41.5

Functional description

This section describes the function of the SRX.

41.5.1

Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the [Channel Enable Register \(SRX\\_CHNL\\_EN\)](#). There are some registers which must be configured and some which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then reconfigure the channel parameters. The following must to be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in [Global Control Register \(SRX\\_GBL\\_CTRL\)](#) to generate the time stamping clock

- Rx Prescaler Value in [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX\\_CHn\\_CLK\\_CTRL\)](#) to generate the channel's receiver clock
- Compensation enable in [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX\\_CHn\\_CLK\\_CTRL\)](#)
- Channel Configuration settings in the [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_CONFIG\)](#)
- Number of Data Nibbles in Channel in the [Data Control Register 1 \(SRX\\_DATA\\_CTRL1\)](#)
- Control bits that control whether messages received in channel are to read by interrupt or DMA in [Fast Message DMA Control Register \(SRX\\_FDMA\\_CTRL\)](#), [Slow Serial Message DMA Control Register \(SRX\\_SDMA\\_CTRL\)](#), [Fast Message Ready Interrupt Control Register \(SRX\\_FRDY\\_IE\)](#) and [Slow Serial Message DMA Control Register \(SRX\\_SDMA\\_CTRL\)](#)

## 41.5.2 DMA read logic

The SENT Receiver module generates separate DMA requests for all Fast Messages and Slow Serial Messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in [Time stamp logic](#).

### 41.5.2.1 DMA request for Fast Message reading via FIFO

A single DMA request is generated for all Fast Messages received on any channel. There is a DMA read FIFO to store the incoming messages from all the channels and allow them to be read via DMA. The DMA operation will happen as follows:

- DMA request will be asserted when number of messages stored in FIFO crosses the configured watermark level (in [Global Control Register \(GBL\\_CTRL\)](#)).
- DMA request will be de-asserted when number of messages stored goes below watermark level. It is assumed that DMA Controller's TCD would be set to transfer bytes equal to the messages indicated by watermark level so as to empty the FIFO.
- It is assumed that when responding to a DMA request, the DMA controller will read at a rate faster than the rate at which messages are getting received and stored in FIFO.

- The complete received message can be read by three consecutive read accesses to DMA Fast Message Data Read Register. The message will be read out in following sequence:
  - Fast Message data as described by DMA Fast Message Data Read Register (DMA\_FMSG\_DATA)
  - CRC for the Fast Message as described by DMA Fast Message CRC Read Register (DMA\_FMSG\_CRC)
  - Time stamp value for the Fast Message as described by DMA Fast Message Time Stamp Read Register (DMA\_FMSG\_TS)
- The channel number is prefixed in each valid message (no error) to allow software to identify messages pertaining to a channel
- [Table 41-82](#) shows the format in which the messages will be stored in any memory-mapped message buffer and when being read out from FIFO.
- Since multiple messages can be received at the same time, there is a [Fixed round robin sequencing logic](#), which will scan all active channels configured for DMA and store their message into the FIFO one by one. Channel configured for DMA but do not have ready messages will be automatically skipped till their turn comes again in the round robin sequence.
- Messages received can be stored in a different order to which they are actually received. The time stamp will indicate the order of reception of messages in a particular channel. However, the time stamp cannot be used to determine the order across channels.

This figure below shows the data for the three 32-bit accesses to be made by DMA to get one complete message with time stamp.

**Table 41-82. Format of storing of Fast Messages in FIFO**

| CH NUM<br>[3:0]   | Status and<br>Comm [3:0] | Data 1 [3:0] | Data 2 [3:0] | Data 3 [3:0] | Data 4 [3:0] | Data 5 [3:0] | Data 6 [3:0] |
|-------------------|--------------------------|--------------|--------------|--------------|--------------|--------------|--------------|
|                   |                          |              | CRC [3:0]    |              |              |              |              |
| TIME STAMP [31:0] |                          |              |              |              |              |              |              |

Figure 41-81. Fast Message DMA Read Logic using FIFO

### 41.5.2.1.1 Fixed round robin sequencing logic

Figure 41-81 shows a scenario where 8 channels (0-7) with all channels are enabled for DMA reading except channel 2. DMA request will be asserted when FIFO has received packets more than watermark level set. Figure 41-81 shows channels 6 and 4 have not received the complete message. The following points describe the complete round robin sequencing scheme.

- The round robin sequencing logic which stores the messages in the FIFO by looping through each channels' Fast Message register and checking for the availability of the message.
- As shown in Figure 41-81, the arbitration logic will check for messages in sequence 0 -> 1 -> 3 -> 5 -> 7 and back to channel 0 and keep looping. Channel 2 is skipped as it's not enabled to be read via DMA) and channel 4 and 6 are skipped as message is not received completely at the instance the sequencing logic checked their buffers. This sequence continues in this fashion.
- The sequence in which messages are stored in FIFO is not deterministic and depends on the sequence they are detected after the noise filtering by the input filter of the channel.
- The DMA controller responds to the DMA request by reading from the DMA Fast Message Read register. When a DMA read happens, a message is read from the FIFO and split into three 32-bit values and provided to DMA in the order as described in previous section. The three 32-bit values together form one complete Fast Message.
- Once all three 32-bit access are completed, the next data from the FIFO is popped.

Figure 41-81 also shows how the received data (light gray colored boxes) from a channel is stored in FIFO along with the time stamp and channel number appended (both white colored).

### 41.5.2.2 DMA request for Fast Message reading when FIFO is disabled

In this mode no FIFO will be used as it is disabled via the FIFO Enable bit in the Global Control Register (GBL\_CTRL). Fast Messages received are stored in a single system bus clock domain buffer to be read out by the DMA Controller via the DMA Fast Message Read register set. Note the DMA Controller must read all 3 DMA Read Registers to obtain the complete message, unlike the case when FIFO is enabled and message is read out from the DMA Fast Message Data Read register only. The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast Message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA Controller should read the complete message by accessing each register of the DMA Fast Message Read register set, the registers being:
  - [DMA Fast Message Data Read Register \(SRX\\_DMA\\_FMSG\\_DATA\)](#)
  - [DMA Fast Message CRC Read Register \(SRX\\_DMA\\_FMSG\\_CRC\)](#)
  - [DMA Fast Message Time Stamp Read Register \(SRX\\_DMA\\_FMSG\\_TS\)](#)
- A fixed round robin sequencing runs, as shown in [Figure 41-82](#), and this logic checks for messages in sequence 0→1→3→5→7 and back to channel 0 and so on. Channel 2 is skipped as it is not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 read accesses to the above mentioned registers)
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA Controller.

## Functional description

**Figure 41-82. Fast Message DMA read logic (when FIFO is disabled)**

### 41.5.2.3 DMA request for Slow Serial Message reading

A separate DMA request (different from DMA request for Fast Message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers

- Similar to DMA read for Fast Messages, data for slow serial messages will be read from DMA Slow Serial Message Read register set in memory map, the register set comprising of:
  - [DMA Slow Serial Message Bit3 Read Register \(SRX\\_DMA\\_SMSG\\_BIT3\)](#)
  - [DMA Slow Serial Message Bit2 Read Register \(SRX\\_DMA\\_SMSG\\_BIT2\)](#)
  - [DMA Slow Serial Message Time Stamp Read Register \(SRX\\_DMA\\_SMSG\\_TS\)](#)
- A fixed round robin sequencing logic will be running and it will update the DMA Slow Serial Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 DMA read accesses to the above mentioned registers)
- The channel number and time stamp will also be appended for every message
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- Since serial messages receive rate is very slow, user software should ensure there is no overflow
- The fixed round robin sequence logic for DMA read is the same as that used for Fast Messages (see [DMA request for Fast Message reading when FIFO is disabled](#))

[Figure 41-83](#) shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow Serial Message Read register set.

