run in overflow condition feature exists on the USART module.
	PLIB_USART_ExistsRunInSleepMode	Identifies whether the Run in Sleep mode feature exists on the USART module.

f) Data Types and Constants

	Name	Description
	USART_HANDSHAKE_MODE	Lists the USART handshake modes.
	USART_LINECONTROL_MODE	Data type defining the different configurations by which the USART data flow can be configured.
	USART_MODULE_ID	Enumeration: USART_MODULE_ID This enumeration defines the number of modules that are available on the microcontroller. This is the superset of all of the possible instances that might be available on Microchip microcontrollers. Refer to the data sheet to get the correct number of modules defined for desired microcontroller.
	_USART_MODULE_ID	
	USART_OPERATION_MODE	Data type defining the different configurations by which the USART can be enabled.
	USART_RECEIVE_INTR_MODE	Data type defining the different Receive FIFO levels by which the USART receive interrupt modes can be configured.
	USART_TRANSMIT_INTR_MODE	Data type defining the different transmit FIFO levels by which the USART transmit interrupt modes can be configured.

Description

This section describes the Application Programming Interface (API) functions of the USART Peripheral Library.

Refer to each section for a detailed description.

a) General Functions

PLIB_USART_Disable Function

Disables the specific USART module

File

plib_usart.h

C

```
void PLIB_USART_Disable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific USART module.

Remarks

The default state after any reset for a USART module is the disable state. If the USART is disabled, all of the related pins are in control of the general purpose I/O logic.

Disabling the USART module resets the buffers to empty states. Any data characters in the buffers are lost and the baud rate is reset. All error and status bits are also reset.

Disabling the USART while the USART is active, will abort all pending transmissions and receptions. Re-enabling the USART will restart the module in the same configuration.

When disabled, the USART power consumption is minimal. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_Disable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_Disable (USART_MODULE_ID index)

PLIB_USART_Enable Function

Enables the specific USART module.

File

plib_usart.h

C

```
void PLIB_USART_Enable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific USART module.

Remarks

By calling this function, the USART pins are controlled by the USART module. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_Enable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_Enable (USART_MODULE_ID index)

PLIB_USART_HandshakeModeSelect Function

Sets the data flow configuration.

File

plib_usart.h

C

```
void PLIB_USART_HandshakeModeSelect(USART_MODULE_ID index, USART_HANDSHAKE_MODE handshakeConfig);
```

Returns

None.

Description

This function sets the USART data flow configuration based on the mask provided and the specified baud rate.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsHandshakeMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_HandshakeModeSelect(MY_USART_INSTANCE,
                                    USART_HANDSHAKE_MODE_SIMPLEX);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	For possible data flow configurations, refer to USART_HANDSHAKE_MODE

Function

void PLIB_USART_HandshakeModeSelect(USART_MODULE_ID index,
USART_HANDSHAKE_MODE handshakeConfig)

PLIB_USART_IrDADisable Function

Disables the IrDA encoder and decoder.

File

plib_usart.h

C

```
void PLIB_USART_IrDADisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the IrDA encoder and decoder.

Remarks

By default, the IrDA Encoder and Decoder are disabled.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsIrDA in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_IrDADisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_IrDADisable (USART_MODULE_ID index)

PLIB_USART_IrDAEnable Function

Enables the IrDA encoder and decoder.

File

plib_usart.h

C

```
void PLIB_USART_IrDAEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the IrDA encoder and decoder.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsIrDA in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_IrDAEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_IrDAEnable (USART_MODULE_ID index)

PLIB_USART_LineControlModeSelect Function

Sets the data flow configuration.

File

plib_usart.h

C

```
void PLIB_USART_LineControlModeSelect(USART_MODULE_ID index, USART_LINECONTROL_MODE dataFlowConfig);
```

Returns

None.

Description

This function sets the USART data flow configuration based on the mask provided and the specified baud rate.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsLineControlMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_LineControlModeSelect(MY_USART_INSTANCE,
                                 USART_8N1);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mode	For possible data flow configurations, refer to USART_LINECONTROL_MODE

Function

void PLIB_USART_LineControlModeSelect(USART_MODULE_ID index,
USART_LINECONTROL_MODE dataFlowConfig)

PLIB_USART_LoopbackDisable Function

Disables Loopback mode.

File

plib_usart.h

C

```
void PLIB_USART_LoopbackDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables Loopback mode.

Remarks

By default, Loopback mode is disabled. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsLoopback in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_LoopbackDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_LoopbackDisable (USART_MODULE_ID index)

PLIB_USART_LoopbackEnable Function

Enables Loopback mode.

File

plib_usart.h

C

```
void PLIB_USART_LoopbackEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables Loopback mode.

Remarks

By default, Loopback mode is disabled.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsLoopback in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_LoopbackEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_LoopbackEnable (USART_MODULE_ID index)

PLIB_USART_OperationModeSelect Function

Configures the operation mode of the USART module.

File

plib_usart.h

C

```
void PLIB_USART_OperationModeSelect(USART_MODULE_ID index, USART_OPERATION_MODE operationmode);
```

Returns

None.

Description

This function configures the operation mode of the USART (i.e., controls the pins used by the USART module). Refer to USART_OPERATION_MODE for the possible settings.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsOperationMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_OperationModeSelect(MY_USART_INSTANCE, USART_ENABLE_TX_RX_BCLK_USED);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
operationmode	One of the possible values from USART_OPERATION_MODE

Function

void PLIB_USART_OperationModeSelect(USART_MODULE_ID index,
USART_OPERATION_MODE operationmode)

PLIB_USART_StopInIdleDisable Function

Disables the Stop in Idle mode (the USART module continues operation when the device is in Idle mode).

File

plib_usart.h

C

```
void PLIB_USART_StopInIdleDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the Stop in Idle mode. The USART module continues operation when the device is in Idle mode.

Remarks

By default, the USART module will continue operation in Idle mode.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_StopInIdleDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_StopInIdleDisable (USART_MODULE_ID index)

PLIB_USART_StopInIdleEnable Function

Discontinues operation when the device enters Idle mode.

File

plib_usart.h

C

```
void PLIB_USART_StopInIdleEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the USART module to discontinue operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_StopInIdleEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_StopInIdleEnable (USART_MODULE_ID index)

PLIB_USART_WakeOnStartDisable Function

Disables the wake-up on start bit detection feature during Sleep mode.

File

plib_usart.h

C

```
void PLIB_USART_WakeOnStartDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the wake-up on start bit detection feature during Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsWakeOnStart in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_WakeOnStartDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_WakeOnStartDisable (USART_MODULE_ID index)

PLIB_USART_WakeOnStartEnable Function

Enables the wake-up on start bit detection feature during Sleep mode.

File

plib_usart.h

C

```
void PLIB_USART_WakeOnStartEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the wake-up on start feature during Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsWakeOnStart in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_WakeOnStartEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_WakeOnStartEnable (USART_MODULE_ID index)

PLIB_USART_WakeOnStartIsEnabled Function

Gets the state of the sync break event completion.

File

plib_usart.h

C

```
bool PLIB_USART_WakeOnStartIsEnabled(USART_MODULE_ID index);
```

Returns

None.

Description

This function returns the status of the sync break event, when called after enabling using PLIB_USART_WakeOnStartEnable.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsWakeOnStart in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

//Call the interface just prior to entering the sleep mode.
PLIB_USART_WakeOnStartEnable(MY_USART_INSTANCE);

// Check the status if the Sync break event is over.
if(PLIB_USART_WakeOnStartIsEnabled(MY_USART_INSTANCE))
{
   // Do Something
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_WakeOnStartIsEnabled (USART_MODULE_ID index)

PLIB_USART_ErrorsGet Function

Return the status of all errors in the specified USART module.

File

plib_usart.h

C

```
USART_ERROR PLIB_USART_ErrorsGet(USART_MODULE_ID index);
```

Returns

Returns a bitmap of USART error status.

Description

This function returns status of all errors in the specified USART module. The return value can be bitwise AND'ed with a USART_ERROR type to know the status of a specific error.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability. Availability of this function can also be determined if all of the followings functions return true:

- PLIB_USART_ExistsReceiverFramingErrorStatus
- PLIB_USART_ExistsReceiverParityErrorStatus
- PLIB_USART_ExistsReceiverOverrunStatus

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

USART_ERROR error;

// Get the status of all errors.
error = PLIB_USART_ErrorsGet(MY_USART_INSTANCE);

// Check if parity error is active
if(error & USART_ERROR_PARITY)
{
    // Parity error is active.
}
else if(error & USART_ERROR_FRAMING)
```

```
{
    // Framing error is active.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

USART_ERROR PLIB_USART_ErrorsGet (USART_MODULE_ID index)

PLIB_USART_InitializeModeGeneral Function

Enables or disables general features of the USART module.

File

plib_usart.h

C

```
void PLIB_USART_InitializeModeGeneral(USART_MODULE_ID index, bool autobaud, bool loopBackMode, bool
wakeFromSleep, bool irdaMode, bool stopInIdle);
```

Returns

None.

Description

This function enables or disables general features of the USART module.

Remarks

Enabling the wake from sleep feature will cause the first character that is received by the USART module to be discarded. This feature should only be enabled if the CPU is to placed in power saving mode.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability. Availability of this function can also be determined if all of the following functions return true:

- PLIB_USART_ExistsLoopback
- PLIB_USART_ExistsBaudRateAutoDetect
- PLIB_USART_ExistsWakeOnStart
- PLIB_USART_ExistsIrDA
- PLIB_USART_ExistsStopInIdle

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Enable loopback, disable IrDA, disable auto baud detection and disable
// wake from sleep. Enable stop in idle
PLIB_USART_InitializeModeGeneral(MY_USART_INSTANCE, false, true,
                                                    false, false, true);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
autobaud	If true, auto baud rate detection is enabled. If false the feature is disabled.
loopBackMode	If true, loop back is enabled. If false the feature is disabled.
wakeFromSleep	If true, the USART module will wake up the CPU from sleep mode on USART activity. If false the feature is disabled.
irdaMode	If true, the IrDA mode is enabled. If false the feature is disabled.
stopInIdle	If true, module will stop functioning when CPU enters Idle mode. If false, the feature is disabled.

Function

void PLIB_USART_InitializeModeGeneral(USART_MODULE_ID index, bool autobaud,
bool loopBackMode, bool wakeFromSleep, bool irdaMode, bool stopInIdle);

PLIB_USART_InitializeOperation Function

Configures the Receive and Transmit FIFO interrupt levels and the hardware lines to be used by the module.

File

plib_usart.h

C

```
void PLIB_USART_InitializeOperation(USART_MODULE_ID index, USART_RECEIVE_INTR_MODE receiveInterruptMode,
USART_TRANSMIT_INTR_MODE transmitInterruptMode, USART_OPERATION_MODE operationMode);
```

Returns

None.

Description

This function configures the Receive and Transmit FIFO interrupt levels and the hardware lines to be used by the module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability. Availability of this function can also be determined if all of the following functions return true:

- PLIB_USART_ExistsReceiverInterruptMode
- PLIB_USART_ExistsTransmitterInterruptMode
- PLIB_USART_ExistsOperationMode

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Set receive FIFO to interrupt when FIFO is 3/4 level full
// Set Transmit FIFO to interrupt when FIFO is empty
// USART module will only use RX and TX hardware lines

PLIB_USART_InitializeOperation(MY_USART_INSTANCE, USART_RECEIVE_FIFO_3B4FULL,
    USART_TRANSMIT_FIFO_EMPTY  , USART_ENABLE_TX_RX_USED);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
receiveInterruptMode	Receiver FIFO interrupt level
transmitInterruptMode	Transmit FIFO interrupt level
operationMode	Hardware lines to be used by the USART.

Function

void PLIB_USART_InitializeOperation(USART_MODULE_ID index ,
USART_RECEIVE_INTR_MODE receiveInterruptMode,
USART_TRANSMIT_INTR_MODE transmitInterruptMode,
USART_OPERATION_MODE operationMode);

PLIB_USART_AddressGet Function

Gets the address for the Address Detect mode.

File

plib_usart.h

C

```
uint8_t PLIB_USART_AddressGet(USART_MODULE_ID index);
```

Returns

- address - The address being used

Description

This function returns the address value being used for the Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
uint8_t address = 0;
address = PLIB_USART_AddressGet (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

uint8_t PLIB_USART_AddressGet

(

USART_MODULE_ID index

)

PLIB_USART_AddressMaskGet Function

Gets the address mask for the Address Detect mode.

File

plib_usart.h

C

```
uint8_t PLIB_USART_AddressMaskGet(USART_MODULE_ID index);
```

Returns

- mask - Address mask being used

Description

This function returns the address mask value being used for the Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressMask in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
uint8_t mask = 0;
mask = PLIB_USART_AddressMaskGet (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_USART_AddressMaskGet
(
USART_MODULE_ID index
)

PLIB_USART_AddressMaskSet Function

Sets the address mask for the Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_AddressMaskSet(USART_MODULE_ID index, uint8_t mask);
```

Returns

None.

Description

This function sets the address mask for the Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressMask in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
uint8_t mask = 0x0F;
PLIB_USART_AddressMaskSet (MY_USART_INSTANCE, mask);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
mask	Address match mask bits

Function

void PLIB_USART_AddressMaskSet
(
USART_MODULE_ID index,
uint8_t mask
)

PLIB_USART_AddressSet Function

Sets the address for the Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_AddressSet(USART_MODULE_ID index, uint8_t address);
```

Returns

None.

Description

This function sets the address for the Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
uint8_t address = 0x02;
PLIB_USART_AddressSet (MY_USART_INSTANCE, address);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	Address

Function

void PLIB_USART_AddressSet

(

USART_MODULE_ID index,

uint8_t address

)

PLIB_USART_ModuleIsBusy Function

Returns the USART module's running status.

File

plib_usart.h

C

```
bool PLIB_USART_ModuleIsBusy(USART_MODULE_ID index);
```

Returns

- true - USART module is busy
- false - USART module is idle

Description

This function checks if the USART module status is busy. The following functions should not be used when the module status is busy:

- PLIB_USART_LineControlModeSelect
- PLIB_USART_BaudRateHighSet
- PLIB_USART_BaudRateHighEnable
- PLIB_USART_BaudRateHighDisable
- PLIB_USART_ReceiverIdleStateLowEnable
- PLIB_USART_ReceiverIdleStateLowDisable
- PLIB_USART_BaudRateAutoDetectEnable
- PLIB_USART_LoopbackEnable
- PLIB_USART_LoopbackDisable
- PLIB_USART_WakeOnStartEnable
- PLIB_USART_WakeOnStartDisable
- PLIB_USART_OperationModeSelect
- PLIB_USART_HandshakeModeSelect

- PLIB_USART_IrDAEnable
- PLIB_USART_IrDADisable
- PLIB_USART_StopInIdleEnable
- PLIB_USART_StopInIdleDisable
- PLIB_USART_RunInOverflowEnable
- PLIB_USART_RunInOverflowDisable
- PLIB_USART_BRGClockSourceSelect
- PLIB_USART_RunInSleepModeEnable
- PLIB_USART_RunInSleepModeDisable

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsModuleBusyStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1
bool moduleStatus;

moduleStatus = PLIB_USART_ModuleIsBusy (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_USART_ModuleIsBusy (USART_MODULE_ID index)

PLIB_USART_RunInOverflowDisable Function

Disables the Run in overflow condition mode.

File

plib_usart.h

C

```
void PLIB_USART_RunInOverflowDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the USART module from accepting new data when an overflow error condition is detected.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_RunInOverflowDisable (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_RunInOverflowDisable (USART_MODULE_ID index)

PLIB_USART_RunInOverflowEnable Function

Enables the USART module to continue to operate when an overflow error condition has occurred.

File

plib_usart.h

C

```
void PLIB_USART_RunInOverflowEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the USART module to continue to operate when an overflow error condition has occurred.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_RunInOverflowEnable (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_RunInOverflowEnable (USART_MODULE_ID index)

PLIB_USART_RunInOverflowIsEnabled Function

Gets the status of the Run in Overflow condition.

File

plib_usart.h

C

```
bool PLIB_USART_RunInOverflowIsEnabled(USART_MODULE_ID index);
```

Returns

- true - Run in overflow condition is enabled
- false - Run in overflow condition is disabled

Description

This function indicates if the USART module has been enabled to run in an overflow condition.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInOverflow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

bool status;
status = PLIB_USART_RunInOverflowIsEnabled (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_USART_RunInOverflowIsEnabled (USART_MODULE_ID index)

PLIB_USART_RunInSleepModeDisable Function

Turns off the USART module's BRG clock during Sleep mode.

File

plib_usart.h

C

```
void PLIB_USART_RunInSleepModeDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function turns off the USART module's BRG clock during Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_RunInSleepModeDisable (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_RunInSleepModeDisable (USART_MODULE_ID index)

PLIB_USART_RunInSleepModeEnable Function

Allows the USART module's BRG clock to run when the device enters Sleep mode.

File

plib_usart.h

C

```
void PLIB_USART_RunInSleepModeEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the USART module's BRG clock to continue operation when the device enters the Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_RunInSleepModeEnable (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_RunInSleepModeEnable (USART_MODULE_ID index)

PLIB_USART_RunInSleepModeIsEnabled Function

Gets the status of Run in Sleep mode.

File

plib_usart.h

C

```
bool PLIB_USART_RunInSleepModeIsEnabled(USART_MODULE_ID index);
```

Returns

- true - Run in Sleep mode is enabled
- false - Run in Sleep mode is disabled

Description

This function indicates if the USART module has been enabled to run in Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsRunInSleepMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

bool status;
status = PLIB_USART_RunInSleepModeIsEnabled (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

bool PLIB_USART_RunInSleepModeIsEnabled (USART_MODULE_ID index)

b) Baud Rate Generator Functions

PLIB_USART_BaudRateAutoDetectEnable Function

Enables baud rate measurement on the next character, which requires reception of the Sync character.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateAutoDetectEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the baud rate measurement on the next character, which requires reception of the Sync character.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateAutoDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BaudRateAutoDetectEnable(MY_USART_INSTANCE);

// Wait until the baud rate is detected.
while(!PLIB_USART_BaudRateAutoDetectIsComplete(MY_USART_INSTANCE));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_BaudRateAutoDetectEnable (USART_MODULE_ID index)

PLIB_USART_BaudRateAutoDetectIsComplete Function

Gets the state of the automatic baud detection.

File

plib_usart.h

C

```
bool PLIB_USART_BaudRateAutoDetectIsComplete(USART_MODULE_ID index);
```

Returns

- true - Baud rate detection is not complete
- false - Baud rate detection is complete

Description

This function gets the state of the automatic baud detection and returns a '0' if the baud rate auto detection is complete.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateAutoDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BaudRateAutoDetectEnable(MY_USART_INSTANCE);

// Wait until the baud rate is detected.
while(!PLIB_USART_BaudRateAutoDetectIsComplete(MY_USART_INSTANCE));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_BaudRateAutoDetectIsComplete (USART_MODULE_ID index)

PLIB_USART_BaudRateGet Function

Gets the baud rate current in use.

File

plib_usart.h

C

```
uint32_t PLIB_USART_BaudRateGet(USART_MODULE_ID index, int32_t clockFrequency);
```

Returns

- BaudRate - Baud rate value

Description

This function gets the baud rate that is currently in use. The clock frequency needs to be passed to the function.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRate in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint32_t baudRate ;
PLIB_USART_BaudRateSet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
baudRate = PLIB_USART_BaudRateGet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
clockFrequency	Clock Frequency

Function

uint32_t PLIB_USART_BaudRateGet (USART_MODULE_ID index,
int32_t clockFrequency);

PLIB_USART_BaudRateHighDisable Function

Disables the high baud rate selection.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateHighDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the high baud rate selection.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateHigh in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BaudRateHighDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_BaudRateHighDisable (USART_MODULE_ID index)

PLIB_USART_BaudRateHighEnable Function

Enables high baud rate selection.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateHighEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables high baud rate selection.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateHigh in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BaudRateHighEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_BaudRateHighEnable (USART_MODULE_ID index)

PLIB_USART_BaudRateHighSet Function

Sets the baud rate to the desired value.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateHighSet(USART_MODULE_ID index, uint32_t clockFrequency, uint32_t baudRate);
```

Returns

None.

Description

This function sets the baud rate to the desired value.

Remarks

Setting a new baud rate value causes the baud rate timer to reset. This ensures that the baud rate timer does not have to overflow before outputting the new baud rate.

If the system clock is changed during an active receive operation, a receiver error or data loss may result. To avoid this issue verify that no receptions are in progress before changing the system clock.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRateHigh in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint32_t baudRateValue ;
PLIB_USART_BaudRateHighSet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
baudRateValue = PLIB_USART_BaudRateGet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
baudRate	Baud Rate Value, it is the baud rate value
clockFrequency	Clock Frequency

Function

void PLIB_USART_BaudRateHighSet (USART_MODULE_ID index,

uint32_t clockFrequency, uint32_t baudRate);

PLIB_USART_BaudRateSet Function

Sets the baud rate to the desired value.

File

plib_usart.h

C

```
void PLIB_USART_BaudRateSet(USART_MODULE_ID index, uint32_t clockFrequency, uint32_t baudRate);
```

Returns

None.

Description

This function sets the baud rate to the desired value.

Remarks

Setting a new baud rate value causes the baud rate timer to reset. This ensures that the baud rate timer does not have to overflow before outputting the new baud rate.

If the system clock is changed during an active receive operation, a receiver error or data loss may result. To avoid this issue verify that no receptions are in progress before changing the system clock.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBaudRate in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint32_t baudRateValue ;
PLIB_USART_BaudRateSet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
baudRateValue = PLIB_USART_BaudRateGet(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
baudRate	Baud Rate Value
clockFrequency	Clock Frequency

Function

void PLIB_USART_BaudRateSet (USART_MODULE_ID index, uint32_t clockFrequency,

uint32_t baudRate);

PLIB_USART_BaudSetAndEnable Function

Sets the baud rate to the desired value and enables the USART receiver, transmitter and the USART module.

File

plib_usart.h

C

```
void PLIB_USART_BaudSetAndEnable(USART_MODULE_ID index, uint32_t systemClock, uint32_t baud);
```

Returns

None.

Description

This function sets the baud rate to the desired value and enables the USART receiver, USART transmitter and USART module.

Remarks

Setting a new baud rate value causes the baud rate timer to reset. This ensures that the baud rate timer does not have to overflow before outputting the new baud rate.

If the system clock is changed during an active receive operation, a receiver error or data loss may result. To avoid this issue verify that no receptions are in progress before changing the system clock.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability. Availability of this function can also be determined if all of the following functions return true:

- PLIB_USART_ExistsBaudRate
- PLIB_USART_ExistsTransmitterEnable
- PLIB_USART_ExistsReceiverEnable
- PLIB_USART_ExistsEnable

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint32_t baudRateValue ;
PLIB_USART_BaudSetAndEnable(MY_USART_INSTANCE, MY_CLOCK_FREQUENCY, 9600);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
baudRate	Baud Rate Value
clockFrequency	Clock Frequency

Function

void PLIB_USART_BaudSetAndEnable (USART_MODULE_ID index, uint32_t clockFrequency, uint32_t baudRate);

PLIB_USART_BRGClockSourceGet Function

Gets the BRG clock source of the USART module.

File

plib_usart.h

C

```
USART_BRG_CLOCK_SOURCE PLIB_USART_BRGClockSourceGet(USART_MODULE_ID index);
```

Returns

One of the possible values of USART_BRG_CLOCK_SOURCE

Description

This function returns the BRG Clock source of the USART. Refer to USART_BRG_CLOCK_SOURCE for the possible clock sources.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBRGClockSourceSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

USART_BRG_CLOCK_SOURCE brgClockSource;
brgClockSource = PLIB_USART_BRGClockSourceGet (MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance

Function

USART_BRG_CLOCK_SOURCE PLIB_USART_BRGClockSourceGet (USART_MODULE_ID index)

PLIB_USART_BRGClockSourceSelect Function

Configures the BRG clock source of the USART module.

File

plib_usart.h

C

```
void PLIB_USART_BRGClockSourceSelect(USART_MODULE_ID index, USART_BRG_CLOCK_SOURCE brgClockSource);
```

Returns

None.

Description

This function configures the BRG Clock source of the USART. Refer to USART_BRG_CLOCK_SOURCE for the possible clock sources.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsBRGClockSourceSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_BRGClockSourceSelect (MY_USART_INSTANCE, USART_BRG_CLOCK_SOURCE_FRC_IN_SLEEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
brgClockSource	One of the possible values from USART_BRG_CLOCK_SOURCE

Function

void PLIB_USART_BRGClockSourceSelect
(
    USART_MODULE_ID index,
USART_BRG_CLOCK_SOURCE brgClockSource
)

c) Transmitter Functions

PLIB_USART_Transmitter9BitsSend Function

Data to be transmitted in the byte mode with the 9th bit.

File

plib_usart.h

C

```
void PLIB_USART_Transmitter9BitsSend(USART_MODULE_ID index, int8_t data, bool Bit9th);
```

Returns

None.

Description

The data is transmitted in the byte mode for the specified USART module, with 9th bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitter9BitsSend in your application to determine whether this feature is available.

Preconditions

The USART module should be configured to use the 9 data bits.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint8_t data = 'a';

if(!PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE))
{
    PLIB_USART_Transmitter9BitsSend(MY_USART_INSTANCE, data, false);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Data to be transmitted.
9thBit	9th bit of the data to be transmitted.

Function

void PLIB_USART_Transmitter9BitsSend (USART_MODULE_ID index,

int8_t data, bool 9thBit)

PLIB_USART_TransmitterBreakSend Function

Transmits the break character.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterBreakSend(USART_MODULE_ID index);
```

Returns

None.

Description

This function transmits the break character.

Remarks

After the break has been transmitted, the application can start transmitting next bytes.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterBreak in your application to determine whether this feature is available.

Preconditions

The application should wait for the transmitter to be idle, before calling this function.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Wait for the Transmit buffer to be empty.
while(PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE));

// Transmit the break character.
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);

// wait for the break transmission to complete
while(!PLIB_USART_TransmitterBreakSendIsComplete(MY_USART_INSTANCE));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterBreakSend (USART_MODULE_ID index)

PLIB_USART_TransmitterBreakSendIsComplete Function

Returns the status of the break transmission

File

plib_usart.h

C

```
bool PLIB_USART_TransmitterBreakSendIsComplete(USART_MODULE_ID index);
```

Returns

- true - Transmit break on the next transmission
- false - Break transmission completed or not started

Description

The function returns the status of the break transmission.

Remarks

After the break has been transmitted, the application can start transmitting next bytes.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterBreak in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Wait for the Transmit buffer to be empty.
while(PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE));

// Transmit the break character.
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);

// wait for the break transmission to complete
while(!PLIB_USART_TransmitterBreakSendIsComplete(MY_USART_INSTANCE));
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_TransmitterBreakSendIsComplete (USART_MODULE_ID index)

PLIB_USART_TransmitterBufferIsFull Function

Gets the transmit buffer full status.

File

plib_usart.h

C

```
bool PLIB_USART_TransmitterBufferIsFull(USART_MODULE_ID index);
```

Returns

- true - The transmit buffer is full
- false - The transmit buffer is not full, at least one more character can be written

Description

This function gets the transmit status of the specified USART module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterBufferFullStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Wait for the Transmit buffer to be empty.
while(PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE));

// Transmit the break character.
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_TransmitterBufferIsFull (USART_MODULE_ID index)

PLIB_USART_TransmitterByteSend Function

Data to be transmitted in the Byte mode.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterByteSend(USART_MODULE_ID index, int8_t data);
```

Returns

None.

Description

The data is transmitted in the Byte mode for the specified USART module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitter in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint8_t data = 'a';
if(!PLIB_USART_TransmitterBufferIsFull(MY_USART_INSTANCE))
{
    PLIB_USART_TransmitterByteSend(MY_USART_INSTANCE, data);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
data	Data to be transmitted.

Function

void PLIB_USART_TransmitterByteSend (USART_MODULE_ID index, int8_t data)

PLIB_USART_TransmitterDisable Function

Disables the specific USART module transmitter.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the specific USART module transmitter.

Remarks

Disabling the transmitter during a transmission will cause the transmission to be aborted.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterDisable (USART_MODULE_ID index)

PLIB_USART_TransmitterEnable Function

Enables the specific USART module transmitter.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the specific USART module transmitter.

Remarks

The transmitter should not be enabled until the USART is enabled. The transmissions will not be enabled otherwise.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterEnable in your application to determine whether this feature is available.

Preconditions

The USART module should be enabled using the function PLIB_USART_Enable before this function is called.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterEnable (USART_MODULE_ID index)

PLIB_USART_TransmitterIdleIsLowDisable Function

Disables the Transmit Idle Low state.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterIdleIsLowDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the Transmit Idle Low state. In USART Synchronous mode, this function configures that the TX polarity the idle state is high. When IrDA is enabled, this function sets the IrDA encoded Transmit Idle state to a '0'.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterIdleIsLow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterIdleIsLowDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterIdleIsLowDisable (USART_MODULE_ID index)

PLIB_USART_TransmitterIdleIsLowEnable Function

Enables the Transmit Idle Low state.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterIdleIsLowEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the Transmit Idle Low state. In the USART Synchronous mode, this function configures that the TX polarity, the idle state is low.

When IrDA is enabled, this function sets that IrDA encoded Transmit Idle state to a '1'.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterIdleIsLow in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterIdleIsLowEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_TransmitterIdleIsLowEnable (USART_MODULE_ID index)

PLIB_USART_TransmitterInterruptModeSelect Function

Sets the USART transmitter interrupt mode.

File

plib_usart.h

C

```
void PLIB_USART_TransmitterInterruptModeSelect(USART_MODULE_ID index, USART_TRANSMIT_INTR_MODE fifolevel);
```

Returns

None.

Description

This function sets the condition in which the USART module should generate an interrupt.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterInterruptMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_TransmitterInterruptModeSelect(MY_USART_INSTANCE,
    USART_TRANSMIT_FIFO_EMPTY );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
interruptMode	Interrupt mode; for possible configurations, refer to USART_TRANSMIT_INTR_MODE

Function

void PLIB_USART_TransmitterInterruptModeSelect(USART_MODULE_ID index,
USART_TRANSMIT_INTR_MODE interruptMode)

PLIB_USART_TransmitterIsEmpty Function

Gets the transmit shift register empty status.

File

plib_usart.h

C

```
bool PLIB_USART_TransmitterIsEmpty(USART_MODULE_ID index);
```

Returns

- true - The transmit shift register is empty
- false - The transmit shift register is not empty

Description

This function gets the transmit shift register empty status.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsTransmitterEmptyStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

// Wait for the Transmit buffer to be empty.
while(!PLIB_USART_TransmitterIsEmpty(MY_USART_INSTANCE));

// Transmit the break character.
PLIB_USART_TransmitterBreakSend(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_TransmitterIsEmpty (USART_MODULE_ID index)

PLIB_USART_TransmitterAddressGet Function

Returns the address of the USART TX register

File

plib_usart.h

C

```
void* PLIB_USART_TransmitterAddressGet(USART_MODULE_ID index);
```

Returns

Address of the USART TX register

Description

This function returns the address of the USART TX register.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_TransmitterAddressGet(USART_MODULE_ID index)

d) Receiver Functions

PLIB_USART_ReceiverAddressAutoDetectDisable Function

Disables the automatic Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverAddressAutoDetectDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the automatic Address Detect mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressAutoDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverAddressAutoDetectDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverAddressAutoDetectDisable (
USART_MODULE_ID index)

PLIB_USART_ReceiverAddressAutoDetectEnable Function

Setup the automatic Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverAddressAutoDetectEnable(USART_MODULE_ID index, int8_t Mask);
```

Returns

None.

Description

This function configures the automatic Address Detect mode. Uses the mask as the address character for automatic address detection.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressAutoDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverAddressAutoDetectEnable(MY_USART_INSTANCE,
                                           MY_DEVICE_ADDRESS);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
Mask	Address character to be used, when enabled

Function

void PLIB_USART_ReceiverAddressAutoDetectEnable(USART_MODULE_ID index,

int8_t Mask)

PLIB_USART_ReceiverAddressDetectDisable Function

Enables the Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverAddressDetectDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the Address Detect mode. If it is enabled, and the device is addressed, disable the Address Detect mode to continue receiving bytes.

Remarks

All bytes are received, and the 9th bit can be used as the parity bit. By default, the address detect is disabled.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverAddressDetectDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverAddressDetectDisable (USART_MODULE_ID index)

PLIB_USART_ReceiverAddressDetectEnable Function

Enables the Address Detect mode.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverAddressDetectEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the Address Detect mode. If it is enabled, and the device is addressed, disable the Address Detect mode to continue receiving bytes.

Remarks

If 9 data bits are not selected, this bit has no effect.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressDetect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverAddressDetectEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverAddressDetectEnable (USART_MODULE_ID index)

PLIB_USART_ReceiverAddressIsReceived Function

Checks and return if the data received is an address.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverAddressIsReceived(USART_MODULE_ID index);
```

Returns

- true - if the data received has the 9th bit set
- false - if the address received has the 9th bit cleared

Description

Checks and return if the data received is an address. The address has the 9th bit set. If data received has the 9th bit set, the function returns true; otherwise, the function returns false.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverAddressDetect in your application to determine whether this feature is available.

Preconditions

The USART module should be configured to use the 9 data bits.

Example

```
#define MY_USART_INSTANCE USART_ID_1

int8_t address;

if(PLIB_USART_ReceiverAddressIsReceived(MY_USART_INSTANCE))
{
    address = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverAddressIsReceived (USART_MODULE_ID index)

PLIB_USART_ReceiverByteReceive Function

Data to be received in the Byte mode.

File

plib_usart.h

C

```
int8_t PLIB_USART_ReceiverByteReceive(USART_MODULE_ID index);
```

Returns

- data - Data to be received

Description

The data to be received in Byte mode from the specified USART module. Call the functions PLIB_USART_ReceiverFramingErrorHasOccurred, PLIB_USART_ReceiverParityErrorHasOccurred and PLIB_USART_ReceiverOverrunHasOccurred to get any error that occurred.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiver in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

bool isError;
uint8_t mydata;

if(PLIB_USART_ReceiverDataIsAvailable(MY_USART_INSTANCE))
{
    mydata = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
}

isError = PLIB_USART_ReceiverFramingErrorHasOccurred(MY_USART_INSTANCE)     |
              PLIB_USART_ReceiverParityErrorHasOccurred(MY_USART_INSTANCE) |
              PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE);

if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

int8_t PLIB_USART_ReceiverByteReceive (USART_MODULE_ID index)

PLIB_USART_ReceiverDataIsAvailable Function

Identifies if the receive data is available for the specified USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverDataIsAvailable(USART_MODULE_ID index);
```

Returns

- true - The data is available
- false - The data is not available

Description

This function identifies if the receive data is available for the specified USART module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverDataAvailableStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

int8_t mydata;

if(PLIB_USART_ReceiverDataIsAvailable(MY_USART_INSTANCE))
{
    mydata = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverDataIsAvailable (USART_MODULE_ID index)

PLIB_USART_ReceiverDisable Function

Disables the USART receiver.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables the USART receiver.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverDisable (USART_MODULE_ID index)

PLIB_USART_ReceiverEnable Function

Enables the USART receiver.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables the USART receiver.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverEnable (USART_MODULE_ID index)

PLIB_USART_ReceiverFramingErrorHasOccurred Function

Gets the framing error status.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverFramingErrorHasOccurred(USART_MODULE_ID index);
```

Returns

- true - The framing error was detected on the current character
- false - The framing error was not detected on the current character

Description

This function gets the framing error status.

Remarks

Reading the error clears the error.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverFramingErrorStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

status = PLIB_USART_ReceiverFramingErrorHasOccurred(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverFramingErrorHasOccurred (USART_MODULE_ID index)

PLIB_USART_ReceiverIdleStateLowDisable Function

Disables receive polarity inversion.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverIdleStateLowDisable(USART_MODULE_ID index);
```

Returns

None.

Description

This function disables receive polarity inversion. In the USART Synchronous mode, this function configures that the data is not inverted.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverIdleStateLowEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverIdleStateLowDisable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverIdleStateLowDisable (USART_MODULE_ID index);

PLIB_USART_ReceiverIdleStateLowEnable Function

Enables receive polarity inversion.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverIdleStateLowEnable(USART_MODULE_ID index);
```

Returns

None.

Description

This function enables receive polarity inversion. In the USART Synchronous mode, this function configures that the data is inverted.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverIdleStateLowEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverIdleStateLowEnable(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverIdleStateLowEnable (USART_MODULE_ID index)

PLIB_USART_ReceiverInterruptModeSelect Function

Sets the USART receiver FIFO level.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverInterruptModeSelect(USART_MODULE_ID index, USART_RECEIVE_INTR_MODE interruptMode);
```

Returns

None.

Description

This function sets the USART receiver FIFO level.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverInterruptMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

PLIB_USART_ReceiverInterruptModeSelect(MY_USART_INSTANCE,
    USART_RECEIVE_FIFO_ONE_CHAR );
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
fifolevel	For possible configurations, refer to USART_RECEIVE_INTR_MODE

Function

void PLIB_USART_ReceiverInterruptModeSelect(USART_MODULE_ID index,
USART_RECEIVE_INTR_MODE interruptMode)

PLIB_USART_ReceiverIsIdle Function

Identifies if the receiver is idle.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverIsIdle(USART_MODULE_ID index);
```

Returns

- true - The receive buffer is idle
- false - The receive buffer is not idle

Description

This function identifies if the receiver is idle.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverIdleStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

int8_t mydata;

if(PLIB_USART_ReceiverIsIdle(MY_USART_INSTANCE))
{
    mydata = PLIB_USART_ReceiverByteReceive(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverIsIdle (USART_MODULE_ID index)

PLIB_USART_ReceiverOverrunErrorClear Function

Clears a USART vverrun error.

File

plib_usart.h

C

```
void PLIB_USART_ReceiverOverrunErrorClear(USART_MODULE_ID index);
```

Returns

None.

Description

This function clears an overrun error. Clearing the error, resets the receive buffer.

Remarks

WARNING: Calling this API will clear all of the previously received data.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverOverrunStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USART_ReceiverOverrunErrorClear (USART_MODULE_ID index)

PLIB_USART_ReceiverOverrunHasOccurred Function

Identifies if there was a receiver overrun error.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverOverrunHasOccurred(USART_MODULE_ID index);
```

Returns

- true - The receive buffer has overflowed
- false - The receive buffer has not overflowed

Description

This function identifies if there was a receiver overrun error.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverOverrunStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

if(PLIB_USART_ReceiverOverrunHasOccurred(MY_USART_INSTANCE))
{
    PLIB_USART_ReceiverOverrunErrorClear(MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverOverrunHasOccurred (USART_MODULE_ID index)

PLIB_USART_ReceiverParityErrorHasOccurred Function

Gets the parity error status.

File

plib_usart.h

C

```
bool PLIB_USART_ReceiverParityErrorHasOccurred(USART_MODULE_ID index);
```

Returns

- true - The parity error was detected on the current character
- false - The parity error was not detected on the current character

Description

This function gets the parity error status.

Remarks

Reading the error clears the error. A Parity error is irrelevant in case of 9-bit mode. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiverParityErrorStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

status = PLIB_USART_ReceiverParityErrorHasOccurred(MY_USART_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

bool PLIB_USART_ReceiverParityErrorHasOccurred (USART_MODULE_ID index)

PLIB_USART_ReceiverAddressGet Function

Returns the address of the USART RX register

File

plib_usart.h

C

```
void* PLIB_USART_ReceiverAddressGet(USART_MODULE_ID index);
```

Returns

Address of the USART RX register

Description

This function returns the address of the USART RX register.

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ReceiverAddressGet(USART_MODULE_ID index)

PLIB_USART_Receiver9BitsReceive Function

Data to be received in the byte mode with the 9th bit.

File

plib_usart.h

C

```
int16_t PLIB_USART_Receiver9BitsReceive(USART_MODULE_ID index);
```

Returns

- data - Data to be received

Description

The data to be received in Byte mode from the specified USART module. with the 9th bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USART_ExistsReceiver9Bits in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#define MY_USART_INSTANCE USART_ID_1

uint16_t mydata;

if(PLIB_USART_ReceiverDataIsAvailable(MY_USART_INSTANCE))
{
    mydata = PLIB_USART_Receiver9BitsReceive (MY_USART_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

int16_t PLIB_USART_Receiver9BitsReceive (USART_MODULE_ID index)

e) Feature Existence Functions

PLIB_USART_ExistsBaudRate Function

Identifies whether the BaudRate feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsBaudRate(USART_MODULE_ID index);
```

Returns

- true - The BaudRate feature is supported on the device
- false - The BaudRate feature is not supported on the device

Description

This function identifies whether the BaudRate feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_BaudRateSet
- PLIB_USART_BaudRateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsBaudRate(USART_MODULE_ID index)

PLIB_USART_ExistsBaudRateAutoDetect Function

Identifies whether the BaudRateAutoDetect feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsBaudRateAutoDetect(USART_MODULE_ID index);
```

Returns

- true - The BaudRateAutoDetect feature is supported on the device
- false - The BaudRateAutoDetect feature is not supported on the device

Description

This function identifies whether the BaudRateAutoDetect feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_BaudRateAutoDetectEnable
- PLIB_USART_BaudRateAutoDetectIsComplete

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsBaudRateAutoDetect(USART_MODULE_ID index)

PLIB_USART_ExistsBaudRateHigh Function

Identifies whether the BaudRateHigh feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsBaudRateHigh(USART_MODULE_ID index);
```

Returns

- true - The BaudRateHigh feature is supported on the device
- false - The BaudRateHigh feature is not supported on the device

Description

This function identifies whether the BaudRateHigh feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_BaudRateHighSet
- PLIB_USART_BaudRateHighDisable
- PLIB_USART_BaudRateHighEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsBaudRateHigh(USART_MODULE_ID index)

PLIB_USART_ExistsEnable Function

Identifies whether the EnableControl feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsEnable(USART_MODULE_ID index);
```

Returns

- true - The EnableControl feature is supported on the device
- false - The EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the USART module. When this function returns true, these functions are

supported on the device:

- PLIB_USART_Disable
- PLIB_USART_Enable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsEnable(USART_MODULE_ID index)

PLIB_USART_ExistsHandshakeMode Function

Identifies whether the HandShakeMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsHandshakeMode(USART_MODULE_ID index);
```

Returns

- true - The HandShakeMode feature is supported on the device
- false - The HandShakeMode feature is not supported on the device

Description

This function identifies whether the HandShakeMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_HandshakeModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsHandshakeMode(USART_MODULE_ID index)

PLIB_USART_ExistsIrDA Function

Identifies whether the IrDAControl feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsIrDA(USART_MODULE_ID index);
```

Returns

- true - The IrDAControl feature is supported on the device

- false - The IrDAControl feature is not supported on the device

Description

This function identifies whether the IrDAControl feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_IrDADisable
- PLIB_USART_IrDAEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsIrDA(USART_MODULE_ID index)

PLIB_USART_ExistsLineControlMode Function

Identifies whether the LineControlMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsLineControlMode(USART_MODULE_ID index);
```

Returns

- true - The LineControlMode feature is supported on the device
- false - The LineControlMode feature is not supported on the device

Description

This function identifies whether the LineControlMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_LineControlModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsLineControlMode(USART_MODULE_ID index)

PLIB_USART_ExistsLoopback Function

Identifies whether the Loopback feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsLoopback(USART_MODULE_ID index);
```

Returns

- true - The Loopback feature is supported on the device
- false - The Loopback feature is not supported on the device

Description

This function identifies whether the Loopback feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_LoopbackEnable
- PLIB_USART_LoopbackDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsLoopback(USART_MODULE_ID index)

PLIB_USART_ExistsOperationMode Function

Identifies whether the OperationMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsOperationMode(USART_MODULE_ID index);
```

Returns

- true - The OperationMode feature is supported on the device
- false - The OperationMode feature is not supported on the device

Description

This function identifies whether the OperationMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_OperationModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsOperationMode(USART_MODULE_ID index)

PLIB_USART_ExistsReceiver Function

Identifies whether the Receiver feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiver(USART_MODULE_ID index);
```

Returns

- true - The Receiver feature is supported on the device
- false - The Receiver feature is not supported on the device

Description

This function identifies whether the Receiver feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverByteReceive
- PLIB_USART_ReceiverAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiver(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverAddressAutoDetect Function

Identifies whether the ReceiverAddressAutoDetect feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverAddressAutoDetect(USART_MODULE_ID index);
```

Returns

- true - The ReceiverAddressAutoDetect feature is supported on the device
- false - The ReceiverAddressAutoDetect feature is not supported on the device

Description

This function identifies whether the ReceiverAddressAutoDetect feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverAddressAutoDetectEnable
- PLIB_USART_ReceiverAddressAutoDetectDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverAddressAutoDetect(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverAddressDetect Function

Identifies whether the ReceiverAddressDetect feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverAddressDetect(USART_MODULE_ID index);
```

Returns

- true - The ReceiverAddressDetect feature is supported on the device
- false - The ReceiverAddressDetect feature is not supported on the device

Description

This function identifies whether the ReceiverAddressDetect feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverAddressDetectEnable
- PLIB_USART_ReceiverAddressDetectDisable
- PLIB_USART_ReceiverAddressIsReceived

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverAddressDetect(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverDataAvailableStatus Function

Identifies whether the ReceiverDataAvailable feature exists on the USART module

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverDataAvailableStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverDataAvailable feature is supported on the device
- false - The ReceiverDataAvailable feature is not supported on the device

Description

This function identifies whether the ReceiverDataAvailable feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverDataIsAvailable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverDataAvailableStatus(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverEnable Function

Identifies whether the ReceiverEnableControl feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverEnable(USART_MODULE_ID index);
```

Returns

- true - The ReceiverEnableControl feature is supported on the device
- false - The ReceiverEnableControl feature is not supported on the device

Description

This function identifies whether the ReceiverEnableControl feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverEnable
- PLIB_USART_ReceiverDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverEnable(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverFramingErrorStatus Function

Identifies whether the ReceiverFramingError feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverFramingErrorStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverFramingError feature is supported on the device
- false - The ReceiverFramingError feature is not supported on the device

Description

This function identifies whether the ReceiverFramingError feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverFramingErrorHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverFramingErrorStatus(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverIdleStateLowEnable Function

Identifies whether the ReceiverPolarityInvert feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverIdleStateLowEnable(USART_MODULE_ID index);
```

Returns

- true - The ReceiverPolarityInvert feature is supported on the device
- false - The ReceiverPolarityInvert feature is not supported on the device

Description

This function identifies whether the ReceiverPolarityInvert feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverIdleStateLowEnable
- PLIB_USART_ReceiverIdleStateLowDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverIdleStateLowEnable(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverIdleStatus Function

Identifies whether the ReceiverIdle feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverIdleStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverIdle feature is supported on the device
- false - The ReceiverIdle feature is not supported on the device

Description

This function identifies whether the ReceiverIdle feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverIsIdle

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverIdleStatus(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverInterruptMode Function

Identifies whether the ReceiverInterruptMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverInterruptMode(USART_MODULE_ID index);
```

Returns

- true - The ReceiverInterruptMode feature is supported on the device
- false - The ReceiverInterruptMode feature is not supported on the device

Description

This function identifies whether the ReceiverInterruptMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverInterruptModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverInterruptMode(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverOverrunStatus Function

Identifies whether the ReceiverOverrunError feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverOverrunStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverOverrunError feature is supported on the device
- false - The ReceiverOverrunError feature is not supported on the device

Description

This function identifies whether the ReceiverOverrunError feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_ReceiverOverrunErrorClear
- PLIB_USART_ReceiverOverrunHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverOverrunStatus(USART_MODULE_ID index)

PLIB_USART_ExistsReceiverParityErrorStatus Function

Identifies whether the ReceiverParityError feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverParityErrorStatus(USART_MODULE_ID index);
```

Returns

- true - The ReceiverParityError feature is supported on the device
- false - The ReceiverParityError feature is not supported on the device

Description

This function identifies whether the ReceiverParityError feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ReceiverParityErrorHasOccurred

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverParityErrorStatus(USART_MODULE_ID index)

PLIB_USART_ExistsStopInIdle Function

Identifies whether the StopInIdle feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsStopInIdle(USART_MODULE_ID index);
```

Returns

- true - The StopInIdle feature is supported on the device
- false - The StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_StopInIdleEnable
- PLIB_USART_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsStopInIdle(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitter Function

Identifies whether the Transmitter feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitter(USART_MODULE_ID index);
```

Returns

- true - The Transmitter feature is supported on the device
- false - The Transmitter feature is not supported on the device

Description

This function identifies whether the Transmitter feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_TransmitterByteSend
- PLIB_USART_TransmitterAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitter(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitter9BitsSend Function

Identifies whether the Transmitter9Bits feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitter9BitsSend(USART_MODULE_ID index);
```

Returns

- true - The Transmitter9Bits feature is supported on the device
- false - The Transmitter9Bits feature is not supported on the device

Description

This function identifies whether the Transmitter9Bits feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_Transmitter9BitsSend

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitter9BitsSend(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterBreak Function

Identifies whether the TransmitterBreak feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterBreak(USART_MODULE_ID index);
```

Returns

- true - The TransmitterBreak feature is supported on the device
- false - The TransmitterBreak feature is not supported on the device

Description

This function identifies whether the TransmitterBreak feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_TransmitterBreakSend
- PLIB_USART_TransmitterBreakSendIsComplete

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterBreak(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterBufferFullStatus Function

Identifies whether the TransmitterBufferFull feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterBufferFullStatus(USART_MODULE_ID index);
```

Returns

- true - The TransmitterBufferFull feature is supported on the device
- false - The TransmitterBufferFull feature is not supported on the device

Description

This function identifies whether the TransmitterBufferFull feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_TransmitterBufferIsFull

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterBufferFullStatus(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterEmptyStatus Function

Identifies whether the TransmitterEmpty feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterEmptyStatus(USART_MODULE_ID index);
```

Returns

- true - The TransmitterEmpty feature is supported on the device
- false - The TransmitterEmpty feature is not supported on the device

Description

This function identifies whether the TransmitterEmpty feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_TransmitterIsEmpty

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterEmptyStatus(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterEnable Function

Identifies whether the TransmitterEnableControl feature exists on the USART module

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterEnable(USART_MODULE_ID index);
```

Returns

- true - The TransmitterEnableControl feature is supported on the device
- false - The TransmitterEnableControl feature is not supported on the device

Description

This function identifies whether the TransmitterEnableControl feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_TransmitterEnable
- PLIB_USART_TransmitterDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterEnable(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterIdleIsLow Function

Identifies whether the TransmitterIdleIsLow feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterIdleIsLow(USART_MODULE_ID index);
```

Returns

- true - The TransmitterIdleIsLow feature is supported on the device
- false - The TransmitterIdleIsLow feature is not supported on the device

Description

This function identifies whether the TransmitterIdleIsLow feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_TransmitterIdleIsLowDisable
- PLIB_USART_TransmitterIdleIsLowEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterIdleIsLow(USART_MODULE_ID index)

PLIB_USART_ExistsTransmitterInterruptMode Function

Identifies whether the TransmitterInterruptMode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsTransmitterInterruptMode(USART_MODULE_ID index);
```

Returns

- true - The TransmitterInterruptMode feature is supported on the device
- false - The TransmitterInterruptMode feature is not supported on the device

Description

This function identifies whether the TransmitterInterruptMode feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_TransmitterInterruptModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsTransmitterInterruptMode(USART_MODULE_ID index)

PLIB_USART_ExistsWakeOnStart Function

Identifies whether the WakeOnStart feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsWakeOnStart(USART_MODULE_ID index);
```

Returns

- true - The WakeOnStart feature is supported on the device
- false - The WakeOnStart feature is not supported on the device

Description

This function identifies whether the WakeOnStart feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_WakeOnStartEnable
- PLIB_USART_WakeOnStartDisable
- PLIB_USART_WakeOnStartIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsWakeOnStart(USART_MODULE_ID index)

PLIB_USART_ExistsReceiver9Bits Function

Identifies whether the 9 Bits Receiver feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiver9Bits(USART_MODULE_ID index);
```

Returns

- true - The feature is supported on the device
- false - The feature is not supported on the device

Description

This function identifies whether the 9 Bits Receiver feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_Receiver9BitsReceive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiver9Bits (USART_MODULE_ID index)

PLIB_USART_ExistsBRGClockSourceSelect Function

Identifies whether the BRG Clock source select feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsBRGClockSourceSelect(USART_MODULE_ID index);
```

Returns

- true - The BRG clock source select feature is supported on the device
- false - The BRG clock source select feature is not supported on the device

Description

This function identifies whether the BRG Clock source select feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_BRGClockSourceSelect
- PLIB_USART_BRGClockSourceGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsBRGClockSourceSelect (USART_MODULE_ID index)

PLIB_USART_ExistsModuleBusyStatus Function

Identifies whether the module running status feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsModuleBusyStatus(USART_MODULE_ID index);
```

Returns

- true - The Module running status feature is supported on the device
- false - The Module running status feature is not supported on the device

Description

This function identifies whether the module running status feature is available on the USART module. When this function returns true, this function is supported on the device:

- PLIB_USART_ModuleIsBusy

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsModuleBusyStatus (USART_MODULE_ID index)

PLIB_USART_ExistsReceiverAddress Function

Identifies whether the Receiver Address feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverAddress(USART_MODULE_ID index);
```

Returns

- true - The Receiver address feature is supported on the device
- false - The Receiver address feature is not supported on the device

Description

This function identifies whether the Receiver Address feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_AddressSet
- PLIB_USART_AddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverAddress (USART_MODULE_ID index)

PLIB_USART_ExistsReceiverAddressMask Function

Identifies whether the Receiver Address Mask feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsReceiverAddressMask(USART_MODULE_ID index);
```

Returns

- true - The Receiver address mask feature is supported on the device
- false - The Receiver address mask feature is not supported on the device

Description

This function identifies whether the Receiver Address Mask feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_AddressMaskSet
- PLIB_USART_AddressMaskGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsReceiverAddressMask (USART_MODULE_ID index)

PLIB_USART_ExistsRunInOverflow Function

Identifies whether the Run in overflow condition feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsRunInOverflow(USART_MODULE_ID index);
```

Returns

- true - The Run in Overflow condition feature is supported on the device
- false - The Run in Overflow condition feature is not supported on the device

Description

This function identifies whether the Run in Overflow condition feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_RunInOverflowEnable
- PLIB_USART_RunInOverflowDisable
- PLIB_USART_RunInOverflowIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsRunInOverflow (USART_MODULE_ID index)

PLIB_USART_ExistsRunInSleepMode Function

Identifies whether the Run in Sleep mode feature exists on the USART module.

File

plib_usart.h

C

```
bool PLIB_USART_ExistsRunInSleepMode(USART_MODULE_ID index);
```

Returns

- true - The Run in Sleep mode feature is supported on the device
- false - The Run in Sleep mode feature is not supported on the device

Description

This function identifies whether the Run in Sleep mode feature is available on the USART module. When this function returns true, these functions are supported on the device:

- PLIB_USART_RunInSleepModeEnable
- PLIB_USART_RunInSleepModeDisable

- PLIB_USART_RunInSleepModeIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USART_ExistsRunInSleepMode (USART_MODULE_ID index)

f) Data Types and Constants

USART_HANDSHAKE_MODE Enumeration

Lists the USART handshake modes.

File

plib_usart_help.h

C

```
typedef enum {
  USART_HANDSHAKE_MODE_FLOW_CONTROL,
  USART_HANDSHAKE_MODE_SIMPLEX
} USART_HANDSHAKE_MODE;
```

Members

Members	Description
USART_HANDSHAKE_MODE_FLOW_CONTROL	Enables flow control
USART_HANDSHAKE_MODE_SIMPLEX	Enables simplex mode communication, no flow control

Description

USART Handshake modes

This enumeration lists the USART handshake modes.

Remarks

None.

USART_LINECONTROL_MODE Enumeration

Data type defining the different configurations by which the USART data flow can be configured.

File

plib_usart_help.h

C

```
typedef enum {
  USART_8N1,
  USART_8E1,
  USART_8O1,
  USART_8N2,
  USART_8E2,
  USART_8O2,
  USART_9N1,
  USART_9N2
} USART_LINECONTROL_MODE;
```

Members

Members	Description
USART_8N1	8 Data Bits, No Parity,one Stop Bit
USART_8E1	8 Data Bits, Even Parity, 1 stop bit
USART_8O1	8 Data Bits, odd Parity, 1 stop bit
USART_8N2	8 Data Bits, No Parity,two Stop Bits
USART_8E2	8 Data Bits, Even Parity, 2 stop bits
USART_8O2	8 Data Bits, odd Parity, 2 stop bits
USART_9N1	9 Data Bits, No Parity, 1 stop bit
USART_9N2	9 Data Bits, No Parity, 2 stop bits

Description

Data Flow configuration

This data type defines the different configurations by which the USART can be configured for the data flow.

Remarks

None.

USART_MODULE_ID Enumeration

File

plib_usart_help.h

C

```
typedef enum {
  USART_ID_1,
  USART_ID_2,
  USART_ID_3,
  USART_ID_4,
  USART_ID_5,
  USART_ID_6,
  USART_NUMBER_OF_MODULES
} USART_MODULE_ID;
```

Members

Members	Description
USART_ID_1	USART 1
USART_ID_2	USART 2
USART_ID_3	USART 3
USART_ID_4	USART 4
USART_ID_5	USART 5
USART_ID_6	USART 6
USART_NUMBER_OF_MODULES	Total number of USART modules available

Description

Enumeration: USART_MODULE_ID

This enumeration defines the number of modules that are available on the microcontroller. This is the superset of all of the possible instances that might be available on Microchip microcontrollers.

Refer to the data sheet to get the correct number of modules defined for desired microcontroller.

_USART_MODULE_ID Macro

File

plib_usart_help.h

C

```
#define _USART_MODULE_ID
```

USART_OPERATION_MODE Enumeration

Data type defining the different configurations by which the USART can be enabled.

File

plib_usart_help.h

C

```
typedef enum {
  USART_ENABLE_TX_RX_BCLK_USED,
  USART_ENABLE_TX_RX_CTS_RTS_USED,
  USART_ENABLE_TX_RX_RTS_USED,
  USART_ENABLE_TX_RX_USED
} USART_OPERATION_MODE;
```

Members

Members	Description
USART_ENABLE_TX_RX_BCLK_USED	TX, RX and BCLK pins are used by USART module
USART_ENABLE_TX_RX_CTS_RTS_USED	TX, RX, CTS and RTS pins are used by USART module
USART_ENABLE_TX_RX_RTS_USED	TX, RX and RTS pins are used by USART module
USART_ENABLE_TX_RX_USED	TX and RX pins are used by USART module

Description

Enable configuration

This data type defines the different configurations by which the USART can be enabled.

Remarks

The actual definition of this enumeration is device-specific.

USART_RECEIVE_INTR_MODE Enumeration

Data type defining the different Receive FIFO levels by which the USART receive interrupt modes can be configured.

File

plib_usart_help.h

C

```
typedef enum {
  USART_RECEIVE_FIFO_HALF_FULL,
  USART_RECEIVE_FIFO_3B4FULL,
  USART_RECEIVE_FIFO_ONE_CHAR
} USART_RECEIVE_INTR_MODE;
```

Members

Members	Description
USART_RECEIVE_FIFO_HALF_FULL	Interrupt when receive buffer is half full
USART_RECEIVE_FIFO_3B4FULL	Interrupt when receive buffer is 3/4 full
USART_RECEIVE_FIFO_ONE_CHAR	Interrupt when a character is received

Description

Receive Interrupt mode configuration

This data type defining the different Receive FIFO levels by which the USART receive interrupt modes can be configured.

Remarks

None.

USART_TRANSMIT_INTR_MODE Enumeration

Data type defining the different transmit FIFO levels by which the USART transmit interrupt modes can be configured.

File

plib_usart_help.h

C

```
typedef enum {
  USART_TRANSMIT_FIFO_EMPTY,
  USART_TRANSMIT_FIFO_IDLE,
  USART_TRANSMIT_FIFO_NOT_FULL
} USART_TRANSMIT_INTR_MODE;
```

Members

Members	Description
USART_TRANSMIT_FIFO_EMPTY	Interrupt when the transmit buffer becomes empty
USART_TRANSMIT_FIFO_IDLE	Interrupt when all characters are transmitted
USART_TRANSMIT_FIFO_NOT_FULL	Interrupt when at least one location is empty in the transmit buffer

Description

Transmit Interrupt mode configuration

This data type defining the different transmit FIFO levels by which the USART transmit interrupt modes can be configured.

Remarks

None.

Functions

	Name	Description
	PLIB_USART_AddressGet	Gets the address for the Address Detect mode.
	PLIB_USART_AddressMaskGet	Gets the address mask for the Address Detect mode.
	PLIB_USART_AddressMaskSet	Sets the address mask for the Address Detect mode.
	PLIB_USART_AddressSet	Sets the address for the Address Detect mode.
	PLIB_USART_BaudRateAutoDetectEnable	Enables baud rate measurement on the next character, which requires reception of the Sync character.
	PLIB_USART_BaudRateAutoDetectIsComplete	Gets the state of the automatic baud detection.
	PLIB_USART_BaudRateGet	Gets the baud rate current in use.
	PLIB_USART_BaudRateHighDisable	Disables the high baud rate selection.
	PLIB_USART_BaudRateHighEnable	Enables high baud rate selection.
	PLIB_USART_BaudRateHighSet	Sets the baud rate to the desired value.
	PLIB_USART_BaudRateSet	Sets the baud rate to the desired value.
	PLIB_USART_BaudSetAndEnable	Sets the baud rate to the desired value and enables the USART receiver, transmitter and the USART module.
	PLIB_USART_BRGClockSourceGet	Gets the BRG clock source of the USART module.
	PLIB_USART_BRGClockSourceSelect	Configures the BRG clock source of the USART module.
	PLIB_USART_Disable	Disables the specific USART module
	PLIB_USART_Enable	Enables the specific USART module.

	PLIB_USART_ErrorsGet	Return the status of all errors in the specified USART module.
	PLIB_USART_ExistsBaudRate	Identifies whether the BaudRate feature exists on the USART module.
	PLIB_USART_ExistsBaudRateAutoDetect	Identifies whether the BaudRateAutoDetect feature exists on the USART module.
	PLIB_USART_ExistsBaudRateHigh	Identifies whether the BaudRateHigh feature exists on the USART module.
	PLIB_USART_ExistsBRGClockSourceSelect	Identifies whether the BRG Clock source select feature exists on the USART module.
	PLIB_USART_ExistsEnable	Identifies whether the EnableControl feature exists on the USART module.
	PLIB_USART_ExistsHandshakeMode	Identifies whether the HandShakeMode feature exists on the USART module.
	PLIB_USART_ExistsIrDA	Identifies whether the IrDAControl feature exists on the USART module.
	PLIB_USART_ExistsLineControlMode	Identifies whether the LineControlMode feature exists on the USART module.
	PLIB_USART_ExistsLoopback	Identifies whether the Loopback feature exists on the USART module.
	PLIB_USART_ExistsModuleBusyStatus	Identifies whether the module running status feature exists on the USART module.
	PLIB_USART_ExistsOperationMode	Identifies whether the OperationMode feature exists on the USART module.
	PLIB_USART_ExistsReceiver	Identifies whether the Receiver feature exists on the USART module.
	PLIB_USART_ExistsReceiver9Bits	Identifies whether the 9 Bits Receiver feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddress	Identifies whether the Receiver Address feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressAutoDetect	Identifies whether the ReceiverAddressAutoDetect feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressDetect	Identifies whether the ReceiverAddressDetect feature exists on the USART module.
	PLIB_USART_ExistsReceiverAddressMask	Identifies whether the Receiver Address Mask feature exists on the USART module.
	PLIB_USART_ExistsReceiverDataAvailableStatus	Identifies whether the ReceiverDataAvailable feature exists on the USART module
	PLIB_USART_ExistsReceiverEnable	Identifies whether the ReceiverEnableControl feature exists on the USART module.
	PLIB_USART_ExistsReceiverFramingErrorStatus	Identifies whether the ReceiverFramingError feature exists on the USART module.
	PLIB_USART_ExistsReceiverIdleStateLowEnable	Identifies whether the ReceiverPolarityInvert feature exists on the USART module.
	PLIB_USART_ExistsReceiverIdleStatus	Identifies whether the ReceiverIdle feature exists on the USART module.
	PLIB_USART_ExistsReceiverInterruptMode	Identifies whether the ReceiverInterruptMode feature exists on the USART module.
	PLIB_USART_ExistsReceiverOverrunStatus	Identifies whether the ReceiverOverrunError feature exists on the USART module.
	PLIB_USART_ExistsReceiverParityErrorStatus	Identifies whether the ReceiverParityError feature exists on the USART module.
	PLIB_USART_ExistsRunInOverflow	Identifies whether the Run in overflow condition feature exists on the USART module.
	PLIB_USART_ExistsRunInSleepMode	Identifies whether the Run in Sleep mode feature exists on the USART module.
	PLIB_USART_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the USART module.
	PLIB_USART_ExistsTransmitter	Identifies whether the Transmitter feature exists on the USART module.
	PLIB_USART_ExistsTransmitter9BitsSend	Identifies whether the Transmitter9Bits feature exists on the USART module.
	PLIB_USART_ExistsTransmitterBreak	Identifies whether the TransmitterBreak feature exists on the USART module.
	PLIB_USART_ExistsTransmitterBufferFullStatus	Identifies whether the TransmitterBufferFull feature exists on the USART module.
	PLIB_USART_ExistsTransmitterEmptyStatus	Identifies whether the TransmitterEmpty feature exists on the USART module.
	PLIB_USART_ExistsTransmitterEnable	Identifies whether the TransmitterEnableControl feature exists on the USART module
	PLIB_USART_ExistsTransmitterIdleIsLow	Identifies whether the TransmitterIdleIsLow feature exists on the USART module.
	PLIB_USART_ExistsTransmitterInterruptMode	Identifies whether the TransmitterInterruptMode feature exists on the USART module.
	PLIB_USART_ExistsWakeOnStart	Identifies whether the WakeOnStart feature exists on the USART module.
	PLIB_USART_HandshakeModeSelect	Sets the data flow configuration.
	PLIB_USART_InitializeModeGeneral	Enables or disables general features of the USART module.
	PLIB_USART_InitializeOperation	Configures the Receive and Transmit FIFO interrupt levels and the hardware lines to be used by the module.

	PLIB_USART_IrDADisable	Disables the IrDA encoder and decoder.
	PLIB_USART_IrDAEnable	Enables the IrDA encoder and decoder.
	PLIB_USART_LineControlModeSelect	Sets the data flow configuration.
	PLIB_USART_LoopbackDisable	Disables Loopback mode.
	PLIB_USART_LoopbackEnable	Enables Loopback mode.
	PLIB_USART_ModuleIsBusy	Returns the USART module's running status.
	PLIB_USART_OperationModeSelect	Configures the operation mode of the USART module.
	PLIB_USART_Receiver9BitsReceive	Data to be received in the byte mode with the 9th bit.
	PLIB_USART_ReceiverAddressAutoDetectDisable	Disables the automatic Address Detect mode.
	PLIB_USART_ReceiverAddressAutoDetectEnable	Setup the automatic Address Detect mode.
	PLIB_USART_ReceiverAddressDetectDisable	Enables the Address Detect mode.
	PLIB_USART_ReceiverAddressDetectEnable	Enables the Address Detect mode.
	PLIB_USART_ReceiverAddressGet	Returns the address of the USART RX register
	PLIB_USART_ReceiverAddressIsReceived	Checks and return if the data received is an address.
	PLIB_USART_ReceiverByteReceive	Data to be received in the Byte mode.
	PLIB_USART_ReceiverDataIsAvailable	Identifies if the receive data is available for the specified USART module.
	PLIB_USART_ReceiverDisable	Disables the USART receiver.
	PLIB_USART_ReceiverEnable	Enables the USART receiver.
	PLIB_USART_ReceiverFramingErrorHasOccurred	Gets the framing error status.
	PLIB_USART_ReceiverIdleStateLowDisable	Disables receive polarity inversion.
	PLIB_USART_ReceiverIdleStateLowEnable	Enables receive polarity inversion.
	PLIB_USART_ReceiverInterruptModeSelect	Sets the USART receiver FIFO level.
	PLIB_USART_ReceiverIsIdle	Identifies if the receiver is idle.
	PLIB_USART_ReceiverOverrunErrorClear	Clears a USART vverrun error.
	PLIB_USART_ReceiverOverrunHasOccurred	Identifies if there was a receiver overrun error.
	PLIB_USART_ReceiverParityErrorHasOccurred	Gets the parity error status.
	PLIB_USART_RunInOverflowDisable	Disables the Run in overflow condition mode.
	PLIB_USART_RunInOverflowEnable	Enables the USART module to continue to operate when an overflow error condition has occurred.
	PLIB_USART_RunInOverflowIsEnabled	Gets the status of the Run in Overflow condition.
	PLIB_USART_RunInSleepModeDisable	Turns off the USART module's BRG clock during Sleep mode.
	PLIB_USART_RunInSleepModeEnable	Allows the USART module's BRG clock to run when the device enters Sleep mode.
	PLIB_USART_RunInSleepModeIsEnabled	Gets the status of Run in Sleep mode.
	PLIB_USART_StopInIdleDisable	Disables the Stop in Idle mode (the USART module continues operation when the device is in Idle mode).
	PLIB_USART_StopInIdleEnable	Discontinues operation when the device enters Idle mode.
	PLIB_USART_Transmitter9BitsSend	Data to be transmitted in the byte mode with the 9th bit.
	PLIB_USART_TransmitterAddressGet	Returns the address of the USART TX register
	PLIB_USART_TransmitterBreakSend	Transmits the break character.
	PLIB_USART_TransmitterBreakSendIsComplete	Returns the status of the break transmission
	PLIB_USART_TransmitterBufferIsFull	Gets the transmit buffer full status.
	PLIB_USART_TransmitterByteSend	Data to be transmitted in the Byte mode.
	PLIB_USART_TransmitterDisable	Disables the specific USART module transmitter.
	PLIB_USART_TransmitterEnable	Enables the specific USART module transmitter.
	PLIB_USART_TransmitterIdleIsLowDisable	Disables the Transmit Idle Low state.
	PLIB_USART_TransmitterIdleIsLowEnable	Enables the Transmit Idle Low state.
	PLIB_USART_TransmitterInterruptModeSelect	Sets the USART transmitter interrupt mode.
	PLIB_USART_TransmitterIsEmpty	Gets the transmit shift register empty status.
	PLIB_USART_WakeOnStartDisable	Disables the wake-up on start bit detection feature during Sleep mode.
	PLIB_USART_WakeOnStartEnable	Enables the wake-up on start bit detection feature during Sleep mode.
	PLIB_USART_WakeOnStartIsEnabled	Gets the state of the sync break event completion.

Description

USART Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USART

Peripheral Library for all families of Microchip microcontrollers. The functions in this file are common to the USART module.

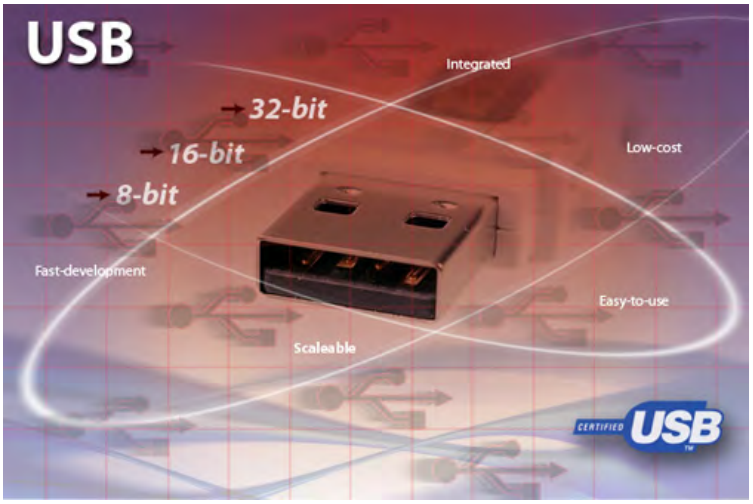
USB Peripheral Library

This section describes the USB Peripheral Library.

Introduction

This library provides a low-level abstraction of the USB module on Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences from one microcontroller variant to another.

Description



USB Overview

USB is an asynchronous serial interface with a tiered star configuration. USB is implemented as a master/slave configuration. On a given bus, there can be multiple (up to 127) slaves (devices), but there is only one master (host). There are three possible module implementations: host, device and OTG dual role. The user should have an understanding of the USB documents available on the USB implementers web site (www.usb.org).

Device

The USB device accepts data from the host and responds to requests for data. It performs some peripheral functions, such as a mouse or data storage device.

- Functionality may be class or vendor-specific
- Draws 100 mA or less before configuration
- Can draw up to 500 mA after successful negotiation with the host
- Can support low-speed, full-speed or high-speed protocol. Hi-speed support requires implementation of full-speed. (*Low, Full, and Hi-Speed supported by this module.*)
- Supports control transfers. Supports data transfers required for implementation
- Optionally supports Session Request Protocol (SRP)
- Can be bus-powered or self-powered

Host

The host is the master in a USB system and is responsible for identifying all devices connected to it (enumeration), initiating all transfers, allocating bus bandwidth and supplying power to any bus-powered USB devices connected directly to it. There are two types of hosts.

USB Standard Host:

- A large variety of devices are supported
- This host supports all USB transfer types
- USB hubs are supported to allow connection of multiple devices simultaneously
- Device drivers can be updated to support new devices
- A type ‘A’ receptacle is used for each port
- Each port must be able to deliver a minimum of 100 mA for a configured or unconfigured
- device, and optionally, up to 500 mA for a configured device
- Full-Speed and Low-Speed must be supported. Hi-Speed can be supported.

- This is a typical personal computer implementation

Embedded Host

- Only supports a specific list of devices, referred to as a Targeted Peripheral List (TPL)
- This type of host is only required to support transfer types required by devices in the TPL
- USB hub support is optional (*Provided in this module*)
- Device drivers are not required to be pocketable
- A type ‘A’ receptacle is used for each port
- Only speeds required by devices in the TLP must be supported. (*Low, Full, and Hi-Speed supported by this module.*)
- Each port must be able to deliver a minimum of 100 mA for a configured or unconfigured device, and optionally, up to 500 mA for a configured device
- This is a typical implementation for a microcontroller

USB On-the-Go (OTG)

The OTG dual role device supports both USB host and device functionality. OTG dual role devices use a micro-AB receptacle. This allows a micro-A or a micro-B plug to be attached. Both the micro-A and micro-B plugs have an additional pin, the ID pin, to signify the connection type. The plug type, micro-A or micro-B, determines the default role of the OTG device, host or USB device. An OTG device will perform the role of a host when a micro-A plug is detected. When a micro-B plug is detected, the role of a USB device is performed.

When an OTG device is directly connected to another OTG device using an OTG cable, micro-A to micro-B, Host Negotiation Protocol (HNP) can be used to swap the roles of the host and USB device between the two without disconnecting and reconnecting cabling. To differentiate between the two OTG devices, the term, "A-device", is used to refer to the device connected to the micro-A plug and "B-device" is used to refer to the OTG device connected to the micro-B plug.

OTG dual role operating as a host (A-device):

- Only supports a specific list of devices, referred to as a Targeted Peripheral List (TPL). Generic class support is not allowed.
- Only required to support transaction types required by devices in the TPL
- USB hub support is optional. (*Multi-point support provided by this module.*)
- Device drivers are not required to be pocketable
- Only a single micro-AB receptacle is used
- Only Full-Speed must be supported. Hi-Speed and/or Low-Speed can be supported. (*Low, Full, and Hi-Speed supported by this module.*)
- The USB port must be able to deliver a minimum of 8 mA for a configured or unconfigured device, and optionally, up to 500 mA for a configured device
- Supports Host Negotiation Protocol (HNP) and Session Request Protocol (SRP). The host can switch roles to become a device. The initial role as a host or device is determined by the plug type, micro-A or micro-B, inserted into the micro-AB receptacle
- The A-device supplies VBUS power, when the bus is powered, even if the roles are swapped using HNP

OTG dual role operating as a USB device (B-device):

- Class or vendor-specific functionality
- Draws 8 mA or less before configuration
- Is typically self-powered due to low-current requirements, but can draw up to 500 mA after successful negotiation with the host
- Only a single micro-AB receptacle is used
- Must support Full-Speed. Support of Low-Speed and/or Hi-Speed is optional
- Supports control transactions. Supports data transactions required for implementation.
- Supports Session Request Protocol (SRP) and/or Host Negotiation Protocol (HNP). (*This module supports both SRP and HNP.*)
- The A-device supplies VBUS power, when the bus is powered, even if the roles are swapped using HNP

Additional Features of the Hi-Speed USB Module

- Operates either as a function controller of a Hi-Speed/Full-Speed USB device or as the host/device in a point-to-point or multi-point communications with other USB function
- Supports OTG communications with on or more Hi-Speed, Full-Speed, or Low-Speed devices
- Provides soft connect/disconnect.
- In addition to Endpoint Zero, supports seven transmit and seven receive endpoints
- Dynamic FIFO sizing for Endpoints 1-7. (Endpoint Zero FIFO fixed at 64 bytes.) FIFOs use module-internal SRAM.
- Module-internal eight channel DMA with access to all FIFOs
- All host transaction scheduling supported in hardware
- Supports Link Power Management

Using the Library

This topic describes the basic architecture of the USB Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_usb.h`

The interface to the USB Peripheral Library is defined in the `plib_usb.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the USB Peripheral Library must include `peripheral.h`.

Library File:

The USB Peripheral Library is part of the processor-specific peripheral library archive (`.a`) file installed with the compiler. Libraries in this archive are automatically available to the linker (in the default search path) for any project built using the Microchip compiler.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Hardware Abstraction Models

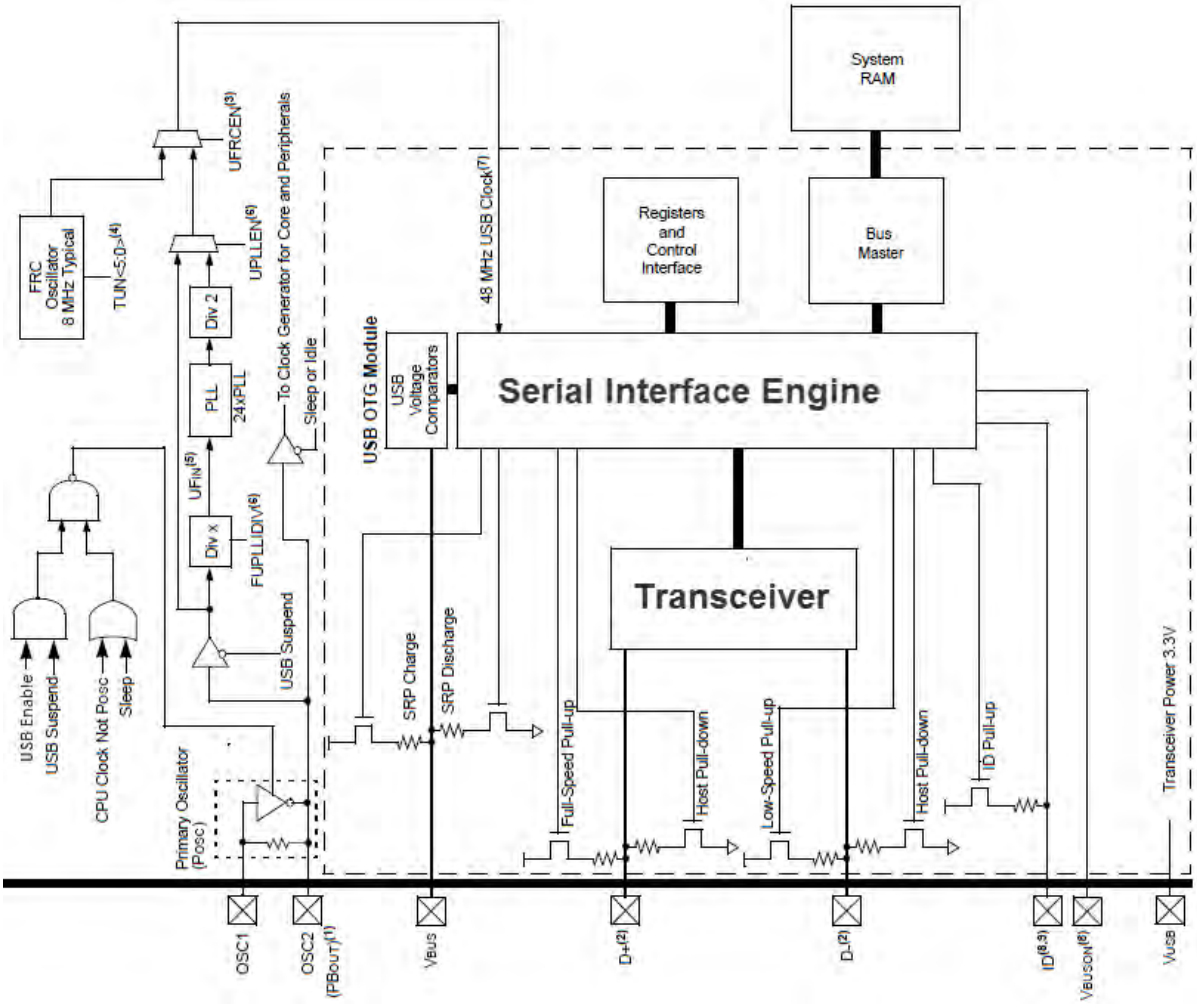
This section describes the hardware abstraction model for the USB Peripheral Library.

Description

Hardware Abstraction Model

The following figure shows the USB Module for the PIC32 family of devices.

PIC32 USB Module



Note 1: PB clock is only available on this pin for select EC modes.
2: Pins can be used as digital inputs when USB is not enabled.
3: This bit field is contained in the OSCCON register.
4: This bit field is contained in the OSCTRM register.
5: USB PLL UF_{IN} requirements: 4 MHz $\leq UF_{IN} \leq$ 5 MHz.
6: This bit field is contained in the DEVCFG2 register.
7: A 48 MHz clock is required for proper USB operation.
8: Pins can be used as GPIO when the USB OTG module is disabled.
9: Pin is pulled high internally when USB OTG module is enabled.

The USB OTG module contains analog and digital components to provide a USB 2.0 full-speed and low-speed embedded host, full-speed device, or On-The-Go (OTG) implementation with a minimum of external components. This module in Host mode is intended for use as an embedded host and therefore does not implement a Universal Host Controller Interface (UHCI) or a Open Host Controller Interface (OHCI).

The USB OTG module consists of the clock generator, the USB voltage comparators, the transceiver, the Serial Interface Engine (SIE), a dedicated USB Bus Master, pull-up and pull-down resistors and the register interface.

The clock generator provides the 48 MHz clock, which is required for USB full-speed and low-speed communication. The voltage comparators monitor the voltage on the VBUS pin to determine the state of the bus. The transceiver provides the analog translation between the USB bus and the digital logic. The SIE is a state machine that transfers data to and from the endpoint buffers, and generates the hardware protocol for data transfers. The USB Bus Master transfers data between the data buffers in RAM and the SIE. The integrated pull-up and pull-down resistors eliminate the need for external signaling components. The register interface allows the CPU to configure and communicate with the module.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the USB module.

Library Interface Section	Description
USB Setup Functions	This section provides functions to perform general USB peripheral setup such as functions to set USB Speed, control on-chip pull ups, etc.
Buffer Descriptor Table Functions	This section provides functions that allow the application to setup, configure and access/modify the Buffer Descriptors in the Buffer Descriptor Table.
USB Activity Functions	This section provides function that allow the application to monitor bus conditions on the USB.
USB Bus Signaling Functions	This section provides functions that allow the application to generate Reset and Resume Signaling.
Last Transaction Status Functions	This section provides functions that allow the application to query conditions of the USB peripheral.
Endpoints Functions	This section provides functions that allow the application to manage endpoints.
Interrupts Functions	This section provides functions that allow the application to enable, disable and query the status interrupts in the USB peripheral.
Host Functions	This section provides functions that are required to operate the USB module while in Host mode.
On-The-Go (OTG) Functions	This section provides functions that are required to operate the USB module while in OTG mode.
External Transceiver Support Functions	This section provides function that are required to operate to enable/disable the external transceiver interface.

VBUS Support Functions	This section provides functions that allow VBUS level monitoring and VBUS boost PWM module control.
Test Support Functions	This section provides functions that enable/disable test signals needed for eye pattern measurement.

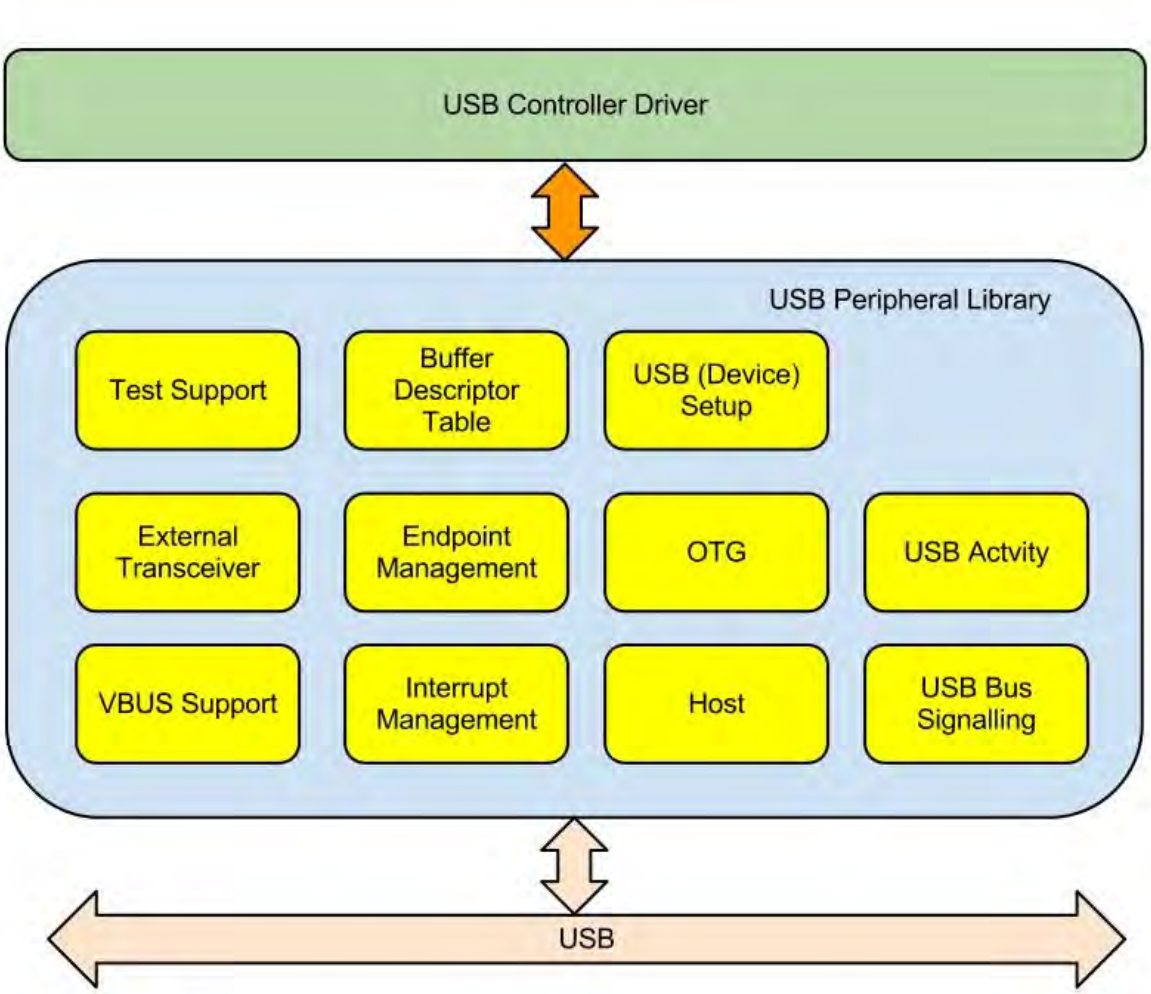
How the Library Works

Provides information on how the library works.

Description

The following figure describes the abstraction model employed by the USB Peripheral Library.

USB Peripheral Library Abstraction Model



USB Buffers and the Buffer Descriptor Table (BDT)

This section describes USB buffers and the Buffer Descriptor Table.

Description

All USB endpoints are implemented using buffers and control bits in RAM. Both software and the USB module have access to these buffers and control bits. To arbitrate this access a semaphore flag system is used.

Each endpoint can be configured for transmit only, receive only or transmit *and* receive. Transmit and receive functions have separate buffers. For each buffer there is a Buffer Descriptor (BD) in the Buffer Descriptor Table (BDT). On most devices the BDT has room for two transmit and two receive buffers for each endpoint, supporting ping-pong buffering. Buffer descriptors must be aligned on 512 byte boundaries to enable the USB module to correctly read each entry.

The starting address of the Buffer Descriptor Table is set by the PLIB_USB_BDTBaseAddressSet.