**Note:** The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in

**Figure 41-83. Slow Serial Message DMA read logic**

The formats in which the 3 types of Serial Messages will be stored in the buffers are shown in figures below.

**Table 41-83. Enhanced Serial Message with 8-bit ID field**

|                   |  |   |    |           |  |  |    |  |   |                   |          |  |   |          |  |   |
|-------------------|--|---|----|-----------|--|--|----|--|---|-------------------|----------|--|---|----------|--|---|
| 31                |  | 1 | 16 |           |  |  | 15 |  | 0 |                   | 0        |  |   |          |  |   |
| CH NUM<br>[3:0]   |  | P |    |           |  |  |    |  | 0 | C                 | ID [7:4] |  | 0 | ID [3:0] |  | 0 |
|                   |  |   |    | CRC [5:0] |  |  |    |  |   | Data Field [11:0] |          |  |   |          |  |   |
| TIME STAMP [31:0] |  |   |    |           |  |  |    |  |   |                   |          |  |   |          |  |   |

**Table 41-84. Enhanced Serial Message with 4-bit ID field**

|                   |  |   |  |           |  |  |  |    |   |                   |          |   |   |                       |  |   |
|-------------------|--|---|--|-----------|--|--|--|----|---|-------------------|----------|---|---|-----------------------|--|---|
| 31                |  | 1 |  | 16        |  |  |  | 15 |   | 1                 |          | 0 |   |                       |  |   |
| CH NUM<br>[3:0]   |  | P |  |           |  |  |  |    | 0 | C                 | ID [3:0] |   | 0 | Data Field<br>[15:12] |  | 0 |
|                   |  |   |  | CRC [5:0] |  |  |  |    |   | Data Field [11:0] |          |   |   |                       |  |   |
| TIME STAMP [31:0] |  |   |  |           |  |  |  |    |   |                   |          |   |   |                       |  |   |

Table 41-83 and Table 41-84 shows the enhanced serial messages. Bit C (shown in figure) or CFG (as shown in DMA Slow Serial Message Bit3 Read Register (DMA\_SMSG\_BIT3) description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in DMA Slow Serial Message Bit3 Read Register (DMA\_SMSG\_BIT3) description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Table 41-85 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE Specification.

**Table 41-85. Short serial message**

|                   |   |           |          |                  |
|-------------------|---|-----------|----------|------------------|
| 31                | 0 | 16        | 15       | 0                |
| CH NUM<br>[3:0]   | P |           |          |                  |
|                   |   | CRC [3:0] | ID [3:0] | Data Field [7:0] |
| TIME STAMP [31:0] |   |           |          |                  |

Again, three 32-bit accesses to be made by DMA to get one complete message with time stamp.

### 41.5.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast Message, an interrupt will be asserted when any of the channels has received a complete Fast Message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the Register Interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or Slow Messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast Message Read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow Message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

### **41.5.3.1 Suggested software interrupt service routine steps**

These are suggested step to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

#### **When separate Fast Message and Slow Serial Message Interrupts are used:**

The Fast Message Interrupt should have higher priority than Slow Serial Message Interrupt. The suggested ISR steps for a Fast Message Interrupts can be

- Read the Fast Message Ready Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register set (3 registers). Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Fast Message Status Registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow Serial Message Interrupt can be same as for Fast Message ISR.

#### **When common Fast Message and Slow Serial Message Interrupts are used:**

The suggested ISR steps can be

- Read the Fast Message Status Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Slow Serial Message Status Register into a new variable

- Shift out bits starting from MSB from this new variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow Serial Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, software can again check both Fast and Slow Serial Message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

## 41.5.4 Overflow behavior

This section describes the overflow behavior.

### 41.5.4.1 Fast messages buffers/FIFO

Overflow in Fast Message buffers or FIFO can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full. When FIFO is used, overflow is indicated when the FIFO gets full and another fast message is to be stored.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (i.e. all 3 read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

### 41.5.4.2 Slow message buffers

Overflow in Slow Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

### 41.5.5 Adjustment for variation in sensor (Tx) clock

The clock used by the Channel Receiver (referred to as Receiver Clock, or Rx\_CLK) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register ([Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(SRX\\_CHn\\_CLK\\_CTRL\)](#)). Software can use this value to determine the variation in Tx Clock.

#### Note

A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

#### 41.5.5.1 Adjustment for nibble length variation

Section 6.2 of SAE Specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

### 41.5.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflow occurs, the new pin value (i.e. sensor input) is validated and latched in the filtered output flop (also running on high frequency receiver clock). If the opposite edge appears on the sensor input before validation (i.e. overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_CONFIG\)](#). When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register ([Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_CONFIG\)](#)). A timing diagram of the input filter when FIL\_CNT is 1, is shown in the following figure.

**Figure 41-84. Input programmable filter timing diagram**

### 41.5.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%

- Not the expected number of falling edges between calibration pulses. (Message length is pre-defined by each sensor device and programmed by user for each channel)
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or Recommended.
- Any nibble data values measured as  $< 0$  or  $> 15$
- Successive calibration pulses differ by  $> +1.5625\%$  (1/64) or  $< -1.5625\%$ . The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register ([Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_STATUS\)](#)). If error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM\_EDGES\_ERR) are automatically masked out until a valid calibration pulse is detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to CPU in case the channel become unstable and send wrong data continuously.

#### 41.5.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL\_LEN\_ERR status bit on failure.

#### 41.5.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by  $> +1.5625\%$  (1/64) or  $< -1.5625\%$ . The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625%. So if protocol clock is  $T_{HF\_CLK}$  and channel tick period is

$T_{TX\_CLK}$  then the check will be of  $1.5625\% \pm \{100 \times (4 \times T_{HF\_CLK}) / (42 \times T_{TX\_CLK})\}$ . So it won't allow variance in clock of a channel by  $1.5625\% - \{100 \times (4 \times T_{HF\_CLK}) / (42 \times T_{TX\_CLK})\}$ . This check will assert the CAL\_DIAG\_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL\_RESYNC bit will be asserted on every third successive error detected by this check.

### 41.5.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check ("Not the expected number of edges check") will assert the NUM\_EDGES\_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL\_DIAG\_ERR and CAL\_LEN\_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

### 41.5.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 nibble values(11.5 ticks to 27.5 ticks):

- Status and Communication nibble
- all Data nibbles
- CRC nibble

The nibble value check will assert the NIB\_VAL\_ERR status bit on failure. This error can be flagged along with NUM\_EDGES\_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

#### **41.5.7.5 CRC check**

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow Serial Message (4-bit CRC) and Enhanced Serial Message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using either the legacy CRC implementation method or the new recommended CRC implementation via a control bit in the channel's corresponding control register. Please refer to SAE SENT Specification for details on CRC algorithm.

Asserting the CHn\_CONFIG\_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast Serial Messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG\_CRC\_ERR or SMSG\_CRC\_ERR status bit on failure, depending on whether the check is run for Fast Message or Slow Message.