```
#define USB_MAX_EP_NUMBER 15
```

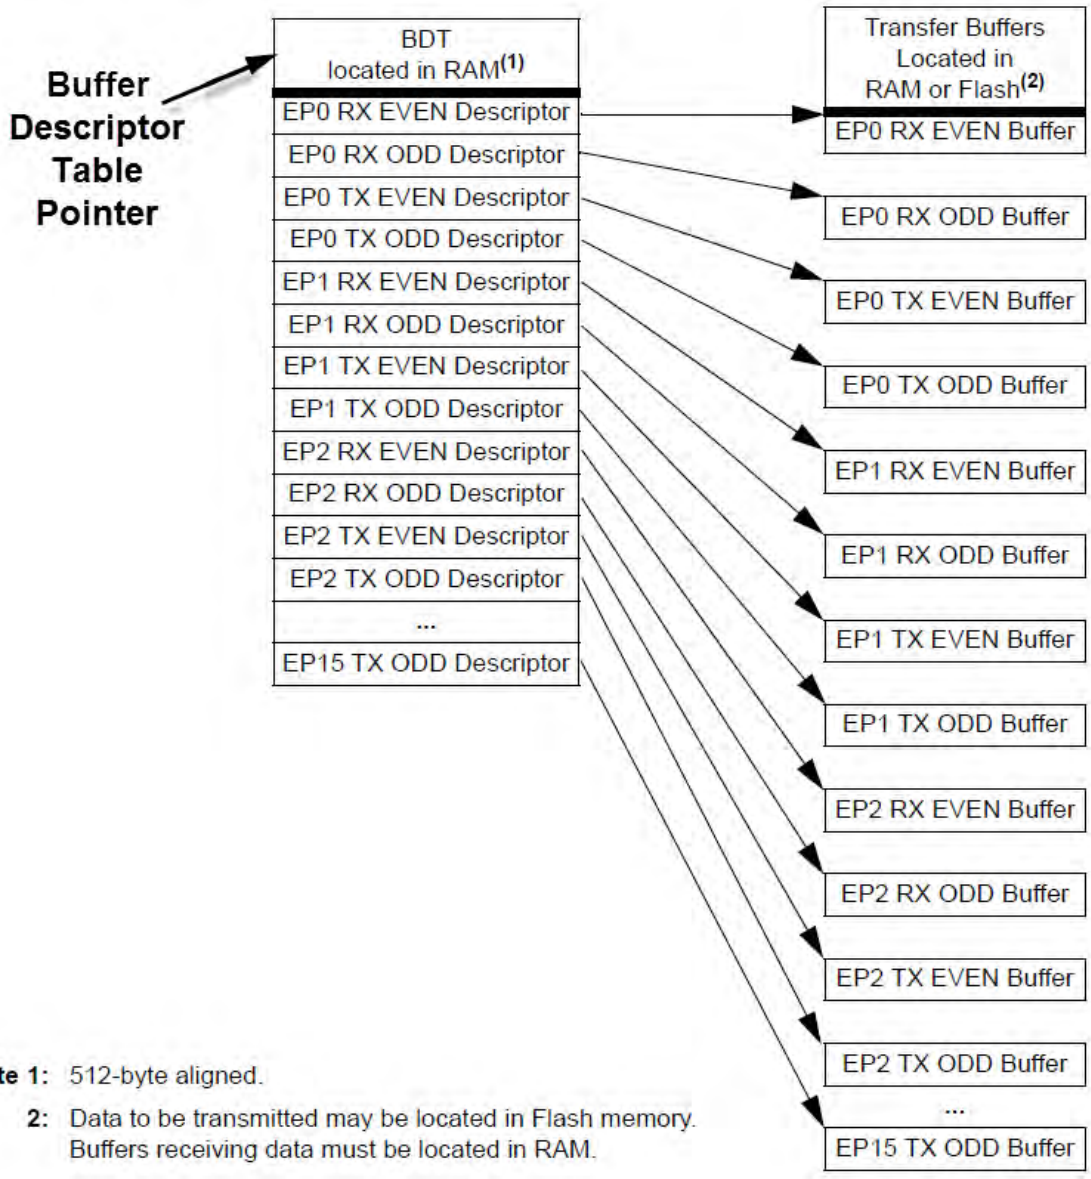
```
#define BDT_NUM_ENTRIES      (((USB_MAX_EP_NUMBER + 1) * 4)-2)

volatile union USB_BDT_ENTRY_TAG gBDT[BDT_NUM_ENTRIES] __attribute__ (( aligned (512) ));
```

Each Buffer Descriptor entry in the BDT has a **bufferAddress** pointer to the Buffer Descriptor's buffer in memory (RAM or FLASH).

The following figure shows the structure for PIC32 devices. These devices support ping-pong buffering for all endpoints.

Buffer Descriptor Table and Endpoint Buffers



With 16 endpoints (Endpoints 0 - 15) there are 64 possible entries in the Buffer Descriptor Table:

```
//                                          (Even,Odd) or (Ping,Pong)
//                                             (RX,TX) |
//                            (EP0      to       EPn)  |  |
volatile USB_BDT_ENTRY myBDT[(USB_MAX_EP_NUMBER + 1)][2][2] __attribute__ (( aligned (512) ));
```

Peripheral library functions are provided to support reading each BD while hiding the details of BDT addressing that can change when ping-pong buffering is disabled for one or more endpoints. The format of Buffer Descriptors vary from family to family and it is not important to know the differences, since peripheral library functions hide these details. To understand the information stored in each Buffer Descriptor Table entry it is informative to look at the C language description for one family of devices. (All device families support the same information but with different ways of packing the data into memory.)

For PIC32 devices each BD is 8 bytes long and is described by this C code:

```
    typedef union _USB_BDT_ENTRY __attribute__ ((packed))
    {
        uint64_t          dlValue;        //Double Long Integer Value
        uint32_t           lValue[2];     //Long  Integer Values
        uint16_t           sValue[4];     //Short Integer Values
```

```
        struct __attribute__ ((packed))
        {
            USB_BD_STATUS  bufferStatus;  //(RW) Buffer Status
            uint16_t       byteCount:10;  //(RW) Byte Count
            uint8_t                : 6;  //(  ) Reserved
            uint32_t       bufferAddress; //(RW) Buffer Address in Data Ram or Flash
        };
    } USB_BDT_ENTRY;
```

For transmit buffers, byteCount, is set to the length of the buffer using PLIB_USB_BufferByteCountSet. For receive buffers PLIB_USB_BufferByteCountSet is used to set the maximum allowable receive data length. PLIB_USB_BufferByteCountGet is used to determine how many bytes were actually transmitted or received. The memory address of each buffer is found in bufferAddress. The functions PLIB_USB_BufferAddressSet and PLIB_USB_BufferAddressGet support this field in the Buffer Descriptor.

Buffer status is stored in the 16 least significant bits of each BDT entry:

```
    typedef union _USB_BD_STATUS __attribute__ ((packed))
    {
        uint16_t       sValue;                  //Short Integer Value
        struct __attribute__ ((packed))
        {
            uint8_t                          :2; //(  )Reserved
            uint8_t    stallEnable           :1; //( W) Buffer Stall Enable
            uint8_t    dataToggleSyncEnable :1; //( W) Data Toggle Synch Enable
            uint8_t                          :1; //(  ) Reserved
            uint8_t                          :1; //(  ) Reserved
            uint8_t    dataToggle            :1; //(RW) Data Toggle Synch Value
            uint8_t    uSBOwnsBuffer         :1; //(RW) USB Ownership of buffer and BDT entry
        };
        struct __attribute__ ((packed))
        {
            uint8_t                          :2; //(  ) Reserved
            uint8_t    packetID              :4; //(R ) Packet Identifier (PID)
        };
    } USB_BD_STATUS;
```

The fields stallEnable and dataToggleSyncEnable in the Buffer Descriptor status structure are writeable but not readable. The function PLIB_USB_BufferStallEnable sets the stallEnable bit. (Hardware will clear the bit after receiving a SETUP token from the host.) The functions PLIB_USB_BufferDataToggleSyncEnable and PLIB_USB_BufferDataToggleSyncDisable manipulate dataToggleSyncEnable .

On a read from the status structure stallEnable and dataToggleSyncEnable and the next two (reserved) bits are replaced by the Packet Identifier (PID), called packetID in the structure. The function PLIB_USB_BufferPIDGet reads packetID.

The rest of the status structure is writeable and readable: dataToggle and uSBOwnsBuffer.

The dataToggle (DATA0 or DATA1) of a receive buffer is determined by using PLIB_USB_BufferDataToggleGet. For transmit buffers the dataToggle value is set using PLIB_USB_BufferDataToggleSelect .

The field uSBOwnsBuffer is used by both software and the USB module as a semaphore. The function PLIB_USB_BufferReleaseToUSB releases the buffer to the USB module and the function PLIB_USB_BufferReleasedToSW returns a Boolean true when the buffer is released back to software by the USB module. As long as PLIB_USB_BufferReleasedToSW returns false, software should not change the Buffer Descriptor Table entry or its associated buffer.

USB Setup Example

This section provides example code for setting up the USB module.

Description

Following is an example of how to set up the USB module:

```
#define USB_MAX_EP_NUMBER 15

#define BDT_NUM_ENTRIES      (((USB_MAX_EP_NUMBER + 1) * 4)-2)

volatile union USB_BDT_ENTRY_TAG gBDT[BDT_NUM_ENTRIES] __attribute__ (( aligned (512) ));

unsigned int bufferTransactionCount[BDT_NUM_ENTRIES];

    // Turn off USB module
    PLIB_USB_Disable( usbID );

    // Set up the Hardware
    if ( usbModuleSetup.StopInIdle )
    {
        PLIB_USB_StopInIdleEnable( usbID );
```

```
    }
    else
    {
        PLIB_USB_StopInIdleDisable( usbID );
    }

    if ( usbModuleSetup.SuspendInSleep )
    {
        PLIB_USB_AutoSuspendEnable( usbID );
    }
    else
    {
        PLIB_USB_AutoSuspendDisable( usbID );
    }

    PLIB_USB_OperatingModeSelect( usbID, usbModuleSetup.OpMode );

    PLIB_USB_PingPongModeSelect( usbID, usbModuleSetup.ppMode );

    // Reset all ping pong buffers to "Even"
    PLIB_USB_PingPongFreeze( usbID );
    PLIB_USB_PingPongUnfreeze( usbID );

    // Interrupt flag cleared on the safer side
    IFS1bits.USBIF = 0;

    // Enable USB module interrupts
    PLIB_USB_InterruptEnable( usbID, DRV_USB_GEN_INT_ENABLES );

    // Disable all OTG interrupts
    PLIB_USB_OTG_InterruptDisable( usbID, DRV_USB_OTB_INT_ENABLES );

    // Enable all Error interrupts
    PLIB_USB_ErrorInterruptEnable( usbID, DRV_USB_ERR_INT_ENABLES );

    // Enable the interrupt source in case of interrupt mode
    IEC1bits.USBIE = 1;

    // Setting the Interrupt Priority in case of interrupt mode.
    IPC11bits.USBIP = 4;

    // Initialize BDT
    for ( iEntry = 0; iEntry < BDT_NUM_ENTRIES; iEntry++ )
    {
        gBDT[iEntry].lValue[0] = 0ul;
        gBDT[iEntry].lValue[1] = 0ul;

        bufferTransactionCount[iEntry] = 0;
    }//end for ( iEntry = 0; iEntry < BDT_NUM_ENTRIES; iEntry++ )

    // Inform USB module of BDT's address in memory
    PLIB_USB_BDTBaseAddressSet( usbID , (void *)((uint32_t)KVA_TO_PA(gBDT)) );

    /***********************/
    /* SET UP ENDPOINT ZERO */
    /***********************/
    PLIB_USB_BufferAddressSet( usbID, (void*)gBDT, PLIB_USB_PingPongModeGet( usbID ),
                               0, USB_BUFFER_RX, USB_BUFFER_EVEN, pSetupRcvBuffer );

    // Configure Endpoint Zero control register
    PLIB_USB_EP0LSDirectConnectDisable( usbID );   // For Hosts, included for completeness
    PLIB_USB_EP0NakRetryEnable( usbID );           // For Hosts, included for completeness
    PLIB_USB_EPnControlTransferEnable( usbID, 0 ); // Enable control transfers
    PLIB_USB_EPnRxSelect( usbID, 0, USB_EP_RX );   // Enable receive
    PLIB_USB_EPnHandshakeEnable( usbID, 0 );       // Enable handshaking

    // Set up Endpoint Zero's receive buffer BDT entries
    ppMode = PLIB_USB_PingPongModeGet( usbID ); // Ping Pong Mode needed for BDT entry indexing
```

```
    // Clear PID bits
    PLIB_USB_BufferPIDBitsClear(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN); //Rx0

    // Disable buffer stall
    PLIB_USB_BufferStallDisable(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN); //Rx0

    // Enable Data Toggle Synchronization
    PLIB_USB_BufferDataToggleSyncEnable(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN); //Rx0

    // Set Data0/1 to Data0
    PLIB_USB_BufferDataToggleSelect(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN,USB_BUFFER_DATA
0);
//Rx0

    // Setup packets have 8 bytes of data payload
    PLIB_USB_BufferByteCountSet(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN,8);

    // Release buffers to USB module
    PLIB_USB_BufferReleaseToUSB(usbID,(void*)gBDT,ppMode,0,USB_BUFFER_RX,USB_BUFFER_EVEN);

    PLIB_USB_Enable( gDrvUSBObj[hDriver].usbID ); // Turn on USB module
```

Configuring the Library

The library is configured for the supported USB module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) USB Setup Functions

	Name	Description
	PLIB_USB_AllInterruptEnable	Configures the USB peripheral general interrupts, error interrupts and OTG interrupts.
	PLIB_USB_AutoSuspendDisable	Disables USB OTG Auto-suspend mode.
	PLIB_USB_AutoSuspendEnable	Enables USB Auto-suspend mode.
	PLIB_USB_DeviceAddressGet	Returns the address of the USB module in Device mode.
	PLIB_USB_DeviceAddressSet	Sets the USB Device's address.
	PLIB_USB_Disable	Disables (powers down) the USB module.
	PLIB_USB_Enable	Enables (powers up) the USB module.
	PLIB_USB_FullSpeedDisable	Forces the USB module to operate at low speed.
	PLIB_USB_FullSpeedEnable	Enables the USB to operate at full speed.
	PLIB_USB_OnChipPullUpDisable	Disables on-chip pull-ups.
	PLIB_USB_OnChipPullUpEnable	Enables on-chip pull-ups.
	PLIB_USB_OperatingModeSelect	Selects the operating mode of the USB module.
	PLIB_USB_PingPongModeGet	Returns the Ping-Pong Configuration setting.
	PLIB_USB_PingPongModeSelect	Selects the Ping-Pong Configuration setting.
	PLIB_USB_SleepGuardDisable	This function disables Sleep Guard. Entry into Sleep mode is immediate.
	PLIB_USB_SleepGuardEnable	Entry into Sleep mode is blocked if bus activity is detected or if an interrupt is pending.
	PLIB_USB_StopInIdleDisable	Allows the USB module to continue operation when the device enters Idle mode.
	PLIB_USB_StopInIdleEnable	Enables USB module operation to stop when the device enters Idle mode.
	PLIB_USB_SuspendDisable	Disables USB OTG Suspend mode.
	PLIB_USB_SuspendEnable	Enables USB Suspend mode.
	PLIB_USB_UOEMonitorDisable	Disables the OE signal output.
	PLIB_USB_UOEMonitorEnable	Enables the OE signal output.

b) Buffer Descriptor Table Functions

	Name	Description
	PLIB_USB_BDTBaseAddressGet	Returns the base address of the Buffer Descriptor Table.
	PLIB_USB_BDTBaseAddressSet	Sets the base address for the Buffer Descriptor Table for PIC32 devices.
	PLIB_USB_BufferAddressGet	Gets the memory address of an endpoint buffer.
	PLIB_USB_BufferAddressSet	Sets the endpoint buffer address.

	PLIB_USB_BufferAllCancelReleaseToUSB	Cancels all endpoint buffer releases to the USB module and hands over the buffer to the CPU.
	PLIB_USB_BufferByteCountGet	Returns the endpoint buffer byte count.
	PLIB_USB_BufferByteCountSet	Sets the buffer byte count.
	PLIB_USB_BufferCancelReleaseToUSB	Cancels release of the endpoint buffer by software, allowing software to again access the buffer.
	PLIB_USB_BufferClearAll	Clears (zeros out) entries in the Buffer Descriptor Table.
	PLIB_USB_BufferClearAllDTSEnable	Clears the endpoint descriptor entry and enables data toggle synchronization.
	PLIB_USB_BufferDataToggleGet	Returns data synchronization (DATA0 or DATA1) for the endpoint buffer.
	PLIB_USB_BufferDataToggleSelect	Sets the endpoint buffer to DATA0 or DATA1.
	PLIB_USB_BufferDataToggleSyncDisable	Disables DATA0/DATA1 synchronization between the device and host.
	PLIB_USB_BufferDataToggleSyncEnable	Enables DATA0/DATA1 synchronization between the device and host.
	PLIB_USB_BufferEP0RxStatusInitialize	Initializes the Endpoint 0 RX endpoint buffer descriptors.
	PLIB_USB_BufferIndexGet	Gets the Buffer Descriptor Table index for a buffer.
	PLIB_USB_BufferPIDBitsClear	Clears the Buffer Status bits in the Buffer Descriptor Table.
	PLIB_USB_BufferPIDGet	Returns the token packet ID (PID) from the endpoint buffer status.
	PLIB_USB_BufferReleasedToSW	Returns the boolean flag value of 'true' when the buffer has been released by the USB module.
	PLIB_USB_BufferReleaseToUSB	Releases the endpoint buffer by software, allowing the USB module access to the buffer.
	PLIB_USB_BufferSchedule	Hands over a buffer to the USB module along with the buffer address and byte count.
	PLIB_USB_BufferStallDisable	Disables STALL handshaking for the associated endpoint buffer.
	PLIB_USB_BufferStallEnable	Enables STALL handshaking for the associated endpoint buffer.
	PLIB_USB_BufferStallGet	Returns the buffer stall status for an endpoint/direction/ping-pong.

c) Endpoints Functions

	Name	Description
	PLIB_USB_EP0HostSetup	Sends token to the specified address.
	PLIB_USB_EP0LSDirectConnectDisable	Disables direct connection to a low-speed device for Endpoint 0.
	PLIB_USB_EP0LSDirectConnectEnable	Enables direct connection to a low-speed device for Endpoint 0.
	PLIB_USB_EP0NakRetryDisable	Disables retrying of NAKed transactions.
	PLIB_USB_EP0NakRetryEnable	Enables retrying NAK'd transactions for Endpoint 0.
	PLIB_USB_EPnAttributesClear	Clears the set attributes of the specified endpoint.
	PLIB_USB_EPnAttributesSet	Configures attributes of the endpoint such as direction, handshake capability and direction.
	PLIB_USB_EPnControlTransferDisable	Disables endpoint control transfers.
	PLIB_USB_EPnControlTransferEnable	Enables endpoint control transfers.
	PLIB_USB_EPnDirectionDisable	Disables the specified endpoint direction.
	PLIB_USB_EPnHandshakeDisable	Disables endpoint handshaking.
	PLIB_USB_EPnHandshakeEnable	Enables endpoint handshaking.
	PLIB_USB_EPnIsStalled	Tests whether the endpoint epValue is stalled.
	PLIB_USB_EPnRxDisable	Disables an endpoint's ability to process IN tokens.
	PLIB_USB_EPnRxEnable	Enables an endpoint to process IN tokens.
	PLIB_USB_EPnRxSelect	Selects receive capabilities of an endpoint.
	PLIB_USB_EPnStallClear	Clears an endpoint's stalled flag.
	PLIB_USB_EPnTxDisable	Disables an endpoint's ability to process OUT tokens.
	PLIB_USB_EPnTxEnable	Enables an endpoint to process OUT tokens.
	PLIB_USB_EPnTxRxSelect	Selects transmit and/or receive capabilities of an endpoint.
	PLIB_USB_EPnTxSelect	Selects transmit capabilities of an endpoint.

d) Interrupts Functions

	Name	Description
	PLIB_USB_InterruptDisable	Disables a general interrupt for the USB module.
	PLIB_USB_InterruptEnable	Enables a general interrupt for the USB module.
	PLIB_USB_InterruptEnableGet	Returns the enable/disable status of general USB module interrupts
	PLIB_USB_InterruptFlagAllGet	Returns a logically ORed bit map of active general USB interrupt flags.

	PLIB_USB_InterruptFlagClear	Clears a general interrupt flag for the USB module.
	PLIB_USB_InterruptFlagGet	Tests a general interrupt flag for the USB module.
	PLIB_USB_InterruptFlagSet	Sets a general interrupt flag for the USB module.
	PLIB_USB_InterruptIsEnabled	Returns true if interrupts are enabled.

e) Error Interrupts Functions

	Name	Description
	PLIB_USB_ErrorInterruptDisable	Disables an error interrupt for the USB module.
	PLIB_USB_ErrorInterruptEnable	Enables an error interrupt for the USB module.
	PLIB_USB_ErrorInterruptFlagAllGet	Returns a logically ORed bit map of active error interrupt flags.
	PLIB_USB_ErrorInterruptFlagClear	Clears an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptFlagGet	Tests an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptFlagSet	Sets an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptIsEnabled	Returns true if interrupts are enabled.

f) Last Transaction Status Functions

	Name	Description
	PLIB_USB_LastTransactionDetailsGet	Returns the details of the last completed transaction.
	PLIB_USB_LastTransactionDirectionGet	Indicates the direction of the last transaction.
	PLIB_USB_LastTransactionEndPtGet	Returns the endpoint number of the last USB transfer.
	PLIB_USB_LastTransactionPingPongStateGet	Indicates whether the last transaction was to an EVEN buffer or an ODD buffer.

g) Host Functions

	Name	Description
	PLIB_USB_IsBusyWithToken	Indicates whether there is a token being executed by the USB module as Host.
	PLIB_USB_SOFDisable	Disables the automatic generation of the SOF token.
	PLIB_USB_SOFEnable	Enables the automatic generation of the SOF token every 1 ms.
	PLIB_USB_SOFThresholdGet	Returns the Start-of-Frame (SOF) Count bits.
	PLIB_USB_SOFThresholdSet	Sets the Start-of-Frame (SOF) threshold value.
	PLIB_USB_TokenEPGet	Returns the specified Endpoint address.
	PLIB_USB_TokenEPSet	Sets the Endpoint address for a host transaction.
	PLIB_USB_TokenPIDGet	Returns the token transaction type.
	PLIB_USB_TokenPIDSet	Sets the token transaction type to pidValue.
	PLIB_USB_TokenSpeedSelect	Selects low speed or full speed for subsequent token executions.

h) USB Bus Signaling Functions

	Name	Description
	PLIB_USB_ResetSignalDisable	Disables reset signaling on the USB bus.
	PLIB_USB_ResetSignalEnable	Enables reset signaling on the USB bus.
	PLIB_USB_ResumeSignalingDisable	Disables resume signaling.
	PLIB_USB_ResumeSignalingEnable	Enables resume signaling.

i) On-The-Go (OTG) Functions

	Name	Description
	PLIB_USB_OTG_BSessionHasEnded	Returns the status of the B-Session End Indicator bit.
	PLIB_USB_OTG_IDPinStateIsTypeA	Returns the ID Pin state.
	PLIB_USB_OTG_LineStateIsStable	Returns the status of the Line Stable Indicator bit.
	PLIB_USB_OTG_PullUpPullDownSetup	Enables or disables pull-up and pull-down resistors.
	PLIB_USB_OTG_SessionValid	Returns the status of the Session Valid Indicator bit.
	PLIB_USB_OTG_VBusChargeDisable	Disables VBUS line charge.
	PLIB_USB_OTG_VBusChargeEnable	Enables the VBUS line to be charged through a pull-up resistor.
	PLIB_USB_OTG_VBusChargeTo3V	Sets the VBUS line to charge to 3.3V.
	PLIB_USB_OTG_VBusChargeTo5V	Sets the VBUS line to charge to 5V.
	PLIB_USB_OTG_VBusDischargeDisable	Disables VBUS line discharge.
	PLIB_USB_OTG_VBusDischargeEnable	Enables VBUS line to be discharged through a resistor.

	PLIB_USB_OTG_VBusPowerOff	Turns off power on the VBUS Line.
	PLIB_USB_OTG_VBusPowerOn	Turns on power for the VBUS line.
	PLIB_USB_OTG_VBusValid	Returns the status of the A-VBUS valid indicator.

j) OTG Interrupts Functions

	Name	Description
	PLIB_USB_OTG_InterruptDisable	Disables a USB On-The-Go (OTG) Interrupt for the USB module.
	PLIB_USB_OTG_InterruptEnable	Enables a USB On-The-Go (OTG) Interrupt for the USB module.
	PLIB_USB_OTG_InterruptFlagClear	Clears a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptFlagGet	Tests a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptFlagSet	Sets a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptIsEnabled	Returns whether or not interrupts are enabled.

k) USB Activity Functions

	Name	Description
	PLIB_USB_ActivityPending	Returns whether or not USB activity is pending.
	PLIB_USB_FrameNumberGet	Returns the USB frame number.
	PLIB_USB_JStateIsActive	Live differential receiver J State flag.
	PLIB_USB_PacketTransferDisable	Disables the Serial Interface Engine (SIE).
	PLIB_USB_PacketTransferEnable	Re-enables the Serial Interface Engine (SIE), allowing token and packet processing.
	PLIB_USB_PacketTransferIsDisabled	Indicates that a setup token has been received from the Host and that token/packet processing is disabled.
	PLIB_USB_SE0InProgress	Returns whether a single-ended zero event is in progress.

l) External Transceiver Support Functions

	Name	Description
	PLIB_USB_I2CInterfaceForExtModuleDisable	Specifies external module(s) are controlled via dedicated pins.
	PLIB_USB_I2CInterfaceForExtModuleEnable	Specifies external module(s) are controlled via the I2C interface.
	PLIB_USB_TransceiverDisable	Disables the on-chip transceiver
	PLIB_USB_TransceiverEnable	Enables the on-chip transceiver.

m) VBUS Support Functions

	Name	Description
	PLIB_USB_ExternalComparatorMode2Pin	Sets the 2-pin input configuration for VBUS comparators.
	PLIB_USB_ExternalComparatorMode3Pin	Sets the 3-pin input configuration for VBUS Comparators.
	PLIB_USB_PWMCounterDisable	Disables the PWM counter used to generate the VBUS for the USB module.
	PLIB_USB_PWMCounterEnable	Enables the PWM counter used to generate the VBUS for the USB module.
	PLIB_USB_PWMDisable	Disables the PWM Generator.
	PLIB_USB_PWMEnable	Enables the PWM Generator.
	PLIB_USB_PWMPolaritiyActiveLow	Sets the PWM output to active-high and resets low.
	PLIB_USB_PWMPolarityActiveHigh	Sets the PWM output to active-low and resets high.
	PLIB_USB_VBoostDisable	Disables the On-Chip 5V Boost Regulator Circuit Disabled bit.
	PLIB_USB_VBoostEnable	Enables the On-Chip 5V Boost Regulator Circuit Enabled bit.
	PLIB_USB_VBUSComparatorDisable	Disables the on-chip VBUS Comparator.
	PLIB_USB_VBUSComparatorEnable	Enables the on-chip VBUS Comparator.
	PLIB_USB_VBUSPullUpDisable	Disables the pull-up on the VBUS pin.
	PLIB_USB_VBUSPullUpEnable	Enables the pull-up on the VBUS pin.

n) Test Support Functions

	Name	Description
	PLIB_USB_EyePatternDisable	Disables the USB eye pattern test.
	PLIB_USB_EyePatternEnable	Enables USB eye pattern test.

o) Other Functions

	Name	Description
	PLIB_USB_ModuleIsBusy	Indicates if the USB module is not ready to be enabled.

	PLIB_USB_PingPongFreeze	Resets all Ping-Pong buffer pointers to even buffers.
	PLIB_USB_PingPongReset	Resets the USB peripheral internal Ping-Pong indicator to point to even buffers.
	PLIB_USB_PingPongUnfreeze	Enables Ping-Pong buffering.
	PLIB_USB_TokenSend	Sends token to the specified address.

p) Feature Existence Functions

	Name	Description
	PLIB_USB_ExistsActivityPending	Identifies whether the ActivityPending feature exists on the USB module.
	PLIB_USB_ExistsALL_Interrupt	Identifies whether the ALL_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsAutomaticSuspend	Identifies whether the AutomaticSuspend feature exists on the USB module.
	PLIB_USB_ExistsBDTBaseAddress	Identifies whether the BDTBaseAddress feature exists on the USB module.
	PLIB_USB_ExistsBDTFunctions	Identifies whether the BDTFunctions feature exists on the USB module.
	PLIB_USB_ExistsBufferFreeze	Identifies whether the BufferFreeze feature exists on the USB module.
	PLIB_USB_ExistsDeviceAddress	Identifies whether the DeviceAddress feature exists on the USB module.
	PLIB_USB_ExistsEP0LowSpeedConnect	Identifies whether the EP0LowSpeedConnect feature exists on the USB module.
	PLIB_USB_ExistsEP0NAKRetry	Identifies whether the EP0NAKRetry feature exists on the USB module.
	PLIB_USB_ExistsEPnRxEnable	Identifies whether the EPnRxEnableEnhanced feature exists on the USB module.
	PLIB_USB_ExistsEPnTxRx	Identifies whether the EPnTxRx feature exists on the USB module.
	PLIB_USB_ExistsERR_Interrupt	Identifies whether the ERR_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsERR_InterruptStatus	Identifies whether the ERR_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsEyePattern	Identifies whether the EyePattern feature exists on the USB module.
	PLIB_USB_ExistsFrameNumber	Identifies whether the FrameNumber feature exists on the USB module.
	PLIB_USB_ExistsGEN_Interrupt	Identifies whether the GEN_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsGEN_InterruptStatus	Identifies whether the GEN_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsHostBusyWithToken	Identifies whether the HostBusyWithToken feature exists on the USB module.
	PLIB_USB_ExistsHostGeneratesReset	Identifies whether the HostGeneratesReset feature exists on the USB module.
	PLIB_USB_ExistsLastDirection	Identifies whether the LastDirection feature exists on the USB module.
	PLIB_USB_ExistsLastEndpoint	Identifies whether the LastEndpoint feature exists on the USB module.
	PLIB_USB_ExistsLastPingPong	Identifies whether the LastPingPong feature exists on the USB module.
	PLIB_USB_ExistsLastTransactionDetails	Identifies whether the LastTransactionDetails feature exists on the USB module.
	PLIB_USB_ExistsLiveJState	Identifies whether the LiveJState feature exists on the USB module.
	PLIB_USB_ExistsLiveSingleEndedZero	Identifies whether the LiveSingleEndedZero feature exists on the USB module.
	PLIB_USB_ExistsModuleBusy	Identifies whether the ModuleBusy feature exists on the USB module.
	PLIB_USB_ExistsModulePower	Identifies whether the ModulePower feature exists on the USB module.
	PLIB_USB_ExistsNextTokenSpeed	Identifies whether the NextTokenSpeed feature exists on the USB module.
	PLIB_USB_ExistsOnChipPullup	Identifies whether the OnChipPullup feature exists on the USB module.
	PLIB_USB_ExistsOnChipTransceiver	Identifies whether the OnChipTransceiver feature exists on the USB module.
	PLIB_USB_ExistsOpModeSelect	Identifies whether the OpModeSelect feature exists on the USB module.
	PLIB_USB_ExistsOTG_ASessionValid	Identifies whether the OTG_ASessionValid feature exists on the USB module.
	PLIB_USB_ExistsOTG_BSessionEnd	Identifies whether the OTG_BSessionEnd feature exists on the USB module.
	PLIB_USB_ExistsOTG_IDPinState	Identifies whether the OTG_IDPinState feature exists on the USB module.
	PLIB_USB_ExistsOTG_Interrupt	Identifies whether the OTG_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsOTG_InterruptStatus	Identifies whether the OTG_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsOTG_LineState	Identifies whether the OTG_LineState feature exists on the USB module.
	PLIB_USB_ExistsOTG_PullUpPullDown	Identifies whether the OTG_PullUpPullDown feature exists on the USB module.
	PLIB_USB_ExistsOTG_SessionValid	Identifies whether the OTG_SessionValid feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusCharge	Identifies whether the OTG_VbusCharge feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusDischarge	Identifies whether the OTG_VbusDischarge feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusPowerOnOff	Identifies whether the OTG_VbusPowerOnOff feature exists on the USB module.
	PLIB_USB_ExistsPacketTransfer	Identifies whether the PacketTransfer feature exists on the USB module.
	PLIB_USB_ExistsPingPongMode	Identifies whether the PingPongMode feature exists on the USB module.
	PLIB_USB_ExistsResumeSignaling	Identifies whether the ResumeSignaling feature exists on the USB module.
	PLIB_USB_ExistsSleepEntryGuard	Identifies whether the SleepEntryGuard feature exists on the USB module.
	PLIB_USB_ExistsSOFThreshold	Identifies whether the SOFThreshold feature exists on the USB module.
	PLIB_USB_ExistsSpeedControl	Identifies whether the SpeedControl feature exists on the USB module.

	PLIB_USB_ExistsStartOfFrames	Identifies whether the StartOfFrames feature exists on the USB module.
	PLIB_USB_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the USB module.
	PLIB_USB_ExistsSuspend	Identifies whether the Suspend feature exists on the USB module.
	PLIB_USB_ExistsTokenEP	Identifies whether the TokenEP feature exists on the USB module.
	PLIB_USB_ExistsTokenPID	Identifies whether the TokenPID feature exists on the USB module.
	PLIB_USB_ExistsUOEMonitor	Identifies whether the UOEMonitor feature exists on the USB module.

q) Data Types and Constants

	Name	Description
	USB_BUFFER_DATA01	Provides enumeration data toggle for a buffer.
	USB_BUFFER_DIRECTION	Provides enumeration transmit/receive direction for a buffer.
	USB_BUFFER_PING_PONG	Enumerates the ping-pong buffer (Even vs. Odd).
	USB_BUFFER_SCHEDULE_DATA01	Provides enumeration data toggle for a buffer.
	USB_EP_TXRX	Provides enumeration transmit/receive setup for an endpoint.
	USB_OPMODES	Provides enumeration of operating modes supported by USB.
	USB_OTG_INTERRUPTS	Provides enumeration of interrupts related to the USB On-The-Go (OTG) module.
	USB_OTG_PULL_UP_PULL_DOWN	USB OTG pull-Up and pull-Down resistors for D+ and D- .
	USB_PID	Legal PID values.
	USB_PING_PONG_MODE	Supports the four modes of ping-pong buffering.
	USB_PING_PONG_STATE	Decodes which buffer (Even vs. Odd) was used for the last transaction.
	USB_TOKEN_SPEED	Provides enumeration of available token speeds.
	USB_MAX_EP_NUMBER	Maximum number of endpoints supported (not including EP0).

Description

This section describes the Application Programming Interface (API) functions of the USB Peripheral Library.

Refer to each section for a detailed description.

a) USB Setup Functions

PLIB_USB_AllInterruptEnable Function

Configures the USB peripheral general interrupts, error interrupts and OTG interrupts.

File

plib_usb.h

C

```
void PLIB_USB_AllInterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS usbInterruptsFlag,
USB_ERROR_INTERRUPTS usbErrorInterruptsFlag, USB_OTG_INTERRUPTS otgInterruptFlag);
```

Returns

None.

Description

This function configures the USB peripheral general interrupts, error interrupts and OTG interrupts.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsALL_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// This code snippet disables all OTG interrupts, disables
// the SOF interrupt and enables all error interrupts.
USB_OTG_INTERRUPTS otgInterruptEnables = ~USB_OTG_INT_ALL ;
USB_INTERRUPTS generalInterruptEnables = USB_INT_ALL & ~USB_INT_SOF ;
```

```
USB_ERROR_INTERRUPTS errorInterruptEnables = USB_ERR_INT_ALL ;

PLIB_USB_AllInterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS usbInterruptsFlag,
    USB_ERROR_INTERRUPTS usbErrorInterruptsFlag,
    USB_OTG_INTERRUPTS otgInterruptFlag);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
usbInterruptsFlag	General interrupts to be configured
usbErrorInterruptsFlag	USB Error interrupts to be configured
otgInterruptFlag	OTG interrupts to be configured

Function

void PLIB_USB_AllInterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS usbInterruptsFlag,
USB_ERROR_INTERRUPTS usbErrorInterruptsFlag, USB_OTG_INTERRUPTS otgInterruptFlag);

PLIB_USB_AutoSuspendDisable Function

Disables USB OTG Auto-suspend mode.

File

plib_usb.h

C

```
void PLIB_USB_AutoSuspendDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables USB OTG Auto-suspend mode. The USB OTG module will operate normally and does not automatically suspend upon entry to Sleep mode. Software must use PLIB_USB_SuspendEnable to suspend the module, including the USB 48 MHz clock

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsAutomaticSuspend in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_AutoSuspendDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_AutoSuspendDisable (USB_MODULE_ID index)

PLIB_USB_AutoSuspendEnable Function

Enables USB Auto-suspend mode.

File

plib_usb.h

C

```
void PLIB_USB_AutoSuspendEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables USB Auto-suspend mode. The USB module automatically suspends upon entry to Sleep mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsAutomaticSuspend in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_AutoSuspendEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_AutoSuspendEnable (USB_MODULE_ID index)

PLIB_USB_DeviceAddressGet Function

Returns the address of the USB module in Device mode.

File

plib_usb.h

C

```
uint8_t PLIB_USB_DeviceAddressGet(USB_MODULE_ID index);
```

Returns

Device Address

Description

This function returns the address of the USB module in Device mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsDeviceAddressin your application to determine whether this feature is available.

Preconditions

None.

Example

```
myUSBAddress = PLIB_USB_DeviceAddressGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint8_t PLIB_USB_DeviceAddressGet (USB_MODULE_ID index)

PLIB_USB_DeviceAddressSet Function

Sets the USB Device's address.

File

plib_usb.h

C

```
void PLIB_USB_DeviceAddressSet(USB_MODULE_ID index, uint8_t address);
```

Returns

None.

Description

This function sets the USB Device's address as part of enumeration.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsDeviceAddressin your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
uint8_t myUSBAddress = ....;
PLIB_USB_DeviceAddressSet(MY_USB_INSTANCE, myUSBAddress);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
address	USB address

Function

void PLIB_USB_DeviceAddressSet (USB_MODULE_ID index, uint8_t address)

PLIB_USB_Disable Function

Disables (powers down) the USB module.

File

plib_usb.h

C

```
void PLIB_USB_Disable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables (powers down) the USB module.

Remarks

For PIC32 devices, the USB module must be in Device mode before the USB module is powered down.

For PIC32 devices, all reads or writes to module registers after powering down the module will be invalid until PLIB_USB_ModuleIsBusy (MY_USB_INSTANCE) == false.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsModulePower in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#if defined(__PIC32MX__)
  // Disable Host, Device, or OTG before powering down
  PLIB_USB_OperatingModeSelect( MY_USB_INSTANCE, USB_OPMODE_NONE );
```

```
    // Turn off USB
    PLIB_USB_Disable(MY_USB_INSTANCE);
    // For PIC32, wait until module is no longer busy before trying to
    // access any USB module registers.
    while ( PLIB_USB_ModuleIsBusy (MY_USB_INSTANCE) )
    {
        //wait
    }
#endif
    // Can now read or modify USB module status
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_Disable (USB_MODULE_ID index)

PLIB_USB_Enable Function

Enables (powers up) the USB module.

File

plib_usb.h

C

```
void PLIB_USB_Enable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables (powers up) the USB module.

Remarks

See also PLIB_USB_ModuleIsBusy.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsModulePoweryour application to determine whether this feature is available.

Preconditions

None.

Example

```
    // Complete Needed setup for the module
    PLIB_USB_Enable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_Enable (USB_MODULE_ID index)

PLIB_USB_FullSpeedDisable Function

Forces the USB module to operate at low speed.

File

plib_usb.h

C

```
void PLIB_USB_FullSpeedDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function forces the USB module to operate at low speed.

Remarks

For PIC32 devices: Host mode only.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSpeedControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_FullSpeedDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_FullSpeedDisable (USB_MODULE_ID index)

PLIB_USB_FullSpeedEnable Function

Enables the USB to operate at full speed.

File

plib_usb.h

C

```
void PLIB_USB_FullSpeedEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the USB to operate at full speed.

Remarks

For PIC32 devices: Host mode only.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSpeedControl in your application to determine whether this feature is available.

Preconditions

Use only before the USB module is enabled by calling PLIB_USB_Enable.

Example

```
PLIB_USB_FullSpeedEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_FullSpeedEnable (USB_MODULE_ID index)

PLIB_USB_OnChipPullUpDisable Function

Disables on-chip pull-ups.

File

plib_usb.h

C

```
void PLIB_USB_OnChipPullUpDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables on-chip pull-ups.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOnChipPullup in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OnChipPullUpDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OnChipPullUpDisable (USB_MODULE_ID index)

PLIB_USB_OnChipPullUpEnable Function

Enables on-chip pull-ups.

File

plib_usb.h

C

```
void PLIB_USB_OnChipPullUpEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables on-chip pull-ups. Pull-up on D+ in Full-Speed mode. Pull-up on D- in Low-Speed mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOnChipPullup in your application to determine whether this feature is available.

Preconditions

Use only before the USB module is enabled by calling PLIB_USB_Enable.

Example

```
PLIB_USB_OnChipPullUpEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OnChipPullUpEnable (USB_MODULE_ID index)

PLIB_USB_OperatingModeSelect Function

Selects the operating mode of the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OperatingModeSelect(USB_MODULE_ID index, USB_OPMODES opMode);
```

Returns

None.

Description

This function selects the operating mode of the USB module, either Host, Device, or OTG.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOpModeSelect in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OperatingModeSelect( MY_USB_INSTANCE, USB_OPMODE_DEVICE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
opMode	Selected operating mode: USB_OPMODE_DEVICE, USB_OPMODE_HOST, or USB_OPMODE_OTG

Function

void PLIB_USB_OperatingModeSelect(USB_MODULE_ID index, USB_OPMODES opMode)

PLIB_USB_PingPongModeGet Function

Returns the Ping-Pong Configuration setting.

File

plib_usb.h

C

```
USB_PING_PONG_MODE PLIB_USB_PingPongModeGet(USB_MODULE_ID index);
```

Returns

Ping-Pong Mode - One of USB_PING_PONG__ALL_BUT_EP0, USB_PING_PONG__FULL_PING_PONG, USB_PING_PONG__EP0_OUT_ONLY, USB_PING_PONG__NO_PING_PONG

Description

This function returns the Ping-Pong Configuration setting.

Remarks

None.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPingPongMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
ppConfig = PLIB_USB_PingPongModeGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_PING_PONG_MODE PLIB_USB_PingPongModeGet (USB_MODULE_ID index)

PLIB_USB_PingPongModeSelect Function

Selects the Ping-Pong Configuration setting.

File

plib_usb.h

C

```
void PLIB_USB_PingPongModeSelect(USB_MODULE_ID index, USB_PING_PONG_MODE ppConfig);
```

Returns

None.

Description

This function selects the Ping-Pong Configuration setting.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPingPongMode in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_PingPongModeSelect(MY_USB_INSTANCE,USB_PING_PONG__ALL_BUT_EP0);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
ppConfig	Ping-Pong configuration selection. One of USB_PING_PONG__ALL_BUT_EP0, USB_PING_PONG__FULL_PING_PONG, USB_PING_PONG__EP0_OUT_ONLY, USB_PING_PONG__NO_PING_PONG

Function

void PLIB_USB_PingPongModeSelect (USB_MODULE_ID index, USB_PING_PONG_MODE ppConfig)

PLIB_USB_SleepGuardDisable Function

File

plib_usb.h

C

```
void PLIB_USB_SleepGuardDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables Sleep Guard. Entry into Sleep mode is immediate.

Remarks

Not available on all PIC32 devices. Refer to the specific device data sheet for details.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSleepEntryGuard in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_SleepGuardDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SleepGuardDisable (USB_MODULE_ID index)

Summary.

Disables Sleep Guard. Entry into Sleep mode is immediate.

PLIB_USB_SleepGuardEnable Function

Entry into Sleep mode is blocked if bus activity is detected or if an interrupt is pending.

File

plib_usb.h

C

```
void PLIB_USB_SleepGuardEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function block entry into Sleep mode if bus activity is detected or if an interrupt is pending.

Remarks

Not available on all PIC32 devices. Refer to the specific device data sheet for details. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSleepEntryGuard in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_SleepGuardEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SleepGuardEnable (USB_MODULE_ID index)

PLIB_USB_StopInIdleDisable Function

Allows the USB module to continue operation when the device enters Idle mode.

File

plib_usb.h

C

```
void PLIB_USB_StopInIdleDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function allows the USB module to continue operation when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_StopInIdleDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_StopInIdleDisable (USB_MODULE_ID index)

PLIB_USB_StopInIdleEnable Function

Enables USB module operation to stop when the device enters Idle mode.

File

plib_usb.h

C

```
void PLIB_USB_StopInIdleEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables USB module operation to stop when the device enters Idle mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsStopInIdle in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_StopInIdleEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_StopInIdleEnable (USB_MODULE_ID index)

PLIB_USB_SuspendDisable Function

Disables USB OTG Suspend mode.

File

plib_usb.h

C

```
void PLIB_USB_SuspendDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables USB OTG Suspend mode. The USB OTG module will operate normally.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSuspend in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_SuspendDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SuspendDisable (USB_MODULE_ID index)

PLIB_USB_SuspendEnable Function

Enables USB Suspend mode.

File

plib_usb.h

C

```
void PLIB_USB_SuspendEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables USB Suspend mode. The 48 MHz USB clock will be gated off. The transceiver is placed in a low-power state.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSuspend in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_SuspendEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SuspendEnable (USB_MODULE_ID index)

PLIB_USB_UOEMonitorDisable Function

Disables the OE signal output.

File

plib_usb.h

C

```
void PLIB_USB_UOEMonitorDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the OE signal output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsUOEMonitor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Disable the OE output.
PLIB_USB_UOEMonitorDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_UOEMonitorDisable(USB_MODULE_ID index);

PLIB_USB_UOEMonitorEnable Function

Enables the OE signal output.

File

plib_usb.h

C

```
void PLIB_USB_UOEMonitorEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the OE signal output.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsUOEMonitor in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Enable the OE output.
PLIB_USB_UOEMonitorEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_UOEMonitorEnable(USB_MODULE_ID index);

b) Buffer Descriptor Table Functions

PLIB_USB_BDTBaseAddressGet Function

Returns the base address of the Buffer Descriptor Table.

File

plib_usb.h

C

```
void* PLIB_USB_BDTBaseAddressGet(USB_MODULE_ID index);
```

Returns

None.

Description

This function returns the base address of the Buffer Descriptor Table.

Remarks

Must be set for PIC32 devices using PLIB_USB_BDTBaseAddressSet.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTBaseAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
void * pMyBDT;
pMyBDT = PLIB_USB_BDTBaseAddressGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void * PLIB_USB_BDTBaseAddressGet (USB_MODULE_ID index)

PLIB_USB_BDTBaseAddressSet Function

Sets the base address for the Buffer Descriptor Table for PIC32 devices.

File

plib_usb.h

C

```
void PLIB_USB_BDTBaseAddressSet(USB_MODULE_ID index, void* address);
```

Returns

None.

Description

This function sets the base address for the Buffer Descriptor Table. This function is only available on PIC32 devices.

Remarks

The address of the Buffer Descriptor Table must be 512 byte-aligned. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTBaseAddress in your application to determine whether this feature is available.

Preconditions

None.

Example

```
#if defined(__PIC32MX__)
  // For PIC32
  PLIB_USB_BDTBaseAddressSet(MY_USB_INSTANCE, (void *)((uint32_t)KVA_TO_PA(&myBDT)) );
#else
  // Everybody else
  PLIB_USB_BDTBaseAddressSet(MY_USB_INSTANCE, (void *)(&myBDT) );
#endif
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
address	Physical memory address in RAM of Buffer Descriptor Table

Function

void PLIB_USB_BDTBaseAddressSet (USB_MODULE_ID index, void * address)

PLIB_USB_BufferAddressGet Function

Gets the memory address of an endpoint buffer.

File

plib_usb.h

C

```
void* PLIB_USB_BufferAddressGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Buffer address in memory.

Description

This function gets the memory address of an endpoint buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint Value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void * PLIB_USB_BufferAddressGet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferAddressSet Function

Sets the endpoint buffer address.

File

plib_usb.h

C

```
void PLIB_USB_BufferAddressSet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong, void* bufferAddress);
```

Returns

None.

Description

This function sets the endpoint buffer address.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD
bufferAddress	address in memory of endpoint transmit or receive buffer

Function

void PLIB_USB_BufferAddressSet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong,
void * bufferAddress)

PLIB_USB_BufferAllCancelReleaseToUSB Function

Cancels all endpoint buffer releases to the USB module and hands over the buffer to the CPU.

File

plib_usb.h

C

```
void PLIB_USB_BufferAllCancelReleaseToUSB(USB_MODULE_ID index, void * pBDT, USB_PING_PONG_MODE ppMode, int nEndpoints);
```

Returns

None.

Description

This function cancels all endpoint buffer releases to the USB module and hands over the buffer to the CPU.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Cancel all buffer releases to USB.
//BDT has 3 Endpoints.

PLIB_USB_BufferAllCancelReleaseToUSB(MY_USB_INSTANCE, pBDT,
                                USB_PING_PONG_NO_PING_PONG, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pBDT	Pointer to the Buffer Descriptor Table
ppMode	Buffer Descriptor Table Ping-Pong mode
nEndpoints	Number of endpoints in the Buffer-Descriptor table

Function

void PLIB_USB_BufferAllCancelReleaseToUSB(USB_MODULE_ID index,
void * pBDT, USB_PING_PONG_MODE ppMode, int nEndpoints);

PLIB_USB_BufferByteCountGet Function

Returns the endpoint buffer byte count.

File

plib_usb.h

C

```
uint16_t PLIB_USB_BufferByteCountGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Endpoint buffer byte count.

Description

This function returns the endpoint buffer byte count, the actual number of bytes transmitted or received.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

uint16_t PLIB_USB_BufferByteCountGet (USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,

uint8_t epValue,

USB_BUFFER_DIRECTION bufferDirection,

USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferByteCountSet Function

Sets the buffer byte count.

File

plib_usb.h

C

```
void PLIB_USB_BufferByteCountSet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong, uint16_t
bufferByteCount);
```

Returns

None.

Description

This function sets the number of bytes to be transmitted or the maximum number of bytes to be received.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD
bufferByteCount	number of bytes to be transmitted or the maximum number of bytes to be received

Function

PLIB_USB_BufferByteCountSet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong,
uint16_t bufferByteCount)

PLIB_USB_BufferCancelReleaseToUSB Function

Cancels release of the endpoint buffer by software, allowing software to again access the buffer.

File

plib_usb.h

C

```
void PLIB_USB_BufferCancelReleaseToUSB(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function cancels the release of the endpoint buffer by software, allowing software to again access the buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferCancelReleaseToUSB (USB_MODULE_ID index,
void * pBDT,

USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferClearAll Function

Clears (zeros out) entries in the Buffer Descriptor Table.

File

plib_usb.h

C

```
void PLIB_USB_BufferClearAll(USB_MODULE_ID index, void * pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function clears (zeros out) the entries in the Buffer Descriptor Table.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferClearAll(USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferClearAllDTSEnable Function

Clears the endpoint descriptor entry and enables data toggle synchronization.

File

plib_usb.h

C

```
void PLIB_USB_BufferClearAllDTSEnable(USB_MODULE_ID index, void * pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection);
```

Returns

None.

Description

This function clears the endpoint descriptor entry and enables data toggle synchronization.

Remarks

None.

Preconditions

None.

Example

```
//Clear endpoint 6 buffer descriptor transmit entry and
//enable data toggle synchronization.

PLIB_USB_BufferClearAllDTSEnable ( MY_USB_INSTANCE, pBDT,
    USB_PING_PONG_NO_PING_PONG, 6, USB_BUFFER_TX);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pBDT	pointer to Buffer Descriptor Table
pingpong	Ping-Pong mode.
epvalue	Endpoint to be be affected
bufferDirection	Endpoint direction

Function

void PLIB_USB_BufferClearAllDTSEnable(USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,

uint8_t epValue,

USB_BUFFER_DIRECTION bufferDirection);

PLIB_USB_BufferDataToggleGet Function

Returns data synchronization (DATA0 or DATA1) for the endpoint buffer.

File

plib_usb.h

C

```
USB_BUFFER_DATA01 PLIB_USB_BufferDataToggleGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode,
uint8_t epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Data Toggle value, USB_BUFFER_DATA0 or USB_BUFFER_DATA1, for the buffer

Description

This function returns data synchronization (DATA0 or DATA1) for the endpoint buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

USB_BUFFER_DATA01

PLIB_USB_BufferDataToggleGet (USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,

uint8_t epValue,

USB_BUFFER_DIRECTION bufferDirection,

USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferDataToggleSelect Function

Sets the endpoint buffer to DATA0 or DATA1.

File

plib_usb.h

C

```
void PLIB_USB_BufferDataToggleSelect(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong, USB_BUFFER_DATA01
bufferData01);
```

Returns

None.

Description

This function sets the endpoint buffer to DATA0 or DATA1.

Remarks

See PLIB_USB_BufferDataToggleGet to determine the received data toggle setting. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD
bufferData01	USB_BUFFER_DATA0 or USB_BUFFER_DATA1

Function

void PLIB_USB_BufferDataToggleSelect (USB_MODULE_ID index,

void * pBDT,

USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong,
USB_BUFFER_DATA01 bufferData01)

PLIB_USB_BufferDataToggleSyncDisable Function

Disables DATA0/DATA1 synchronization between the device and host.

File

plib_usb.h

C

```
void PLIB_USB_BufferDataToggleSyncDisable(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode,
uint8_t epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function disables DATA0/DATA1 synchronization between the device and host.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferDataToggleSyncDisable (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferDataToggleSyncEnable Function

Enables DATA0/DATA1 synchronization between the device and host.

File

plib_usb.h

C

```
void PLIB_USB_BufferDataToggleSyncEnable(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode,
uint8_t epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function enables DATA0/DATA1 synchronization between the device and host.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferDataToggleSyncEnable (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferEP0RxStatusInitialize Function

Initializes the Endpoint 0 RX endpoint buffer descriptors.

File

plib_usb.h

C

```
void PLIB_USB_BufferEP0RxStatusInitialize(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode,
USB_BUFFER_PING_PONG pingpong, uint16_t bufferByteCount);
```

Returns

None.

Description

This function initializes the Endpoint 0 RX endpoint buffer descriptors. This function will clear the Endpoint 0 RX Buffer Descriptor status field, load the endpoint size and release the buffer to the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Initialize EP0 RX even buffer descriptor and release back to
//USB. Buffer size is 64
```

```
PLIB_USB_BufferEP0RxStatusInitialize ( MY_USB_INSTANCE, pBDT,
    USB_PING_PONG_NO_PING_PONG, USB_BUFFER_EVEN, 64);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pBDT	Pointer to Buffer Descriptor Table
pingpong	Ping-Pong mode
bufferByteCount	size of the EP0 RX buffer in bytes

Function

void PLIB_USB_BufferEP0RxStatusInitialize (USB_MODULE_ID index,
void* pBDT,
USB_PING_PONG_MODE ppMode,
USB_BUFFER_PING_PONG pingpong,
uint16_t bufferByteCount);

PLIB_USB_BufferIndexGet Function

Gets the Buffer Descriptor Table index for a buffer.

File

plib_usb.h

C

```
uint8_t PLIB_USB_BufferIndexGet(USB_MODULE_ID index, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Buffer index into the Buffer Descriptor Table.

Description

This function gets the Buffer Descriptor Table index for a buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

uint8_t PLIB_USB_BufferIndexGet (USB_MODULE_ID index,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferPIDBitsClear Function

Clears the Buffer Status bits in the Buffer Descriptor Table.

File

plib_usb.h

C

```
void PLIB_USB_BufferPIDBitsClear(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function clears the Buffer Status bits in the Buffer Descriptor Table.

Remarks

Call PLIB_USB_BufferPIDBitsClear before setting buffer control bits. This is equivalent to: PLIB_USB_BufferCancelReleaseToUSB(...) PLIB_USB_BufferDataToggleSelect(...,USB_BUFFER_DATA0) PLIB_USB_BufferDataToggleSyncDisable(...) PLIB_USB_BufferStallDisable(...) This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

The associated buffer must have been released by the USB module (i.e., PLIB_USB_BufferReleasedToSW returns 'true'.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferPIDBitsClear (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferPIDGet Function

Returns the token packet ID (PID) from the endpoint buffer status.

File

plib_usb.h

C

```
uint8_t PLIB_USB_BufferPIDGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

Endpoint buffer packet ID (PID).

Description

This function returns the token packet ID (PID) from the endpoint buffer status.

Remarks

There is no equivalent "Set" routine, since this field is read-only in the buffer status register within the Buffer Descriptor Table. It is set when the buffer has been transmitted or received by the USB module and the usbOwnsBuffer field has been cleared by the USB module, releasing the buffer for software access. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

uint8_t PLIB_USB_BufferPIDGet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferReleasedToSW Function

Returns the boolean flag value of 'true' when the buffer has been released by the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_BufferReleasedToSW(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

- true - The buffer has been released by hardware
- false - The buffer is still controlled by hardware

Description

This function returns the boolean flag value of 'true' when the buffer has been released by the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

bool PLIB_USB_BufferReleasedToSW (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferReleaseToUSB Function

Releases the endpoint buffer by software, allowing the USB module access to the buffer.

File

plib_usb.h

C

```
void PLIB_USB_BufferReleaseToUSB(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function releases the endpoint buffer by software, allowing the USB module access to buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferReleaseToUSB (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,

USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferSchedule Function

Hands over a buffer to the USB module along with the buffer address and byte count.

File

plib_usb.h

C

```
void PLIB_USB_BufferSchedule(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong, void * bufferAddress, int16_t
bufferByteCount, USB_BUFFER_SCHEDULE_DATA01 bufferData01);
```

Returns

None.

Description

This function sets the endpoint descriptor buffer address, sets the send/receive byte count, and then hands over the buffer to the USB module.

Remarks

This function does the work of three other functions: PLIB_USB_BufferAddressSet, PLIB_USB_BufferByteCountSet, PLIB_USB_BufferReleaseToUSB

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

None.

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD
bufferAddress	Address of the application buffer
bufferByteCount	Send or expected receive byte count
bufferData01	USB_BUFFER_SET_DATA0, USB_BUFFER_SET_DATA1, or USB_BUFFER_DONTCHANGE (The last choice leaves the existing DATA0/1 value of the buffer alone.)

Function

void PLIB_USB_BufferSchedule(USB_MODULE_ID index ,
void* pBDT ,
USB_PING_PONG_MODE ppMode ,
uint8_t epValue ,
USB_BUFFER_DIRECTION bufferDirection ,
USB_BUFFER_PING_PONG bufferPingPong ,
void * bufferAddress ,
int16_t bufferByteCount ,
USB_BUFFER_SCHEDULE_DATA01 bufferData01)

PLIB_USB_BufferStallDisable Function

Disables STALL handshaking for the associated endpoint buffer.

File

plib_usb.h

C

```
void PLIB_USB_BufferStallDisable(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function disables STALL handshaking for the associated endpoint buffer.

Remarks

Release of a STALL handshake for the buffer is done by hardware when the host sends a SETUP token to the associated endpoint or resets the USB module This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available. .

Preconditions

The associated buffer must have been released by the USB module (i.e., PLIB_USB_BufferReleasedToSW returns 'true').

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferStallDisable (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferStallEnable Function

Enables STALL handshaking for the associated endpoint buffer.

File

plib_usb.h

C

```
void PLIB_USB_BufferStallEnable(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t
epValue, USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

None.

Description

This function enables STALL handshaking for the associated endpoint buffer.

Remarks

Release of a STALL handshake for the buffer is done by hardware when the host sends a SETUP token to the associated endpoint or resets the USB module. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

The associated buffer must have been released by the USB module (i.e. PLIB_USB_BufferReleasedToSW returns 'true').

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

void PLIB_USB_BufferStallEnable (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,
uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

PLIB_USB_BufferStallGet Function

Returns the buffer stall status for an endpoint/direction/ping-pong.

File

plib_usb.h

C

```
bool PLIB_USB_BufferStallGet(USB_MODULE_ID index, void* pBDT, USB_PING_PONG_MODE ppMode, uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection, USB_BUFFER_PING_PONG bufferPingPong);
```

Returns

- true - Buffer stall is enabled
- false - Buffer stall is not enabled

Description

This function returns the buffer stall status for an endpoint/direction/ping-pong.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBDTFunctions in your application to determine whether this feature is available.

Preconditions

the associated buffer must have been released by the USB module (i.e., PLIB_USB_BufferReleasedToSW returns 'true').

Example

Parameters

Parameters	Description
index	Dummy argument, identifier for the device instance of interest
pBDT	Pointer to start of Buffer Descriptor Table
ppMode	Ping-Pong buffering mode
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
bufferDirection	USB_BUFFER_RX or USB_BUFFER_TX
bufferPingPong	USB_BUFFER_EVEN or USB_BUFFER_ODD

Function

bool PLIB_USB_BufferStallGet (USB_MODULE_ID index,
void * pBDT,
USB_PING_PONG_MODE ppMode,

uint8_t epValue,
USB_BUFFER_DIRECTION bufferDirection,
USB_BUFFER_PING_PONG bufferPingPong)

c) Endpoints Functions

PLIB_USB_EP0HostSetup Function

Sends token to the specified address.

File

plib_usb.h

C

```
void PLIB_USB_EP0HostSetup(USB_MODULE_ID index);
```

Returns

None.

Description

This function configures endpoint 0 for typical host operation. Control transfers are enable. Transmit and Receive is enabled. Handshaking is enabled. Low Speed connection is disabled. NAK retry is disabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Configure endpoint 0 for host operation

PLBIB_USB_EP0HostSetup(USB_MODULE_ID index);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0HostSetup(USB_MODULE_ID index);

PLIB_USB_EP0LSDirectConnectDisable Function

Disables direct connection to a low-speed device for Endpoint 0.

File

plib_usb.h

C

```
void PLIB_USB_EP0LSDirectConnectDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables direct connection to a low-speed device for Endpoint 0.

Remarks

Host mode and U1EP0 only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEP0LowSpeedConnect in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
PLIB_USB_EP0LSDirectConnectDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0LSDirectConnectDisable (USB_MODULE_ID index)

PLIB_USB_EP0LSDirectConnectEnable Function

Enables direct connection to a low-speed device for Endpoint 0.

File

plib_usb.h

C

```
void PLIB_USB_EP0LSDirectConnectEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables direct connection to a low-speed device for Endpoint 0.

Remarks

Host Mode and U1EP0 only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEP0LowSpeedConnect in your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
PLIB_USB_EP0LSDirectConnectEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0LSDirectConnectEnable (USB_MODULE_ID index)

PLIB_USB_EP0NakRetryDisable Function

Disables retrying of NAKed transactions.

File

plib_usb.h

C

```
void PLIB_USB_EP0NakRetryDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables retrying of NAKed transactions.

Remarks

Host/OTG only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEP0NAKRetry in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host or OTG modes.

Example

```
PLIB_USB_EP0NakRetryDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0NakRetryDisable (USB_MODULE_ID index)

PLIB_USB_EP0NakRetryEnable Function

Enables retrying NAK'd transactions for Endpoint 0.

File

plib_usb.h

C

```
void PLIB_USB_EP0NakRetryEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables retrying NAK'd transactions for Endpoint 0.

Remarks

Host/OTG only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEP0NAKRetry in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host or OTG modes.

Example

```
PLIB_USB_EP0NakRetryEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EP0NakRetryEnable (USB_MODULE_ID index)

PLIB_USB_EPnAttributesClear Function

Clears the set attributes of the specified endpoint.

File

plib_usb.h

C

```
void PLIB_USB_EPnAttributesClear(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

Clears the set attributes of the specified endpoint. The endpoint transmit receive, handshake and setup packet handling capability is disabled.

Remarks

None.

Preconditions

None.

Example

```
// This clears up the endpoint 0 attributes and thus disables
// the endpoints
PLIB_USB_EPnAttributesClear(MY_USB_INSTANCE, 0);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnAttributesClear (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnAttributesSet Function

Configures attributes of the endpoint such as direction, handshake capability and direction.

File

plib_usb.h

C

```
void PLIB_USB_EPnAttributesSet(USB_MODULE_ID index, uint8_t epValue, int direction, bool isControl, bool handshake);
```

Returns

None.

Description

Configures attributes of the endpoint such as direction, handshake capability and direction. If the isControl flag is true, then the direction and handshake parameters are ignored and the endpoint is configured for control transfers.

Remarks

None.

Preconditions

None.

Example

```
// This enables endpoint 0 for control transfers.
PLIB_USB_EPnAttributesSet(MY_USB_INSTANCE, 0, 0, true, true);
// This enables endpoint 2 for non control transfer, direction
// is RX and handshake enable.
PLIB_USB_EPnAttributesSet(MY_USB_INSTANCE, 2, 1, false, true);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
direction	Endpoint direction, if 1 then RX and if 0 then TX.

isControl	If true endpoint is configured for control transfers.
handshake	If true, then handshake is enabled on the endpoint else it is disabled.

Function

void PLIB_USB_EPnAttributesSet (USB_MODULE_ID index,
uint8_t epValue, int direction, bool isControl, bool handshake)

PLIB_USB_EPnControlTransferDisable Function

Disables endpoint control transfers.

File

plib_usb.h

C

```
void PLIB_USB_EPnControlTransferDisable(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function disables endpoint control transfers when endpoint transmit and endpoint receive are both enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnControlTransferDisable(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnControlTransferDisable (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnControlTransferEnable Function

Enables endpoint control transfers.

File

plib_usb.h

C

```
void PLIB_USB_EPnControlTransferEnable(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function enables endpoint control transfers when endpoint transmit and endpoint receive are both enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnControlTransferEnable(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnControlTransferEnable (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnDirectionDisable Function

Disables the specified endpoint direction.

File

plib_usb.h

C

```
void PLIB_USB_EPnDirectionDisable(USB_MODULE_ID index, uint8_t epValue, int direction);
```

Returns

None.

Description

Disables the specified endpoint direction.

Remarks

None.

Preconditions

None.

Example

```
// This function disables the TX direction of endpoint 1
PLIB_USB_EPnDirectionDisable(MY_USB_INSTANCE, 1, 1);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
direction	If 1, then TX direction is disabled. If 0 RX direction is disabled.

Function

void PLIB_USB_EPnDirectionDisable (USB_MODULE_ID index,

uint8_t epValue, int direction)

PLIB_USB_EPnHandshakeDisable Function

Disables endpoint handshaking.

File

plib_usb.h

C

```
void PLIB_USB_EPnHandshakeDisable(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function disables endpoint handshaking. Typically used for Isochronous endpoints.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnHandshakeDisable(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnHandshakeDisable (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnHandshakeEnable Function

Enables endpoint handshaking.

File

plib_usb.h

C

```
void PLIB_USB_EPnHandshakeEnable(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function enables endpoint handshaking.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnHandshakeEnable(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnHandshakeEnable (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnIsStalled Function

Tests whether the endpoint epValue is stalled.

File

plib_usb.h

C

```
bool PLIB_USB_EPnIsStalled(USB_MODULE_ID index, uint8_t epValue);
```

Returns

- true - The endpoint is stalled
- false - The endpoint is not stalled

Description

This function tests whether the endpoint epValue is stalled.

Remarks

Not valid before an endpoint is enabled. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if( PLIB_USB_EPnIsStalled(MY_USB_INSTANCE, someEP) )
{
    // Handle the stall
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

bool PLIB_USB_EPnIsStalled (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnRxDisable Function

Disables an endpoint's ability to process IN tokens.

File

plib_usb.h

C

```
void PLIB_USB_EPnRxDisable(USB_MODULE_ID index, uint8_t endpoint);
```

Returns

None.

Description

This function disables an endpoint's ability to process IN tokens.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//De-provision endpoint 3 to process IN Token
PLIB_USB_EPnRxDisable(MY_USB_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
endpoint	Endpoint to be affected

Function

void PLIB_USB_EPnRxDisable(USB_MODULE_ID index, uint8_t endpoint);

PLIB_USB_EPnRxEnable Function

Enables an endpoint to process IN tokens.

File

plib_usb.h

C

```
void PLIB_USB_EPnRxEnable(USB_MODULE_ID index, uint8_t endpoint);
```

Returns

None.

Description

This function enables an endpoint to process IN tokens.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//Provision endpoint 3 to process IN Token
PLIB_USB_EPnRxEnable(MY_USB_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
endpoint	Endpoint to be affected

Function

void PLIB_USB_EPnRxEnable(USB_MODULE_ID index, uint8_t endpoint);

PLIB_USB_EPnRxSelect Function

Selects receive capabilities of an endpoint.

File

plib_usb.h

C

```
void PLIB_USB_EPnRxSelect(USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx);
```

Returns

None.

Description

This function selects receive capabilities of an endpoint.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnRxSelect(MY_USB_INSTANCE, someEP, USB_EP_RX);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
epTxRx	Transmit/Receive setting for endpoint: USB_EP_RX, USB_EP_NOTXRX

Function

void PLIB_USB_EPnRxSelect (USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx)

PLIB_USB_EPnStallClear Function

Clears an endpoint's stalled flag.

File

plib_usb.h

C

```
void PLIB_USB_EPnStallClear(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function clears an endpoint's stalled flag.

Remarks

Not valid before an endpoint is enabled. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if( PLIB_USB_EPnIsStalled(MY_USB_INSTANCE, someEP) )
{
    // Handle the stall
    PLIB_USB_EPnStallClear(MY_USB_INSTANCE, someEP);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_EPnStallClear (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_EPnTxDisable Function

Disables an endpoint's ability to process OUT tokens.

File

plib_usb.h

C

```
void PLIB_USB_EPnTxDisable(USB_MODULE_ID index, uint8_t endpoint);
```

Returns

None.

Description

This function disables an endpoint's ability to process OUT tokens.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
//De-provision endpoint 3 to process OUT Token
PLIB_USB_EPnTxDisable(MY_USB_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
endpoint	Endpoint to be affected

Function

void PLIB_USB_EPnTxDisable(USB_MODULE_ID index, uint8_t endpoint);

PLIB_USB_EPnTxEnable Function

Enables an endpoint to process OUT tokens.

File

plib_usb.h

C

```
void PLIB_USB_EPnTxEnable(USB_MODULE_ID index, uint8_t endpoint);
```

Returns

None.

Description

This function enables an endpoint to process OUT tokens.

Remarks

None.

Preconditions

None.

Example

```
//Provision endpoint 3 to process OUT Token
PLIB_USB_EPnTxEnable(MY_USB_INSTANCE, 3);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
endpoint	Endpoint to be affected

Function

void PLIB_USB_EPnTxEnable(USB_MODULE_ID index, uint8_t endpoint);

PLIB_USB_EPnTxRxSelect Function

Selects transmit and/or receive capabilities of an endpoint.

File

plib_usb.h

C

```
void PLIB_USB_EPnTxRxSelect(USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx);
```

Returns

None.

Description

This function selects transmit and/or receive capabilities of an endpoint.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnTxRxSelect(MY_USB_INSTANCE, someEP, USB_EP_TXRX);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
epTxRx	Transmit/Receive setting for endpoint: USB_EP_TX, USB_EP_RX, USB_EP_TX_RX, USB_EP_NOTXRX

Function

void PLIB_USB_EPnTxRxSelect (USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx)

PLIB_USB_EPnTxSelect Function

Selects transmit capabilities of an endpoint.

File

plib_usb.h

C

```
void PLIB_USB_EPnTxSelect(USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx);
```

Returns

None.

Description

This function selects transmit capabilities of an endpoint.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEPnRxEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EPnTxSelect(MY_USB_INSTANCE, someEP, USB_EP_TX);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint
epTxRx	Transmit/Receive setting for endpoint: USB_EP_TX, USB_EP_NOTXRX

Function

void PLIB_USB_EPnTxSelect (USB_MODULE_ID index, uint8_t epValue, USB_EP_TXRX epTxRx)

d) Interrupts Functions

PLIB_USB_InterruptDisable Function

Disables a general interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_InterruptDisable(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function disables a general interrupt source for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_InterruptDisable( MY_USB_INSTANCE, USB_INT_ERROR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_InterruptDisable(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptEnable Function

Enables a general interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_InterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function enables general interrupt sources of the USB module to trigger a USB interrupt.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_InterruptEnable( MY_USB_INSTANCE, USB_INT_ERROR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_InterruptEnable(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptEnableGet Function

Returns the enable/disable status of general USB module interrupts

File

plib_usb.h

C

```
USB_INTERRUPTS PLIB_USB_InterruptEnableGet(USB_MODULE_ID index);
```

Returns

A bit map containing status of enabled interrupts.

Description

Returns the enable/disable status of general USB module interrupts

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
USB_INTERRUPTS enabledInterrupts;
enabledInterrupts = PLIB_USB_InterruptEnableGet( MY_USB_INSTANCE);
if(enabledInterrupts|USB_INT_ATTACH)
{
    // This means Attach interrupt is enabled.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_INTERRUPTS PLIB_USB_InterruptEnableGet(USB_MODULE_ID index)

PLIB_USB_InterruptFlagAllGet Function

Returns a logically ORed bit map of active general USB interrupt flags.

File

plib_usb.h

C

```
USB_INTERRUPTS PLIB_USB_InterruptFlagAllGet(USB_MODULE_ID index);
```

Returns

Returns a logically ORed bit map of active general USB interrupt flags.

Description

This function returns a logically ORed bit map of active general USB interrupt flags.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
USB_INTERRUPTS interruptEnables;

interruptEnables = PLIB_USB_InterruptFlagAllGet(MY_USB_INSTANCE);
if(interruptEnables | USB_INT_DEVICE_RESET)
{
    // Device received reset signaling
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_INTERRUPTS PLIB_USB_InterruptFlagAllGet(USB_MODULE_ID index);

PLIB_USB_InterruptFlagClear Function

Clears a general interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_InterruptFlagClear(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function clears a general interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_InterruptFlagClear( MY_USB_INSTANCE, USB_INT_ERROR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_InterruptFlagClear(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptFlagGet Function

Tests a general interrupt flag for the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_InterruptFlagGet(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function tests a general interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_InterruptFlagGet(MY_USB_INSTANCE,USB_INT_ANY) )
    if ( PLIB_USB_InterruptFlagGet(MY_USB_INSTANCE,USB_INT_ERROR) )
    {
        PLIB_USB_InterruptFlagClear(MY_USB_INSTANCE,USB_INT_ERROR);
        // Error clean up
    }
    if ( PLIB_USB_InterruptFlagGet(MY_USB_INSTANCE,USB_INT_HOST_DETACH) )
    {
        PLIB_USB_InterruptFlagClear(MY_USB_INSTANCE,USB_INT_HOST_DETACH);
        // Device detached clean up
    }
```

```
        .
        .
        .
    }
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_InterruptFlagGet(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptFlagSet Function

Sets a general interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_InterruptFlagSet(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function sets a general interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_InterruptFlagSet( MY_USB_INSTANCE, USB_INT_ERROR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_InterruptFlagSet(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

PLIB_USB_InterruptIsEnabled Function

Returns true if interrupts are enabled.

File

plib_usb.h

C

```
bool PLIB_USB_InterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

- true - Interrupts are enabled
- false - Interrupts are not enabled

Description

This function returns true if interrupts are enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_InterruptIsEnabled( MY_USB_INSTANCE, USB_INT_ERROR ) )
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_InterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

e) Error Interrupts Functions

PLIB_USB_ErrorInterruptDisable Function

Disables an error interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_ErrorInterruptDisable(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function disables an error interrupt source for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_ErrorInterruptDisable( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_ErrorInterruptDisable(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptEnable Function

Enables an error interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_ErrorInterruptEnable(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function enables error interrupt sources of the USB module to trigger a USB interrupt.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_ErrorInterruptEnable( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_ErrorInterruptEnable(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptFlagAllGet Function

Returns a logically ORed bit map of active error interrupt flags.

File

plib_usb.h

C

```
USB_ERROR_INTERRUPTS PLIB_USB_ErrorInterruptFlagAllGet(USB_MODULE_ID index);
```

Returns

Returns a logically ORed bit map of active error interrupt flags.

Description

This function returns a logically ORed bit map of active error interrupt flags.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
USB_ERROR_INTERRUPTS errorInterruptEnables;

errorInterruptEnables = PLIB_USB_ErrorInterruptFlagAllGet(MY_USB_INSTANCE);
```

```
if(errorInterruptEnables | USB_ERR_INT_DEVICE_EOF_ERROR)
{
    // End of frame error occurred.
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_ERROR_INTERRUPTS PLIB_USB_ErrorInterruptFlagAllGet(USB_MODULE_ID index);

PLIB_USB_ErrorInterruptFlagClear Function

Clears an error interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_ErrorInterruptFlagClear(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function clears an error interrupt source flag for the USB module.

Remarks

None.

Preconditions

None.

Example

```
PLIB_USB_ErrorInterruptFlagClear( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_ErrorInterruptFlagClear(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptFlagGet Function

Tests an error interrupt flag for the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ErrorInterruptFlagGet(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function tests an error interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_ErrorInterruptFlagGet(MY_USB_INSTANCE,USB_ERR_INT_ANY) )
    if ( PLIB_USB_ErrorInterruptFlagGet(MY_USB_INSTANCE,USB_ERR_INT_PID_CHECK_FAILURE) )
    {
        PLIB_USB_ErrorInterruptFlagClear(MY_USB_INSTANCE,USB_ERR_INT_PID_CHECK_FAILURE);
        // PID Error Check failure cleanup
    }
    if ( PLIB_USB_ErrorInterruptFlagGet(MY_USB_INSTANCE,USB_ERR_INT_DEVICE_EOF_ERROR) )
    {
        PLIB_USB_ErrorInterruptFlagClear(MY_USB_INSTANCE,USB_ERR_INT_DEVICE_EOF_ERROR);
        // EOF error cleanup
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_ErrorInterruptFlagGet(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptFlagSet Function

Sets an error interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_ErrorInterruptFlagSet(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function sets an error interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_ErrorInterruptFlagSet( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_ErrorInterruptFlagSet(USB_MODULE_ID index, USB_ERROR_INTERRUPTS interruptFlag)

PLIB_USB_ErrorInterruptIsEnabled Function

Returns true if interrupts are enabled.

File

plib_usb.h

C

```
bool PLIB_USB_ErrorInterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

- true - Interrupts are enabled
- false - Interrupts are not enabled

Description

This function determines whether interrupts are enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsERR_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_ErrorInterruptIsEnabled( MY_USB_INSTANCE, USB_ERR_INT_BAD_CRC16 ) )
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_ErrorInterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

f) Last Transaction Status Functions

PLIB_USB_LastTransactionDetailsGet Function

Returns the details of the last completed transaction.

File

plib_usb.h

C

```
void PLIB_USB_LastTransactionDetailsGet(USB_MODULE_ID index, USB_BUFFER_DIRECTION * direction,
USB_PING_PONG_STATE * pingpong, uint8_t * endpoint);
```

Returns

None.

Description

This function returns the details of the last completed transaction.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLastTransactionDetails in your application to determine whether this feature is available.

Preconditions

None.

Example

```
USB_BUFFER_DIRECTION direction;
USB_PING_PONG_STATE pingpong;
uint8_t endpoint;

interruptEnables = PLIB_USB_InterruptFlagAllGet(MY_USB_INSTANCE);
if(interruptEnables | USB_INT_TOKEN_DONE)
{
    // Find out details of the token
    PLIB_USB_LastTransactionDetailsGet(MY_USB_INSTANCE, &direction,
                                    &pingpong, &endpoint);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
direction	Return value contains direction of the last transfer
pingpong	Return value contains Ping-Pong indication of the the last transfer
endpoint	Return value contains the endpoint which processed the last transfer

Function

void PLIB_USB_LastTransactionDetailsGet(USB_MODULE_ID index,

USB_BUFFER_DIRECTION * direction,

USB_PING_PONG_STATE * pingpong,

uint8_t * endpoint);

PLIB_USB_LastTransactionDirectionGet Function

Indicates the direction of the last transaction.

File

plib_usb.h

C

```
USB_BUFFER_DIRECTION PLIB_USB_LastTransactionDirectionGet(USB_MODULE_ID index);
```

Returns

USB_LastDirection: USB_RECEIVE_TRANSFER or USB_TRANSMIT_TRANSFER

Description

This function indicates the direction of the last transaction, either transmit or receive.

Remarks

None.

Preconditions

None.

Example

See PLIB_USB_LastTransactionEndPtGet.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_BUFFER_DIRECTION PLIB_USB_LastTransactionDirectionGet (USB_MODULE_ID index)

PLIB_USB_LastTransactionEndPtGet Function

Returns the endpoint number of the last USB transfer.

File

plib_usb.h

C

```
uint8_t PLIB_USB_LastTransactionEndPtGet(USB_MODULE_ID index);
```

Returns

endPoint - Endpoint of last completed USB transfer

Description

This function returns the endpoint number of the last USB transfer, which is actually the index into the Buffer Descriptor Table of the last USB transfer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLastDirection in your application to determine whether this feature is available.

Preconditions

None.

Example

```
while ( !PLIB_USB_INT_FlagGet(MY_USB_INSTANCE,USB_INT_GEN,TOKEN_DONE) )
{
    // Do nothing, wait until completion of next transaction
}

// Retrieve information relating to the last completed transaction
endpoint  = PLIB_USB_LastTransactionEndPtGet(MY_USB_INSTANCE);
direction = PLIB_USB_LastTransactionDirectionGet(MY_USB_INSTANCE);
pingPongState = PLIB_USB_LastTransactionPingPongStateGet(MY_USB_INSTANCE);

// Clearing the Token Processing Done flag advances the status FIFO to
// oldest transaction in the FIFO.  Wait for completion of next transaction
// before using PLIB_USB_Last*Get functions again to read status.
PLIB_USB_INT_FlagClear(MY_USB_INSTANCE,USB_INT_GEN,TOKEN_DONE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint8_t PLIB_USB_LastTransactionEndPtGet (USB_MODULE_ID index)

PLIB_USB_LastTransactionPingPongStateGet Function

Indicates whether the last transaction was to an EVEN buffer or an ODD buffer.

File

plib_usb.h

C

```
USB_PING_PONG_STATE PLIB_USB_LastTransactionPingPongStateGet(USB_MODULE_ID index);
```

Returns

USB_PING_PONG_STATE.

Description

This function indicates whether the last transaction was to an Even buffer or an Odd buffer.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLastPingPong in your application to determine whether this feature is available.

Preconditions

None.

Example

See PLIB_USB_LastTransactionEndPtGet.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_PING_PONG_STATE PLIB_USB_LastTransactionPingPongStateGet (USB_MODULE_ID index)

g) Host Functions

PLIB_USB_IsBusyWithToken Function

Indicates whether there is a token being executed by the USB module as Host.

File

plib_usb.h

C

```
bool PLIB_USB_IsBusyWithToken(USB_MODULE_ID index);
```

Returns

None.

Description

This function indicates whether there is a token being executed by the USB module as Host. Software should check that the previous token is finished before issuing a new token.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsHostBusyWithToken in your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
while( PLIB_USB_IsBusyWithToken(MY_USB_INSTANCE) )
{
    // do nothing
}
// Issue new token
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_IsBusyWithToken (USB_MODULE_ID index)

PLIB_USB_SOFDisable Function

Disables the automatic generation of the SOF token.

File

plib_usb.h

C

```
void PLIB_USB_SOFDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the automatic generation of the SOF token.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsStartOfFrames in your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
PLIB_USB_SOFDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SOFDisable (USB_MODULE_ID index)

PLIB_USB_SOFEnable Function

Enables the automatic generation of the SOF token every 1 ms.

File

plib_usb.h

C

```
void PLIB_USB_SOFEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the automatic generation of the SOF token every 1 ms.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsStartOfFrames in your application to determine whether this feature is available.

Preconditions

USB module must be in Host mode.

Example

```
PLIB_USB_SOFEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_SOFEnable (USB_MODULE_ID index)

PLIB_USB_SOFThresholdGet Function

Returns the Start-of-Frame (SOF) Count bits.

File

plib_usb.h

C

```
uint8_t PLIB_USB_SOFThresholdGet(USB_MODULE_ID index);
```

Returns

SOF threshold value.

Description

This function returns the Start-of-Frame (SOF) Count bits. (Value represents 10 + (packet size of n bytes);).

Remarks

Host mode only.

```
    SOF Threshold Value = packet byte count + 10
                        = 0b0100_1010 = 0x4A = 74 for 64-byte packet
                        = 0b0010_1010 = 0x2A = 42 for 32-byte packet
                        = 0b0001_1010 = 0x1A = 26 for 16-byte packet
                        = 0x0001_0010 = 0x12 = 18 for  8-byte packet
```

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSOFThreshold in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
  thresholdSOF = PLIB_USB_SOFThresholdGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint8_t PLIB_USB_SOFThresholdGet (USB_MODULE_ID index)

PLIB_USB_SOFThresholdSet Function

Sets the Start-of-Frame (SOF) threshold value.

File

plib_usb.h

C

```
void PLIB_USB_SOFThresholdSet(USB_MODULE_ID index, uint8_t threshold);
```

Returns

None.

Description

This function sets the Start-of-Frame (SOF) threshold value.

Remarks

Host mode only.

```
    SOF Threshold Value = packet byte count + 10
                        = 0b0100_1010 = 0x4A = 74 for 64-byte packet
                        = 0b0010_1010 = 0x2A = 42 for 32-byte packet
                        = 0b0001_1010 = 0x1A = 26 for 16-byte packet
                        = 0x0001_0010 = 0x12 = 18 for  8-byte packet
```

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsSOFThreshold in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
// Set SOF threshold for 64-byte packets
PLIB_USB_SOFThresholdSet(MY_USB_INSTANCE,64+10);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
threshold	SOF threshold

Function

void PLIB_USB_SOFThresholdSet (USB_MODULE_ID index, uint8_t threshold)

PLIB_USB_TokenEPGet Function

Returns the specified Endpoint address.

File

plib_usb.h

C

```
uint8_t PLIB_USB_TokenEPGet(USB_MODULE_ID index);
```

Returns

Endpoint value - 0 <= epValue <= Module Maximum Endpoint.

Description

This function returns the address of the specified Endpoint.

Remarks

Host mode only.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsTokenEP in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
someEP = PLIB_USB_TokenEPGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint8_t PLIB_USB_TokenEPGet (USB_MODULE_ID index)

PLIB_USB_TokenEPSet Function

Sets the Endpoint address for a host transaction.

File

plib_usb.h

C

```
void PLIB_USB_TokenEPSet(USB_MODULE_ID index, uint8_t epValue);
```

Returns

None.

Description

This function sets the Endpoint address for a host transaction.

Remarks

Host mode only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsTokenEP in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
uint8_t someEP = 0x03;
PLIB_USB_TokenEPSet(MY_USB_INSTANCE, someEP);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
epValue	Endpoint value, 0 <= epValue <= Module Maximum Endpoint

Function

void PLIB_USB_TokenEPSet (USB_MODULE_ID index, uint8_t epValue)

PLIB_USB_TokenPIDGet Function

Returns the token transaction type.

File

plib_usb.h

C

```
USB_PID PLIB_USB_TokenPIDGet(USB_MODULE_ID index);
```

Returns

Packet ID of token, USB_PID_SETUP, USB_PID_IN, or USB_PID_OUT

Description

This function returns the token transaction type.

Remarks

Host mode only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsTokenPID in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
somePID = PLIB_USB_TokenPIDGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_PID PLIB_USB_TokenPIDGet (USB_MODULE_ID index)

PLIB_USB_TokenPIDSet Function

Sets the token transaction type to pidValue.

File

plib_usb.h

C

```
void PLIB_USB_TokenPIDSet(USB_MODULE_ID index, USB_PID pidValue);
```

Returns

None.

Description

This function sets the token transaction type to pidValue.

Remarks

Host mode only. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsTokenPID in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
somePID = USB_PID_SETUP;
PLIB_USB_TokenPIDSet (MY_USB_INSTANCE, somePID );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pidValue	USB_PID_SETUP, USB_PID_IN, or USB_PID_OUT

Function

void PLIB_USB_TokenPIDSet (USB_MODULE_ID index, USB_PID pidValue)

PLIB_USB_TokenSpeedSelect Function

Selects low speed or full speed for subsequent token executions.

File

plib_usb.h

C

```
void PLIB_USB_TokenSpeedSelect(USB_MODULE_ID index, USB_TOKEN_SPEED tokenSpeed);
```

Returns

None.

Description

This function selects low speed or full speed for subsequent token executions.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsNextTokenSpeed in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
PLIB_USB_TokenSpeedSet(MY_USB_INSTANCE,USB_LOWSPEED_TOKENS);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
tokenSpeed	Speed for next token execution: USB_LOWSPEED_TOKENS or USB_FULLSPEED_TOKENS

Function

void PLIB_USB_TokenSpeedSelect (USB_MODULE_ID index, USB_TOKEN_SPEED tokenSpeed)

h) USB Bus Signaling Functions

PLIB_USB_ResetSignalDisable Function

Disables reset signaling on the USB bus.

File

plib_usb.h

C

```
void PLIB_USB_ResetSignalDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables reset signaling on the USB bus.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsHostGeneratesReset in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

See PLIB_USB_ResetSignalEnable.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ResetSignalDisable (USB_MODULE_ID index)

PLIB_USB_ResetSignalEnable Function

Enables reset signaling on the USB bus.

File

plib_usb.h

C

```
void PLIB_USB_ResetSignalEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables reset signaling on the USB bus.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsHostGeneratesReset in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
// Snippet to perform a software reset:
PLIB_USB_ResetSignalEnable(MY_USB_INSTANCE);
// ... delay 50ms
PLIB_USB_ResetSignalDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ResetSignalEnable (USB_MODULE_ID index)

PLIB_USB_ResumeSignalingDisable Function

Disables resume signaling.

File

plib_usb.h

C

```
void PLIB_USB_ResumeSignalingDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables resume signaling.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsResumeSignaling in your application to determine whether this feature is available.

Preconditions

None.

Example

See PLIB_USB_ResumeSignalingEnable.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ResumeSignalingDisable (USB_MODULE_ID index)

PLIB_USB_ResumeSignalingEnable Function

Enables resume signaling.