The FMSG\_CRC\_ERR can be flagged along with the NUM\_EDGES\_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

#### **41.5.7.6 Pause pulse diagnostic**

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per spec). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic

to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP\_DIAG\_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

When the Single Edge Nibble Transmission (SENT) Receiver (SRX) is configured to receive a pause pulse (Channel 'n' Configuration Register - CHn\_CONFIG[PAUSE\_EN] = 1) and the length of the pause pulse from the sensor is in range of the valid calibration pulse length, the NUM\_EDGES error can get asserted spuriously (Channel 'n' Status Register - CHn\_STATUS(NUM\_EDGES\_ERR) = 1) when there is any diagnostic error (other than number of expected edges error) or overflow in the incoming messages from the sensor.

Software can distinguish a spurious NUM\_EDGES\_ERR error from a real one by monitoring other error bits. The following tables will help distinguish between a false and real assertion of NUM\_EDGES\_ERR error and other errors. Software should handle the first error detected as per application needs and other bits can be evaluated based on these tables. Table 1 contains information due to erratum behavior and Table 2 below contains clarification of normal NUM\_EDGES\_ERR behavior.

**Table 41-86. Behavior of NUM\_EDGES\_ERR**

| First Error Detected | Other error bits asserted    | Cause for extra error bits getting asserted                                                                                                                                                                                                                                                                                                                                     | Action                           |
|----------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| NIB_VAL_ERR          | NUM_EDGES_ERR asserted twice | Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are seen as back to back calibration pulses and no edges in between. | Ignore both NUM_EDGES_ERR error  |
| FMSG_CRC_ERR         | NUM_EDGES_ERR asserted twice | Upon detection of the first error, the state machine goes into a state where it waits for a calibration pulse, the first NUM_EDGES_ERR error is for the current message as the state machine does not detect an end of message. The second error comes when both the Pause pulse and the Calibration pulse are                                                                  | Ignore both NUM_EDGES_ERR errors |

*Table continues on the next page...*

**Table 41-86. Behavior of NUM\_EDGES\_ERR  
(continued)**

|             |                             |                                                                                                                                                                                                                                      |                            |
|-------------|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|
|             |                             | seen as back to back calibration pulses and no edges in between.                                                                                                                                                                     |                            |
| CAL_LEN_ERR | NUM_EDGES_ERR asserted once | Since the calibration pulse is not detected as a valid calibration pulse, the internal edges counter does not detect the end of one message and start of bad message (which has CAL_LEN_ERR); hence the NUM_EDGES_ERR gets asserted. | Ignore NUM_EDGES_ERR error |

Resynchronization of SENT Receiver in case of any diagnostic error is shown in figure [Figure 41-85](#).

Figure 41-85. SENT receiver resynchronization

Table 41-87. Expected behavior, clarification of NUM\_EDGES\_ERR cases

| First Error Detected                              | Other error bits asserted | Cause for extra error bits getting asserted                                                                                                                 | Action                 |
|---------------------------------------------------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|
| NUM_EDGES_ERR (when edges are less than expected) | NIB_VAL_ERR is asserted   | When the actual number of edges in the message are less than expected, then a pause pulse gets detected as a nibble since the state machine expects nibbles | Ignore the NIB_VAL_ERR |

Table continues on the next page...

**Table 41-87. Expected behavior, clarification of NUM\_EDGES\_ERR cases (continued)**

|                                                   |                                          |                                                                                                                                                                                                                                                                                                                                                        |                                    |
|---------------------------------------------------|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|
|                                                   |                                          | when actually there is a pause pulse present. This generates NIB_VAL_ERR.                                                                                                                                                                                                                                                                              |                                    |
| NUM_EDGES_ERR (when edges are more than expected) | NIB_VAL_ERR and PP_DIAG_ERR are asserted | When the actual number of edges in a message are more than expected, then after receiving the programmed number of data nibbles, the state machine expects a pause pulse. However, the pause pulse comes later and gets detected as a nibble and hence NIB_VAL_ERR is asserted. Since the message length is not correct, PP_DIAG_ERR is also asserted. | Ignore NIB_VAL_ERR and PP_DIAG_ERR |

### 41.5.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.

The clock for this counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value (in [Global Control Register \(SRX\\_GBL\\_CTRL\)](#)) in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver channel being used, or it can be set at some fixed value determined by application, such as 1  $\mu$ s. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value is 59 to generate a time stamp clock of 1  $\mu$ s resolution.

#### Note

The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

The time stamp for a serial message is sampled at the end of the message i.e. when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

#### 41.5.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

### 41.5.9 Bus Idle Diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in [Channel 'n' Configuration Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_CONFIG\)](#)). Status bit (bus\_idle in [Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_STATUS\)](#)) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.

## 41.6 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's Register Interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

## 41.6.1 Clocking strategy

The following figure shows the clock domain in which each module is functioning.

Figure 41-86. SENT Receiver module clock domains

## 41.6.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast Message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast Message size with valid checksum as per SAE Specifications is 154 ticks. At 3  $\mu$ s receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4  $\mu$ s (after compensation). This gives us the time in which the minimum size Fast Message is received in any channel as  $154 \times 2.4 = 369.6$   $\mu$ s. Now since messages are arriving in parallel, 369.6  $\mu$ s is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that ' $N_{\text{CHNL}}$ ' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be  $369.6/N_{\text{CHNL}}$   $\mu$ s or  $\sim 370/N_{\text{CHNL}}$   $\mu$ s. Since the CPU or the DMA needs to make three 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as ' $T_{\text{RD}}$ ' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

$$3 \times T_{\text{RD}} + T_{\text{ISR}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

where  $T_{\text{ISR}}$  is the overhead in initiating an ISR and  $T_{\text{WAKUP}}$  is the time to wakeup from low power mode

For DMA,

$$3 \times T_{\text{RD}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

Replacing  $T_{\text{RD}} = N_{\text{RD}} \times T_{\text{SYS\_CLK}}$  and  $T_{\text{ISR}} = N_{\text{ISR}} \times T_{\text{SYS\_CLK}}$ , where  $N_{\text{RD}}$  is the number of System Bus Clock cycles in one 32-bit read access,  $N_{\text{ISR}}$  is the number of System Bus Clock Cycles in initiating an interrupt service routine and  $T_{\text{SYS\_CLK}}$  is the period of the same clock, we get

For CPU,

$$(3 \times N_{\text{RD}} + N_{\text{ISR}}) \times T_{\text{SYS\_CLK}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

(all units is  $\mu$ s)

For DMA,

$$3 \times N_{\text{RD}} \times T_{\text{SYS\_CLK}} + T_{\text{WAKUP}} < 370 / N_{\text{CHNL}}$$

(all units is  $\mu$ s)

### 41.6.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per formula:  $\text{Guard Band} > 2.5 * T_{\text{HF\_CLK}}$

where  $T_{\text{HF\_CLK}}$  is the High Frequency Receiver Clock or Protocol Clock in ns and Guard Band is guard band in ns as specified in SAE specification, at particular transmitter uTick.

#### Note

$T_{\text{HF\_CLK}}$  in the above equation should be chosen based on the fastest sensor clock (with minimum guard band as specified in SAE spec) among all channels in the device.

# Chapter 42

## Enhanced Serial Communication Interface (eSCI)

### 42.1 Chip-specific eSCI information

This chip has six instances of the eSCI module. Some feature details vary among the instances.

The following table summarizes the feature differences. The table does not list feature details that the instances share.

**Table 42-1. eSCI instance feature differences**

| Instance                           | DMA support                                                                |
|------------------------------------|----------------------------------------------------------------------------|
| eSCI_A and eSCI_B                  | Yes                                                                        |
| eSCI_C, eSCI_D, eSCI_E, and eSCI_F | No: descriptions of eSCI DMA functionality do not apply to these instances |

#### NOTE

For eSCI\_D, the single wire feature does not apply for TX/RX via PCSA3 because this pad works only as an output.

#### 42.1.1 eSCI clocking

For information about eSCI clock sources and the eSCI's module clock (MCLK), see the [Clock generation](#) diagram, the [Peripheral clocks](#) diagram, and other details in the Clocking chapter.

#### 42.1.2 eSCI registers: core access in supervisor mode

On this chip, all core accesses to eSCI registers occur in supervisor mode.

## 42.2 Introduction

The eSCI block is an enhanced SCI block with a LIN master interface layer and DMA support. The LIN master layer complies with the specifications LIN 1.3, LIN 2.0, LIN 2.1, and SAE J2602/1.

### 42.2.2 Acronyms and Abbreviations

The following table contains acronyms and abbreviations used in this document.

**Table 42-2. Acronyms and Abbreviations**

| Term   | Description                                                                     |
|--------|---------------------------------------------------------------------------------|
| eSCI   | Enhanced SCI block with LIN support and DMA support                             |
| SCI    | Serial Communications Interface                                                 |
| LIN    | Local Interconnect Network - A protocol for low-cost automobile networks        |
| LIN PE | LIN Protocol Engine, Finite State Machine to control logic of the LIN hardware. |
| MCLK   | Module Clock, defined in <a href="#">Module Clock</a>                           |
| TCLK   | Transmitter Clock, defined in <a href="#">Transmitter Clock</a>                 |
| RCLK   | Receiver Clock, defined in <a href="#">Receiver Clock</a>                       |
| RSC    | Receiver Sample Counter, defined in <a href="#">Receiver Clock</a>              |

### 42.2.3 Glossary

**Table 42-3. Glossary**

| Term            | Definition                                              |
|-----------------|---------------------------------------------------------|
| Logic level one | The voltage that corresponds to Boolean true (1) state. |

*Table continues on the next page...*

**Table 42-3. Glossary (continued)**

| Term             | Definition                                                                                                                                                                                                         |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Logic level zero | The voltage that corresponds to Boolean false (0) state.                                                                                                                                                           |
| Set              | To set a bit or bits means to establish logic level one on the bit or bits.                                                                                                                                        |
| Clear            | To clear a bit or bits means to establish logic level zero on the bit or bits.                                                                                                                                     |
| Asserted         | A signal that is asserted is in its active state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one. |
| Preamble         | The term preamble describes an idle character which is <i>transmitted</i> by the eSCI module.                                                                                                                      |
| Bit time         | Duration of a single bit in a transmitted byte field or character, equivalent to the duration of one transmitter clock cycle defined in <a href="#">Transmitter Clock</a>                                          |
| frame            | Entity that consists of the start bit followed by payload bits followed by one or more stop bits                                                                                                                   |
| LIN byte field   | Special instance of a frame                                                                                                                                                                                        |
| SCI frame        | Special instance of a frame                                                                                                                                                                                        |
| LIN frame        | Sequence of break character followed by LIN byte fields                                                                                                                                                            |
| LIN TX frame     | A LIN frame with the frame header, data byte fields, and checksum field transmitted by the eSCI module                                                                                                             |
| LIN RX frame     | A LIN frame with the header field transmitted by the eSCI module and the data byte fields and checksum field received by the eSCI module                                                                           |
| module is idle   | Module is idle, described in <a href="#">Module Idle Condition</a>                                                                                                                                                 |

## 42.2.4 Overview

The eSCI block allows asynchronous serial communications with peripheral devices and other CPUs. It includes special support to interface to LIN slave devices.

Figure 42-1. eSCI Block Diagram

## 42.2.5 Features

The eSCI block includes these distinctive features:

- Full-duplex operation
- Standard mark/space non-return-to-zero (NRZ) format
- 13-bit baud rate selection
- Programmable frame, payload, and character format
- Support of 2 stop bits in receiver path
- Hardware parity generation and checking
  - Programmable even or odd parity
- Programmable polarity of RXD pin
- Separately enabled transmitter and receiver
- Two receiver wake-up methods:

- Idle line wake up
- Address mark wake up
- Interrupt-driven operation with eight flags:
  - Transmitter empty
  - Transmission complete
  - Receiver full
  - Idle receiver input
  - Receiver overrun
  - Noise error
  - Framing error
  - Parity error
- Receiver framing error detection
- 1/16 bit-time noise detection
- 2 channel DMA interface
- LIN support
  - LIN Master Node functionality (master and slave task)
  - Compatible with LIN slaves from revisions 1.x and 2.0 of the LIN standard
  - Detection of Bit Errors, Physical Bus Errors and Checksum Errors
  - All status bit can generate maskable interrupts
  - Application layer CRC support
  - Programmable CRC polynomial
  - Detection and generation of wake-up characters
  - Programmable wake-up delimiter time
  - Programmable slave timeout
  - Can be configured to include header bits in checksum
  - LIN DMA interface

## 42.2.6 Modes of Operation

The eSCI module has two functional operational modes, SCI and LIN mode. The availability of register bits and fields depends on the selected operational mode.

### 42.2.6.1 Module Idle Condition

Doze mode, Disable mode and Stop mode can only be entered when the module is idle. The module is idle if

- all five active status bits DACT, WACT, LACT, TACT, and RACT in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) are 0, and
- no interrupt request is pending, i.e either the interrupt flag or its related interrupt enable is 0.

To ensure that the module goes idle, the application should clear all interrupt enable bits before triggering the mode change.

### 42.2.6.2 SCI Mode

The SCI mode is the default functional operational mode and is described in [SCI Mode](#).

### 42.2.6.3 LIN Mode

The LIN mode is the second functional operational mode and is described in [LIN Mode](#).

### 42.2.6.4 Disabled Mode

In the Disabled mode the eSCI module indicates to the clocking system, that all module clocks can be turned off.

The eSCI module is in the Disabled Mode, if the MDIS bit in the Control Register 2 (eSCI\_CR2) is set and the module is idle.

## 42.3 External Signal Description

The eSCI module is connected to a total of two external pins.

### 42.3.1 Detailed Signal Descriptions

#### 42.3.1.1 eSCI Transmit Pin (TXD)

This pin serves as transmit data output and as the receive data input of eSCI.

#### 42.3.1.2 eSCI Receive Pin (RXD)

This pin serves as receive data input of the eSCI.

## 42.4 Memory Map and Register Definition

Writes to a reserved register location do not have any effect and reads of these locations return a zero.

### NOTE

All R/W registers are writable only in supervisor mode of the core performing the write.

**eSCI memory map**

### 42.4.1 Baud Rate Register (eSCI\_BRR)

This register provides the control value for the serial baud rate. The baud rate and clock generation is specified in [Baud Rate and Clock Generation](#).

A byte write access to only the upper byte of this register (eSCI\_BRR[0:7 ]) will not change the content of the register, instead, the written byte is stored internally into a shadow register. A subsequent byte write access to only the lower byte of this register (eSCI\_BRR[8:15 ]) updates the lower byte and copies the content of the shadow register into the upper byte.

A byte write access to only the lower byte of this register (eSCI\_BRR[8:15 ]) without a preceding byte write access to only the upper byte copies a value of all zero into the upper byte.

A 16-bit write access to this register updates both the lower and upper byte immediately and is the recommended write access type for this register.