File

plib_usb.h

C

```
void PLIB_USB_ResumeSignalingEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables resume signaling. Resume allows the peripheral to perform a remote wake-up by executing resume signaling.

Remarks

Software must enable resume signaling for 10 ms if the device is in Device mode, or for 25 ms if the device is in Host mode, and then disable resume signaling to enable remote wake-up. In Host mode, the USB module will append a low-speed EOP to the end resume signaling when it is disabled. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsResumeSignaling in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Perform resume signaling:
PLIB_USB_ResumeSignalingEnable(MY_USB_INSTANCE);
// Delay 10ms
PLIB_USB_ResumeSignalingDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ResumeSignalingEnable (USB_MODULE_ID index)

i) On-The-Go (OTG) Functions

PLIB_USB_OTG_BSessionHasEnded Function

Returns the status of the B-Session End Indicator bit.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_BSessionHasEnded(USB_MODULE_ID index);
```

Returns

- true - The VBUS Voltage is below VB_SESS_END on the B-device
- false - The VBUS voltage is above VB_SESS_END on the B-device

Description

This function returns the status of the B-Session End Indicator bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_BSessionEnd in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if ( !PLIB_USB_OTG_BSessionHasEnded(MY_USB_INSTANCE) )
{
    // B session valid
}
else
{
    // B session not valid
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_BSessionHasEnded (USB_MODULE_ID index)

PLIB_USB_OTG_IDPinStateIsTypeA Function

Returns the ID Pin state.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_IDPinStateIsTypeA(USB_MODULE_ID index);
```

Returns

- true - Type A Cable attached,
- false - No cable is attached or a Type B cable is attached

Description

This function returns ID Pin state.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_IDPinState in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if ( PLIB_USB_OTG_IDPinStateIsTypeA(MY_USB_INSTANCE) )
{
    // Type A cable attached
}
else
{
    // No cable or Type B cable attached
};
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_IDPinStateIsTypeA (USB_MODULE_ID index)

PLIB_USB_OTG_LineStateIsStable Function

Returns the status of the Line Stable Indicator bit.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_LineStateIsStable(USB_MODULE_ID index);
```

Returns

- true - The USB line state has been stable for the previous 1 ms
- false - The USB line state has not been stable for the previous 1 ms

Description

This function returns the status of the Line Stable Indicator bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_LineState in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if( PLIB_USB_OTG_LineStateIsStable(MY_USB_INSTANCE) ) {
    // Line has been stable
    // ... rest of code ...
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_LineStateIsStable (USB_MODULE_ID index)

PLIB_USB_OTG_PullUpPullDownSetup Function

Enables or disables pull-up and pull-down resistors.

File

plib_usb.h

C

```
void PLIB_USB_OTG_PullUpPullDownSetup(USB_MODULE_ID index, USB_OTG_PULL_UP_PULL_DOWN resistor, bool
enableResistor);
```

Returns

None.

Description

This function enables or disables pull-up and pull-down resistors.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_PullUpPullDown in your application to determine whether this feature is available.

Preconditions

USB On-The-Go (OTG) must be enabled.

Example

```
// Enable pull-up resistor for D+
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DPLUS_PULLUP,true);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
resistor	USB_OTG_DPLUS_PULLUP, USB_OTG_DMINUS_PULLUP, USB_OTG_DPLUS_PULLDN, or USB_OTG_DMINUS_PULLDN
enableResistor	true to enable resistor, false to disable it

Function

void PLIB_USB_OTG_PullUpPullDownSetup(USB_MODULE_ID index,
USB_OTG_PULL_UP_PULL_DOWN resistor,
bool enableResistor)

PLIB_USB_OTG_SessionValid Function

Returns the status of the Session Valid Indicator bit.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_SessionValid(USB_MODULE_ID index);
```

Returns

- true - The VBUS voltage is above Session Valid on the A or B device
- false - The VBUS voltage is below Session Valid on the A or B device

Description

This function returns the status of the Session Valid Indicator bit.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_SessionValid in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if ( PLIB_USB_OTG_SessionValid(MY_USB_INSTANCE) )
{
    // Session valid
}
else
{
    // Session not valid
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_SessionValid (USB_MODULE_ID index)

PLIB_USB_OTG_VBusChargeDisable Function

Disables VBUS line charge.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusChargeDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables VBUS line charge.

Remarks

Not available on PIC32 devices. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusCharge in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusChargeDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusChargeDisable (USB_MODULE_ID index)

PLIB_USB_OTG_VBusChargeEnable Function

Enables the VBUS line to be charged through a pull-up resistor.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusChargeEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the VBUS line to be charged through a pull-up resistor.

Remarks

Not available on PIC32 devices. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusDischarge in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusChargeEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusChargeEnable (USB_MODULE_ID index)

PLIB_USB_OTG_VBusChargeTo3V Function

Sets the VBUS line to charge to 3.3V.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusChargeTo3V(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the VBUS line to charge to 3.3V.

Remarks

Not available on PIC32 devices.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusChargeTo3V(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusChargeTo3V(USB_MODULE_ID index)

PLIB_USB_OTG_VBusChargeTo5V Function

Sets the VBUS line to charge to 5V.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusChargeTo5V(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the VBUS line to charge to 5V.

Remarks

Not available on PIC32 devices.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusChargeTo5V (MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusChargeTo5V (USB_MODULE_ID index)

PLIB_USB_OTG_VBusDischargeDisable Function

Disables VBUS line discharge.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusDischargeDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables VBUS line discharge.

Remarks

Not available on PIC32 devices. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusDischarge in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusDischargeDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusDischargeDisable (USB_MODULE_ID index)

PLIB_USB_OTG_VBusDischargeEnable Function

Enables VBUS line to be discharged through a resistor.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusDischargeEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the VBUS line to be discharged through a resistor.

Remarks

Not available on PIC32 devices. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusCharge in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusDischargeEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusDischargeEnable (USB_MODULE_ID index)

PLIB_USB_OTG_VBusPowerOff Function

Turns off power on the VBUS Line.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusPowerOff(USB_MODULE_ID index);
```

Returns

None.

Description

This function turns off power on the VBUS Line.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusPowerOnOff in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusPowerOff(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusPowerOff (USB_MODULE_ID index)

PLIB_USB_OTG_VBusPowerOn Function

Turns on power for the VBUS line.

File

plib_usb.h

C

```
void PLIB_USB_OTG_VBusPowerOn(USB_MODULE_ID index);
```

Returns

None.

Description

This function turns on power for the VBUS line.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_VbusPowerOnOff in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_VBusPowerOn(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_OTG_VBusPowerOn (USB_MODULE_ID index)

PLIB_USB_OTG_VBusValid Function

Returns the status of the A-VBUS valid indicator.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_VBusValid(USB_MODULE_ID index);
```

Returns

- true - The VBUS voltage is above VA_VBUS_VLD on the A-device,
- false - The VBUS voltage is below VA_VBUS_VLD on the A-device

Description

This function returns the status of the A-VBUS valid indicator.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_ASessionValid in your application to determine whether this feature is available.

Preconditions

The USB module must be in OTG mode.

Example

```
if ( PLIB_USB_OTG_VBusValid(MY_USB_INSTANCE) )
{
    // VBUS voltage above session valid for A device
}
else
{
    // VBUS voltage below session valid for A device
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_OTG_VBusValid (USB_MODULE_ID index)

j) OTG Interrupts Functions

PLIB_USB_OTG_InterruptDisable Function

Disables a USB On-The-Go (OTG) Interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OTG_InterruptDisable(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function disables a USB On-The-Go (OTG) interrupt source for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_InterruptDisable( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_OTG_InterruptDisable(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptEnable Function

Enables a USB On-The-Go (OTG) Interrupt for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OTG_InterruptEnable(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function enables USB On-The-Go (OTG) interrupt sources of the USB module to trigger a USB interrupt.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_InterruptEnable( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_OTG_InterruptEnable(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptFlagClear Function

Clears a USB On-The-Go (OTG) Interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OTG_InterruptFlagClear(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function clears a USB On-The-Go (OTG) interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_InterruptFlagClear( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_OTG_InterruptFlagClear(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptFlagGet Function

Tests a USB On-The-Go (OTG) Interrupt flag for the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_InterruptFlagGet(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function tests a USB On-The-Go (OTG) interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_OTG_InterruptFlagGet(MY_USB_INSTANCE,USB_OTG_INT_ANY) )
    if ( PLIB_USB_OTG_InterruptFlagGet(MY_USB_INSTANCE,USB_OTG_INT_BDEVICE_SESSION_END) )
    {
        PLIB_USB_OTG_InterruptFlagClear(MY_USB_INSTANCE,USB_OTG_INT_ADEVICE_VBUS_VALID );
        // Device A VBUS Valid Change
    }
    if ( PLIB_USB_OTG_InterruptFlagGet(MY_USB_INSTANCE,USB_OTG_INT_BDEVICE_SESSION_END) )
    {
        PLIB_USB_OTG_InterruptFlagClear(MY_USB_INSTANCE,USB_OTG_INT_BDEVICE_SESSION_END);
        // Device B VBUS Valid Change
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_OTG_InterruptFlagGet(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptFlagSet Function

Sets a USB On-The-Go (OTG) Interrupt flag for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_OTG_InterruptFlagSet(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag);
```

Returns

None.

Description

This function sets a USB On-The-Go (OTG) interrupt source flag for the USB module.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_InterruptStatus in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_OTG_InterruptFlagSet( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USB_OTG_InterruptFlagSet(USB_MODULE_ID index, USB_OTG_INTERRUPTS interruptFlag)

PLIB_USB_OTG_InterruptIsEnabled Function

Returns whether or not interrupts are enabled.

File

plib_usb.h

C

```
bool PLIB_USB_OTG_InterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag);
```

Returns

- true - Interrupts are enabled
- false - Interrupts are not enabled

Description

This function returns whether or not interrupts are enabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOTG_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if ( PLIB_USB_OTG_InterruptIsEnabled( MY_USB_INSTANCE, USB_OTG_INT_ID_STATE_CHANGE  ) )
{

}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

bool PLIB_USB_OTG_InterruptIsEnabled(USB_MODULE_ID index, USB_INTERRUPTS interruptFlag)

k) USB Activity Functions

PLIB_USB_ActivityPending Function

Returns whether or not USB activity is pending.

File

plib_usb.h

C

```
bool PLIB_USB_ActivityPending(USB_MODULE_ID index);
```

Returns

- true - The USB module should not be suspended
- false - No interrupts are pending or module may be suspended or powered down

Description

This function returns whether or not USB bus activity has been detected, an interrupt is pending, or an interrupt is yet to be generated.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsActivityPending in your application to determine whether this feature is available.

Preconditions

None.

Example

```
while ( PLIB_USB_ActivityPending(MY_USB_INSTANCE) )
{
    // Wait
}
// Suspend USB module.
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_ActivityPending (USB_MODULE_ID index)

PLIB_USB_FrameNumberGet Function

Returns the USB frame number.

File

plib_usb.h

C

```
uint16_t PLIB_USB_FrameNumberGet(USB_MODULE_ID index);
```

Returns

Current frame number in lower 11 bits.

Description

This function returns the USB frame number in the lower 11 bits.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsFrameNumber in your application to determine whether this feature is available.

Preconditions

None.

Example

```
frameNumber = PLIB_USB_FrameNumberGet(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

uint16_t PLIB_USB_FrameNumberGet (USB_MODULE_ID index)

PLIB_USB_JStateIsActive Function

Live differential receiver J State flag.

File

plib_usb.h

C

```
bool PLIB_USB_JStateIsActive(USB_MODULE_ID index);
```

Returns

None.

Description

This function indicates the live JState (differential '0' in low speed, differential '1' in full speed) on the bus.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLiveJState in your application to determine whether this feature is available.

Preconditions

The USB module must be in Host mode.

Example

```
// Enable Host Mode
PLIB_USB_OperatingModeSelect(MY_USB_INSTANCE,USB_OPMODE_HOST);

// Enable D+ and D- pull-down resistors
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DPLUS_PULLDN, true);
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DMINUS_PULLDN,true);

// Disable D+ and D- pull-up resistors
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DPLUS_PULLUP, false);
PLIB_USB_OTG_PullUpPullDownSetup(MY_USB_INSTANCE,USB_OTG_DMINUS_PULLUP,false);

// Enable SOF Packet generation
PLIB_USB_SOFEnable(MY_USB_INSTANCE);

// Enable the device attach interrupt
PLIB_USB_INT_Enable(MY_USB_INSTANCE,USB_INT_OTG,ACTIVITY_DETECT);

// Wait for the Attach interrupt.
while(!PLIB_USB_INT_FlagGet(MY_USB_INSTANCE,USB_INT_OTG,ACTIVITY_DETECT) )
{
    //Do nothing
}

// Check JState
if( PLIB_USB_JStateIsActive(MY_USB_INSTANCE) )
{
    // Full Speed
    PLIB_USB_FullSpeedEnable(MY_USB_INSTANCE);
}
else
{
    // Low Speed
    PLIB_USB_FullSpeedDisable(MY_USB_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_JStateIsActive (USB_MODULE_ID index)

PLIB_USB_PacketTransferDisable Function

Disables the Serial Interface Engine (SIE).

File

plib_usb.h

C

```
void PLIB_USB_PacketTransferDisable(USB_MODULE_ID index);
```

Returns

None.

```
  if( PLIB_USB_PacketTransferIsDisabled(MY_USB_INSTANCE) )
  {
      // SETUP token received, do the needful operations
      .
      .
      .
      // SETUP handling completed, enable Setup token and packet processing:
      PLIB_USB_PacketTransferDisable(MY_USB_INSTANCE);
  }
```

Description

This function disables the Serial Interface Engine (SIE).

Remarks

Not valid when the USB module is in Host mode. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPacketTransfer in your application to determine whether this feature is available.

Preconditions

USB module must be in device mode.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PacketTransferDisable (USB_MODULE_ID index)

PLIB_USB_PacketTransferEnable Function

Re-enables the Serial Interface Engine (SIE), allowing token and packet processing.

File

plib_usb.h

C

```
void PLIB_USB_PacketTransferEnable(USB_MODULE_ID index);
```

Returns

None.

```
  if( PLIB_USB_PacketTransferIsDisabled(MY_USB_INSTANCE) )
  {
      // SETUP token received, do the needful operations
      .
      .
      .
      // SETUP handling completed, enable Setup token and packet processing:
      PLIB_USB_PacketTransferEnable(MY_USB_INSTANCE);
  }
```

Description

This function re-enables the Serial Interface Engine (SIE), allowing token and packet processing.

Remarks

Not valid when the USB module is in Host mode. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPacketTransfer in your application to determine whether this feature is available.

Preconditions

USB module must be in device mode.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PacketTransferEnable (USB_MODULE_ID index)

PLIB_USB_PacketTransferIsDisabled Function

Indicates that a setup token has been received from the Host and that token/packet processing is disabled.

File

plib_usb.h

C

```
bool PLIB_USB_PacketTransferIsDisabled(USB_MODULE_ID index);
```

Returns

None.

Description

This function indicates that a setup token has been received from the Host and that the Serial Interface Engine (SIE) has been turned off, disabling token and packet processing.

Remarks

Not valid when USB is Host. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsPacketTransfer in your application to determine whether this feature is available.

Preconditions

USB module must be in device mode.

Example

```
if( PLIB_USB_PacketTransferIsDisabled(MY_USB_INSTANCE) )
{
    // SETUP token received, do the needful operations
    .
    .
    .
    // SETUP handling completed, enable Setup token and packet processing:
    PLIB_USB_PacketTransferEnable(MY_USB_INSTANCE);
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_PacketTransferIsDisabled (USB_MODULE_ID index)

PLIB_USB_SE0InProgress Function

Returns whether a single-ended zero event is in progress.

File

plib_usb.h

C

```
bool PLIB_USB_SE0InProgress(USB_MODULE_ID index);
```

Returns

- true - A single ended zero event (SE0) is occurring

- false - A single-ended zero event (SE0) is not occurring

Description

This function returns whether a single-ended zero event is in progress.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsLiveSingleEndedZero in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if( PLIB_USB_SE0InProgress(MY_USB_INSTANCE) )
{
    // handle the SE0 event
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_SE0InProgress(USB_MODULE_ID index)

l) External Transceiver Support Functions

PLIB_USB_I2CInterfaceForExtModuleDisable Function

Specifies external module(s) are controlled via dedicated pins.

File

plib_usb.h

C

```
void PLIB_USB_I2CInterfaceForExtModuleDisable(USB_MODULE_ID index);
```

Returns

None.

Description

Specifies that external module(s) are controlled via dedicated pins.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_I2CInterfaceForExtModuleDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_I2CInterfaceForExtModuleDisable (USB_MODULE_ID index)

PLIB_USB_I2CInterfaceForExtModuleEnable Function

Specifies external module(s) are controlled via the I2C interface.

File

plib_usb.h

C

```
void PLIB_USB_I2CInterfaceForExtModuleEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function specifies that external module(s) are controlled via the I2C interface.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_I2CInterfaceForExtModuleEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_I2CInterfaceForExtModuleEnable (USB_MODULE_ID index)

PLIB_USB_TransceiverDisable Function

Disables the on-chip transceiver

File

plib_usb.h

C

```
void PLIB_USB_TransceiverDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the on-chip transceiver and enables the interface to the off-chip transceiver.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOnChipTransceiver in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_TransceiverDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_TransceiverDisable (USB_MODULE_ID index)

PLIB_USB_TransceiverEnable Function

Enables the on-chip transceiver.

File

plib_usb.h

C

```
void PLIB_USB_TransceiverEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the on-chip transceiver. The interface to the off-chip transceiver is disabled.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsOnChipTransceiver in your application to determine whether this feature is available.

Preconditions

Use only before the USB module is enabled by calling PLIB_USB_Enable.

Example

```
PLIB_USB_TransceiverEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_TransceiverEnable (USB_MODULE_ID index)

m) VBUS Support Functions

PLIB_USB_ExternalComparatorMode2Pin Function

Sets the 2-pin input configuration for VBUS comparators.

File

plib_usb.h

C

```
void PLIB_USB_ExternalComparatorMode2Pin(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the 2-pin input configuration for VBUS Comparators.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_ExternalComparatorMode2Pin(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ExternalComparatorMode2Pin (USB_MODULE_ID index)

PLIB_USB_ExternalComparatorMode3Pin Function

Sets the 3-pin input configuration for VBUS Comparators.

File

plib_usb.h

C

```
void PLIB_USB_ExternalComparatorMode3Pin(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the 3-pin input configuration for VBUS comparators.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_ExternalComparatorMode3Pin(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_ExternalComparatorMode3Pin (USB_MODULE_ID index)

PLIB_USB_PWMCounterDisable Function

Disables the PWM counter used to generate the VBUS for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_PWMCounterDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the PWM counter used to generate the VBUS for the USB module.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMDisable(MY_USB_INSTANCE);
PLIB_USB_PWMCounterDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMCounterDisable(USB_MODULE_ID index);

PLIB_USB_PWMCounterEnable Function

Enables the PWM counter used to generate the VBUS for the USB module.

File

plib_usb.h

C

```
void PLIB_USB_PWMCounterEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the PWM counter used to generate the VBUS for the USB module.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMEnable(MY_USB_INSTANCE);
PLIB_USB_PWMCounterEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMCounterEnable(USB_MODULE_ID index)

PLIB_USB_PWMDisable Function

Disables the PWM Generator.

File

plib_usb.h

C

```
void PLIB_USB_PWMDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the PWM Generator. PWM output held in a reset state defined by PLIB_USB_PWMPolarityActiveHigh or PLIB_USB_PWMPolarityActiveLow.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMDisable (MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMDisable (USB_MODULE_ID index)

PLIB_USB_PWMEnable Function

Enables the PWM Generator.

File

plib_usb.h

C

```
void PLIB_USB_PWMEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the PWM Generator.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMEnable (USB_MODULE_ID index)

PLIB_USB_PWMPolaritiyActiveLow Function

Sets the PWM output to active-high and resets low.

File

plib_usb.h

C

```
void PLIB_USB_PWMPolaritiyActiveLow(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the PWM output to active-high and resets low.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMPolaritiyActiveLow (USB_MODULE_ID index)

PLIB_USB_PWMPolarityActiveHigh Function

Sets the PWM output to active-low and resets high.

File

plib_usb.h

C

```
void PLIB_USB_PWMPolarityActiveHigh(USB_MODULE_ID index);
```

Returns

None.

Description

This function sets the PWM output to active-low and resets high.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_PWMPolaritiy (MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PWMPolarityActiveHigh (USB_MODULE_ID index)

PLIB_USB_VBoostDisable Function

Disables the On-Chip 5V Boost Regulator Circuit Disabled bit.

File

plib_usb.h

C

```
void PLIB_USB_VBoostDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the On-Chip 5V Boost Regulator Circuit Disabled bit.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBoostDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBoostDisable (USB_MODULE_ID index)

PLIB_USB_VBoostEnable Function

Enables the On-Chip 5V Boost Regulator Circuit Enabled bit.

File

plib_usb.h

C

```
void PLIB_USB_VBoostEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the On-Chip 5V Boost Regulator Circuit Enabled bit.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBoostEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBoostEnable (USB_MODULE_ID index)

PLIB_USB_VBUSComparatorDisable Function

Disables the on-chip VBUS Comparator.

File

plib_usb.h

C

```
void PLIB_USB_VBUSComparatorDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the on-chip VBUS Comparator.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBUSComparatorDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBUSComparatorDisable (USB_MODULE_ID index)

PLIB_USB_VBUSComparatorEnable Function

Enables the on-chip VBUS Comparator.

File

plib_usb.h

C

```
void PLIB_USB_VBUSComparatorEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the on-chip VBUS Comparator.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBUSComparatorEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBUSComparatorEnable (USB_MODULE_ID index)

PLIB_USB_VBUSPullUpDisable Function

Disables the pull-up on the VBUS pin.

File

plib_usb.h

C

```
void PLIB_USB_VBUSPullUpDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the pull-up on the VBUS pin.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBUSPullUpDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBUSPullUpDisable (USB_MODULE_ID index)

PLIB_USB_VBUSPullUpEnable Function

Enables the pull-up on the VBUS pin.

File

plib_usb.h

C

```
void PLIB_USB_VBUSPullUpEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the pull-up on the VBUS pin.

Remarks

This feature is not available on all devices. Please refer to the specific device data sheet to determine whether this feature is available on your device.

Preconditions

None.

Example

```
PLIB_USB_VBUSPullUpEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_VBUSPullUpEnable (USB_MODULE_ID index)

n) Test Support Functions

PLIB_USB_EyePatternDisable Function

Disables the USB eye pattern test.

File

plib_usb.h

C

```
void PLIB_USB_EyePatternDisable(USB_MODULE_ID index);
```

Returns

None.

Description

This function disables the USB eye pattern test.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEyePattern in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EyePatternDisable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EyePatternDisable (USB_MODULE_ID index)

PLIB_USB_EyePatternEnable Function

Enables USB eye pattern test.

File

plib_usb.h

C

```
void PLIB_USB_EyePatternEnable(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables the USB eye pattern test.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsEyePattern in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_EyePatternEnable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_EyePatternEnable (USB_MODULE_ID index)

o) Other Functions

PLIB_USB_ModuleIsBusy Function

Indicates if the USB module is not ready to be enabled.

File

plib_usb.h

C

```
bool PLIB_USB_ModuleIsBusy(USB_MODULE_ID index);
```

Returns

- true - USB module is active or disabled, but not ready to be enabled
- false - USB module is not active and is ready to be enabled

Description

This function indicates if the USB module is not ready to be enabled.

Remarks

If PLIB_USB_ModuleIsBusy(MY_USB_INSTANCE) == true and the USB module is disabled, and all status returned for the module, all enables/disables for the module will produce undefined results.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsModuleBusyin your application to determine whether this feature is available.

Preconditions

None.

Example

```
#ifdef (__PIC32MX__)
  while ( PLIB_USB_ModuleIsBusy(MY_USB_INSTANCE) )
  {
      // wait
  }
#endif
  PLIB_USB_Disable(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

bool PLIB_USB_ModuleIsBusy (USB_MODULE_ID index)

PLIB_USB_PingPongFreeze Function

Resets all Ping-Pong buffer pointers to even buffers.

File

plib_usb.h

C

```
void PLIB_USB_PingPongFreeze(USB_MODULE_ID index);
```

Returns

None.

Description

This function resets all Ping-Pong buffer pointers to even buffers.

Remarks

Buffers remain "frozen" at "Even" until they are unfrozen using PLIB_USB_PingPongUnfreeze.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBufferFreeze in your application to determine whether this feature is available.

Preconditions

None.

Example

```
  // Reset all ping-pong buffers to "Even"
  PLIB_USB_PingPongFreeze(MY_USB_INSTANCE);
  PLIB_USB_PingPongUnfreeze(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PingPongFreeze (USB_MODULE_ID index)

PLIB_USB_PingPongReset Function

Resets the USB peripheral internal Ping-Pong indicator to point to even buffers.

File

plib_usb.h

C

```
void PLIB_USB_PingPongReset(USB_MODULE_ID index);
```

Returns

None.

Description

This function resets the USB peripheral internal Ping-Pong indicator to point to Even buffers.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBufferFreeze in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_USB_PingPongReset(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PingPongReset (USB_MODULE_ID index)

PLIB_USB_PingPongUnfreeze Function

Enables Ping-Pong buffering.

File

plib_usb.h

C

```
void PLIB_USB_PingPongUnfreeze(USB_MODULE_ID index);
```

Returns

None.

Description

This function enables Ping-Pong buffering.

Remarks

See PLIB_USB_PingPongFreeze. This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsBufferFreeze in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Reset all Ping-Pong buffers to "Even"
PLIB_USB_PingPongFreeze(MY_USB_INSTANCE);
PLIB_USB_PingPongUnfreeze(MY_USB_INSTANCE);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

void PLIB_USB_PingPongUnfreeze (USB_MODULE_ID index)

PLIB_USB_TokenSend Function

Sends token to the specified address.

File

plib_usb.h

C

```
void PLIB_USB_TokenSend(USB_MODULE_ID index, USB_PID pidValue, uint8_t endpoint, uint8_t deviceAddress,
bool isLowSpeed);
```

Returns

None.

Description

This function sends the specified token to the specified endpoint and address. The token is placed on the bus at the next available time. The token can be executed at low speed.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_USB_ExistsGEN_Interrupt in your application to determine whether this feature is available.

Preconditions

None.

Example

```
// Send an OUT token to endpoint 1 device address 2 at full speed
PLIB_USB_SendToken(MY_USB_INSTANCE, USB_PID_OUT, 1, 2, false);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
pidValue	PID of the token to be placed on the bus.
endpoint	Device endpoint to which the token should be sent.
isLowSpeed	Is true if the token should be executed at low speed.

Function

void PLIB_USB_TokenSend(USB_MODULE_ID index, USB_PID pidValue,

uint8_t endpoint, uint8_t deviceAddress, bool isLowSpeed);

p) Feature Existence Functions

PLIB_USB_ExistsActivityPending Function

Identifies whether the ActivityPending feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsActivityPending(USB_MODULE_ID index);
```

Returns

- true - The ActivityPending feature is supported on the device
- false - The ActivityPending feature is not supported on the device

Description

This function identifies whether the ActivityPending feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_ActivityPending

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsActivityPending(USB_MODULE_ID index)

PLIB_USB_ExistsALL_Interrupt Function

Identifies whether the ALL_Interrupt feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsALL_Interrupt(USB_MODULE_ID index);
```

Returns

- true - The ALL_Interrupt feature is supported on the device
- false - The ALL_Interrupt feature is not supported on the device

Description

This function identifies whether the ALL_Interrupt feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_AllInterruptEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsALL_Interrupt(USB_MODULE_ID index)

PLIB_USB_ExistsAutomaticSuspend Function

Identifies whether the AutomaticSuspend feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsAutomaticSuspend(USB_MODULE_ID index);
```

Returns

- true - The AutomaticSuspend feature is supported on the device
- false - The AutomaticSuspend feature is not supported on the device

Description

This function identifies whether the AutomaticSuspend feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_AutoSuspendDisable

- PLIB_USB_AutoSuspendEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsAutomaticSuspend(USB_MODULE_ID index)

PLIB_USB_ExistsBDTBaseAddress Function

Identifies whether the BDTBaseAddress feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsBDTBaseAddress(USB_MODULE_ID index);
```

Returns

- true - The BDTBaseAddress feature is supported on the device
- false - The BDTBaseAddress feature is not supported on the device

Description

This function identifies whether the BDTBaseAddress feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_BDTBaseAddressGet
- PLIB_USB_BDTBaseAddressSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsBDTBaseAddress(USB_MODULE_ID index)

PLIB_USB_ExistsBDTFunctions Function

Identifies whether the BDTFunctions feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsBDTFunctions(USB_MODULE_ID index);
```

Returns

- true - The BDTFunctions feature is supported on the device
- false - The BDTFunctions feature is not supported on the device

Description

This function identifies whether the BDTFunctions feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_BufferAddressGet
- PLIB_USB_BufferAddressSet
- PLIB_USB_BufferByteCountGet
- PLIB_USB_BufferByteCountSet
- PLIB_USB_BufferCancelReleaseToUSB
- PLIB_USB_BufferAllCancelReleaseToUSB
- PLIB_USB_BufferClearAll
- PLIB_USB_BufferDataToggleGet
- PLIB_USB_BufferDataToggleSelect
- PLIB_USB_BufferDataToggleSyncEnable
- PLIB_USB_BufferDataToggleSyncDisable
- PLIB_USB_BufferIndexGet
- PLIB_USB_BufferPIDBitsClear
- PLIB_USB_BufferPIDGet
- PLIB_USB_BufferReleasedToSW
- PLIB_USB_BufferReleaseToUSB
- PLIB_USB_BufferSchedule
- PLIB_USB_BufferStallDisable
- PLIB_USB_BufferStallEnable
- PLIB_USB_BufferStallGet
- PLIB_USB_BufferEP0RxStatusInitialize
- PLIB_USB_BufferClearAllDTSEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsBDTFunctions(USB_MODULE_ID index)

PLIB_USB_ExistsBufferFreeze Function

Identifies whether the BufferFreeze feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsBufferFreeze(USB_MODULE_ID index);
```

Returns

- true - The BufferFreeze feature is supported on the device
- false - The BufferFreeze feature is not supported on the device

Description

This function identifies whether the BufferFreeze feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_PingPongFreeze
- PLIB_USB_PingPongUnfreeze
- PLIB_USB_PingPongReset

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsBufferFreeze(USB_MODULE_ID index)

PLIB_USB_ExistsDeviceAddress Function

Identifies whether the DeviceAddress feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsDeviceAddress(USB_MODULE_ID index);
```

Returns

- true - The DeviceAddress feature is supported on the device
- false - The DeviceAddress feature is not supported on the device

Description

This function identifies whether the DeviceAddress feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_DeviceAddressSet
- PLIB_USB_DeviceAddressGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsDeviceAddress(USB_MODULE_ID index)

PLIB_USB_ExistsEP0LowSpeedConnect Function

Identifies whether the EP0LowSpeedConnect feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEP0LowSpeedConnect(USB_MODULE_ID index);
```

Returns

- true - The EP0LowSpeedConnect feature is supported on the device
- false - The EP0LowSpeedConnect feature is not supported on the device

Description

This function identifies whether the EP0LowSpeedConnect feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EP0LSDirectConnectEnable
- PLIB_USB_EP0LSDirectConnectDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEP0LowSpeedConnect(USB_MODULE_ID index)

PLIB_USB_ExistsEP0NAKRetry Function

Identifies whether the EP0NAKRetry feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEP0NAKRetry(USB_MODULE_ID index);
```

Returns

- true - The EP0NAKRetry feature is supported on the device
- false - The EP0NAKRetry feature is not supported on the device

Description

This function identifies whether the EP0NAKRetry feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EP0NakRetryEnable
- PLIB_USB_EP0NakRetryDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEP0NAKRetry(USB_MODULE_ID index)

PLIB_USB_ExistsEPnRxEnable Function

Identifies whether the EPnRxEnableEnhanced feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEPnRxEnable(USB_MODULE_ID index);
```

Returns

- true - The EPnRxEnableEnhanced feature is supported on the device
- false - The EPnRxEnableEnhanced feature is not supported on the device

Description

This function identifies whether the EPnRxEnableEnhanced feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EPnRxEnable
- PLIB_USB_EPnRxDisable
- PLIB_USB_EPnTxEnable
- PLIB_USB_EPnTxDisable
- PLIB_USB_EPnHandshakeEnable
- PLIB_USB_EPnHandshakeDisable
- PLIB_USB_EPnControlTransferEnable
- PLIB_USB_EPnControlTransferDisable
- PLIB_USB_EPnIsStalled
- PLIB_USB_EPnStallClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEPnRxEnable(USB_MODULE_ID index)

PLIB_USB_ExistsEPnTxRx Function

Identifies whether the EPnTxRx feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEPnTxRx(USB_MODULE_ID index);
```

Returns

- true - The EPnTxRx feature is supported on the device
- false - The EPnTxRx feature is not supported on the device

Description

This function identifies whether the EPnTxRx feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EPnTxSelect
- PLIB_USB_EPnRxSelect
- PLIB_USB_EPnTxRxSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEPnTxRx(USB_MODULE_ID index)

PLIB_USB_ExistsERR_Interrupt Function

Identifies whether the ERR_Interrupt feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsERR_Interrupt(USB_MODULE_ID index);
```

Returns

- true - The ERR_Interrupt feature is supported on the device
- false - The ERR_Interrupt feature is not supported on the device

Description

This function identifies whether the ERR_Interrupt feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ErrorInterruptEnable
- PLIB_USB_ErrorInterruptDisable
- PLIB_USB_ErrorInterruptIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsERR_Interrupt(USB_MODULE_ID index)

PLIB_USB_ExistsERR_InterruptStatus Function

Identifies whether the ERR_InterruptStatus feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsERR_InterruptStatus(USB_MODULE_ID index);
```

Returns

- true - The ERR_InterruptStatus feature is supported on the device
- false - The ERR_InterruptStatus feature is not supported on the device

Description

This function identifies whether the ERR_InterruptStatus feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ErrorInterruptFlagSet
- PLIB_USB_ErrorInterruptFlagClear

- PLIB_USB_ErrorInterruptFlagGet
- PLIB_USB_ErrorInterruptFlagAllGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsERR_InterruptStatus(USB_MODULE_ID index)

PLIB_USB_ExistsEyePattern Function

Identifies whether the EyePattern feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsEyePattern(USB_MODULE_ID index);
```

Returns

- true - The EyePattern feature is supported on the device
- false - The EyePattern feature is not supported on the device

Description

This function identifies whether the EyePattern feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_EyePatternDisable
- PLIB_USB_EyePatternEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsEyePattern(USB_MODULE_ID index)

PLIB_USB_ExistsFrameNumber Function

Identifies whether the FrameNumber feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsFrameNumber(USB_MODULE_ID index);
```

Returns

- true - The FrameNumber feature is supported on the device

- false - The FrameNumber feature is not supported on the device

Description

This function identifies whether the FrameNumber feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_FrameNumberGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsFrameNumber(USB_MODULE_ID index)

PLIB_USB_ExistsGEN_Interrupt Function

Identifies whether the GEN_Interrupt feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsGEN_Interrupt(USB_MODULE_ID index);
```

Returns

- true - The GEN_Interrupt feature is supported on the device
- false - The GEN_Interrupt feature is not supported on the device

Description

This function identifies whether the GEN_Interrupt feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_InterruptEnable
- PLIB_USB_InterruptDisable
- PLIB_USB_InterruptIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsGEN_Interrupt(USB_MODULE_ID index)

PLIB_USB_ExistsGEN_InterruptStatus Function

Identifies whether the GEN_InterruptStatus feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsGEN_InterruptStatus(USB_MODULE_ID index);
```

Returns

- true - The GEN_InterruptStatus feature is supported on the device
- false - The GEN_InterruptStatus feature is not supported on the device

Description

This function identifies whether the GEN_InterruptStatus feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_InterruptFlagSet
- PLIB_USB_InterruptFlagClear
- PLIB_USB_InterruptFlagGet
- PLIB_USB_InterruptFlagAllGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsGEN_InterruptStatus(USB_MODULE_ID index)

PLIB_USB_ExistsHostBusyWithToken Function

Identifies whether the HostBusyWithToken feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsHostBusyWithToken(USB_MODULE_ID index);
```

Returns

- true - The HostBusyWithToken feature is supported on the device
- false - The HostBusyWithToken feature is not supported on the device

Description

This function identifies whether the HostBusyWithToken feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_IsBusyWithToken

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsHostBusyWithToken(USB_MODULE_ID index)

PLIB_USB_ExistsHostGeneratesReset Function

Identifies whether the HostGeneratesReset feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsHostGeneratesReset(USB_MODULE_ID index);
```

Returns

- true - The HostGeneratesReset feature is supported on the device
- false - The HostGeneratesReset feature is not supported on the device

Description

This function identifies whether the HostGeneratesReset feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ResetSignalEnable
- PLIB_USB_ResetSignalDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsHostGeneratesReset(USB_MODULE_ID index)

PLIB_USB_ExistsLastDirection Function

Identifies whether the LastDirection feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLastDirection(USB_MODULE_ID index);
```

Returns

- true - The LastDirection feature is supported on the device
- false - The LastDirection feature is not supported on the device

Description

This function identifies whether the LastDirection feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_LastTransactionDirectionGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLastDirection(USB_MODULE_ID index)

PLIB_USB_ExistsLastEndpoint Function

Identifies whether the LastEndpoint feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLastEndpoint(USB_MODULE_ID index);
```

Returns

- true - The LastEndpoint feature is supported on the device
- false - The LastEndpoint feature is not supported on the device

Description

This function identifies whether the LastEndpoint feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_LastTransactionEndPtGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLastEndpoint(USB_MODULE_ID index)

PLIB_USB_ExistsLastPingPong Function

Identifies whether the LastPingPong feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLastPingPong(USB_MODULE_ID index);
```

Returns

- true - The LastPingPong feature is supported on the device
- false - The LastPingPong feature is not supported on the device

Description

This function identifies whether the LastPingPong feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_LastTransactionPingPongStateGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLastPingPong(USB_MODULE_ID index)

PLIB_USB_ExistsLastTransactionDetails Function

Identifies whether the LastTransactionDetails feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLastTransactionDetails(USB_MODULE_ID index);
```

Returns

- true - The LastTransactionDetails feature is supported on the device
- false - The LastTransactionDetails feature is not supported on the device

Description

This function identifies whether the LastTransactionDetails feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_LastTransactionDetailsGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLastTransactionDetails(USB_MODULE_ID index)

PLIB_USB_ExistsLiveJState Function

Identifies whether the LiveJState feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLiveJState(USB_MODULE_ID index);
```

Returns

- true - The LiveJState feature is supported on the device
- false - The LiveJState feature is not supported on the device

Description

This function identifies whether the LiveJState feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_JStateIsActive

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLiveJState(USB_MODULE_ID index)

PLIB_USB_ExistsLiveSingleEndedZero Function

Identifies whether the LiveSingleEndedZero feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsLiveSingleEndedZero(USB_MODULE_ID index);
```

Returns

- true - The LiveSingleEndedZero feature is supported on the device
- false - The LiveSingleEndedZero feature is not supported on the device

Description

This function identifies whether the LiveSingleEndedZero feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_SE0InProgress

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsLiveSingleEndedZero(USB_MODULE_ID index)

PLIB_USB_ExistsModuleBusy Function

Identifies whether the ModuleBusy feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsModuleBusy(USB_MODULE_ID index);
```

Returns

- true - The ModuleBusy feature is supported on the device
- false - The ModuleBusy feature is not supported on the device

Description

This function identifies whether the ModuleBusy feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ModuleIsBusy

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsModuleBusy(USB_MODULE_ID index)

PLIB_USB_ExistsModulePower Function

Identifies whether the ModulePower feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsModulePower(USB_MODULE_ID index);
```

Returns

- true - The ModulePower feature is supported on the device
- false - The ModulePower feature is not supported on the device

Description

This function identifies whether the ModulePower feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_Enable
- PLIB_USB_Disable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsModulePower(USB_MODULE_ID index)

PLIB_USB_ExistsNextTokenSpeed Function

Identifies whether the NextTokenSpeed feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsNextTokenSpeed(USB_MODULE_ID index);
```

Returns

- true - The NextTokenSpeed feature is supported on the device
- false - The NextTokenSpeed feature is not supported on the device

Description

This function identifies whether the NextTokenSpeed feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_TokenSpeedSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsNextTokenSpeed(USB_MODULE_ID index)

PLIB_USB_ExistsOnChipPullup Function

Identifies whether the OnChipPullup feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOnChipPullup(USB_MODULE_ID index);
```

Returns

- true - The OnChipPullup feature is supported on the device
- false - The OnChipPullup feature is not supported on the device

Description

This function identifies whether the OnChipPullup feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OnChipPullUpDisable
- PLIB_USB_OnChipPullUpEnable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOnChipPullup(USB_MODULE_ID index)

PLIB_USB_ExistsOnChipTransceiver Function

Identifies whether the OnChipTransceiver feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOnChipTransceiver(USB_MODULE_ID index);
```

Returns

- true - The OnChipTransceiver feature is supported on the device
- false - The OnChipTransceiver feature is not supported on the device

Description

This function identifies whether the OnChipTransceiver feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_TransceiverEnable
- PLIB_USB_TransceiverDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOnChipTransceiver(USB_MODULE_ID index)

PLIB_USB_ExistsOpModeSelect Function

Identifies whether the OpModeSelect feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOpModeSelect(USB_MODULE_ID index);
```

Returns

- true - The OpModeSelect feature is supported on the device
- false - The OpModeSelect feature is not supported on the device

Description

This function identifies whether the OpModeSelect feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OperatingModeSelect

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOpModeSelect(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_ASessionValid Function

Identifies whether the OTG_ASessionValid feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_ASessionValid(USB_MODULE_ID index);
```

Returns

- true - The OTG_ASessionValid feature is supported on the device
- false - The OTG_ASessionValid feature is not supported on the device

Description

This function identifies whether the OTG_ASessionValid feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_VBusValid

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_ASessionValid(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_BSessionEnd Function

Identifies whether the OTG_BSessionEnd feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_BSessionEnd(USB_MODULE_ID index);
```

Returns

- true - The OTG_BSessionEnd feature is supported on the device
- false - The OTG_BSessionEnd feature is not supported on the device

Description

This function identifies whether the OTG_BSessionEnd feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_BSessionHasEnded

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_BSessionEnd(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_IDPinState Function

Identifies whether the OTG_IDPinState feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_IDPinState(USB_MODULE_ID index);
```

Returns

- true - The OTG_IDPinState feature is supported on the device
- false - The OTG_IDPinState feature is not supported on the device

Description

This function identifies whether the OTG_IDPinState feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_IDPinStateIsTypeA

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_IDPinState(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_Interrupt Function

Identifies whether the OTG_Interrupt feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_Interrupt(USB_MODULE_ID index);
```

Returns

- true - The OTG_Interrupt feature is supported on the device
- false - The OTG_Interrupt feature is not supported on the device

Description

This function identifies whether the OTG_Interrupt feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_InterruptEnable
- PLIB_USB_OTG_InterruptDisable
- PLIB_USB_OTG_InterruptIsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_Interrupt(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_InterruptStatus Function

Identifies whether the OTG_InterruptStatus feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_InterruptStatus(USB_MODULE_ID index);
```

Returns

- true - The OTG_InterruptStatus feature is supported on the device
- false - The OTG_InterruptStatus feature is not supported on the device

Description

This function identifies whether the OTG_InterruptStatus feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_InterruptFlagSet
- PLIB_USB_OTG_InterruptFlagClear
- PLIB_USB_OTG_InterruptFlagGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_InterruptStatus(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_LineState Function

Identifies whether the OTG_LineState feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_LineState(USB_MODULE_ID index);
```

Returns

- true - The OTG_LineState feature is supported on the device
- false - The OTG_LineState feature is not supported on the device

Description

This function identifies whether the OTG_LineState feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_LineStateIsStable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_LineState(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_PullUpPullDown Function

Identifies whether the OTG_PullUpPullDown feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_PullUpPullDown(USB_MODULE_ID index);
```

Returns

- true - The OTG_PullUpPullDown feature is supported on the device
- false - The OTG_PullUpPullDown feature is not supported on the device

Description

This function identifies whether the OTG_PullUpPullDown feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_PullUpPullDownSetup

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_PullUpPullDown(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_SessionValid Function

Identifies whether the OTG_SessionValid feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_SessionValid(USB_MODULE_ID index);
```

Returns

- true - The OTG_SessionValid feature is supported on the device
- false - The OTG_SessionValid feature is not supported on the device

Description

This function identifies whether the OTG_SessionValid feature is available on the USB module. When this function returns true, this function is supported on the device:

- PLIB_USB_OTG_SessionValid

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_SessionValid(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_VbusCharge Function

Identifies whether the OTG_VbusCharge feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_VbusCharge(USB_MODULE_ID index);
```

Returns

- true - The OTG_VbusCharge feature is supported on the device
- false - The OTG_VbusCharge feature is not supported on the device

Description

This function identifies whether the OTG_VbusCharge feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_VBusChargeEnable
- PLIB_USB_OTG_VBusChargeDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_VbusCharge(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_VbusDischarge Function

Identifies whether the OTG_VbusDischarge feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_VbusDischarge(USB_MODULE_ID index);
```

Returns

- true - The OTG_VbusDischarge feature is supported on the device
- false - The OTG_VbusDischarge feature is not supported on the device

Description

This function identifies whether the OTG_VbusDischarge feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_VBusDischargeEnable
- PLIB_USB_OTG_VBusDischargeDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_VbusDischarge(USB_MODULE_ID index)

PLIB_USB_ExistsOTG_VbusPowerOnOff Function

Identifies whether the OTG_VbusPowerOnOff feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsOTG_VbusPowerOnOff(USB_MODULE_ID index);
```

Returns

- true - The OTG_VbusPowerOnOff feature is supported on the device
- false - The OTG_VbusPowerOnOff feature is not supported on the device

Description

This function identifies whether the OTG_VbusPowerOnOff feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_OTG_VBusPowerOff
- PLIB_USB_OTG_VBusPowerOn

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsOTG_VbusPowerOnOff(USB_MODULE_ID index)

PLIB_USB_ExistsPacketTransfer Function

Identifies whether the PacketTransfer feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsPacketTransfer(USB_MODULE_ID index);
```

Returns

- true - The PacketTransfer feature is supported on the device
- false - The PacketTransfer feature is not supported on the device

Description

This function identifies whether the PacketTransfer feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_PacketTransferIsDisabled
- PLIB_USB_PacketTransferEnable
- PLIB_USB_PacketTransferDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsPacketTransfer(USB_MODULE_ID index)

PLIB_USB_ExistsPingPongMode Function

Identifies whether the PingPongMode feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsPingPongMode(USB_MODULE_ID index);
```

Returns

- true - The PingPongMode feature is supported on the device
- false - The PingPongMode feature is not supported on the device

Description

This function identifies whether the PingPongMode feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_PingPongModeSelect
- PLIB_USB_PingPongModeGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsPingPongMode(USB_MODULE_ID index)

PLIB_USB_ExistsResumeSignaling Function

Identifies whether the ResumeSignaling feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsResumeSignaling(USB_MODULE_ID index);
```

Returns

- true - The ResumeSignaling feature is supported on the device
- false - The ResumeSignaling feature is not supported on the device

Description

This function identifies whether the ResumeSignaling feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_ResumeSignalingEnable
- PLIB_USB_ResumeSignalingDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsResumeSignaling(USB_MODULE_ID index)

PLIB_USB_ExistsSleepEntryGuard Function

Identifies whether the SleepEntryGuard feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsSleepEntryGuard(USB_MODULE_ID index);
```

Returns

- true - The SleepEntryGuard feature is supported on the device
- false - The SleepEntryGuard feature is not supported on the device

Description

This function identifies whether the SleepEntryGuard feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_SleepGuardEnable
- PLIB_USB_SleepGuardDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsSleepEntryGuard(USB_MODULE_ID index)

PLIB_USB_ExistsSOFThreshold Function

Identifies whether the SOFThreshold feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsSOFThreshold(USB_MODULE_ID index);
```

Returns

- true - The SOFThreshold feature is supported on the device
- false - The SOFThreshold feature is not supported on the device

Description

This function identifies whether the SOFThreshold feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_SOFThresholdGet
- PLIB_USB_SOFThresholdSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsSOFThreshold(USB_MODULE_ID index)

PLIB_USB_ExistsSpeedControl Function

Identifies whether the SpeedControl feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsSpeedControl(USB_MODULE_ID index);
```

Returns

- true - The SpeedControl feature is supported on the device
- false - The SpeedControl feature is not supported on the device

Description

This function identifies whether the SpeedControl feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_FullSpeedEnable
- PLIB_USB_FullSpeedDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsSpeedControl(USB_MODULE_ID index)

PLIB_USB_ExistsStartOfFrames Function

Identifies whether the StartOfFrames feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsStartOfFrames(USB_MODULE_ID index);
```

Returns

- true - The StartOfFrames feature is supported on the device
- false - The StartOfFrames feature is not supported on the device

Description

This function identifies whether the StartOfFrames feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_SOFEnable
- PLIB_USB_SOFDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsStartOfFrames(USB_MODULE_ID index)

PLIB_USB_ExistsStopInIdle Function

Identifies whether the StopInIdle feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsStopInIdle(USB_MODULE_ID index);
```

Returns

- true - The StopInIdle feature is supported on the device
- false - The StopInIdle feature is not supported on the device

Description

This function identifies whether the StopInIdle feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_StopInIdleEnable
- PLIB_USB_StopInIdleDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsStopInIdle(USB_MODULE_ID index)

PLIB_USB_ExistsSuspend Function

Identifies whether the Suspend feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsSuspend(USB_MODULE_ID index);
```

Returns

- true - The Suspend feature is supported on the device
- false - The Suspend feature is not supported on the device

Description

This function identifies whether the Suspend feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_SuspendEnable
- PLIB_USB_SuspendDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsSuspend(USB_MODULE_ID index)

PLIB_USB_ExistsTokenEP Function

Identifies whether the TokenEP feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsTokenEP(USB_MODULE_ID index);
```

Returns

- true - The TokenEP feature is supported on the device
- false - The TokenEP feature is not supported on the device

Description

This function identifies whether the TokenEP feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_TokenEPGet
- PLIB_USB_TokenEPSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsTokenEP(USB_MODULE_ID index)

PLIB_USB_ExistsTokenPID Function

Identifies whether the TokenPID feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsTokenPID(USB_MODULE_ID index);
```

Returns

- true - The TokenPID feature is supported on the device
- false - The TokenPID feature is not supported on the device

Description

This function identifies whether the TokenPID feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_TokenPIDGet
- PLIB_USB_TokenPIDSet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsTokenPID(USB_MODULE_ID index)

PLIB_USB_ExistsUOEMonitor Function

Identifies whether the UOEMonitor feature exists on the USB module.