Address: 0h base + 0h offset = 0h

|       |   |   |   |     |   |   |   |   |   |   |    |    |    |    |    |    |
|-------|---|---|---|-----|---|---|---|---|---|---|----|----|----|----|----|----|

#### eSCI\_BRR field descriptions

| Field           | Description                                                                             |
|-----------------|-----------------------------------------------------------------------------------------|
| 0–2<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |
| 3–15<br>SBR     | Serial Baud Rate. This field provides the baud rate control value SBR.                  |

## 42.4.2 Control Register 1 (eSCI\_CR1)

This register provides bits to configure the functionality of the module, provides the interrupt enable bits for the interrupt flags provided in [Interrupt Flag and Status Register 1 \(eSCI\\_IFSR1\)](#) and provides the control bits for the transmitter and receiver.

**Table 42-7. Receive Source Mode Selection**

| LOOPS | RSRC | Receiver Input Mode |

### eSCI\_CR1 field descriptions

| Field         | Description                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>LOOPS    | Loop Mode Select. This control bit together with the RSRC control bit defines the receiver source mode. The mode coding is defined in <a href="#">Table 42-7</a> and the modes are described in <a href="#">Receiver Input Mode Selection</a> .         |
| 1<br>Reserved | This field is reserved.<br>Application must not write 1 to this bit.                                                                                                                                                                                    |
| 2<br>RSRC     | Receiver Source Control. This control bit together with the LOOPS control bit defines the receiver source mode. The mode coding is defined in <a href="#">Table 42-7</a> and the modes are described in <a href="#">Receiver Input Mode Selection</a> . |
| 3<br>M        | Frame Format Mode. This control bit together with the M2 bit of the <a href="#">Control Register 3 (eSCI_CR3)</a> controls the frame format used. The supported frame formats and the related settings are defined in <a href="#">Frame Formats</a> .   |
| 4<br>WAKE     | Receiver Wake-up Condition. This control bit defines the wake-up condition for the receiver. The receiver wake-up is described in <a href="#">Multiprocessor Communication</a> .<br>0 Idle line wake-up.<br>1 Address mark wake-up                      |
| 5<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                 |
| 6<br>PE       | Parity Enable. This control bit enables the parity bit generation and checking. The location of the parity bits is shown in <a href="#">Frame Formats</a> .                                                                                             |

## eSCI\_CR1 field descriptions (continued)

| Field      | Description                                                                                                                                                                                                                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | 0 Parity bit generation and checking disabled.<br>1 Parity bit generation and checking enabled.                                                                                                                                                                                                              |
| 7<br>PT    | Parity Type. This control bit defines whether even or odd parity has to be used.<br><br>0 Even parity (even number of ones in character clears the parity bit).<br>1 Odd parity (odd number of ones in character clears the parity bit).                                                                     |
| 8<br>TIE   | Transmitter Interrupt Enable. This bit controls the eSCI_IFSR1[TRDE] interrupt request generation.<br><br>0 TDRE interrupt request generation disabled.<br>1 TDRE interrupt request generation enabled.                                                                                                      |
| 9<br>TCIE  | Transmission Complete Interrupt Enable. This bit controls the eSCI_IFSR1[TC] interrupt request generation.<br><br>0 TC interrupt request generation disabled.<br>1 TC interrupt request generation enabled.                                                                                                  |
| 10<br>RIE  | Receiver Full Interrupt Enable. This bit controls the eSCI_IFSR1[RDRF] interrupt request generation.<br><br>0 RDRF interrupt request generation disabled.<br>1 RDRF interrupt request generation enabled.                                                                                                    |
| 11<br>ILIE | Idle Line Interrupt Enable. This bit controls the eSCI_IFSR1[IDLE] interrupt request generation.<br><br>0 IDLE interrupt request generation disabled.<br>1 IDLE interrupt request generation enabled.                                                                                                        |
| 12<br>TE   | Transmitter Enable. This control bit enables and disables the transmitter. The control features of the transmitter are described in <a href="#">Transmitter States and Transitions</a> .<br><br>0 Transmitter disabled.<br>1 Transmitter enabled.                                                            |
| 13<br>RE   | Receiver Enable. This control bit enables and disables the receiver. The control features of the receiver are described in <a href="#">Receiver States and Transitions</a> .<br><br>0 Receiver disabled.<br>1 Receiver enabled.                                                                              |
| 14<br>RWU  | Receiver Wake-Up Mode. This bit controls and indicates the receiver wake-up mode, which is described in <a href="#">Multiprocessor Communication</a> .<br><br><b>NOTE:</b> This bit should be set in SCI mode only.<br><br>0 Normal receiver operation.<br>1 Receiver is in wake-up mode.                    |
| 15<br>SBK  | Send Break Character. This bit controls the transmission of break characters, which is described in <a href="#">Break Character Transmission</a> .<br><br><b>NOTE:</b> This bit should be set in SCI mode only.<br><br>0 No break characters will be transmitted.<br>1 Break characters will be transmitted. |

### 42.4.3 Control Register 2 (eSCI\_CR2)

This register provides bits to configure the functionality of the module, and interrupt enable bits for the interrupt flags provided in [Interrupt Flag and Status Register 1 \(eSCI\\_IFSR1\)](#) and control bits for the transmitter and receiver.

Address: 0h base + 4h offset = 4h

| Bit   | 0    | 1   | 2    | 3      | 4     | 5     | 6    | 7     |
|-------|------|-----|------|--------|-------|-------|------|-------|
| Read  | MDIS | FBR | BSTP | BERRIE | RXDMA | TXDMA | BRCL | TXDIR |
| Write |      |     |      |        |       |       |      |       |
| Reset | 0    | 0   | 1    | 0      | 0     | 0     | 0    | 0     |

#### eSCI\_CR2 field descriptions

| Field       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>MDIS   | Module Disabled Mode. This bit controls the Module Mode of Operation, which is described in <a href="#">Modes of Operation</a> .<br><br>0 Module is not in Disabled Mode.<br>1 Module is in Disabled Mode, if module is idle.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 1<br>FBR    | Fast Bit Error Detection. This bit controls the Bit Error Detection mode.<br><b>NOTE:</b> This bit is used in LIN mode only.<br><br>0 Standard Bit error detection performed as described in <a href="#">Standard Bit Error Detection</a> .<br>1 Fast Bit error detection performed as described in <a href="#">Fast Bit Error Detection</a> .                                                                                                                                                                                                                                                                                                                 |
| 2<br>BSTP   | DMA Stop on Bit Error or Physical Bus Error. This bit controls the transmit DMA requests generation in case of bit errors or physical bus errors. Bit errors are indicated by the BERR flag in the <a href="#">Interrupt Flag and Status Register 1 (eSCI_IFSR1)</a> and physical bus errors are indicated by the PBERR flag in the <a href="#">Interrupt Flag and Status Register 2 (eSCI_IFSR2)</a> .<br><b>NOTE:</b> This bit is used in LIN mode only.<br><br>0 Transmit DMA requests generated regardless of bit errors or physical bus errors.<br>1 Transmit DMA requests are not generated if eSCI_IFSR1[BERR] flag or eSCI_IFSR2[PBERR] flags are set. |
| 3<br>BERRIE | Bit Error Interrupt Enable. This bit controls the BERR interrupt request generation.<br><br>0 BERR interrupt request generation disabled.<br>1 BERR interrupt request generation enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 4<br>RXDMA  | Receive DMA Control. This bit enables the receive DMA feature. When this bit is cleared, a pending receive DMA request is deasserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

*Table continues on the next page...*

**eSCI\_CR2 field descriptions (continued)**

| Field       | Description                                                                                                                                                                                                                                                                                                                                   |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             | 0 Receive DMA disabled.<br>1 Receive DMA enabled.                                                                                                                                                                                                                                                                                             |
| 5<br>TXDMA  | Transmit DMA Control. This bit enables the transmit DMA feature. When this bit is cleared, a pending transmit DMA request is deasserted.<br><br>0 Transmit DMA disabled.<br>1 Transmit DMA enabled.                                                                                                                                           |
| 6<br>BRCL   | Break Character Length. This bit is used to define the length of the break character to be transmitted. The settings are specified in <a href="#">Break Character Formats</a> .                                                                                                                                                               |
| 7<br>TXDIR  | TXD pin output driver control. This bit has no effect. In this device, TXDIR does not control the output driver of the TXD pin in Single Wire Mode. The function is controlled by the relevant Pad Control Register in the System Integration Unit.                                                                                           |
| 8<br>BESM   | Fast Bit Error Detection Sample Mode. This bit defines the sample point for the Fast Bit Error Detection Mode.<br><br><b>NOTE:</b> This bit is used in LIN mode only.<br><br>0 Sample point is RS9.<br>1 Sample point is RS13.                                                                                                                |
| 9<br>BESTP  | Bit Error Transmit Stop. This control bit defines the behavior of the eSCI Transmit Pin TXD while the bit error flag eSCI_IFSR1[BERR] is 1.<br><br><b>NOTE:</b> This bit is used in LIN mode only.<br><br>0 Application Data Values driven onto TXD pin.<br>1 Recessive Data Value 1 driven onto TXD pin.                                     |
| 10<br>RXPOL | RXD Pin polarity. This bit controls the polarity of the RXD pin. See <a href="#">Inverted Data Frame Formats</a> .<br><br>0 Normal Polarity.<br>1 Inverted Polarity.                                                                                                                                                                          |

**eSCI\_CR2 field descriptions (continued)**

| Field | Description                               |
|-------|-------------------------------------------|
| 0     | PF interrupt request generation disabled. |
| 1     | PF interrupt request generation enabled.  |

**42.4.4 SCI Data Register (eSCI\_SDR)**

In SCI mode this register is used to provide transmit data and retrieve received data. In LIN mode any write access to this register is ignored. In case of read accesses to this register during data transmission/reception this register provides a part of the transmitted/received data.

If the application writes to the lower byte of this register (eSCI\_SDR[8:15 ]), the internal commit flag iCMT, which is not visible to the application, is set to indicate that the register has been updated and ready to transmit new data.

If the application reads from the lower byte of this register (eSCI\_SDR[8:15 ]), a signal is send to the internal receiver unit to indicate that the register was read and is ready to receive new data. The read access will not change the content of any register.

## 42.4.5 Interrupt Flag and Status Register 1 (eSCI\_IFSR1)

This register provides interrupt flags that indicate the occurrence of module events. The related interrupt enable bits are located in [Control Register 1 \(eSCI\\_CR1\)](#) and [Control Register 2 \(eSCI\\_CR2\)](#).

Address: 0h base + 8h offset = 8h

**eSCI\_IFSR1 field descriptions**

| Field     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>TDRE | Transmit Data Register Empty Interrupt Flag. This interrupt flag is set when the content of the <a href="#">SCI Data Register (eSCI_SDR)</a> was transferred into internal shift register.<br><b>NOTE:</b> This flag is set in SCI mode only.                                                                                                                                                                                                                                                                        |
| 1<br>TC   | Transmit Complete Interrupt Flag. This interrupt flag is set when a frame, break or idle character transmission has been completed and no data were written into <a href="#">SCI Data Register (eSCI_SDR)</a> after the last setting of the TDRE flag and the SBK bit in <a href="#">Control Register 1 (eSCI_CR1)</a> is 0.<br><b>NOTE:</b> This flag is set in SCI mode only. In case of no data available for transmission, it is also set if the preamble was transmitted after the enabling of the transmitter. |
| 2<br>RDRF | Receive Data Register Full Interrupt Flag. This interrupt flag is set when the payload data of a received frame was transferred into the <a href="#">SCI Data Register (eSCI_SDR)</a> and the receive DMA is disabled.<br><b>NOTE:</b> This flag is set in SCI mode only.                                                                                                                                                                                                                                            |
| 3<br>IDLE | Idle Line Interrupt Flag. This interrupt flag is set when an idle character was detected and the receiver is not in the wake-up state.<br><b>NOTE:</b> This flag is set in SCI mode only.                                                                                                                                                                                                                                                                                                                            |
| 4<br>OR   | Overrun Interrupt Flag. This interrupt flag is set when an overrun was detected as described in <a href="#">Receiver Overrun</a> .<br><b>NOTE:</b> This flag is set in SCI mode only.                                                                                                                                                                                                                                                                                                                                |
| 5<br>NF   | Noise Interrupt Flag. This interrupt flag is set when the receiver has detected noise during the reception of a frame, as described in <a href="#">Bit Sampling</a> .                                                                                                                                                                                                                                                                                                                                                |
| 6<br>FE   | Framing Error Interrupt Flag. This interrupt flag is set when the payload data of a received frame was transferred into the <a href="#">SCI Data Register (eSCI_SDR)</a> or <a href="#">LIN Receive Register (eSCI_LRR)</a> and the receiver has detected a framing error during the reception of that frame, as described in <a href="#">Stop Bit Verification</a> .                                                                                                                                                |

## 42.4.6 Interrupt Flag and Status Register 2 (eSCI\_IFSR2)

This register provides interrupt flags that indicate the occurrence of LIN related events. The related interrupt enable bits are located in [LIN Control Register 1 \(eSCI\\_LCR1\)](#) and [LIN Control Register 2 \(eSCI\\_LCR2\)](#). All interrupt flags in this register will be set in LIN mode only .

Address: 0h base + Ah offset = Ah

**eSCI\_IFSR2 field descriptions**

| Field            | Description                                                                                                                                                                                                                                                                                                                                       |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>RXRDY       | Receive Data Ready Interrupt Flag. This interrupt flag is set when the payload data of a received frame was transferred into the <a href="#">LIN Receive Register (eSCI_LRR)</a> and the receive DMA is disabled.<br><b>NOTE:</b> This bit should be cleared only after reading the data from the <a href="#">LIN Receive Register (eSCI_LRR)</a> |
| 1<br>TXRDY       | Transmit Data Ready Interrupt Flag. This interrupt flag is set when<br>a) the content of the <a href="#">LIN Transmit Register (eSCI_LTR)</a> was processed by the LIN PE to generate frame header or frame transmit data, or<br>b) when the module has transmitted a LIN wakeup signal frame.                                                    |
| 2<br>LWAKE       | LIN Wake-up Received Interrupt Flag. This interrupt flag is set when a LIN Wake-up character was received, as described in <a href="#">LIN Wake Up</a> .                                                                                                                                                                                          |
| 3<br>STO         | Slave Timeout Interrupt Flag. This interrupt flag is set when a Slave-Not-Responding-Error is detected. A detailed description is given in <a href="#">Slave-Not-Responding-Error Detection</a> .                                                                                                                                                 |
| 4<br>PBERR       | Physical Bus Error Interrupt Flag. This interrupt flag is set when the receiver input remains unchanged for at least 31 RCLK clock cycles after the start of a byte transmission, as described in <a href="#">LIN Error Reporting</a> .                                                                                                           |
| 5<br>CERR        | CRC Error Interrupt Flag. This interrupt flag is set when an incorrect CRC pattern was detected for a received LIN frame.                                                                                                                                                                                                                         |
| 6<br>CKERR       | Checksum Error Interrupt Flag. This interrupt flag is set when a checksum error was detected for a received LIN frame.                                                                                                                                                                                                                            |
| 7<br>FRC         | Frame Complete Interrupt Flag. This interrupt flag is set when a LIN TX frame has been completely transmitted or a LIN RX frame has been completely received.                                                                                                                                                                                     |
| 8–13<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                           |

### 42.4.9 LIN Transmit Register (eSCI\_LTR)

This register is used by the application to initiate the LIN frame header generation for both LIN TX frames and LIN RX frames. If a LIN TX frame is generated, this register is used to provide the payload data for the LIN TX frame.