File

plib_usb.h

C

```
bool PLIB_USB_ExistsUOEMonitor(USB_MODULE_ID index);
```

Returns

- true - The UOEMonitor feature is supported on the device
- false - The UOEMonitor feature is not supported on the device

Description

This function identifies whether the UOEMonitor feature is available on the USB module. When this function returns true, these functions are supported on the device:

- PLIB_USB_UOEMonitorEnable
- PLIB_USB_UOEMonitorDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USB_ExistsUOEMonitor(USB_MODULE_ID index)

q) Data Types and Constants

USB_BUFFER_DATA01 Enumeration

Provides enumeration data toggle for a buffer.

File

plib_usb.h

C

```
typedef enum {
  USB_BUFFER_DATA0,
  USB_BUFFER_DATA1
} USB_BUFFER_DATA01;
```

Members

Members	Description
USB_BUFFER_DATA0	DATA0/1 = 0
USB_BUFFER_DATA1	DATA0/1 = 1

Description

USB Endpoint Buffer Data Toggle Enumeration

This data type provides enumeration data toggle for a buffer.

Remarks

None.

USB_BUFFER_DIRECTION Enumeration

Provides enumeration transmit/receive direction for a buffer.

File

plib_usb.h

C

```
typedef enum {
  USB_BUFFER_RX,
  USB_BUFFER_TX
} USB_BUFFER_DIRECTION;
```

Members

Members	Description
USB_BUFFER_RX	Receive
USB_BUFFER_TX	Transmit

Description

USB Endpoint Buffer Direction Enumeration

This data type provides enumeration transmit/receive direction for a buffer.

Remarks

None.

USB_BUFFER_PING_PONG Enumeration

Enumerates the ping-pong buffer (Even vs. Odd).

File

plib_usb.h

C

```
typedef enum {
  USB_BUFFER_EVEN,
  USB_BUFFER_ODD
} USB_BUFFER_PING_PONG;
```

Members

Members	Description
USB_BUFFER_EVEN	Even Buffer
USB_BUFFER_ODD	Odd Buffer

Description

Enumeration of USB Buffer Ping-Pong

This data type enumerates the ping-pong buffer (Even vs. Odd).

Remarks

None.

USB_BUFFER_SCHEDULE_DATA01 Enumeration

Provides enumeration data toggle for a buffer.

File

plib_usb.h

C

```
typedef enum {
  USB_BUFFER_DONTCHANGE,
  USB_BUFFER_SET_DATA0,
```

```
  USB_BUFFER_SET_DATA1
} USB_BUFFER_SCHEDULE_DATA01;
```

Members

Members	Description
USB_BUFFER_DONTCHANGE	Don't Change DATA0/1
USB_BUFFER_SET_DATA0	DATA0/1 = 0
USB_BUFFER_SET_DATA1	DATA0/1 = 1

Description

USB Endpoint Buffer Data Toggle Enumeration for Buffer Schedulint

This data type provides enumeration data toggle for a buffer.

Remarks

None.

USB_EP_TXRX Enumeration

Provides enumeration transmit/receive setup for an endpoint.

File

plib_usb.h

C

```
typedef enum {
  USB_EP_NOTXRX,
  USB_EP_RX,
  USB_EP_TX,
  USB_EP_TX_RX
} USB_EP_TXRX;
```

Members

Members	Description
USB_EP_NOTXRX	Nothing enabled for endpoint
USB_EP_RX	Receive enabled for endpoint
USB_EP_TX	Transmit enabled for endpoint
USB_EP_TX_RX	Transmit and Receive enabled for endpoint

Description

Enumeration of USB Endpoint Transmit/Receive Setup

This data type provides enumeration transmit/receive setup for an endpoint.

Remarks

None.

USB_OPMODES Enumeration

Provides enumeration of operating modes supported by USB.

File

plib_usb.h

C

```
typedef enum {
  USB_OPMODE_NONE,
  USB_OPMODE_DEVICE,
  USB_OPMODE_HOST,
  USB_OPMODE_OTG
} USB_OPMODES;
```

Members

Members	Description
USB_OPMODE_NONE	None
USB_OPMODE_DEVICE	Device
USB_OPMODE_HOST	Host
USB_OPMODE_OTG	OTG

Description

USB Operating Modes Enumeration

This data type provides enumeration of the operating modes supported by the USB module.

Remarks

None.

USB_OTG_INTERRUPTS Enumeration

Provides enumeration of interrupts related to the USB On-The-Go (OTG) module.

File

plib_usb.h

C

```
typedef enum {
  USB_OTG_INT_ADEVICE_VBUS_VALID,
  USB_OTG_INT_OTG_RESERVED,
  USB_OTG_INT_BDEVICE_SESSION_END,
  USB_OTG_INT_SESSION_VALID,
  USB_OTG_INT_ACTIVITY_DETECT,
  USB_OTG_INT_STABLE_LINE_STATE,
  USB_OTG_INT_ONE_MS_TIMEOUT,
  USB_OTG_INT_ID_STATE_CHANGE,
  USB_OTG_INT_ANY,
  USB_OTG_INT_ALL
} USB_OTG_INTERRUPTS;
```

Members

Members	Description
USB_OTG_INT_ADEVICE_VBUS_VALID	State of (VBUS > Va_vbus_vld) on the A device has changed
USB_OTG_INT_OTG_RESERVED	Reserved. Don't use.
USB_OTG_INT_BDEVICE_SESSION_END	State of (VBUS < Vb_sess_end) on the B device has changed
USB_OTG_INT_SESSION_VALID	State of (VBUS > Va_sess_vld) on the A or B devices has changed
USB_OTG_INT_ACTIVITY_DETECT	Activity detected on the D+, D-, ID, or VBUS lines
USB_OTG_INT_STABLE_LINE_STATE	USB line state has been stable for 1 ms, but different from last time
USB_OTG_INT_ONE_MS_TIMEOUT	One millisecond timer has expired
USB_OTG_INT_ID_STATE_CHANGE	Change in state of ID pin detected.
USB_OTG_INT_ANY	All or Any of the above
USB_OTG_INT_ALL	All or Any of the above

Description

USB OTG Interrupts Enumeration

This data type provides enumeration of interrupts related to the USB OTG module.

Remarks

Not applicable if the USB OTG module is not enabled.

USB_OTG_PULL_UP_PULL_DOWN Enumeration

USB OTG pull-Up and pull-Down resistors for D+ and D- .

File

plib_usb.h

C

```
typedef enum {
  USB_OTG_DPLUS_PULLUP,
  USB_OTG_DMINUS_PULLUP,
  USB_OTG_DPLUS_PULLDN,
  USB_OTG_DMINUS_PULLDN
} USB_OTG_PULL_UP_PULL_DOWN;
```

Members

Members	Description
USB_OTG_DPLUS_PULLUP	D+ Pull-Up
USB_OTG_DMINUS_PULLUP	D- Pull-Up
USB_OTG_DPLUS_PULLDN	D+ Pull-Down
USB_OTG_DMINUS_PULLDN	D- Pull-Down

Description

Enumeration of Pull-Up and Pull-Down Resistors for OTG

This data type enumerates the OTG Pull-Up and Pull-Down resistors for D+ and D- .

Remarks

None.

USB_PID Enumeration

Legal PID values.

File

plib_usb.h

C

```
typedef enum {
  USB_PID_SETUP,
  USB_PID_IN,
  USB_PID_OUT
} USB_PID;
```

Members

Members	Description
USB_PID_SETUP	Setup token
USB_PID_IN	IN token
USB_PID_OUT	OUT token

Description

Enumeration of Legal Packet IDs (PIDs)

This data type enumerates the valid (i.e., legal) PID values. While the PID field is four bits long, only these values are legal and should be used. The use of any other values may cause unpredictable results.

USB_PING_PONG_MODE Enumeration

Supports the four modes of ping-pong buffering.

File

plib_usb.h

C

```
typedef enum {
  USB_PING_PONG_ALL_BUT_EP0,
  USB_PING_PONG_FULL_PING_PONG,
  USB_PING_PONG_EP0_OUT_ONLY,
```

```
  USB_PING_PONG_NO_PING_PONG
} USB_PING_PONG_MODE;
```

Members

Members	Description
USB_PING_PONG_ALL_BUT_EP0	Ping-Pong buffering on all endpoints except Endpoint Zero
USB_PING_PONG_FULL_PING_PONG	Ping-Pong buffering on all endpoints
USB_PING_PONG_EP0_OUT_ONLY	Ping-Pong buffering on just Endpoint Zero transmit
USB_PING_PONG_NO_PING_PONG	No ping-pong buffering

Description

Enumeration of USB Ping-Pong Modes

This data type supports the four modes of ping-pong buffering.

Remarks

None.

USB_PING_PONG_STATE Enumeration

Decodes which buffer (Even vs. Odd) was used for the last transaction.

File

plib_usb.h

C

```
typedef enum {
  USB_PING_PONG_EVEN,
  USB_PING_PONG_ODD
} USB_PING_PONG_STATE;
```

Members

Members	Description
USB_PING_PONG_EVEN	Last transaction on Even Buffer
USB_PING_PONG_ODD	Last transaction on Odd Buffer

Description

Enumeration of USB Ping-Pong Indicator

This data type decodes which buffer (Even vs. Odd) was used for the last transaction.

Remarks

None.

USB_TOKEN_SPEED Enumeration

Provides enumeration of available token speeds.

File

plib_usb.h

C

```
typedef enum {
  USB_LOWSPEED_TOKENS,
  USB_FULLSPEED_TOKENS
} USB_TOKEN_SPEED;
```

Members

Members	Description
USB_LOWSPEED_TOKENS	Low Speed Tokens
USB_FULLSPEED_TOKENS	Full Speed Tokens

Description

USB Token Speeds Enumeration

This data type provides enumeration of available token speeds.

Remarks

For Host mode only.

USB_MAX_EP_NUMBER Macro

Maximum number of endpoints supported (not including EP0).

File

plib_usb.h

C

```
#define USB_MAX_EP_NUMBER 15
```

Description

Maximum number of endpoints

This constant defines the maximum number of endpoints supported (not including EP0). It is used in dimensioning the Buffer Descriptor Table (BDT) array.

Files

Files

Name	Description
plib_usb.h	USB Peripheral Library Interface Header for common definitions

Description

This section lists the source and header files used by the library.

plib_usb.h

USB Peripheral Library Interface Header for common definitions

Enumerations

	Name	Description
	USB_BUFFER_DATA01	Provides enumeration data toggle for a buffer.
	USB_BUFFER_DIRECTION	Provides enumeration transmit/receive direction for a buffer.
	USB_BUFFER_PING_PONG	Enumerates the ping-pong buffer (Even vs. Odd).
	USB_BUFFER_SCHEDULE_DATA01	Provides enumeration data toggle for a buffer.
	USB_EP_TXRX	Provides enumeration transmit/receive setup for an endpoint.
	USB_OPMODES	Provides enumeration of operating modes supported by USB.
	USB_OTG_INTERRUPTS	Provides enumeration of interrupts related to the USB On-The-Go (OTG) module.
	USB_OTG_PULL_UP_PULL_DOWN	USB OTG pull-Up and pull-Down resistors for D+ and D- .
	USB_PID	Legal PID values.
	USB_PING_PONG_MODE	Supports the four modes of ping-pong buffering.
	USB_PING_PONG_STATE	Decodes which buffer (Even vs. Odd) was used for the last transaction.
	USB_TOKEN_SPEED	Provides enumeration of available token speeds.

Functions

	Name	Description
	PLIB_USB_ActivityPending	Returns whether or not USB activity is pending.
	PLIB_USB_AllInterruptEnable	Configures the USB peripheral general interrupts, error interrupts and OTG interrupts.
	PLIB_USB_AutoSuspendDisable	Disables USB OTG Auto-suspend mode.
	PLIB_USB_AutoSuspendEnable	Enables USB Auto-suspend mode.

	PLIB_USB_BDTBaseAddressGet	Returns the base address of the Buffer Descriptor Table.
	PLIB_USB_BDTBaseAddressSet	Sets the base address for the Buffer Descriptor Table for PIC32 devices.
	PLIB_USB_BufferAddressGet	Gets the memory address of an endpoint buffer.
	PLIB_USB_BufferAddressSet	Sets the endpoint buffer address.
	PLIB_USB_BufferAllCancelReleaseToUSB	Cancels all endpoint buffer releases to the USB module and hands over the buffer to the CPU.
	PLIB_USB_BufferByteCountGet	Returns the endpoint buffer byte count.
	PLIB_USB_BufferByteCountSet	Sets the buffer byte count.
	PLIB_USB_BufferCancelReleaseToUSB	Cancels release of the endpoint buffer by software, allowing software to again access the buffer.
	PLIB_USB_BufferClearAll	Clears (zeros out) entries in the Buffer Descriptor Table.
	PLIB_USB_BufferClearAllDTSEnable	Clears the endpoint descriptor entry and enables data toggle synchronization.
	PLIB_USB_BufferDataToggleGet	Returns data synchronization (DATA0 or DATA1) for the endpoint buffer.
	PLIB_USB_BufferDataToggleSelect	Sets the endpoint buffer to DATA0 or DATA1.
	PLIB_USB_BufferDataToggleSyncDisable	Disables DATA0/DATA1 synchronization between the device and host.
	PLIB_USB_BufferDataToggleSyncEnable	Enables DATA0/DATA1 synchronization between the device and host.
	PLIB_USB_BufferEP0RxStatusInitialize	Initializes the Endpoint 0 RX endpoint buffer descriptors.
	PLIB_USB_BufferIndexGet	Gets the Buffer Descriptor Table index for a buffer.
	PLIB_USB_BufferPIDBitsClear	Clears the Buffer Status bits in the Buffer Descriptor Table.
	PLIB_USB_BufferPIDGet	Returns the token packet ID (PID) from the endpoint buffer status.
	PLIB_USB_BufferReleasedToSW	Returns the boolean flag value of 'true' when the buffer has been released by the USB module.
	PLIB_USB_BufferReleaseToUSB	Releases the endpoint buffer by software, allowing the USB module access to the buffer.
	PLIB_USB_BufferSchedule	Hands over a buffer to the USB module along with the buffer address and byte count.
	PLIB_USB_BufferStallDisable	Disables STALL handshaking for the associated endpoint buffer.
	PLIB_USB_BufferStallEnable	Enables STALL handshaking for the associated endpoint buffer.
	PLIB_USB_BufferStallGet	Returns the buffer stall status for an endpoint/direction/ping-pong.
	PLIB_USB_DeviceAddressGet	Returns the address of the USB module in Device mode.
	PLIB_USB_DeviceAddressSet	Sets the USB Device's address.
	PLIB_USB_Disable	Disables (powers down) the USB module.
	PLIB_USB_Enable	Enables (powers up) the USB module.
	PLIB_USB_EP0HostSetup	Sends token to the specified address.
	PLIB_USB_EP0LSDirectConnectDisable	Disables direct connection to a low-speed device for Endpoint 0.
	PLIB_USB_EP0LSDirectConnectEnable	Enables direct connection to a low-speed device for Endpoint 0.
	PLIB_USB_EP0NakRetryDisable	Disables retrying of NAKed transactions.
	PLIB_USB_EP0NakRetryEnable	Enables retrying NAK'd transactions for Endpoint 0.
	PLIB_USB_EPnAttributesClear	Clears the set attributes of the specified endpoint.
	PLIB_USB_EPnAttributesSet	Configures attributes of the endpoint such as direction, handshake capability and direction.
	PLIB_USB_EPnControlTransferDisable	Disables endpoint control transfers.
	PLIB_USB_EPnControlTransferEnable	Enables endpoint control transfers.
	PLIB_USB_EPnDirectionDisable	Disables the specified endpoint direction.
	PLIB_USB_EPnHandshakeDisable	Disables endpoint handshaking.
	PLIB_USB_EPnHandshakeEnable	Enables endpoint handshaking.
	PLIB_USB_EPnIsStalled	Tests whether the endpoint epValue is stalled.
	PLIB_USB_EPnRxDisable	Disables an endpoint's ability to process IN tokens.
	PLIB_USB_EPnRxEnable	Enables an endpoint to process IN tokens.
	PLIB_USB_EPnRxSelect	Selects receive capabilities of an endpoint.
	PLIB_USB_EPnStallClear	Clears an endpoint's stalled flag.
	PLIB_USB_EPnTxDisable	Disables an endpoint's ability to process OUT tokens.
	PLIB_USB_EPnTxEnable	Enables an endpoint to process OUT tokens.
	PLIB_USB_EPnTxRxSelect	Selects transmit and/or receive capabilities of an endpoint.
	PLIB_USB_EPnTxSelect	Selects transmit capabilities of an endpoint.
	PLIB_USB_ErrorInterruptDisable	Disables an error interrupt for the USB module.

	PLIB_USB_ErrorInterruptEnable	Enables an error interrupt for the USB module.
	PLIB_USB_ErrorInterruptFlagAllGet	Returns a logically ORed bit map of active error interrupt flags.
	PLIB_USB_ErrorInterruptFlagClear	Clears an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptFlagGet	Tests an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptFlagSet	Sets an error interrupt flag for the USB module.
	PLIB_USB_ErrorInterruptIsEnabled	Returns true if interrupts are enabled.
	PLIB_USB_ExistsActivityPending	Identifies whether the ActivityPending feature exists on the USB module.
	PLIB_USB_ExistsALL_Interrupt	Identifies whether the ALL_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsAutomaticSuspend	Identifies whether the AutomaticSuspend feature exists on the USB module.
	PLIB_USB_ExistsBDTBaseAddress	Identifies whether the BDTBaseAddress feature exists on the USB module.
	PLIB_USB_ExistsBDTFunctions	Identifies whether the BDTFunctions feature exists on the USB module.
	PLIB_USB_ExistsBufferFreeze	Identifies whether the BufferFreeze feature exists on the USB module.
	PLIB_USB_ExistsDeviceAddress	Identifies whether the DeviceAddress feature exists on the USB module.
	PLIB_USB_ExistsEP0LowSpeedConnect	Identifies whether the EP0LowSpeedConnect feature exists on the USB module.
	PLIB_USB_ExistsEP0NAKRetry	Identifies whether the EP0NAKRetry feature exists on the USB module.
	PLIB_USB_ExistsEPnRxEnable	Identifies whether the EPnRxEnableEnhanced feature exists on the USB module.
	PLIB_USB_ExistsEPnTxRx	Identifies whether the EPnTxRx feature exists on the USB module.
	PLIB_USB_ExistsERR_Interrupt	Identifies whether the ERR_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsERR_InterruptStatus	Identifies whether the ERR_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsEyePattern	Identifies whether the EyePattern feature exists on the USB module.
	PLIB_USB_ExistsFrameNumber	Identifies whether the FrameNumber feature exists on the USB module.
	PLIB_USB_ExistsGEN_Interrupt	Identifies whether the GEN_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsGEN_InterruptStatus	Identifies whether the GEN_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsHostBusyWithToken	Identifies whether the HostBusyWithToken feature exists on the USB module.
	PLIB_USB_ExistsHostGeneratesReset	Identifies whether the HostGeneratesReset feature exists on the USB module.
	PLIB_USB_ExistsLastDirection	Identifies whether the LastDirection feature exists on the USB module.
	PLIB_USB_ExistsLastEndpoint	Identifies whether the LastEndpoint feature exists on the USB module.
	PLIB_USB_ExistsLastPingPong	Identifies whether the LastPingPong feature exists on the USB module.
	PLIB_USB_ExistsLastTransactionDetails	Identifies whether the LastTransactionDetails feature exists on the USB module.
	PLIB_USB_ExistsLiveJState	Identifies whether the LiveJState feature exists on the USB module.
	PLIB_USB_ExistsLiveSingleEndedZero	Identifies whether the LiveSingleEndedZero feature exists on the USB module.
	PLIB_USB_ExistsModuleBusy	Identifies whether the ModuleBusy feature exists on the USB module.
	PLIB_USB_ExistsModulePower	Identifies whether the ModulePower feature exists on the USB module.
	PLIB_USB_ExistsNextTokenSpeed	Identifies whether the NextTokenSpeed feature exists on the USB module.
	PLIB_USB_ExistsOnChipPullup	Identifies whether the OnChipPullup feature exists on the USB module.
	PLIB_USB_ExistsOnChipTransceiver	Identifies whether the OnChipTransceiver feature exists on the USB module.
	PLIB_USB_ExistsOpModeSelect	Identifies whether the OpModeSelect feature exists on the USB module.
	PLIB_USB_ExistsOTG_ASessionValid	Identifies whether the OTG_ASessionValid feature exists on the USB module.
	PLIB_USB_ExistsOTG_BSessionEnd	Identifies whether the OTG_BSessionEnd feature exists on the USB module.
	PLIB_USB_ExistsOTG_IDPinState	Identifies whether the OTG_IDPinState feature exists on the USB module.
	PLIB_USB_ExistsOTG_Interrupt	Identifies whether the OTG_Interrupt feature exists on the USB module.
	PLIB_USB_ExistsOTG_InterruptStatus	Identifies whether the OTG_InterruptStatus feature exists on the USB module.
	PLIB_USB_ExistsOTG_LineState	Identifies whether the OTG_LineState feature exists on the USB module.
	PLIB_USB_ExistsOTG_PullUpPullDown	Identifies whether the OTG_PullUpPullDown feature exists on the USB module.
	PLIB_USB_ExistsOTG_SessionValid	Identifies whether the OTG_SessionValid feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusCharge	Identifies whether the OTG_VbusCharge feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusDischarge	Identifies whether the OTG_VbusDischarge feature exists on the USB module.
	PLIB_USB_ExistsOTG_VbusPowerOnOff	Identifies whether the OTG_VbusPowerOnOff feature exists on the USB module.
	PLIB_USB_ExistsPacketTransfer	Identifies whether the PacketTransfer feature exists on the USB module.
	PLIB_USB_ExistsPingPongMode	Identifies whether the PingPongMode feature exists on the USB module.
	PLIB_USB_ExistsResumeSignaling	Identifies whether the ResumeSignaling feature exists on the USB module.
	PLIB_USB_ExistsSleepEntryGuard	Identifies whether the SleepEntryGuard feature exists on the USB module.
	PLIB_USB_ExistsSOFThreshold	Identifies whether the SOFThreshold feature exists on the USB module.
	PLIB_USB_ExistsSpeedControl	Identifies whether the SpeedControl feature exists on the USB module.
	PLIB_USB_ExistsStartOfFrames	Identifies whether the StartOfFrames feature exists on the USB module.

	PLIB_USB_ExistsStopInIdle	Identifies whether the StopInIdle feature exists on the USB module.
	PLIB_USB_ExistsSuspend	Identifies whether the Suspend feature exists on the USB module.
	PLIB_USB_ExistsTokenEP	Identifies whether the TokenEP feature exists on the USB module.
	PLIB_USB_ExistsTokenPID	Identifies whether the TokenPID feature exists on the USB module.
	PLIB_USB_ExistsUOEMonitor	Identifies whether the UOEMonitor feature exists on the USB module.
	PLIB_USB_ExternalComparatorMode2Pin	Sets the 2-pin input configuration for VBUS comparators.
	PLIB_USB_ExternalComparatorMode3Pin	Sets the 3-pin input configuration for VBUS Comparators.
	PLIB_USB_EyePatternDisable	Disables the USB eye pattern test.
	PLIB_USB_EyePatternEnable	Enables USB eye pattern test.
	PLIB_USB_FrameNumberGet	Returns the USB frame number.
	PLIB_USB_FullSpeedDisable	Forces the USB module to operate at low speed.
	PLIB_USB_FullSpeedEnable	Enables the USB to operate at full speed.
	PLIB_USB_I2CInterfaceForExtModuleDisable	Specifies external module(s) are controlled via dedicated pins.
	PLIB_USB_I2CInterfaceForExtModuleEnable	Specifies external module(s) are controlled via the I2C interface.
	PLIB_USB_InterruptDisable	Disables a general interrupt for the USB module.
	PLIB_USB_InterruptEnable	Enables a general interrupt for the USB module.
	PLIB_USB_InterruptEnableGet	Returns the enable/disable status of general USB module interrupts
	PLIB_USB_InterruptFlagAllGet	Returns a logically ORed bit map of active general USB interrupt flags.
	PLIB_USB_InterruptFlagClear	Clears a general interrupt flag for the USB module.
	PLIB_USB_InterruptFlagGet	Tests a general interrupt flag for the USB module.
	PLIB_USB_InterruptFlagSet	Sets a general interrupt flag for the USB module.
	PLIB_USB_InterruptIsEnabled	Returns true if interrupts are enabled.
	PLIB_USB_IsBusyWithToken	Indicates whether there is a token being executed by the USB module as Host.
	PLIB_USB_JStateIsActive	Live differential receiver J State flag.
	PLIB_USB_LastTransactionDetailsGet	Returns the details of the last completed transaction.
	PLIB_USB_LastTransactionDirectionGet	Indicates the direction of the last transaction.
	PLIB_USB_LastTransactionEndPtGet	Returns the endpoint number of the last USB transfer.
	PLIB_USB_LastTransactionPingPongStateGet	Indicates whether the last transaction was to an EVEN buffer or an ODD buffer.
	PLIB_USB_ModuleIsBusy	Indicates if the USB module is not ready to be enabled.
	PLIB_USB_OnChipPullUpDisable	Disables on-chip pull-ups.
	PLIB_USB_OnChipPullUpEnable	Enables on-chip pull-ups.
	PLIB_USB_OperatingModeSelect	Selects the operating mode of the USB module.
	PLIB_USB_OTG_BSessionHasEnded	Returns the status of the B-Session End Indicator bit.
	PLIB_USB_OTG_IDPinStateIsTypeA	Returns the ID Pin state.
	PLIB_USB_OTG_InterruptDisable	Disables a USB On-The-Go (OTG) Interrupt for the USB module.
	PLIB_USB_OTG_InterruptEnable	Enables a USB On-The-Go (OTG) Interrupt for the USB module.
	PLIB_USB_OTG_InterruptFlagClear	Clears a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptFlagGet	Tests a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptFlagSet	Sets a USB On-The-Go (OTG) Interrupt flag for the USB module.
	PLIB_USB_OTG_InterruptIsEnabled	Returns whether or not interrupts are enabled.
	PLIB_USB_OTG_LineStateIsStable	Returns the status of the Line Stable Indicator bit.
	PLIB_USB_OTG_PullUpPullDownSetup	Enables or disables pull-up and pull-down resistors.
	PLIB_USB_OTG_SessionValid	Returns the status of the Session Valid Indicator bit.
	PLIB_USB_OTG_VBusChargeDisable	Disables VBUS line charge.
	PLIB_USB_OTG_VBusChargeEnable	Enables the VBUS line to be charged through a pull-up resistor.
	PLIB_USB_OTG_VBusChargeTo3V	Sets the VBUS line to charge to 3.3V.
	PLIB_USB_OTG_VBusChargeTo5V	Sets the VBUS line to charge to 5V.
	PLIB_USB_OTG_VBusDischargeDisable	Disables VBUS line discharge.
	PLIB_USB_OTG_VBusDischargeEnable	Enables VBUS line to be discharged through a resistor.
	PLIB_USB_OTG_VBusPowerOff	Turns off power on the VBUS Line.
	PLIB_USB_OTG_VBusPowerOn	Turns on power for the VBUS line.
	PLIB_USB_OTG_VBusValid	Returns the status of the A-VBUS valid indicator.
	PLIB_USB_PacketTransferDisable	Disables the Serial Interface Engine (SIE).
	PLIB_USB_PacketTransferEnable	Re-enables the Serial Interface Engine (SIE), allowing token and packet processing.

	PLIB_USB_PacketTransferIsDisabled	Indicates that a setup token has been received from the Host and that token/packet processing is disabled.
	PLIB_USB_PingPongFreeze	Resets all Ping-Pong buffer pointers to even buffers.
	PLIB_USB_PingPongModeGet	Returns the Ping-Pong Configuration setting.
	PLIB_USB_PingPongModeSelect	Selects the Ping-Pong Configuration setting.
	PLIB_USB_PingPongReset	Resets the USB peripheral internal Ping-Pong indicator to point to even buffers.
	PLIB_USB_PingPongUnfreeze	Enables Ping-Pong buffering.
	PLIB_USB_PWMCounterDisable	Disables the PWM counter used to generate the VBUS for the USB module.
	PLIB_USB_PWMCounterEnable	Enables the PWM counter used to generate the VBUS for the USB module.
	PLIB_USB_PWMDisable	Disables the PWM Generator.
	PLIB_USB_PWMEnable	Enables the PWM Generator.
	PLIB_USB_PWMPolaritiyActiveLow	Sets the PWM output to active-high and resets low.
	PLIB_USB_PWMPolarityActiveHigh	Sets the PWM output to active-low and resets high.
	PLIB_USB_ResetSignalDisable	Disables reset signaling on the USB bus.
	PLIB_USB_ResetSignalEnable	Enables reset signaling on the USB bus.
	PLIB_USB_ResumeSignalingDisable	Disables resume signaling.
	PLIB_USB_ResumeSignalingEnable	Enables resume signaling.
	PLIB_USB_SE0InProgress	Returns whether a single-ended zero event is in progress.
	PLIB_USB_SleepGuardDisable	This function disables Sleep Guard. Entry into Sleep mode is immediate.
	PLIB_USB_SleepGuardEnable	Entry into Sleep mode is blocked if bus activity is detected or if an interrupt is pending.
	PLIB_USB_SOFDisable	Disables the automatic generation of the SOF token.
	PLIB_USB_SOFEnable	Enables the automatic generation of the SOF token every 1 ms.
	PLIB_USB_SOFThresholdGet	Returns the Start-of-Frame (SOF) Count bits.
	PLIB_USB_SOFThresholdSet	Sets the Start-of-Frame (SOF) threshold value.
	PLIB_USB_StopInIdleDisable	Allows the USB module to continue operation when the device enters Idle mode.
	PLIB_USB_StopInIdleEnable	Enables USB module operation to stop when the device enters Idle mode.
	PLIB_USB_SuspendDisable	Disables USB OTG Suspend mode.
	PLIB_USB_SuspendEnable	Enables USB Suspend mode.
	PLIB_USB_TokenEPGet	Returns the specified Endpoint address.
	PLIB_USB_TokenEPSet	Sets the Endpoint address for a host transaction.
	PLIB_USB_TokenPIDGet	Returns the token transaction type.
	PLIB_USB_TokenPIDSet	Sets the token transaction type to pidValue.
	PLIB_USB_TokenSend	Sends token to the specified address.
	PLIB_USB_TokenSpeedSelect	Selects low speed or full speed for subsequent token executions.
	PLIB_USB_TransceiverDisable	Disables the on-chip transceiver
	PLIB_USB_TransceiverEnable	Enables the on-chip transceiver.
	PLIB_USB_UOEMonitorDisable	Disables the OE signal output.
	PLIB_USB_UOEMonitorEnable	Enables the OE signal output.
	PLIB_USB_VBoostDisable	Disables the On-Chip 5V Boost Regulator Circuit Disabled bit.
	PLIB_USB_VBoostEnable	Enables the On-Chip 5V Boost Regulator Circuit Enabled bit.
	PLIB_USB_VBUSComparatorDisable	Disables the on-chip VBUS Comparator.
	PLIB_USB_VBUSComparatorEnable	Enables the on-chip VBUS Comparator.
	PLIB_USB_VBUSPullUpDisable	Disables the pull-up on the VBUS pin.
	PLIB_USB_VBUSPullUpEnable	Enables the pull-up on the VBUS pin.

Macros

	Name	Description
	USB_MAX_EP_NUMBER	Maximum number of endpoints supported (not including EP0).

Description

USB Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USB Peripheral Library.

File Name

plib_usb.h

Company

Microchip Technology Inc.

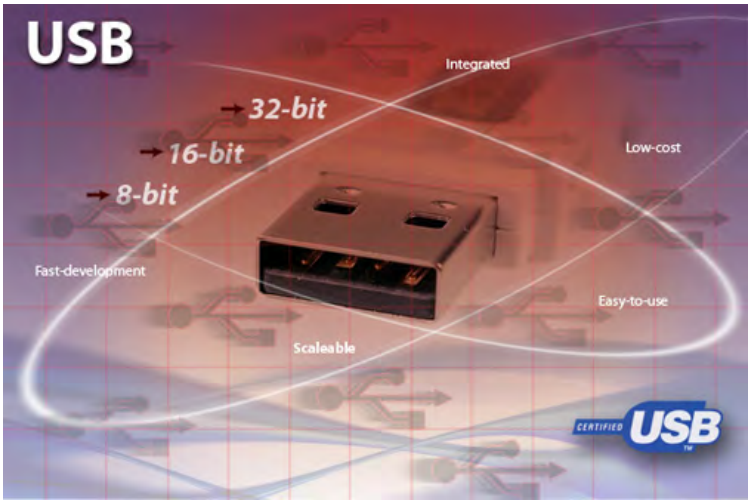
USBHS Peripheral Library

This section describes the Hi-Speed USB (USBHS) Peripheral Library.

Introduction

This library provides a low-level abstraction of the USBHS module on Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, thus hiding differences from one microcontroller variant to another.

Description



USB Overview

USB is an asynchronous serial interface with a tiered star configuration. USB is implemented as a master/slave configuration. On a given bus, there can be multiple (up to 127) slaves (devices), but there is only one master (host). There are three possible module implementations: host, device and OTG dual role. The user should have an understanding of the USB documents available on the USB implementers web site (www.usb.org).

Features of the Hi-Speed USB (USBHS) Module

- Operates either as a function controller of a Hi-Speed/Full-Speed USB device or as the host/device in a point-to-point or multi-point communications with other USB function
- Supports OTG communications with on or more Hi-Speed, Full-Speed, or Low-Speed devices
- Provides soft connect/disconnect.
- In addition to Endpoint Zero, supports seven transmit and seven receive endpoints
- Dynamic FIFO sizing for Endpoints 1-7. (Endpoint Zero FIFO fixed at 64 bytes.) FIFOs use module-internal SRAM.
- Module-internal eight channel DMA with access to all FIFOs
- All host transaction scheduling supported in hardware
- Supports Link Power Management

Using the Library

This topic describes the basic architecture of the USBHS Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_usbhs.h`

The interface to the USBHS Peripheral Library is defined in the `plib_usbhs.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the USBHS Peripheral Library must include `peripheral.h`.

Library File:

The USBHS Peripheral Library is part of the processor-specific peripheral library archive (`.a`) file installed with the compiler. Libraries in this archive are automatically available to the linker (in the default search path) for any project built using the Microchip compiler.

Please refer to the What is MPLAB Harmony? section for how the library interacts with the framework.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the USBHS module.

Library Interface Section	Description
USBHS Setup Functions	This section provides functions to perform general USBHS peripheral setup such as functions to set USB Speed, control on-chip pull ups, etc.
Endpoints Functions	This section provides functions that allow the application to manage endpoints.
Interrupts Functions	This section provides functions that allow the application to enable, disable and query the status interrupts in the USBHS peripheral.
Device Functions	This section provides functions that are required to operate the USBHS module while in Device mode.
Host Functions	This section provides functions that are required to operate the USBHS module while in Host mode.
Status Functions	This section provides functions that read the status of the USBHS module.
VBUS Support Functions	This section provides functions that allow VBUS level monitoring and VBUS boost PWM module control.
Feature Existence Functions	This section provides functions that identify whether a particular feature exists on the USBHS module.

How the Library Works

Provides information on how the library works.

Configuring the Library

The library is configured for the supported High-Speed USB module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) USBHS Setup Functions

	Name	Description
	PLIB_USBHS_HighSpeedDisable	This is function PLIB_USBHS_HighSpeedDisable.
	PLIB_USBHS_HighSpeedEnable	Sets the operation speed of the USB Module.
	PLIB_USBHS_ResetDisable	This is function PLIB_USBHS_ResetDisable.
	PLIB_USBHS_ResetEnable	This is function PLIB_USBHS_ResetEnable.
	PLIB_USBHS_ResumeDisable	This is function PLIB_USBHS_ResumeDisable.
	PLIB_USBHS_ResumeEnable	This is function PLIB_USBHS_ResumeEnable.
	PLIB_USBHS_SessionDisable	This is function PLIB_USBHS_SessionDisable.
	PLIB_USBHS_SessionEnable	This is function PLIB_USBHS_SessionEnable.
	PLIB_USBHS_SoftResetDisable	Disables soft reset.
	PLIB_USBHS_SoftResetEnable	Enables soft reset.
	PLIB_USBHS_SuspendDisable	This is function PLIB_USBHS_SuspendDisable.
	PLIB_USBHS_SuspendEnable	This is function PLIB_USBHS_SuspendEnable.
	PLIB_USBHS_DMAOperationEnable	This is function PLIB_USBHS_DMAOperationEnable.
	PLIB_USBHS_TestModeEnter	This is function PLIB_USBHS_TestModeEnter.
	PLIB_USBHS_TestModeExit	This is function PLIB_USBHS_TestModeExit.
	PLIB_USBHS_PhyIDMonitoringDisable	This is function PLIB_USBHS_PhyIDMonitoringDisable.
	PLIB_USBHS_PhyIDMonitoringEnable	This is function PLIB_USBHS_PhyIDMonitoringEnable.
	PLIB_USBHS_USBIDOverrideDisable	This is function PLIB_USBHS_USBIDOverrideDisable.
	PLIB_USBHS_USBIDOverrideEnable	This is function PLIB_USBHS_USBIDOverrideEnable.
	PLIB_USBHS_USBIDOverrideValueSet	This is function PLIB_USBHS_USBIDOverrideValueSet.
	PLIB_USBHS_IsBDevice	This is function PLIB_USBHS_IsBDevice.

b) Endpoints Functions

	Name	Description
	PLIB_USBHS_Endpoint0FIFOFlush	This is function PLIB_USBHS_Endpoint0FIFOFlush.
	PLIB_USBHS_Endpoint0SetupPacketLoad	Loads the endpoint 0 FIFO with provided setup packet and then enables the endpoint transmit.
	PLIB_USBHS_Endpoint0SetupPacketUnload	This is function PLIB_USBHS_Endpoint0SetupPacketUnload.
	PLIB_USBHS_EndpointFIFOLoad	Loads the endpoint FIFO with provided data and then enables the endpoint transmit.
	PLIB_USBHS_EndpointFIFOUnload	Unloads the endpoint FIFO.
	PLIB_USBHS_EndpointRxFIFOFlush	This is function PLIB_USBHS_EndpointRxFIFOFlush.
	PLIB_USBHS_EndpointRxRequestClear	This is function PLIB_USBHS_EndpointRxRequestClear.
	PLIB_USBHS_EndpointRxRequestEnable	This is function PLIB_USBHS_EndpointRxRequestEnable.
	PLIB_USBHS_EndpointTxFIFOFlush	This is function PLIB_USBHS_EndpointTxFIFOFlush.
	PLIB_USBHS_EP0DataEndSet	This is function PLIB_USBHS_EP0DataEndSet.
	PLIB_USBHS_EP0INHandshakeClear	This is function PLIB_USBHS_EP0INHandshakeClear.
	PLIB_USBHS_EP0INHandshakeSend	This is function PLIB_USBHS_EP0INHandshakeSend.
	PLIB_USBHS_EP0INTokenSend	This is function PLIB_USBHS_EP0INTokenSend.
	PLIB_USBHS_EP0OUTHandshakeSend	This is function PLIB_USBHS_EP0OUTHandshakeSend.
	PLIB_USBHS_EP0RxPktRdyServiced	This is function PLIB_USBHS_EP0RxPktRdyServiced.
	PLIB_USBHS_EP0RxPktRdyServicedDataEnd	This is function PLIB_USBHS_EP0RxPktRdyServicedDataEnd.
	PLIB_USBHS_EP0SentStallClear	This is function PLIB_USBHS_EP0SentStallClear.
	PLIB_USBHS_EP0SetupEndServiced	This is function PLIB_USBHS_EP0SetupEndServiced.
	PLIB_USBHS_EP0StallDisable	This is function PLIB_USBHS_EP0StallDisable.
	PLIB_USBHS_EP0StallEnable	This is function PLIB_USBHS_EP0StallEnable.
	PLIB_USBHS_EP0StatusClear	This is function PLIB_USBHS_EP0StatusClear.
	PLIB_USBHS_EP0StatusGet	This is function PLIB_USBHS_EP0StatusGet.
	PLIB_USBHS_EP0TxPktRdy	This is function PLIB_USBHS_EP0TxPktRdy.
	PLIB_USBHS_EP0TxPktRdyDataEnd	This is function PLIB_USBHS_EP0TxPktRdyDataEnd.
	PLIB_USBHS_HostRxEndpointConfigure	This is function PLIB_USBHS_HostRxEndpointConfigure.
	PLIB_USBHS_HostTxEndpointConfigure	This is function PLIB_USBHS_HostTxEndpointConfigure.
	PLIB_USBHS_RxEPINTokenSend	This is function PLIB_USBHS_RxEPINTokenSend.
	PLIB_USBHS_RxEPStatusClear	This is function PLIB_USBHS_RxEPStatusClear.
	PLIB_USBHS_RxEPStatusGet	This is function PLIB_USBHS_RxEPStatusGet.
	PLIB_USBHS_TxEPStatusClear	This is function PLIB_USBHS_TxEPStatusClear.
	PLIB_USBHS_TxEPStatusGet	This is function PLIB_USBHS_TxEPStatusGet.
	PLIB_USBHS_GetEP0CSRAddress	This is function PLIB_USBHS_GetEP0CSRAddress.
	PLIB_USBHS_GetEP0FIFOAddress	This is function PLIB_USBHS_GetEP0FIFOAddress.
	PLIB_USBHS_LoadEPInIndex	This is function PLIB_USBHS_LoadEPInIndex.

c) Interrupts Functions

	Name	Description
	PLIB_USBHS_TxInterruptDisable	Disables a TX endpoint interrupt source for the USB module.
	PLIB_USBHS_TxInterruptEnable	Enables a TX endpoint Interrupt for the USB module.
	PLIB_USBHS_GenInterruptDisable	Disables a general interrupt for the USB module.
	PLIB_USBHS_GenInterruptEnable	Enables a general interrupt for the USB module.
	PLIB_USBHS_GenInterruptFlagsGet	Gets general interrupt flags.
	PLIB_USBHS_InterruptEnableSet	Enables USB module event interrupts.
	PLIB_USBHS_DMAInterruptDisable	Disables DMA channel interrupts.
	PLIB_USBHS_DMAInterruptEnable	Enables DMA channel interrupts.
	PLIB_USBHS_DMAInterruptFlagsGet	Gets the DMA channel interrupt flags.
	PLIB_USBHS_TxInterruptFlagsGet	Gets the TX endpoint interrupt flags.
	PLIB_USBHS_RxInterruptDisable	Disables a RX endpoint interrupt for the USB module.
	PLIB_USBHS_RxInterruptEnable	Enables a RX endpoint interrupt for the USB module.
	PLIB_USBHS_RxInterruptFlagsGet	Gets RX endpoint interrupt flags.
	PLIB_USBHS_DMAInterruptGet	This is function PLIB_USBHS_DMAInterruptGet.

	PLIB_USBHS_GlobalInterruptDisable	This is function PLIB_USBHS_GlobalInterruptDisable.
	PLIB_USBHS_GlobalInterruptEnable	This is function PLIB_USBHS_GlobalInterruptEnable.

d) Device Functions

	Name	Description
	PLIB_USBHS_DeviceAddressGet	Returns the current USB device address.
	PLIB_USBHS_DeviceAddressSet	Sets the device address.
	PLIB_USBHS_DeviceAttach	This is function PLIB_USBHS_DeviceAttach.
	PLIB_USBHS_DeviceConnect	Tri-states the USB D+ and D- lines.
	PLIB_USBHS_DeviceDetach	This is function PLIB_USBHS_DeviceDetach.
	PLIB_USBHS_DeviceDisconnect	Tri-states the USB D+ and D- lines.
	PLIB_USBHS_DeviceEPFIFOLoad	This is function PLIB_USBHS_DeviceEPFIFOLoad.
	PLIB_USBHS_DeviceEPFIFOUnload	This is function PLIB_USBHS_DeviceEPFIFOUnload.
	PLIB_USBHS_DeviceRxEndpointConfigure	This is function PLIB_USBHS_DeviceRxEndpointConfigure.
	PLIB_USBHS_DeviceRxEndpointStallDisable	This is function PLIB_USBHS_DeviceRxEndpointStallDisable.
	PLIB_USBHS_DeviceRxEndpointStallEnable	This is function PLIB_USBHS_DeviceRxEndpointStallEnable.
	PLIB_USBHS_DeviceTxEndpointConfigure	This is function PLIB_USBHS_DeviceTxEndpointConfigure.
	PLIB_USBHS_DeviceTxEndpointPacketReady	This is function PLIB_USBHS_DeviceTxEndpointPacketReady.
	PLIB_USBHS_DeviceTxEndpointStallDisable	This is function PLIB_USBHS_DeviceTxEndpointStallDisable.
	PLIB_USBHS_DeviceTxEndpointStallEnable	This is function PLIB_USBHS_DeviceTxEndpointStallEnable.

e) Host Functions

	Name	Description
	PLIB_USBHS_HostRxEndpointDataToggleClear	This is function PLIB_USBHS_HostRxEndpointDataToggleClear.
	PLIB_USBHS_HostTxEndpointDataToggleClear	This is function PLIB_USBHS_HostTxEndpointDataToggleClear.

f) Status Functions

	Name	Description
	PLIB_USBHS_FullOrHighSpeedIsConnected	This is function PLIB_USBHS_FullOrHighSpeedIsConnected.
	PLIB_USBHS_HighSpeedIsConnected	This is function PLIB_USBHS_HighSpeedIsConnected.
	PLIB_USBHS_HostModeIsEnabled	This is function PLIB_USBHS_HostModeIsEnabled.
	PLIB_USBHS_ModuleSpeedGet	Returns the speed at which the module is operating.
	PLIB_USBHS_DMAErrorGet	This is function PLIB_USBHS_DMAErrorGet.
	PLIB_USBHS_GetReceiveDataCount	This is function PLIB_USBHS_GetReceiveDataCount.

g) VBUS Support Functions

	Name	Description
	PLIB_USBHS_VbusLevelGet	Returns the current VBUS level encode using the USBHS_VBUS_DETECT_LEVEL enumeration.
	PLIB_USBHS_VBUSLevelGet	This is function PLIB_USBHS_VBUSLevelGet.

h) Feature Existence Functions

	Name	Description
	PLIB_USBHS_ExistsEndpointFIFO	Identifies that the Endpoint FIFO feature exists on the Hi-Speed USB module.
	PLIB_USBHS_ExistsEndpointOperations	This is function PLIB_USBHS_ExistsEndpointOperations.
	PLIB_USBHS_ExistsEP0Status	This is function PLIB_USBHS_ExistsEP0Status.
	PLIB_USBHS_ExistsHighSpeedSupport	This is function PLIB_USBHS_ExistsHighSpeedSupport.
	PLIB_USBHS_ExistsInterrupts	This is function PLIB_USBHS_ExistsInterrupts.
	PLIB_USBHS_ExistsModuleControl	This is function PLIB_USBHS_ExistsModuleControl.
	PLIB_USBHS_ExistsRxEPStatus	This is function PLIB_USBHS_ExistsRxEPStatus.
	PLIB_USBHS_ExistsSoftReset	This is function PLIB_USBHS_ExistsSoftReset.
	PLIB_USBHS_ExistsTxEPStatus	This is function PLIB_USBHS_ExistsTxEPStatus.
	PLIB_USBHS_ExistsClockResetControl	This is function PLIB_USBHS_ExistsClockResetControl.
	PLIB_USBHS_ExistsUSBIDControl	This is function PLIB_USBHS_ExistsUSBIDControl.

i) Data Types and Constants

	Name	Description
	USBHS_CONFIGURATION	Provides the enumeration Configuration bits.
	USBHS_DATA01	Provides an enumeration data toggle for a packet.
	USBHS_DMA_ASSERT_TIMING	Provides enumeration DMA assertion timing (early versus late).
	USBHS_DMA_BURST_MODE	Provides enumeration of all DMA burst modes.
	USBHS_DMA_INTERRUPT	Provides enumeration of interrupts for DMA channels 0-7.
	USBHS_DMA_REQUEST_MODE	Used as an argument to set DMA request mode.
	USBHS_DMA_TRANSFER_MODE	Provides enumeration of all DMA transfer modes.
	USBHS_DYN_FIFO_PACKET_BUFFERING	Provides enumeration of dynamic FIFO double-packet versus single-packet buffering.
	USBHS_DYN_FIFO_SIZE	Provides enumeration of dynamic FIFO sizes.
	USBHS_ENDPOINT_DIRECTION	Used as an argument to identify an endpoint direction.
	USBHS_LPM_INTERRUPT	Provides an enumeration of LPM interrupt sources.
	USBHS_LPM_LINK_STATE	Provides enumeration requested device state after accepting an LPM transaction.
	USBHS_LPM_MODE	Provides enumeration of Link Power Management (LPM) modes.
	USBHS_OPMODES	Provides enumeration of operating modes supported by USB.
	USBHS_PKTS_PER_MICROFRAME	Provides an enumeration of the allowable isochronous packets per microframe when operating in High-Speed mode.
	USBHS_SPEED	Provides enumeration Host endpoint speeds.
	USBHS_TEST_SPEED	Used as an argument for in setting module speeds in Test mode.
	USBHS_TRANSACTION_TYPE	Provides an enumeration of transaction types.
	USBHS_TXRX_FIFO_STATE	Provides enumeration of receive and transmit FIFO states, as reported by status bits.
	USBHS_MAX_DMA_CHANNEL_NUMBER	Number of available DMA Channels.
	USBHS_MAX_EP_NUMBER	Maximum number of endpoints supported (not including EP0).

Description

This section describes the Application Programming Interface (API) functions of the USBHS Peripheral Library.

Refer to each section for a detailed description.

a) USBHS Setup Functions

PLIB_USBHS_HighSpeedDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HighSpeedDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_HighSpeedDisable.

PLIB_USBHS_HighSpeedEnable Function

Sets the operation speed of the USB Module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_HighSpeedEnable(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function sets the operation speed of the USB module.

Remarks

None.

Preconditions

None.

Example

```
// Enable the USB module for high speed support.

PLIB_USBHS_HighSpeedEnable(USBHS_ID_0, USB_SPEED_HIGH);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
speed	The operation speed of the USB module

Function

void PLIB_USBHS_ModuleSpeedSet(USBHS_MODULE_ID index, uint32_t speed)

PLIB_USBHS_ResetDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_ResetDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ResetDisable.

PLIB_USBHS_ResetEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_ResetEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ResetEnable.

PLIB_USBHS_ResumeDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_ResumeDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ResumeDisable.

PLIB_USBHS_ResumeEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_ResumeEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ResumeEnable.

PLIB_USBHS_SessionDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_SessionDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_SessionDisable.

PLIB_USBHS_SessionEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_SessionEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_SessionEnable.

PLIB_USBHS_SoftResetDisable Function

Disables soft reset.

File

plib_usbhs.h

C

```
void PLIB_USBHS_SoftResetDisable(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function disables soft reset.

Remarks

Valid in both Peripheral and Host mode.

Preconditions

None.

Example

```
PLIB_USBHS_SoftResetDisable(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USBHS_SoftResetDisable(USBHS_MODULE_ID index);

PLIB_USBHS_SoftResetEnable Function

Enables soft reset.

File

plib_usbhs.h

C

```
void PLIB_USBHS_SoftResetEnable(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function enables soft reset.

Remarks

Valid in both Peripheral and Host mode.

Preconditions

None.

Example

```
PLIB_USBHS_SoftResetEnable(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USBHS_SoftResetEnable(USBHS_MODULE_ID index);

PLIB_USBHS_SuspendDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_SuspendDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_SuspendDisable.

PLIB_USBHS_SuspendEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_SuspendEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_SuspendEnable.

PLIB_USBHS_DMAOperationEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DMAOperationEnable(USBHS_MODULE_ID index, uint8_t endpoint, uint8_t dmaChannel, void *
address, uint32_t count, bool direction);
```

Description

This is function PLIB_USBHS_DMAOperationEnable.

PLIB_USBHS_TestModeEnter Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_TestModeEnter(USBHS_MODULE_ID index, uint8_t testMode);
```

Description

This is function PLIB_USBHS_TestModeEnter.

PLIB_USBHS_TestModeExit Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_TestModeExit(USBHS_MODULE_ID index, uint8_t testMode);
```

Description

This is function PLIB_USBHS_TestModeExit.

PLIB_USBHS_PhyIDMonitoringDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_PhyIDMonitoringDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_PhyIDMonitoringDisable.

PLIB_USBHS_PhyIDMonitoringEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_PhyIDMonitoringEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_PhyIDMonitoringEnable.

PLIB_USBHS_USBIDOverrideDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_USBIDOverrideDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_USBIDOverrideDisable.

PLIB_USBHS_USBIDOverrideEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_USBIDOverrideEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_USBIDOverrideEnable.

PLIB_USBHS_USBIDOverrideValueSet Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_USBIDOverrideValueSet(USBHS_MODULE_ID index, USBHS_USBID_OVERRIDE_VALUE id);
```

Description

This is function PLIB_USBHS_USBIDOverrideValueSet.

PLIB_USBHS_IsBDevice Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_IsBDevice(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_IsBDevice.

b) Endpoints Functions

PLIB_USBHS_Endpoint0FIFOFlush Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_Endpoint0FIFOFlush(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_Endpoint0FIFOFlush.

PLIB_USBHS_Endpoint0SetupPacketLoad Function

Loads the endpoint 0 FIFO with provided setup packet and then enables the endpoint transmit.

File

plib_usbhs.h

C

```
void PLIB_USBHS_Endpoint0SetupPacketLoad(USBHS_MODULE_ID index, void * setupPacket, uint8_t deviceAddress,
uint8_t hubAddress, uint8_t hubPortAddress, uint32_t speed);
```

Returns

None.

Description

This function loads the endpoint 0 FIFO with provided setup packet. This operation would typically be performed at the start of a endpoint 0 control transfer. Once the FIFO is loaded the function will load the target device address, hub and hub port address and then transmit the packet.

Remarks

Valid in Host mode only. Setup packet size should be 8 bytes. Packet will always be targeted to endpoint 0 of the target device.

Preconditions

None.

Example

```
// Send a setup packet to device 7 control endpoint
// connected directly to module.

PLIB_USBHS_Endpoint0SetupPacketLoad(USBHS_ID_0, setupPacket, 7, 0,
                                                    0, USB_SPEED_HIGH);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
setupPacket	setup packet to be sent to the device
deviceAddress	USB address of the device
hubAddress	USB address of the hub if the device is connected to a hub. Should be zero otherwise.
hubPortAddress	Port number of the hub port to which the device is connected if it is connected to a hub. Should be zero otherwise.
speed	Speed of the device to which the packet should be sent.

Function

void PLIB_USBHS_Endpoint0SetupPacketLoad(USBHS_MODULE_ID index,

void * setupPacket, uint8_t deviceAddress,

uint8_t hubAddress, uint8_t hubPortAddress,

uint32_t speed)

PLIB_USBHS_Endpoint0SetupPacketUnload Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_Endpoint0SetupPacketUnload(USBHS_MODULE_ID index, void * dest);
```

Description

This is function PLIB_USBHS_Endpoint0SetupPacketUnload.

PLIB_USBHS_EndpointFIFOLoad Function

Loads the endpoint FIFO with provided data and then enables the endpoint transmit.

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointFIFOLoad(USBHS_MODULE_ID index, uint8_t endpoint, void * source, size_t nBytes);
```

Returns

None.

Description

This function loads the endpoint FIFO with provided data. This operation would typically be performed for a endpoint transmit operation. Once the FIFO is loaded the function will enable the enable the endpoint for transmit.

Remarks

Valid in both Peripheral and Host mode.

Preconditions

None.

Example

```
// Load endpoint 1 FIFO

PLIB_USBHS_EndpointFIFOLoad(USBHS_ID_0, 1, data, 10);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
endpoint	endpoint of which FIFO needs to be loaded
source	data that should be loaded
nBytes	number of bytes to load.

Function

void PLIB_USBHS_EndpointFIFOLoad(USBHS_MODULE_ID index, uint8_t endpoint,

void * source, size_t nBytes)

PLIB_USBHS_EndpointFIFOUnload Function

Unloads the endpoint FIFO.

File

plib_usbhs.h

C

```
int PLIB_USBHS_EndpointFIFOUnload(USBHS_MODULE_ID index, uint8_t endpoint, void * dest);
```

Returns

Returns the number of functions that were read.

Description

This function unloads the endpoint FIFO. This operation would typically be performed for a endpoint receive operation. The unloaded data is stored in provided buffer.

Remarks

Valid in both Peripheral and Host mode.

Preconditions

The USB module must be configured for Device mode operation.

Example

```
// Load endpoint 1 FIFO
int count;

count = PLIB_USBHS_EndpointFIFOUnload(USBHS_ID_0, 1, dest, 10);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
endpoint	endpoint of which FIFO to be unloaded.
dest	target address where unloaded data should be stored.

Function

int PLIB_USBHS_EndpointFIFOUnload(USBHS_MODULE_ID index, uint8_t endpoint,
void * destination)

PLIB_USBHS_EndpointRxFIFOFlush Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointRxFIFOFlush(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_EndpointRxFIFOFlush.

PLIB_USBHS_EndpointRxRequestClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointRxRequestClear(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_EndpointRxRequestClear.

PLIB_USBHS_EndpointRxRequestEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointRxRequestEnable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_EndpointRxRequestEnable.

PLIB_USBHS_EndpointTxFIFOFlush Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EndpointTxFIFOFlush(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_EndpointTxFIFOFlush.

PLIB_USBHS_EP0DataEndSet Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0DataEndSet(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0DataEndSet.

PLIB_USBHS_EP0INHandshakeClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0INHandshakeClear(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0INHandshakeClear.

PLIB_USBHS_EP0INHandshakeSend Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0INHandshakeSend(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0INHandshakeSend.

PLIB_USBHS_EP0INTokenSend Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0INTokenSend(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0INTokenSend.

PLIB_USBHS_EP0OUTHandshakeSend Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0OUTHandshakeSend(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0OUTHandshakeSend.

PLIB_USBHS_EP0RxPktRdyServiced Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0RxPktRdyServiced(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0RxPktRdyServiced.

PLIB_USBHS_EP0RxPktRdyServicedDataEnd Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0RxPktRdyServicedDataEnd(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0RxPktRdyServicedDataEnd.

PLIB_USBHS_EP0SentStallClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0SentStallClear(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0SentStallClear.

PLIB_USBHS_EP0SetupEndServiced Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0SetupEndServiced(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0SetupEndServiced.

PLIB_USBHS_EP0StallDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0StallDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0StallDisable.

PLIB_USBHS_EP0StallEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0StallEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0StallEnable.

PLIB_USBHS_EP0StatusClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0StatusClear(USBHS_MODULE_ID index, USBHS_EP0_ERROR error);
```

Description

This is function PLIB_USBHS_EP0StatusClear.

PLIB_USBHS_EP0StatusGet Function

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_EP0StatusGet(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0StatusGet.

PLIB_USBHS_EP0TxPktRdy Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0TxPktRdy(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0TxPktRdy.

PLIB_USBHS_EP0TxPktRdyDataEnd Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_EP0TxPktRdyDataEnd(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_EP0TxPktRdyDataEnd.

PLIB_USBHS_HostRxEndpointConfigure Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HostRxEndpointConfigure(USBHS_MODULE_ID index, uint8_t hostEndpoint, uint32_t speed,
uint32_t pipeType, uint16_t endpointSize, uint16_t receiveFIFOAddress, uint16_t fifoSize, uint8_t
targetEndpoint, uint8_t targetDevice, uint8_t targetHub, uint8_t targetHubPort, uint8_t nakInterval);
```

Description

This is function PLIB_USBHS_HostRxEndpointConfigure.

PLIB_USBHS_HostTxEndpointConfigure Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HostTxEndpointConfigure(USBHS_MODULE_ID index, uint8_t hostEndpoint, uint32_t speed,
uint32_t pipeType, uint16_t endpointSize, uint16_t receiveFIFOAddress, uint16_t fifoSize, uint8_t
targetEndpoint, uint8_t targetDevice, uint8_t targetHub, uint8_t targetHubPort, uint8_t nakInterval);
```

Description

This is function PLIB_USBHS_HostTxEndpointConfigure.

PLIB_USBHS_RxEPINTokenSend Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_RxEPINTokenSend(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_RxEPINTokenSend.

PLIB_USBHS_RxEPStatusClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_RxEPStatusClear(USBHS_MODULE_ID index, uint8_t endpoint, USBHS_RXEP_ERROR error);
```

Description

This is function PLIB_USBHS_RxEPStatusClear.

PLIB_USBHS_RxEPStatusGet Function

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_RxEPStatusGet(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_RxEPStatusGet.

PLIB_USBHS_TxEPStatusClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_TxEPStatusClear(USBHS_MODULE_ID index, uint8_t endpoint, USBHS_TXEP_ERROR error);
```

Description

This is function PLIB_USBHS_TxEPStatusClear.

PLIB_USBHS_TxEPStatusGet Function

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_TxEPStatusGet(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_TxEPStatusGet.

PLIB_USBHS_GetEP0CSRAddress Function

File

plib_usbhs.h

C

```
uint8_t * PLIB_USBHS_GetEP0CSRAddress(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_GetEP0CSRAddress.

PLIB_USBHS_GetEP0FIFOAddress Function

File

plib_usbhs.h

C

```
uint8_t * PLIB_USBHS_GetEP0FIFOAddress(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_GetEP0FIFOAddress.

PLIB_USBHS_LoadEPInIndex Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_LoadEPInIndex(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_LoadEPInIndex.

c) Interrupts Functions

PLIB_USBHS_TxInterruptDisable Function

Disables a TX endpoint interrupt source for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_TxInterruptDisable(USBHS_MODULE_ID index, USBHS_EPTXRX_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function disables a TX endpoint interrupt source for the USB module.

Remarks

See also PLIB_USBHS_TxInterruptEnable.

Preconditions

None.

Example

```
PLIB_USBHS_TxInterruptDisable( MY_USB_INSTANCE, USBHS_TXRXINT_EP1 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_TxInterruptDisable(USBHS_MODULE_ID index,
USBHS_EPTXRX_INTERRUPT interruptFlag)

PLIB_USBHS_TxInterruptEnable Function

Enables a TX endpoint Interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_TxInterruptEnable(USBHS_MODULE_ID index, USBHS_EPTXRX_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function enables the TX endpoint interrupt sources of the USB module that are used to trigger a USB interrupt.

Remarks

See also PLIB_USBHS_TxInterruptDisable.

Preconditions

None.

Example

```
PLIB_USBHS_TxInterruptEnable( MY_USB_INSTANCE, USBHS_TXRXINT_EP1 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_TxInterruptEnable(USBHS_MODULE_ID index,
USBHS_EPTXRX_INTERRUPT interruptFlag)

PLIB_USBHS_GenInterruptDisable Function

Disables a general interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_GenInterruptDisable(USBHS_MODULE_ID index, USBHS_GEN_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function disables a general interrupt source for the USB module.

Remarks

See also PLIB_USBHS_GenInterruptEnable.

Preconditions

None.

Example

```
PLIB_USBHS_GenInterruptDisable( MY_USB_INSTANCE, USBHS_GENINT_VBUSERR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_GenInterruptDisable(USBHS_MODULE_ID index,
USBHS_GEN_INTERRUPT interruptFlag)

PLIB_USBHS_GenInterruptEnable Function

Enables a general interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_GenInterruptEnable(USBHS_MODULE_ID index, USBHS_GEN_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function enables the general interrupt sources of the USB module that are used to trigger a USB interrupt.

Remarks

See also PLIB_USBHS_GenInterruptDisable.

Preconditions

None.

Example

```
PLIB_USBHS_GenInterruptEnable( MY_USB_INSTANCE, USBHS_GENINT_VBUSERR );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_GenInterruptEnable(USBHS_MODULE_ID index,
USBHS_GEN_INTERRUPT interruptFlag)

PLIB_USBHS_GenInterruptFlagsGet Function

Gets general interrupt flags.

File

plib_usbhs.h

C

```
USBHS_GEN_INTERRUPT PLIB_USBHS_GenInterruptFlagsGet(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function gets the general interrupt flags.

Remarks

None.

Preconditions

None.

Example

```
USBHS_GEN_INTERRUPT interruptFlags;
interruptFlags = PLIB_USBHS_GenInterruptFlagsGet( MY_USB_INSTANCE );
// All interrupt flags cleared on read.

if ( interruptFlags > 0 )
    if ( interruptFlags & USBHS_GENINT_SUSPEND )
    {
       // Device has detected suspend signaling on the bus.
    }
    if ( interruptFlags & USBHS_GENINT_RESUME )
    {
        //
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_GEN_INTERRUPT PLIB_USBHS_GenInterruptFlagsGet(USBHS_MODULE_ID index)

PLIB_USBHS_InterruptEnableSet Function

Enables USB module event interrupts.

File

plib_usbhs.h

C

```
void PLIB_USBHS_InterruptEnableSet(USBHS_MODULE_ID index, USBHS_GEN_INTERRUPT generalInterrupts,
USBHS_EPTXRX_INTERRUPT transmitInterrupts, USBHS_EPTXRX_INTERRUPT receiveInterrupts);
```

Returns

None.

Description

This function enables USB module event interrupts. Combines the functionality of the PLIB_USBHS_RxInterruptEnable, PLIB_USBHS_TxInterruptEnable, and PLIB_USBHS_GenInterruptEnable functions.

Remarks

None.

Preconditions

None.

Example

```
// Enable the reset interrupt, endpoint 1 transmit interrupt
// and endpoint 2 receive interrupts

PLIB_USBHS_InterruptEnableSet (USBHS_ID_0, USBHS_GENINT_RESET,
    USBHS_TXRXINT_EP1, USBHS_TXRXINT_EP2 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
generalInterrupts	General Module interrupts.
transmitInterrupts	Transmit Endpoint Interrupts to be enabled.
receiveInterrupts	Receive Endpoint Interrupts to be enabled.

Function

void PLIB_USBHS_InterruptEnableSet(USBHS_MODULE_ID index,

USBHS_GEN_INTERRUPT generalInterrupts,

USBHS_EPTXRX_INTERRUPT transmitInterrupts,

USBHS_EPTXRX_INTERRUPT receiveInterrupts);

PLIB_USBHS_DMAInterruptDisable Function

Disables DMA channel interrupts.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DMAInterruptDisable(USBHS_MODULE_ID index, USBHS_DMA_INTERRUPT nChannelNumber);
```

Returns

None.

Description

This function disables DMA Channel interrupts.

Remarks

None.

Preconditions

None.

Example

```
PLIB_USBHS_DMAInterruptDisable (USBHS_ID_0, USBHS_DMAINT_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
dmaChannelInterrupt	DMA channel Interrupt to disable

Function

void PLIB_USBHS_DMAInterruptDisable(USBHS_MODULE_ID index,
USBHS_DMA_INTERRUPT dmaChannelInterrupt)

PLIB_USBHS_DMAInterruptEnable Function

Enables DMA channel interrupts.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DMAInterruptEnable(USBHS_MODULE_ID index, USBHS_DMA_INTERRUPT nChannelNumber);
```

Returns

None.

Description

This function enables DMA Channel interrupts.

Remarks

None.

Preconditions

None.

Example

```
PLIB_USBHS_DMAInterruptEnable (USBHS_ID_0, USBHS_DMAINT_5);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
dmaChannelInterrupt	DMA channel Interrupt to enable

Function

void PLIB_USBHS_DMAInterruptEnable(USBHS_MODULE_ID index,
USBHS_DMA_INTERRUPT dmaChannelInterrupt)

PLIB_USBHS_DMAInterruptFlagsGet Function

Gets the DMA channel interrupt flags.

File

plib_usbhs.h

C

```
USBHS_DMA_INTERRUPT PLIB_USBHS_DMAInterruptFlagsGet(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function gets the DMA channel interrupt flags.

Remarks

None.

Preconditions

None.

Example

```
USBHS_DMA_INTERRUPT interruptFlags;
interruptFlags = PLIB_USBHS_DMAInterruptFlagsGet( MY_USB_INSTANCE );
// All interrupt flags cleared on read.

if ( interruptFlags > 0 )
    if ( interruptFlags & USBHS_DMAINT_1 )
    {
        // DMA Channel 1
    }
    if (interruptFlags & USBHS_DMAINT_2)
    {
        // DMA Channel 2
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_DMA_INTERRUPT PLIB_USBHS_DMAInterruptFlagsGet(USBHS_MODULE_ID index)

PLIB_USBHS_TxInterruptFlagsGet Function

Gets the TX endpoint interrupt flags.

File

plib_usbhs.h

C

```
USBHS_EPTXRX_INTERRUPT PLIB_USBHS_TxInterruptFlagsGet(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function gets the TX endpoint interrupt flags.

Remarks

TX interrupts must first be enabled by calling PLIB_USBHS_TxInterruptEnable.

Preconditions

None.

Example

```
USBHS_EPTXRX_INTERRUPT interruptFlags;
interruptFlags = PLIB_USBHS_TxInterruptFlagsGet( MY_USB_INSTANCE );
// All interrupt flags cleared on read.

if ( interruptFlags > 0 )
    if ( interruptFlags & USBHS_TXRXINT_EP0 )
    {
       // Endpoint Zero
    }
    if ( interruptFlags & USBHS_TXRXINT_EP1 )
    {
        // Endpoint One
    }
    .
    .
    .
}
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_EPTXRX_INTERRUPT PLIB_USBHS_TxInterruptFlagsGet(USBHS_MODULE_ID index)

PLIB_USBHS_RxInterruptDisable Function

Disables a RX endpoint interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_RxInterruptDisable(USBHS_MODULE_ID index, USBHS_EPTXRX_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function disables a RX endpoint interrupt source for the USB module.

Remarks

See also PLIB_USBHS_RxInterruptEnable. USBHS_TXRXINT_EP0 is not a valid argument. For endpoint zero, use PLIB_USBHS_TxInterruptDisable.

Preconditions

None.

Example

```
PLIB_USBHS_RxInterruptDisable( MY_USB_INSTANCE, USBHS_TXRXINT_EP1 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_RxInterruptDisable(USBHS_MODULE_ID index,

USBHS_EPTXRX_INTERRUPT interruptFlag)

PLIB_USBHS_RxInterruptEnable Function

Enables a RX endpoint interrupt for the USB module.

File

plib_usbhs.h

C

```
void PLIB_USBHS_RxInterruptEnable(USBHS_MODULE_ID index, USBHS_EPTXRX_INTERRUPT interruptFlag);
```

Returns

None.

Description

This function enables RX endpoint interrupt sources of the USB module to trigger a USB interrupt.

Remarks

See also PLIB_USBHS_RxInterruptDisable. USBHS_TXRXINT_EP0 is not a valid argument. For endpoint zero use PLIB_USBHS_TxInterruptEnable.

Preconditions

None.

Example

```
PLIB_USBHS_RxInterruptEnable( MY_USB_INSTANCE, USBHS_TXRXINT_EP1 );
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest
interruptFlag	Interrupt

Function

void PLIB_USBHS_RxInterruptEnable(USBHS_MODULE_ID index,

USBHS_EPTXRX_INTERRUPT interruptFlag)

PLIB_USBHS_RxInterruptFlagsGet Function

Gets RX endpoint interrupt flags.

File

plib_usbhs.h

C

```
USBHS_EPTXRX_INTERRUPT PLIB_USBHS_RxInterruptFlagsGet(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function gets the RX endpoint interrupt flags.

Remarks

RX interrupts must first be enabled by calling PLIB_USBHS_RxInterruptEnable. USBHS_TXRXINT_EP0 is not a valid argument. For endpoint zero use PLIB_USBHS_TxInterruptFlagsGet.

Preconditions

None.

Example

```
USBHS_EPTXRX_INTERRUPT interruptFlags;
```

```
    interruptFlags = PLIB_USBHS_RxInterruptFlagsGet( MY_USB_INSTANCE );
    // All interrupt flags cleared on read.

    if ( interruptFlags > 0 )
        if ( interruptFlags & USBHS_TXRXINT_EP1 )
        {
           // Endpoint Zero
        }
        if ( interruptFlags & USBHS_TXRXINT_EP2 )
        {
            // Endpoint One
        }
        .
        .
        .
    }
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_EPTXRX_INTERRUPT PLIB_USBHS_RxInterruptFlagsGet(USBHS_MODULE_ID index)

PLIB_USBHS_DMAInterruptGet Function

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_DMAInterruptGet(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_DMAInterruptGet.

PLIB_USBHS_GlobalInterruptDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_GlobalInterruptDisable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_GlobalInterruptDisable.

PLIB_USBHS_GlobalInterruptEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_GlobalInterruptEnable(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_GlobalInterruptEnable.

d) Device Functions

PLIB_USBHS_DeviceAddressGet Function

Returns the current USB device address.

File

plib_usbhs.h

C

```
uint8_t PLIB_USBHS_DeviceAddressGet(USBHS_MODULE_ID index);
```

Returns

7-bit unsigned integer value indicating the current USB device address.

Description

This function returns the current USB device address.

Remarks

None.

Preconditions

The USB module should have been configured for Device mode operation.

Example

```
// This code example reads the current assigned USB device address.

uint8_t address;
address = PLIB_USBHS_DeviceAddressGet(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

uint8_t PLIB_USBHS_DeviceAddressGet (USBHS_MODULE_ID index)

PLIB_USBHS_DeviceAddressSet Function

Sets the device address.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceAddressSet(USBHS_MODULE_ID index, uint8_t address);
```

Returns

None.

Description

This function sets the device address. This function should be called with the address received from the host in the SET_ADDRESS request.

Remarks

None.

Preconditions

The USB module must be configured for Device mode operation.

Example

```
// This code example assigns a USB device address.

uint8_t address;
```

```
PLIB_USBHS_DeviceAddressSet(USBHS_ID_0, address);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured
address	7-bit USB Device address that should be assigned to this device

Function

void PLIB_USBHS_DeviceAddressSet (USBHS_MODULE_ID index, uint8_t address)

PLIB_USBHS_DeviceAttach Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceAttach(USBHS_MODULE_ID index, uint32_t speed);
```

Description

This is function PLIB_USBHS_DeviceAttach.

PLIB_USBHS_DeviceConnect Function

Tri-states the USB D+ and D- lines.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceConnect(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function enables the USB D+ and D- lines, which connects the device from the host.

Remarks

Only valid for Device mode.

Preconditions

The USB module must be configured for Device mode operation.

Example

```
// Disconnect the device from the host

PLIB_USBHS_DeviceConnect(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USBHS_DeviceConnect(USBHS_MODULE_ID index)

PLIB_USBHS_DeviceDetach Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceDetach(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_DeviceDetach.

PLIB_USBHS_DeviceDisconnect Function

Tri-states the USB D+ and D- lines.

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceDisconnect(USBHS_MODULE_ID index);
```

Returns

None.

Description

This function tri-states the USB D+ and D- lines, which disconnects the device from the host.

Remarks

Only valid for Device mode.

Preconditions

None.

Example

```
// Disconnect the device from the host

PLIB_USBHS_DeviceDisconnect(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance to be configured

Function

void PLIB_USBHS_DeviceDisconnect(USBHS_MODULE_ID index)

PLIB_USBHS_DeviceEPFIFOLoad Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceEPFIFOLoad(USBHS_MODULE_ID index, uint8_t endpoint, void * source, size_t nBytes);
```

Description

This is function PLIB_USBHS_DeviceEPFIFOLoad.

PLIB_USBHS_DeviceEPFIFOUnload Function

File

plib_usbhs.h

C

```
int PLIB_USBHS_DeviceEPFIFOUnload(USBHS_MODULE_ID index, uint8_t endpoint, void * dest);
```

Description

This is function PLIB_USBHS_DeviceEPFIFOUnload.

PLIB_USBHS_DeviceRxEndpointConfigure Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceRxEndpointConfigure(USBHS_MODULE_ID index, uint8_t endpoint, uint16_t endpointSize,
uint16_t fifoAddress, uint8_t fifoSize, uint32_t transferType);
```

Description

This is function PLIB_USBHS_DeviceRxEndpointConfigure.

PLIB_USBHS_DeviceRxEndpointStallDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceRxEndpointStallDisable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceRxEndpointStallDisable.

PLIB_USBHS_DeviceRxEndpointStallEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceRxEndpointStallEnable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceRxEndpointStallEnable.

PLIB_USBHS_DeviceTxEndpointConfigure Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceTxEndpointConfigure(USBHS_MODULE_ID index, uint8_t endpoint, uint16_t endpointSize,
uint16_t fifoAddress, uint8_t fifoSize, uint32_t transferType);
```

Description

This is function PLIB_USBHS_DeviceTxEndpointConfigure.

PLIB_USBHS_DeviceTxEndpointPacketReady Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceTxEndpointPacketReady(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceTxEndpointPacketReady.

PLIB_USBHS_DeviceTxEndpointStallDisable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceTxEndpointStallDisable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceTxEndpointStallDisable.

PLIB_USBHS_DeviceTxEndpointStallEnable Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_DeviceTxEndpointStallEnable(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_DeviceTxEndpointStallEnable.

e) Host Functions

PLIB_USBHS_HostRxEndpointDataToggleClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HostRxEndpointDataToggleClear(USBHS_MODULE_ID index, uint8_t hostEndpoint);
```

Description

This is function PLIB_USBHS_HostRxEndpointDataToggleClear.

PLIB_USBHS_HostTxEndpointDataToggleClear Function

File

plib_usbhs.h

C

```
void PLIB_USBHS_HostTxEndpointDataToggleClear(USBHS_MODULE_ID index, uint8_t hostEndpoint);
```

Description

This is function PLIB_USBHS_HostTxEndpointDataToggleClear.

f) Status Functions

PLIB_USBHS_FullOrHighSpeedIsConnected Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_FullOrHighSpeedIsConnected(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_FullOrHighSpeedIsConnected.

PLIB_USBHS_HighSpeedIsConnected Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_HighSpeedIsConnected(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_HighSpeedIsConnected.

PLIB_USBHS_HostModeIsEnabled Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_HostModeIsEnabled(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_HostModeIsEnabled.

PLIB_USBHS_ModuleSpeedGet Function

Returns the speed at which the module is operating.

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ModuleSpeedGet(USBHS_MODULE_ID index);
```

Returns

Current module operation speed on the USB.

Description

This function returns the speed at which the module is operating. In case of device mode operation, this function returns the speed at which the device attached to the host.

Remarks

None.

Preconditions

None.

Example

```
USB_SPEED speed;
speed = PLIB_USBHS_ModuleSpeedGet(USBHS_ID_0);
```

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USB_SPEED PLIB_USBHS_ModuleSpeedGet(USBHS_MODULE_ID index)

PLIB_USBHS_DMAErrorGet Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_DMAErrorGet(USBHS_MODULE_ID index, uint8_t dmaChannel);
```

Description

This is function PLIB_USBHS_DMAErrorGet.

PLIB_USBHS_GetReceiveDataCount Function

File

plib_usbhs.h

C

```
uint32_t PLIB_USBHS_GetReceiveDataCount(USBHS_MODULE_ID index, uint8_t endpoint);
```

Description

This is function PLIB_USBHS_GetReceiveDataCount.

g) VBUS Support Functions

PLIB_USBHS_VbusLevelGet Function

Returns the current VBUS level encode using the USBHS_VBUS_DETECT_LEVEL enumeration.

File

plib_usbhs.h

C

```
USBHS_VBUS_LEVEL PLIB_USBHS_VbusLevelGet(USBHS_MODULE_ID index);
```

Returns

Detected VBUS level, see USBHS_VBUS_DETECT_LEVEL enumeration.

Description

Returns the current VBUS level encode using the USBHS_VBUS_DETECT_LEVEL enumeration.

Remarks

None.

Preconditions

None.

Example

Parameters

Parameters	Description
index	Identifier for the device instance of interest

Function

USBHS_VBUS_DETECT_LEVEL PLIB_USBHS_VbusLevelGet(USBHS_MODULE_ID index)

PLIB_USBHS_VBUSLevelGet Function

File

plib_usbhs.h

C

```
USBHS_VBUS_LEVEL PLIB_USBHS_VBUSLevelGet(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_VBUSLevelGet.

h) Feature Existence Functions

PLIB_USBHS_ExistsEndpointFIFO Function

Identifies that the Endpoint FIFO feature exists on the Hi-Speed USB module.

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsEndpointFIFO(USBHS_MODULE_ID index);
```

Returns

- true - The feature is supported
- false - The feature is not supported

Description

This interface identifies that the Endpoint FIFO feature is available on the Hi-Speed USB module. When this interface returns true, these functions are supported on the device:

- PLIB_USBHS_EndpointFIFOLoad
- PLIB_USBHS_EndpointFIFOUnload

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_USBHS_ExistsEndpointFIFO(USBHS_MODULE_ID index)

PLIB_USBHS_ExistsEndpointOperations Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsEndpointOperations(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsEndpointOperations.

PLIB_USBHS_ExistsEP0Status Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsEP0Status(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsEP0Status.

PLIB_USBHS_ExistsHighSpeedSupport Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsHighSpeedSupport(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsHighSpeedSupport.

PLIB_USBHS_ExistsInterrupts Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsInterrupts(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsInterrupts.

PLIB_USBHS_ExistsModuleControl Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsModuleControl(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsModuleControl.

PLIB_USBHS_ExistsRxEPStatus Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsRxEPStatus(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsRxEPStatus.

PLIB_USBHS_ExistsSoftReset Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsSoftReset(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsSoftReset.

PLIB_USBHS_ExistsTxEPStatus Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsTxEPStatus(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsTxEPStatus.

PLIB_USBHS_ExistsClockResetControl Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsClockResetControl(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsClockResetControl.

PLIB_USBHS_ExistsUSBIDControl Function

File

plib_usbhs.h

C

```
bool PLIB_USBHS_ExistsUSBIDControl(USBHS_MODULE_ID index);
```

Description

This is function PLIB_USBHS_ExistsUSBIDControl.

i) Data Types and Constants

USBHS_CONFIGURATION Enumeration

Provides the enumeration Configuration bits.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_CONFIG_SOFTCONN,
  USBHS_CONFIG_DYNFIFOSIZE,
```

```
  USBHS_CONFIG_HBWTXISO,
  USBHS_CONFIG_HBWRXISO,
  USBHS_CONFIG_BIGENDIAN,
  USBHS_CONFIG_AUTOSPLIT,
  USBHS_CONFIG_AUTOJOIN
} USBHS_CONFIGURATION;
```

Members

Members	Description
USBHS_CONFIG_SOFTCONN	Soft connect/disconnect supported
USBHS_CONFIG_DYNFIFOSIZE	Dynamic sizing of FIFO buffers supported
USBHS_CONFIG_HBWTXISO	High bandwidth TX isochronous transfers supported
USBHS_CONFIG_HBWRXISO	High bandwidth RX isochronous transfers supported
USBHS_CONFIG_BIGENDIAN	Big Endian byte ordering supported instead of Little Endian
USBHS_CONFIG_AUTOSPLIT	Automatic splitting of bulk packets supported
USBHS_CONFIG_AUTOJOIN	Automatic combining of bulk packets supported

Description

USBHS Hardware Configuration Bits Enumeration

This data type provides the enumeration configuration bits returned by PLIB_USBHS_ConfigurationBitsGet.

Remarks

See also PLIB_USBHS_ConfigurationBitsGet.

USBHS_DATA01 Enumeration

Provides an enumeration data toggle for a packet.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DATA0,
  USBHS_DATA1
} USBHS_DATA01;
```

Members

Members	Description
USBHS_DATA0	DATA0/1 = 0
USBHS_DATA1	DATA0/1 = 1

Description

USBHS Endpoint Data Toggle Enumeration

This data type provides an enumeration data toggle for a packet.

Remarks

None.

USBHS_DMA_ASSERT_TIMING Enumeration

Provides enumeration DMA assertion timing (early versus late).

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMA_ASSERT_EARLY,
  USBHS_DMA_ASSERT_LATE
} USBHS_DMA_ASSERT_TIMING;
```

Members

Members	Description
USBHS_DMA_ASSERT_EARLY	Assert DMA 8 bytes before filling FIFO
USBHS_DMA_ASSERT_LATE	Assert DMA when FIFO is full

Description

USBHS DMA Assertion Timing Enumeration

This data type provides enumeration DMA assertion timing (early versus late).

Remarks

None.

USBHS_DMA_BURST_MODE Enumeration

Provides enumeration of all DMA burst modes.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMA_BURST_MODE0,
  USBHS_DMA_BURST_MODE1,
  USBHS_DMA_BURST_MODE2,
  USBHS_DMA_BURST_MODE3
} USBHS_DMA_BURST_MODE;
```

Members

Members	Description
USBHS_DMA_BURST_MODE0	Burst Mode 0: Bursts of unspecified length
USBHS_DMA_BURST_MODE1	Burst Mode 1: INCR4 or unspecified length
USBHS_DMA_BURST_MODE2	Burst Mode 2: INCR8, INCR4 or unspecified length
USBHS_DMA_BURST_MODE3	Burst Mode 3: INCR16, INCR8, INCR4 or unspecified length

Description

USBHS DMA Burst Modes Enumeration

This data type provides enumeration of all DMA burst modes.

Remarks

None.

USBHS_DMA_INTERRUPT Enumeration

Provides enumeration of interrupts for DMA channels 0-7.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMAINT_1,
  USBHS_DMAINT_2,
  USBHS_DMAINT_3,
  USBHS_DMAINT_4,
  USBHS_DMAINT_5,
  USBHS_DMAINT_6,
  USBHS_DMAINT_7,
  USBHS_DMAINT_8,
  USBHS_DMAINT_ANY,
  USBHS_DMAINT_ALL
} USBHS_DMA_INTERRUPT;
```

Description

USBHS DMA Interrupts Enumeration

This data type provides the enumeration of interrupts for DMA channels 0-7.