If the LIN PE is in the idle state (eSCI\_LCR1[LRES] = 1) or performs a wakeup, each write access to this register is ignored.

In case of a read access, the register provides the last data written into this register in the DATA field.

If the application initiates a LIN TX frame transfer, i.e the TD bit is set to 1, the content and usage shown in [Figure 42-11](#) applies. The initiation and transmit of a TX frame is described in [LIN TX Frame generation](#).

**Figure 42-11. LIN Transmit Register (eSCI\_LTR) - LIN TX frame generation**

If the application initiates an LIN RX frame, i.e the TD bit is set to 0, the content and usage shown in [Figure 42-12](#) applies. The initiation and transmit of a RX frame is described in [LIN RX frame generation](#).

**Figure 42-12. LIN Transmit Register (eSCI\_LTR) - LIN RX frame generation**

Each successful write access to this register increments the internal write access counter and enables the writing to the next field. The write access counter is reset if

- the LIN PE is in the idle state (eSCI\_LCR1[LRES] = 1)
- a LIN TX frame was completely transmitted (eSCI\_IFSR1[FRC] was set to 1)
- a LIN RX frame was completely received (eSCI\_IFSR1[FRC] was set to 1)

**Table 42-15. Structure of the LTR[DATA] when written to**

| Field | Description                                                                                                                                                                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| P     | Identifier Parity. This field provides the identifier parity which is used to create the protected identifier if the automatic identifier parity generation is disabled, i.e the PRTY bit in <a href="#">LIN Control Register 1 (eSCI_LCR1)</a> is 0. |
| ID    | Identifier. This field is used for the identifier field in the protected identifier.                                                                                                                                                                  |
| LEN   | Frame Length. This field defines the number of data bytes to be transmitted or received.                                                                                                                                                              |
| CSM   | Checksum Model. This bit controls the checksum calculation model used.<br>0: Classic Checksum Model (LIN 1.3).<br>1: Enhanced Checksum Model (LIN 2.0).                                                                                               |
| CSE   | Checksum Enable. This bit control the generation and checking of the checksum byte.<br>0: No generation and checking of checksum byte.<br>1: Generation and checking of checksum byte.                                                                |
| CRC   | CRC Enable. This bit controls the generation of checking standard or enhanced LIN frames, which are described in <a href="#">LIN frame formats</a> .                                                                                                  |

## 42.5 Functional Description

This section provides a complete functional description of the eSCI block, detailing the operation of the design from the end user perspective in a number of subsections.

### 42.5.1 Module Control

The operational mode of the module is controlled by the MDIS bit in the Control Register 2 (eSCI\_CR2). The module can transmit and receives data when it is enabled, i.e MDIS=0.

### 42.5.2 Frame Formats

The eSCI module uses the standard NRZ mark/space data format. The eSCI supports three basic frame types, which are the data frames, break characters, and idle characters.

#### 42.5.2.1 Data Frame Formats

Each data frame contains a character that is surrounded by a start bit, an optional parity or address bit, and one or two stop bits. The supported data frame formats for transmission and reception are specified in [Table 42-19](#). The supported data frame formats for reception only are specified in [Table 42-20](#).

**Table 42-19. Supported Data Frame Formats for RX and TX**

| Control                                    |          |    |      | Frame Content |                |                           |             |           |
|--------------------------------------------|----------|----|------|---------------|----------------|---------------------------|-------------|-----------|
| eSCI_CR3                                   | eSCI_CR1 |    |      | Start Bits    | Payload Bits   |                           |             | Stop Bits |
| M2                                         | M        | PE | WAKE |               | Character Bits | Address Bits <sup>1</sup> | Parity Bits |           |
| LIN byte fields (Figure 42-16)             |          |    |      |               |                |                           |             |           |
| 0                                          | 0        | 0  | 0    | 1             | 8              | 0                         | 0           | 1         |
| SCI Frames (8 payload bits)(Figure 42-17)  |          |    |      |               |                |                           |             |           |
| 0                                          | 0        | 0  | 0    | 1             | 8              | 0                         | 0           | 1         |
| 0                                          | 0        | 0  | 1    | 1             | 7              | 1                         | 0           | 1         |
| 0                                          | 0        | 1  | 0    | 1             | 7              | 0                         | 1           | 1         |
| SCI Frames (9 payload bits) (Figure 42-18) |          |    |      |               |                |                           |             |           |
| 0                                          | 1        | 0  | 0    | 1             | 9              | 0                         | 0           | 1         |
| 0                                          | 1        | 0  | 1    | 1             | 8              | 1                         | 0           | 1         |
| 0                                          | 1        | 1  | 0    | 1             | 8              | 0                         | 1           | 1         |

1. The address bit identifies the frame as an address character. See [Multiprocessor Communication](#).

**Table 42-20. Supported Data Frame Formats for RX only**

| Control                                                      |          |    |      | Frame Content |                |              |             |           |
|--------------------------------------------------------------|----------|----|------|---------------|----------------|--------------|-------------|-----------|
| eSCI_CR3                                                     | eSCI_CR1 |    |      | Start Bits    | Payload Bits   |              |             | Stop Bits |
| M2                                                           | M        | PE | WAKE |               | Character Bits | Address Bits | Parity Bits |           |
| SCI Frames (2 stop bits) (see <a href="#">Figure 42-19</a> ) |          |    |      |               |                |              |             |           |
| 1                                                            | 0        | 1  | 0    | 1             | 8              | 0            | 1           | 2         |
| 1                                                            | 1        | 1  | 0    | 1             | 12             | 0            | 1           | 2         |

The structure of the LIN byte fields in normal polarity is shown in [Figure 42-16](#).

**Figure 42-16. LIN Byte Field Format**

The structures of the supported SCI frame formats with 8 payload bits are shown in [Figure 42-17](#).

**Figure 42-17. SCI Frame Formats (8 payload bits)**

The structures of the supported SCI frame formats with 9 payload bits are shown in [Figure 42-18](#).

**Figure 42-18. SCI Frame Formats (9 payload bits)**

The structures of the supported SCI frame formats with 2 stop bits in normal polarity are shown in [Figure 42-19](#). This frame format is supported for reception only.

**Figure 42-19. SCI Frame Formats (2 stop bits)**

**42.5.2.1.1 Inverted Data Frame Formats**

The structures of the supported data frame formats in inverted polarity are shown in the following figure. These frame types are supported for reception only. The polarity of the RXD pin is controlled by the RXPOL bit in the Control Register 2 (eSCI\_CR2).

**Figure 42-20. Inverted SCI Frame Formats**

**42.5.2.2 Break Character Formats**

The supported break character formats are specified in [Table 42-21](#).