Remarks

None.

USBHS_DMA_REQUEST_MODE Enumeration

Used as an argument to set DMA request mode.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMA_MODE0,
  USBHS_DMA_MODE1
} USBHS_DMA_REQUEST_MODE;
```

Description

USBHS DMA Request Mode Enumeration

THis data type is used as an argument to set DMA request mode. Valid only for Endpoints 1-7.

Remarks

Used by PLIB_USBHS_EPnDMARequestModeSet.

USBHS_DMA_TRANSFER_MODE Enumeration

Provides enumeration of all DMA transfer modes.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_DMA_TRANSFER_MODE0,
  USBHS_DMA_TRANSFER_MODE1
} USBHS_DMA_TRANSFER_MODE;
```

Description

USBHS DMA Transfer Modes Enumeration

This data type provides enumeration of all DMA Transfer modes.

Remarks

None.

USBHS_DYN_FIFO_PACKET_BUFFERING Enumeration

Provides enumeration of dynamic FIFO double-packet versus single-packet buffering.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_FIFO_SINGLEPKT,
  USBHS_FIFO_DOUBLEPKT
} USBHS_DYN_FIFO_PACKET_BUFFERING;
```

Description

USBHS Dynamic FIFO Double Packet versus Single Packet Buffering

This data type provides enumeration of dynamic FIFO double-packet versus single-packet buffering.

Remarks

None.

USBHS_DYN_FIFO_SIZE Enumeration

Provides enumeration of dynamic FIFO sizes.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_FIFO_SIZE_8BYTES,
  USBHS_FIFO_SIZE_16BYTES,
  USBHS_FIFO_SIZE_32BYTES,
  USBHS_FIFO_SIZE_64BYTES,
  USBHS_FIFO_SIZE_128BYTES,
  USBHS_FIFO_SIZE_256BYTES,
  USBHS_FIFO_SIZE_512BYTES,
  USBHS_FIFO_SIZE_1024BYTES,
  USBHS_FIFO_SIZE_2048BYTES,
  USBHS_FIFO_SIZE_4096BYTES
} USBHS_DYN_FIFO_SIZE;
```

Description

USBHS Dynamic FIFO Size Enumeration

This data type provides enumeration of dynamic FIFO sizes.

Remarks

FIFO size = 2^(FIFO_Size<3:0> + 3)

USBHS_ENDPOINT_DIRECTION Enumeration

Used as an argument to identify an endpoint direction.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_ENDPOINT_RX,
  USBHS_ENDPOINT_TX
} USBHS_ENDPOINT_DIRECTION;
```

Members

Members	Description
USBHS_ENDPOINT_RX	RX endpoint
USBHS_ENDPOINT_TX	TX endpoint

Description

USBHS Endpoint Direction Enumeration

This data type is used as an argument to identify an endpoint direction. Valid only for Endpoints 1-7.

Remarks

None.

USBHS_LPM_INTERRUPT Enumeration

Provides an enumeration of LPM interrupt sources.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_LPMINT_STALL,
  USBHS_LPMINT_NYET,
  USBHS_LPMINT_ACK,
  USBHS_LPMINT_NOTCOMPLETE,
  USBHS_LPMINT_RESUMED,
  USBHS_LPMINT_ERROR
} USBHS_LPM_INTERRUPT;
```

Members

Members	Description
USBHS_LPMINT_STALL	Host: Device responded with STALL. Peripheral/Device: Sent a STALL.
USBHS_LPMINT_NYET	Host: Device responded with NYET. Peripheral/Device: Sent a NYET.
USBHS_LPMINT_ACK	Host: Device responded with ACK. Peripheral/Device: Sent an ACK.
USBHS_LPMINT_NOTCOMPLETE	Host: LPM transaction failed to complete. Peripheral/Device: NYET sent because data is pending in RX FIFOs.
USBHS_LPMINT_RESUMED	USB Module has resumed operation.
USBHS_LPMINT_ERROR	Host: Received Bit Stuff or PID error. Peripheral/Device: Unsupported LinkState field received.

Description

USBHS Link Power Management (LPM) Interrupts Enumeration

This data type provides an enumeration of LPM interrupt sources.

Remarks

None.

USBHS_LPM_LINK_STATE Enumeration

Provides enumeration requested device state after accepting an LPM transaction.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_LPM_RESERVED_0,
  USBHS_LPM_L1_STATE,
  USBHS_LPM_RESERVED_2,
  USBHS_LPM_RESERVED_3,
  USBHS_LPM_RESERVED_4,
  USBHS_LPM_RESERVED_5,
  USBHS_LPM_RESERVED_6,
  USBHS_LPM_RESERVED_7,
  USBHS_LPM_RESERVED_8,
  USBHS_LPM_RESERVED_9,
  USBHS_LPM_RESERVED_A,
  USBHS_LPM_RESERVED_B,
  USBHS_LPM_RESERVED_C,
  USBHS_LPM_RESERVED_D,
  USBHS_LPM_RESERVED_E,
  USBHS_LPM_RESERVED_F
} USBHS_LPM_LINK_STATE;
```

Description

USBHS Link Power Management Requested State Enumeration

This data type provides enumeration requested device state after accepting an LPM transaction.

Remarks

Used by PLIB_USBHS_LPMRequestedLinkStateGet and PLIB_USBHS_LPMRequestedLinkStateSet.

USBHS_LPM_MODE Enumeration

Provides enumeration of Link Power Management (LPM) modes.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_LPM_DISABLED,
  USBHS_LPM_EXTENDEDNOLPM,
  USBHS_LPM_DISABLED2,
  USBHS_LPM_LPMEXTENDED
} USBHS_LPM_MODE;
```

Members

Members	Description
USBHS_LPM_DISABLED	LPM and Extended transactions not supported and will time-out
USBHS_LPM_EXTENDEDNOLPM	Extended transactions supported but LPM transactions not supported and produce STALLs
USBHS_LPM_DISABLED2	LPM and Extended transactions not supported and will timeout
USBHS_LPM_LPMEXTENDED	LPM and Extended transactions are supported

Description

USBHS Link Power Management (LPM) Mode Enumeration

This data type provides enumeration of Link Power Management (LPM) modes.

Remarks

Used by PLIB_USBHS_LPMModeSet.

USBHS_OPMODES Enumeration

Provides enumeration of operating modes supported by USB.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_OPMODE_NONE,
  USBHS_OPMODE_DEVICE,
  USBHS_OPMODE_HOST,
  USBHS_OPMODE_OTG
} USBHS_OPMODES;
```

Members

Members	Description
USBHS_OPMODE_NONE	None
USBHS_OPMODE_DEVICE	Device
USBHS_OPMODE_HOST	Host
USBHS_OPMODE_OTG	OTG

Description

USB Operating Modes Enumeration

This data type provides enumeration of the operating modes supported by the USB module.

Remarks

None.

USBHS_PKTS_PER_MICROFRAME Enumeration

Provides an enumeration of the allowable isochronous packets per microframe when operating in High-Speed mode.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_ONE_PKTS,
  USBHS_TWO_PKTS,
  USBHS_THREE_PKTS,
  USBHS_RSVD_PKTS
} USBHS_PKTS_PER_MICROFRAME;
```

Description

USBHS Iso Packets Per Microframe Enumeration

This data type provides an enumeration of the allowable isochronous packets per microframe when operating in High-Speed mode.

Remarks

Used by PLIB_USBHS_EPnPacketsInMicroFrameSet.

For Transmit Endpoints: PIC32MZ EC device SFR fields: USBIENCSR0.MULT<1:0> = USBIENCSR0<12:11>, with USBCSR3.ENDPOINT = 1,2,...7

For Receive Endpoints: MG register fields: RXMAXP.m-1 = RXMAXP<12:11>, with INDEX.SelectedEndpoint = 1,2,...7 PIC32MZ EC device SFR fields: USBIENCSR1.MULT<1:0> = USBIENCSR1<12:11>, with USBCSR3.ENDPOINT = 1,2,...7

USBHS_SPEED Enumeration

Provides enumeration Host endpoint speeds.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_LOW_SPEED,
  USBHS_FULL_SPEED,
  USBHS_HIGH_SPEED
} USBHS_SPEED;
```

Description

USBHS Endpoint Speed Enumeration

This data type provides enumeration Host endpoint speeds.

Remarks

Used by PLIB_USBHS_EPnSpeedSet.

USBHS_TEST_SPEED Enumeration

Used as an argument for in setting module speeds in Test mode.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_TEST_LOW_SPEED,
  USBHS_TEST_FULL_SPEED,
  USBHS_TEST_HIGH_SPEED
} USBHS_TEST_SPEED;
```

Description

USBHS Test Speeds Enumeration

This data type is used as an argument for setting module speeds in Test mode.

Remarks

For use with PLIB_USBHS_TestSpeedForce.

USBHS_TRANSACTION_TYPE Enumeration

Provides an enumeration of transaction types.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_TRANSACTION_CONTROL,
  USBHS_TRANSACTION_ISO,
  USBHS_TRANSACTION_BULK,
  USBHS_TRANSACTION_INTERRUPT
} USBHS_TRANSACTION_TYPE;
```

Description

USBHS Endpoint Transaction Type Enumeration

This data type provides an enumeration of transaction types.

Remarks

Used by PLIB_USBHS_EPnTransactionTypeSet

USBHS_TXRX_FIFO_STATE Enumeration

Provides enumeration of receive and transmit FIFO states, as reported by status bits.

File

plib_usbhs.h

C

```
typedef enum {
  USBHS_TX_FIFO_EMPTY,
  USBHS_TX_FIFO_NOT_EMPTY,
  USBHS_RX_FIFO_FULL,
  USBHS_RX_FIFO_NOTFULL
} USBHS_TXRX_FIFO_STATE;
```

Members

Members	Description
USBHS_TX_FIFO_EMPTY	TX FIFO Empty
USBHS_TX_FIFO_NOT_EMPTY	TX FIFO NOT Empty
USBHS_RX_FIFO_FULL	RX FIFO Full
USBHS_RX_FIFO_NOTFULL	RX FIFO NOT Full

Description

USBHS FIFO State Enumeration

This data type provides enumeration of receive and transmit FIFO states, as reported by status bits.

Remarks

None.

For Transmit Endpoints: MG register fields: TXCSRL.FIFONotEmpty = TXCSRL<1>, with INDEX.SelectedEndpoint = 1,2,...7 PIC32MZ EC device SFR fields: USBIENCSR0.FIFONE = USBIENCSR0<17>, with USBCSR3.ENDPOINT = 1,2,...7

For Receive Endpoints: MG register fields: RXCSRL.FIFOFull = RXCSRL<1>, with INDEX.SelectedEndpoint = 1,2,...7 PIC32MZ EC device SFR fields: USBIENCSR1.FIFOFULL = USBIENCSR1<17>, with USBCSR3.ENDPOINT = 1,2,...7

USBHS_MAX_DMA_CHANNEL_NUMBER Macro

Number of available DMA Channels.

File

plib_usbhs.h

C

```
#define USBHS_MAX_DMA_CHANNEL_NUMBER 8
```

Description

Number of DMA Channels

This constant defines the number of available DMA Channels.

USBHS_MAX_EP_NUMBER Macro

Maximum number of endpoints supported (not including EP0).

File

plib_usbhs.h

C

```
#define USBHS_MAX_EP_NUMBER 7
```

Description

Maximum number of endpoints

This constant defines the maximum number of endpoints supported (not including EP0).

Files

Files

Name	Description
plib_usbhs.h	HS USB PLIB Interface Header for definitions common to the Hi-Speed USB module.

Description

This section lists the source and header files used by the library.

plib_usbhs.h

HS USB PLIB Interface Header for definitions common to the Hi-Speed USB module.

Enumerations

	Name	Description
	USBHS_CONFIGURATION	Provides the enumeration Configuration bits.
	USBHS_DATA01	Provides an enumeration data toggle for a packet.
	USBHS_DMA_ASSERT_TIMING	Provides enumeration DMA assertion timing (early versus late).
	USBHS_DMA_BURST_MODE	Provides enumeration of all DMA burst modes.
	USBHS_DMA_INTERRUPT	Provides enumeration of interrupts for DMA channels 0-7.
	USBHS_DMA_REQUEST_MODE	Used as an argument to set DMA request mode.
	USBHS_DMA_TRANSFER_MODE	Provides enumeration of all DMA transfer modes.
	USBHS_DYN_FIFO_PACKET_BUFFERING	Provides enumeration of dynamic FIFO double-packet versus single-packet buffering.
	USBHS_DYN_FIFO_SIZE	Provides enumeration of dynamic FIFO sizes.
	USBHS_ENDPOINT_DIRECTION	Used as an argument to identify an endpoint direction.
	USBHS_LPM_INTERRUPT	Provides an enumeration of LPM interrupt sources.
	USBHS_LPM_LINK_STATE	Provides enumeration requested device state after accepting an LPM transaction.
	USBHS_LPM_MODE	Provides enumeration of Link Power Management (LPM) modes.
	USBHS_OPMODES	Provides enumeration of operating modes supported by USB.
	USBHS_PKTS_PER_MICROFRAME	Provides an enumeration of the allowable isochronous packets per microframe when operating in High-Speed mode.
	USBHS_SPEED	Provides enumeration Host endpoint speeds.
	USBHS_TEST_SPEED	Used as an argument for in setting module speeds in Test mode.
	USBHS_TRANSACTION_TYPE	Provides an enumeration of transaction types.
	USBHS_TXRX_FIFO_STATE	Provides enumeration of receive and transmit FIFO states, as reported by status bits.

Functions

	Name	Description
	PLIB_USBHS_DeviceAddressGet	Returns the current USB device address.
	PLIB_USBHS_DeviceAddressSet	Sets the device address.
	PLIB_USBHS_DeviceAttach	This is function PLIB_USBHS_DeviceAttach.
	PLIB_USBHS_DeviceConnect	Tri-states the USB D+ and D- lines.
	PLIB_USBHS_DeviceDetach	This is function PLIB_USBHS_DeviceDetach.
	PLIB_USBHS_DeviceDisconnect	Tri-states the USB D+ and D- lines.
	PLIB_USBHS_DeviceEPFIFOLoad	This is function PLIB_USBHS_DeviceEPFIFOLoad.
	PLIB_USBHS_DeviceEPFIFOUnload	This is function PLIB_USBHS_DeviceEPFIFOUnload.
	PLIB_USBHS_DeviceRxEndpointConfigure	This is function PLIB_USBHS_DeviceRxEndpointConfigure.
	PLIB_USBHS_DeviceRxEndpointStallDisable	This is function PLIB_USBHS_DeviceRxEndpointStallDisable.
	PLIB_USBHS_DeviceRxEndpointStallEnable	This is function PLIB_USBHS_DeviceRxEndpointStallEnable.
	PLIB_USBHS_DeviceTxEndpointConfigure	This is function PLIB_USBHS_DeviceTxEndpointConfigure.
	PLIB_USBHS_DeviceTxEndpointPacketReady	This is function PLIB_USBHS_DeviceTxEndpointPacketReady.
	PLIB_USBHS_DeviceTxEndpointStallDisable	This is function PLIB_USBHS_DeviceTxEndpointStallDisable.
	PLIB_USBHS_DeviceTxEndpointStallEnable	This is function PLIB_USBHS_DeviceTxEndpointStallEnable.
	PLIB_USBHS_DMAErrorGet	This is function PLIB_USBHS_DMAErrorGet.
	PLIB_USBHS_DMAInterruptDisable	Disables DMA channel interrupts.
	PLIB_USBHS_DMAInterruptEnable	Enables DMA channel interrupts.
	PLIB_USBHS_DMAInterruptFlagsGet	Gets the DMA channel interrupt flags.
	PLIB_USBHS_DMAInterruptGet	This is function PLIB_USBHS_DMAInterruptGet.
	PLIB_USBHS_DMAOperationEnable	This is function PLIB_USBHS_DMAOperationEnable.
	PLIB_USBHS_Endpoint0FIFOFlush	This is function PLIB_USBHS_Endpoint0FIFOFlush.
	PLIB_USBHS_Endpoint0SetupPacketLoad	Loads the endpoint 0 FIFO with provided setup packet and then enables the endpoint transmit.
	PLIB_USBHS_Endpoint0SetupPacketUnload	This is function PLIB_USBHS_Endpoint0SetupPacketUnload.
	PLIB_USBHS_EndpointFIFOLoad	Loads the endpoint FIFO with provided data and then enables the endpoint transmit.
	PLIB_USBHS_EndpointFIFOUnload	Unloads the endpoint FIFO.
	PLIB_USBHS_EndpointRxFIFOFlush	This is function PLIB_USBHS_EndpointRxFIFOFlush.
	PLIB_USBHS_EndpointRxRequestClear	This is function PLIB_USBHS_EndpointRxRequestClear.
	PLIB_USBHS_EndpointRxRequestEnable	This is function PLIB_USBHS_EndpointRxRequestEnable.
	PLIB_USBHS_EndpointTxFIFOFlush	This is function PLIB_USBHS_EndpointTxFIFOFlush.
	PLIB_USBHS_EP0DataEndSet	This is function PLIB_USBHS_EP0DataEndSet.
	PLIB_USBHS_EP0INHandshakeClear	This is function PLIB_USBHS_EP0INHandshakeClear.
	PLIB_USBHS_EP0INHandshakeSend	This is function PLIB_USBHS_EP0INHandshakeSend.
	PLIB_USBHS_EP0INTokenSend	This is function PLIB_USBHS_EP0INTokenSend.
	PLIB_USBHS_EP0OUTHandshakeSend	This is function PLIB_USBHS_EP0OUTHandshakeSend.
	PLIB_USBHS_EP0RxPktRdyServiced	This is function PLIB_USBHS_EP0RxPktRdyServiced.
	PLIB_USBHS_EP0RxPktRdyServicedDataEnd	This is function PLIB_USBHS_EP0RxPktRdyServicedDataEnd.
	PLIB_USBHS_EP0SentStallClear	This is function PLIB_USBHS_EP0SentStallClear.
	PLIB_USBHS_EP0SetupEndServiced	This is function PLIB_USBHS_EP0SetupEndServiced.
	PLIB_USBHS_EP0StallDisable	This is function PLIB_USBHS_EP0StallDisable.
	PLIB_USBHS_EP0StallEnable	This is function PLIB_USBHS_EP0StallEnable.
	PLIB_USBHS_EP0StatusClear	This is function PLIB_USBHS_EP0StatusClear.
	PLIB_USBHS_EP0StatusGet	This is function PLIB_USBHS_EP0StatusGet.
	PLIB_USBHS_EP0TxPktRdy	This is function PLIB_USBHS_EP0TxPktRdy.
	PLIB_USBHS_EP0TxPktRdyDataEnd	This is function PLIB_USBHS_EP0TxPktRdyDataEnd.
	PLIB_USBHS_ExistsClockResetControl	This is function PLIB_USBHS_ExistsClockResetControl.
	PLIB_USBHS_ExistsEndpointFIFO	Identifies that the Endpoint FIFO feature exists on the Hi-Speed USB module.
	PLIB_USBHS_ExistsEndpointOperations	This is function PLIB_USBHS_ExistsEndpointOperations.
	PLIB_USBHS_ExistsEP0Status	This is function PLIB_USBHS_ExistsEP0Status.
	PLIB_USBHS_ExistsHighSpeedSupport	This is function PLIB_USBHS_ExistsHighSpeedSupport.
	PLIB_USBHS_ExistsInterrupts	This is function PLIB_USBHS_ExistsInterrupts.

	PLIB_USBHS_ExistsModuleControl	This is function PLIB_USBHS_ExistsModuleControl.
	PLIB_USBHS_ExistsRxEPStatus	This is function PLIB_USBHS_ExistsRxEPStatus.
	PLIB_USBHS_ExistsSoftReset	This is function PLIB_USBHS_ExistsSoftReset.
	PLIB_USBHS_ExistsTxEPStatus	This is function PLIB_USBHS_ExistsTxEPStatus.
	PLIB_USBHS_ExistsUSBIDControl	This is function PLIB_USBHS_ExistsUSBIDControl.
	PLIB_USBHS_FullOrHighSpeedIsConnected	This is function PLIB_USBHS_FullOrHighSpeedIsConnected.
	PLIB_USBHS_GenInterruptDisable	Disables a general interrupt for the USB module.
	PLIB_USBHS_GenInterruptEnable	Enables a general interrupt for the USB module.
	PLIB_USBHS_GenInterruptFlagsGet	Gets general interrupt flags.
	PLIB_USBHS_GetEP0CSRAddress	This is function PLIB_USBHS_GetEP0CSRAddress.
	PLIB_USBHS_GetEP0FIFOAddress	This is function PLIB_USBHS_GetEP0FIFOAddress.
	PLIB_USBHS_GetReceiveDataCount	This is function PLIB_USBHS_GetReceiveDataCount.
	PLIB_USBHS_GlobalInterruptDisable	This is function PLIB_USBHS_GlobalInterruptDisable.
	PLIB_USBHS_GlobalInterruptEnable	This is function PLIB_USBHS_GlobalInterruptEnable.
	PLIB_USBHS_HighSpeedDisable	This is function PLIB_USBHS_HighSpeedDisable.
	PLIB_USBHS_HighSpeedEnable	Sets the operation speed of the USB Module.
	PLIB_USBHS_HighSpeedIsConnected	This is function PLIB_USBHS_HighSpeedIsConnected.
	PLIB_USBHS_HostModeIsEnabled	This is function PLIB_USBHS_HostModeIsEnabled.
	PLIB_USBHS_HostRxEndpointConfigure	This is function PLIB_USBHS_HostRxEndpointConfigure.
	PLIB_USBHS_HostRxEndpointDataToggleClear	This is function PLIB_USBHS_HostRxEndpointDataToggleClear.
	PLIB_USBHS_HostTxEndpointConfigure	This is function PLIB_USBHS_HostTxEndpointConfigure.
	PLIB_USBHS_HostTxEndpointDataToggleClear	This is function PLIB_USBHS_HostTxEndpointDataToggleClear.
	PLIB_USBHS_InterruptEnableSet	Enables USB module event interrupts.
	PLIB_USBHS_IsBDevice	This is function PLIB_USBHS_IsBDevice.
	PLIB_USBHS_LoadEPInIndex	This is function PLIB_USBHS_LoadEPInIndex.
	PLIB_USBHS_ModuleSpeedGet	Returns the speed at which the module is operating.
	PLIB_USBHS_PhyIDMonitoringDisable	This is function PLIB_USBHS_PhyIDMonitoringDisable.
	PLIB_USBHS_PhyIDMonitoringEnable	This is function PLIB_USBHS_PhyIDMonitoringEnable.
	PLIB_USBHS_ResetDisable	This is function PLIB_USBHS_ResetDisable.
	PLIB_USBHS_ResetEnable	This is function PLIB_USBHS_ResetEnable.
	PLIB_USBHS_ResumeDisable	This is function PLIB_USBHS_ResumeDisable.
	PLIB_USBHS_ResumeEnable	This is function PLIB_USBHS_ResumeEnable.
	PLIB_USBHS_RxEPINTokenSend	This is function PLIB_USBHS_RxEPINTokenSend.
	PLIB_USBHS_RxEPStatusClear	This is function PLIB_USBHS_RxEPStatusClear.
	PLIB_USBHS_RxEPStatusGet	This is function PLIB_USBHS_RxEPStatusGet.
	PLIB_USBHS_RxInterruptDisable	Disables a RX endpoint interrupt for the USB module.
	PLIB_USBHS_RxInterruptEnable	Enables a RX endpoint interrupt for the USB module.
	PLIB_USBHS_RxInterruptFlagsGet	Gets RX endpoint interrupt flags.
	PLIB_USBHS_SessionDisable	This is function PLIB_USBHS_SessionDisable.
	PLIB_USBHS_SessionEnable	This is function PLIB_USBHS_SessionEnable.
	PLIB_USBHS_SoftResetDisable	Disables soft reset.
	PLIB_USBHS_SoftResetEnable	Enables soft reset.
	PLIB_USBHS_SuspendDisable	This is function PLIB_USBHS_SuspendDisable.
	PLIB_USBHS_SuspendEnable	This is function PLIB_USBHS_SuspendEnable.
	PLIB_USBHS_TestModeEnter	This is function PLIB_USBHS_TestModeEnter.
	PLIB_USBHS_TestModeExit	This is function PLIB_USBHS_TestModeExit.
	PLIB_USBHS_TxEPStatusClear	This is function PLIB_USBHS_TxEPStatusClear.
	PLIB_USBHS_TxEPStatusGet	This is function PLIB_USBHS_TxEPStatusGet.
	PLIB_USBHS_TxInterruptDisable	Disables a TX endpoint interrupt source for the USB module.
	PLIB_USBHS_TxInterruptEnable	Enables a TX endpoint Interrupt for the USB module.
	PLIB_USBHS_TxInterruptFlagsGet	Gets the TX endpoint interrupt flags.
	PLIB_USBHS_USBIDOverrideDisable	This is function PLIB_USBHS_USBIDOverrideDisable.
	PLIB_USBHS_USBIDOverrideEnable	This is function PLIB_USBHS_USBIDOverrideEnable.
	PLIB_USBHS_USBIDOverrideValueSet	This is function PLIB_USBHS_USBIDOverrideValueSet.

	PLIB_USBHS_VbusLevelGet	Returns the current VBUS level encode using the USBHS_VBUS_DETECT_LEVEL enumeration.
	PLIB_USBHS_VBUSLevelGet	This is function PLIB_USBHS_VBUSLevelGet.

Macros

	Name	Description
	USBHS_MAX_DMA_CHANNEL_NUMBER	Number of available DMA Channels.
	USBHS_MAX_EP_NUMBER	Maximum number of endpoints supported (not including EP0).

Description

Hi-Speed USB (HS USB) Module Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the USB PLIB for families of Microchip microcontrollers that feature the Hi-Speed USB module.

Remarks

Required to access the High Speed USB Module registers.

File Name

plib_usbhs.h

Company

Microchip Technology Inc.

Watchdog Timer Peripheral Library

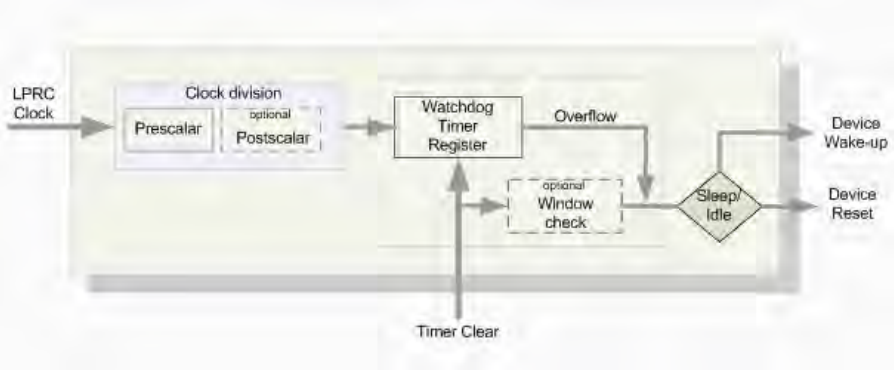
This section describes the Watchdog Timer (WDT) Peripheral Library.

Introduction

This library provides a low-level abstraction of the WDT Peripheral Library that is available on the Microchip family of microcontrollers with a convenient C language interface. It can be used to simplify low-level access to the module without the necessity of interacting directly with the module's registers, there by abstracting differences from one microcontroller variant to another.

Description

The primary function of the Watchdog Timer (WDT) is to reset the microcontroller, in the event of a software malfunction, by resetting the device if it has not been cleared by software. To ensure that application does not hang, the application is supposed to reset the timer periodically. It can also be used to wake the device from Sleep or Idle mode. The WDT is a free-running timer, which uses the Low-Power RC (LPRC) Oscillator and requires no external components. Therefore, the WDT will continue to operate even if the system's primary clock source is stopped.



Using the Library

This topic describes the basic architecture of the WDT Peripheral Library and provides information and examples on its use.

Description

Interface Header File: `plib_wdt.h`

The interface to the WDT Peripheral Library is defined in the `plib_wdt.h` header file, which is included by the peripheral library header file, `peripheral.h`. Any C language source (`.c`) file that uses the WDT Peripheral Library must include `peripheral.h`.

Library File:

The WDT Peripheral Library archive (`.a`) file is installed with MPLAB Harmony.

Please refer to the What is MPLAB Harmony? section for information on how the library interacts with the framework.

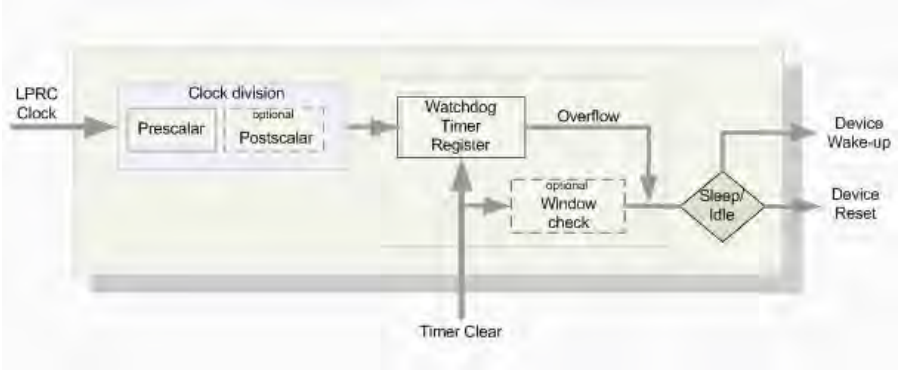
Hardware Abstraction Model

This library provides the low-level abstraction of the *Watchdog timer* module on the Microchip family of microcontrollers with a convenient C language interface. This topic describes how that abstraction is modeled in the software and introduces the library interface.

Note: The interface provided is a superset of all of the functionality of the available Watchdog Timer modules on the device. Please refer to the **"Watchdog Timer"** chapter in the specific device data sheet or the family reference manual section specified in that chapter to determine the set of functions that are supported for each Watchdog Timer module on your device.

Description

Watchdog Timer Software Abstraction Block Diagram



The WDT uses the internal Low-Power RC (LPRC) Oscillator as the clock source. The clock is divided by the configured prescaler value. There may be one more postscaler divisors. The divided clock is then used to increment a counter. The WDT module uses the watchdog register as a timer. If there is no reset signal from the software and if the counter overflows, this results in a reset in normal mode. In the case of Sleep or Idle mode, the overflow will result in a device wake-up.

For Windowed mode, resetting the counter when the count is not in the specified window will also lead to a reset. If the device is in Sleep or Idle mode, the reset signal will be used to wake-up the device.

Library Overview

The library interface routines are divided into various sub-sections, which address one of the blocks or the overall operation of the WDT module

Library Interface Section	Description
General Configuration Functions	This includes module enable, module disable, watchdog timer window enable, watchdog timer window disable and the timer reset routines.
General Status Functions	Status routines for the WDT.

How the Library Works

This section describes how the Watchdog Timer Peripheral Library works.

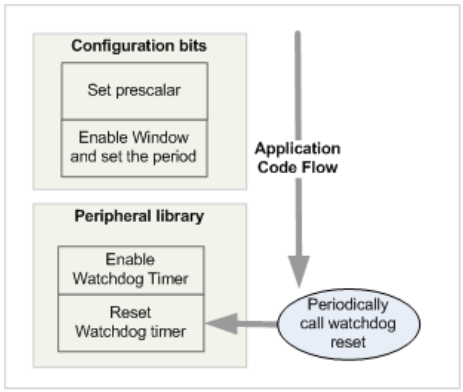
Description

Initializing the WDT module involves these processes.

- Selecting the postscaler
- Enabling the WDT using PLIB_WDT_Enable
- Selecting the window size if the application wants the WDT in Windowed mode using PLIB_WDT_WindowEnable

Note: Selecting the postscaler and window size should be done through the Configuration bits.

The application should periodically clear the timer once it is enabled; otherwise, a time-out will lead to a device Reset. Use PLIB_WDT_TimerClear to clear the WDT. A timer clear before a time-out may also lead to a reset in Windowed mode. The user application can clear the window only in the allowed window. Refer to the specific device data sheet to determine the allowed window period for your device.



Example

```
/*****************************************************************
* This code fragment assumes the WDT is not enabled through    *
* device configuration bits. The Postscaler value must be set *
```

```
* through the device configuration and window size should be  *
* set if applicable                                           *
***************************************************/

/* Initializing the watchdog involves  */
PLIB_WDT_Enable(WDT_ID_0);

//Application loop
while(1)
{
    PLIB_WDT_TimerClear(WDT_ID_0);

    //user code
}
```

Note: Refer to the specific device data sheet for information on the allowed window periods for your device and other Configuration bit settings.

Configuring the Library

The library is configured for the supported Watchdog Timer module when the processor is chosen in the MPLAB X IDE.

Library Interface

a) General Configuration Functions

	Name	Description
	PLIB_WDT_Disable	Disables the WDT module.
	PLIB_WDT_Enable	Enables the WDT module.
	PLIB_WDT_WindowDisable	Disables the WDT Windowed mode.
	PLIB_WDT_WindowEnable	Enables the WDT Window mode.
	PLIB_WDT_TimerClear	Resets the WDT module.

b) General Status Functions

	Name	Description
	PLIB_WDT_IsEnabled	Returns the watchdog timer on/off(enable/disable) status.
	PLIB_WDT_PostscalerValueGet	Returns the WDT postscaler value.
	PLIB_WDT_SleepModePostscalerValueGet	Returns the WDT Sleep Mode postscaler value.

c) Feature Existence Functions

	Name	Description
	PLIB_WDT_ExistsEnableControl	Identifies whether the EnableControl feature exists on the WDT module.
	PLIB_WDT_ExistsPostscalerValue	Identifies whether the PostscalerValue feature exists on the WDT module.
	PLIB_WDT_ExistsTimerClear	Identifies whether the TimerClear feature exists on the WDT module.
	PLIB_WDT_ExistsWindowEnable	Identifies whether the WindowEnable feature exists on the WDT module.
	PLIB_WDT_ExistsSleepModePostscalerValue	Identifies whether the SleepModePostscalerValue feature exists on the WDT module.

d) Data Types and Constants

	Name	Description
	WDT_MODULE_ID	Identifies the supported Watchdog Timer modules.

Description

This section describes the Application Programming Interface (API) functions of the Watchdog Timer Peripheral Library.

Refer to each section for a detailed description.

a) General Configuration Functions

PLIB_WDT_Disable Function

Disables the WDT module.

File

plib_wdt.h

C

```
void PLIB_WDT_Disable(WDT_MODULE_ID index);
```

Returns

None.

Description

This function disables the WDT module if it is enabled in software.

Remarks

This function will not disable the WDT module if it is enabled through its Configuration bits.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

The WDT module must be enabled through software.

Example

```
PLIB_WDT_Disable ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_Disable (WDT_MODULE_ID index)

PLIB_WDT_Enable Function

Enables the WDT module.

File

plib_wdt.h

C

```
void PLIB_WDT_Enable(WDT_MODULE_ID index);
```

Returns

None.

Description

This function enables the WDT module. If it is already enabled through the Configuration bits, it will keep it enabled.

Remarks

Calling this function is not necessary if it is enabled through its Configuration bits.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_WDT_Enable ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_Enable (WDT_MODULE_ID index)

PLIB_WDT_WindowDisable Function

Disables the WDT Windowed mode.

File

plib_wdt.h

C

```
void PLIB_WDT_WindowDisable(WDT_MODULE_ID index);
```

Returns

None.

Description

This function disables the WDT Windowed mode.

Remarks

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsWindowEnable in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_WDT_WindowDisable ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_WindowDisable (WDT_MODULE_ID index)

PLIB_WDT_WindowEnable Function

Enables the WDT Window mode.

File

plib_wdt.h

C

```
void PLIB_WDT_WindowEnable(WDT_MODULE_ID index);
```

Returns

None.

Description

This function enables the WDT Windowed mode.

Remarks

The window size must be set through the Configuration bits.

The example code doesn't include the settings that should be done through the Configuration bits.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use

PLIB_WDT_ExistsWindowEnable in your application to determine whether this feature is available.

Preconditions

The window size must be set through the Configuration bits.

Example

```
PLIB_WDT_WindowEnable ( WDT_ID_0 );
PLIB_WDT_Enable ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_WindowEnable (WDT_MODULE_ID index)

PLIB_WDT_TimerClear Function

Resets the WDT module.

File

plib_wdt.h

C

```
void PLIB_WDT_TimerClear(WDT_MODULE_ID index);
```

Returns

None.

Description

This function resets the WDT module. The WDT module should be cleared periodically before the count crosses and forces the device to reset.

Remarks

Resetting the device before the count reaches the window will cause a reset in Windowed mode.

The example code doesn't include the settings that should be done through the Configuration bits.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsTimerClear in your application to determine whether this feature is available.

Preconditions

None.

Example

```
PLIB_WDT_Enable ( WDT_ID_0 );

//Application loop
while(1)
{
    PLIB_WDT_TimerClear ( WDT_ID_0 );
    //user code
}
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

void PLIB_WDT_TimerClear (WDT_MODULE_ID index)

b) General Status Functions

PLIB_WDT_IsEnabled Function

Returns the watchdog timer on/off(enable/disable) status.

File

plib_wdt.h

C

```
bool PLIB_WDT_IsEnabled(WDT_MODULE_ID index);
```

Returns

- true - If the watchdog timer is on
- false - If the watchdog timer is off

Description

Returns the 'true', if the watchdog timer is already ON. Otherwise returns 'false'.

Remarks

This function returns 'true' if the device is enabled either though the Configuration bits or in the software.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsEnableControl in your application to determine whether this feature is available.

Preconditions

None.

Example

```
if (PLIB_WDT_IsEnabled ( WDT_ID_0 ) )
{
    //Do some action
}
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

bool PLIB_WDT_IsEnabled (WDT_MODULE_ID index)

PLIB_WDT_PostscalerValueGet Function

Returns the WDT postscaler value.

File

plib_wdt.h

C

```
char PLIB_WDT_PostscalerValueGet(WDT_MODULE_ID index);
```

Returns

The postscaler value.

Description

This function returns the WDT postscaler value. The value will correspond to a division factor.

Remarks

The value returned will be right-aligned.

Refer to the specific device data sheet to get the division factor corresponding to the value.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsPostscalerValue in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t value;

PLIB_WDT_Enable ( WDT_ID_0 );
value = PLIB_WDT_PostscalerValueGet ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

char PLIB_WDT_PostscalerValueGet (WDT_MODULE_ID index)

PLIB_WDT_SleepModePostscalerValueGet Function

Returns the WDT Sleep Mode postscaler value.

File

plib_wdt.h

C

```
char PLIB_WDT_SleepModePostscalerValueGet(WDT_MODULE_ID index);
```

Returns

The Sleep Mode postscaler value.

Description

This function returns the WDT postscaler value in Sleep Mode. The value will correspond to a division factor.

Remarks

The value returned will be right-aligned.

Refer to the specific device data sheet to get the division factor corresponding to the value.

This feature may not be available on all devices. Please refer to the specific device data sheet to determine availability or use PLIB_WDT_ExistsSleepModePostscalerValue in your application to determine whether this feature is available.

Preconditions

None.

Example

```
uint8_t value;
value = PLIB_WDT_SleepModePostscalerValueGet ( WDT_ID_0 );
```

Parameters

Parameters	Description
index	Identifies the desired WDT module

Function

char PLIB_WDT_SleepModePostscalerValueGet (WDT_MODULE_ID index)

c) Feature Existence Functions

PLIB_WDT_ExistsEnableControl Function

Identifies whether the EnableControl feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsEnableControl(WDT_MODULE_ID index);
```

Returns

Existence of the EnableControl feature:

- true - When EnableControl feature is supported on the device
- false - When EnableControl feature is not supported on the device

Description

This function identifies whether the EnableControl feature is available on the WDT module. When this function returns true, these functions are supported on the device:

- PLIB_WDT_Enable
- PLIB_WDT_Disable
- PLIB_WDT_IsEnabled

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsEnableControl(WDT_MODULE_ID index)

PLIB_WDT_ExistsPostscalerValue Function

Identifies whether the PostscalerValue feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsPostscalerValue(WDT_MODULE_ID index);
```

Returns

- true - The PostscalerValue feature is supported on the device
- false - The PostscalerValue feature is not supported on the device

Description

This function identifies whether the PostscalerValue feature is available on the WDT module. When this function returns true, this function is supported on the device:

- PLIB_WDT_PostscalerValueGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsPostscalerValue(WDT_MODULE_ID index)

PLIB_WDT_ExistsTimerClear Function

Identifies whether the TimerClear feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsTimerClear(WDT_MODULE_ID index);
```

Returns

- true - The TimerClear feature is supported on the device
- false - The TimerClear feature is not supported on the device

Description

This function identifies whether the TimerClear feature is available on the WDT module. When this function returns true, this function is supported on the device:

- PLIB_WDT_TimerClear

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsTimerClear(WDT_MODULE_ID index)

PLIB_WDT_ExistsWindowEnable Function

Identifies whether the WindowEnable feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsWindowEnable(WDT_MODULE_ID index);
```

Returns

- true - The WindowEnable feature is supported on the device
- false - The WindowEnable feature is not supported on the device

Description

This function identifies whether the WindowEnable feature is available on the WDT module. When this function returns true, these functions are supported on the device:

- PLIB_WDT_WindowEnable
- PLIB_WDT_WindowDisable

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsWindowEnable(WDT_MODULE_ID index)

PLIB_WDT_ExistsSleepModePostscalerValue Function

Identifies whether the SleepModePostscalerValue feature exists on the WDT module.

File

plib_wdt.h

C

```
bool PLIB_WDT_ExistsSleepModePostscalerValue(WDT_MODULE_ID index);
```

Returns

- true - The SleepModePostscalerValue feature is supported on the device
- false - The SleepModePostscalerValue feature is not supported on the device

Description

This function identifies whether the SleepModePostscalerValue feature is available on the WDT module. When this function returns true, this function is supported on the device:

- PLIB_WDT_SleepModePostscalerValueGet

Remarks

None.

Preconditions

None.

Parameters

Parameters	Description
index	Identifier for the device instance

Function

PLIB_WDT_ExistsSleepModePostscalerValue(WDT_MODULE_ID index)

d) Data Types and Constants

WDT_MODULE_ID Enumeration

Identifies the supported Watchdog Timer modules.

File

plib_wdt_help.h

C

```
typedef enum {
  WDT_ID_0,
  WDT_NUMBER_OF_MODULES
} WDT_MODULE_ID;
```

Members

Members	Description
WDT_ID_0	WDT Module 1 ID
WDT_NUMBER_OF_MODULES	Number of available WDT modules.

Description

Watchdog Timer (WDT) Module ID

This enumeration identifies the available Watchdog Timer modules.

Remarks

The caller should not rely on the specific numbers assigned to any of these values as they may change from one processor to the next.

Files

Files

Name	Description
plib_wdt.h	Watchdog Timer (WDT) Peripheral Library interface header for Watchdog Timer common definitions.
plib_wdt_help.h	

Description

This section lists the source and header files used by the library.

plib_wdt.h

Watchdog Timer (WDT) Peripheral Library interface header for Watchdog Timer common definitions.

Functions

	Name	Description
	PLIB_WDT_Disable	Disables the WDT module.
	PLIB_WDT_Enable	Enables the WDT module.
	PLIB_WDT_ExistsEnableControl	Identifies whether the EnableControl feature exists on the WDT module.
	PLIB_WDT_ExistsPostscalerValue	Identifies whether the PostscalerValue feature exists on the WDT module.
	PLIB_WDT_ExistsSleepModePostscalerValue	Identifies whether the SleepModePostscalerValue feature exists on the WDT module.
	PLIB_WDT_ExistsTimerClear	Identifies whether the TimerClear feature exists on the WDT module.
	PLIB_WDT_ExistsWindowEnable	Identifies whether the WindowEnable feature exists on the WDT module.
	PLIB_WDT_IsEnabled	Returns the watchdog timer on/off(enable/disable) status.
	PLIB_WDT_PostscalerValueGet	Returns the WDT postscaler value.
	PLIB_WDT_SleepModePostscalerValueGet	Returns the WDT Sleep Mode postscaler value.
	PLIB_WDT_TimerClear	Resets the WDT module.
	PLIB_WDT_WindowDisable	Disables the WDT Windowed mode.
	PLIB_WDT_WindowEnable	Enables the WDT Window mode.

Description

Watchdog Timer (WDT) Peripheral Library Interface Header

This header file contains the function prototypes and definitions of the data types and constants that make up the interface to the Watchdog Timer Peripheral Library for all families of Microchip microcontrollers. The definitions in this file are common to the Watchdog Timer peripheral.

File Name

plib_wdt.h

Company

Microchip Technology Inc.