**Table 42-21. Supported Break Character Formats**

| Control <sup>1</sup>                                 |          |          | Break Character Content |                |              |
|------------------------------------------------------|----------|----------|-------------------------|----------------|--------------|
| eSCI_CR3                                             | eSCI_CR1 | eSCI_CR2 | Start Bit               | Character Bits | Delemit Bits |
| M2                                                   | M        | BRCL     |                         |                |              |
| LIN Break Symbol (see <a href="#">Figure 42-21</a> ) |          |          |                         |                |              |
| 0                                                    | 0        | 0        | 1                       | 9              | 1            |

Table continues on the next page...

**Table 42-21. Supported Break Character Formats (continued)**

| Control <sup>1</sup>                                    |          |          | Break Character Content |                |              |
|---------------------------------------------------------|----------|----------|-------------------------|----------------|--------------|

1. All codings which are not listed are reserved and must not be used.

The structure and content of the LIN break symbols is shown in [Figure 42-21](#).

**Figure 42-21. LIN Break Symbol Format**

The structure and content of the SCI break characters is shown in [Figure 42-22](#).

**Figure 42-22. SCI Break Character Formats**

### 42.5.2.3 Idle Character Formats

An idle character is a sequence of bits with the value 1. The supported idle character formats are specified in [Table 42-22](#). The preamble has the same structure and content as an idle character.

**Table 42-22. Supported Idle Character Formats**

| Control                                             |             | Idle Character Length |
|-----------------------------------------------------|-------------|-----------------------|
| eSCI_CR3[M2]                                        | eSCI_CR1[M] |                       |
| Idle Characters (see <a href="#">Figure 42-23</a> ) |             |                       |

Table continues on the next page...

Table 42-22. Supported Idle Character Formats (continued)

| Control      |             | Idle Character Length |
|--------------|-------------|-----------------------|
| eSCI_CR3[M2] | eSCI_CR1[M] |                       |
| 0            | 0           | 10                    |
| 0            | 1           | 11                    |
| 1            | 0           | 12                    |
| 1            | 1           | 16                    |

The structure and content of the idle characters is shown in [Figure 42-23](#).

Figure 42-23. Idle Character Formats

42.5.3 Baud Rate and Clock Generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value written to the SBR field in the Baud Rate Register (eSCI\_BRR) determines the module clock divisor. The baud rate clock is synchronized with the bus clock and drives the receiver. The baud rate clock divided by 16 drives the transmitter. The receiver has an acquisition rate of 16 samples per bit time.

The baud rate generator is enabled when the TE bit or RE bit in the Control Register 1 (eSCI\_CR1) is set to 1 for the first time. The baud rate generator is disabled when SBR = 0.

Baud rate generation is subject to one source of error:

- Integer division of the module clock may not give the exact required target baud rate.

The following table lists some examples of achieving target baud rates with a module clock frequency of MCLK = 10.2 MHz.

Table 42-23. Baud Rates Error Example (MCLK = 10.2 MHz)

| eSCI_BRR[SBR] | RCLK (Hz) | TCLK (Hz) | Target Baud Rate | Error (%) |
|---------------|-----------|-----------|------------------|-----------|
| 17            | 600,000.0 | 37,500.0  | 38,400           | 2.3       |

Table continues on the next page...

**Table 42-23. Baud Rates Error Example (MCLK = 10.2 MHz) (continued)**

| eSCI_BRR[SBR] | RCLK (Hz) | TCLK (Hz) | Target Baud Rate | Error (%) |
|---------------|-----------|-----------|------------------|-----------|
| 33            | 309,090.9 | 19,318.2  | 19,200           | .62       |
| 66            | 154,545.5 | 9659.1    | 9600             | .62       |
| 133           | 76,691.7  | 4793.2    | 4800             | .14       |
| 266           | 38,345.9  | 2396.6    | 2400             | .14       |
| 531           | 19,209.0  | 1200.6    | 1200             | .11       |
| 1062          | 9604.5    | 600.3     | 600              | .05       |
| 2125          | 4800.0    | 300.0     | 300              | .00       |
| 4250          | 2400.0    | 150.0     | 150              | .00       |
| 5795          | 1760.1    | 110.0     | 110              | .00       |

### 42.5.3.1 Module Clock

For the frequency of module clock MCLK and the system bus clock, see the chip-specific eSCI information. MCLK has the same phase as the system bus clock.

### 42.5.3.2 Transmitter Clock

The transmitter clock TCLK is used to drive the data to the serial bus via the TXD pin. It is derived from the system bus clock by the baud rate generator. The baud rate generator is controlled by the value of the SBR field in the Baud Rate Register (eSCI\_BRR). The frequency of the transmitter clock is determined by the following equation and defines the length of the transmitted bits, which is denoted as the *bit time*.

$$f_{\text{TCLK}} = \frac{f_{\text{MCLK}}}{16 \cdot \text{SBR}}$$

### 42.5.3.3 Receiver Clock

The receiver clock RCLK is used to sample the data received on the RXD or TXD pin. It is derived from the system bus clock by the baud rate generator. The baud rate generator is controlled by the value of the SBR field in the Baud Rate Register (eSCI\_BRR). The frequency of the receiver sample clock is determined by the following equation.

$$f_{\text{RT}} = \frac{f_{\text{MCLK}}}{\text{SBR}}$$

The frequency of the receiver clock is 16 times the frequency of the transmitter clock, thus each bit is sampled with 16 samples. Each of the 16 samples of a bit has a sample number assigned, which is defined by the receiver sample counter RSC. The n-th sample is denoted by RS<sub>n</sub>. The receiver sample counter RSC is updated with each rising edge of the receiver clock RCLK.

## 42.5.4 Baud Rate Tolerance

A transmitting device may be operating at a baud rate below or above the receiver baud rate. Accumulated bit time misalignment can cause one of the three stop bit data samples RS<sub>8</sub>, RS<sub>9</sub>, and RS<sub>10</sub> to fall outside the actual stop bit. A noise error will occur if the stop bit sample RS<sub>8</sub>, RS<sub>9</sub>, and RS<sub>10</sub> samples are not all the same logical value 1. A framing error will occur if the receiver clock is misaligned in such a way that the majority of the RS<sub>8</sub>, RS<sub>9</sub>, and RS<sub>10</sub> stop bit samples are a logic zero.

### 42.5.4.1 Faster Receiver Tolerance

In this case the receiver has a higher baud rate than the transmitter, thus the stop bit sampling starts already in the last transmitted payload bit. To ensure the correct, noise and framing error free reception of the stop bit, the samples RS<sub>8</sub>, RS<sub>9</sub>, and RS<sub>10</sub> must be located in the transmitted stop bit as shown in the following figure.

**Figure 42-24. Faster Receiver**

The maximum tolerance that ensures error free reception can be calculated with the assumption that RS<sub>7</sub> is sampled during the last transmitted payload bit and RS<sub>8</sub> is sampled in the stop bit.

For an frame with  $n$  payload bits the transmitter starts the transmission of the stop bit

$$t_{XSTOP} = (n + 1) \cdot 16 \cdot RT_{TR}$$

after the start of the transmission of the start bit.

For an frame with  $n$  payload bits the receiver samples the RS8 sample of the stop bit

$$rx_{STOP} = (n + 1) \cdot 16 \cdot RT_{RE} + 7 \cdot RT_{RE}$$

after the successful qualification of the start bit.

To ensure error free reception of the stop bit, the transmitter must start the transmission of the stop bit before the receiver samples RSC8.

$$tx_{STOP} < rx_{STOP}$$

The maximum percent difference between the receiver baud rate and the transmitter baud rate is:

$$\Delta \text{baudrate} \leq \left( \frac{rx_{STOP} - tx_{STOP}}{tx_{STOP}} \right) \times 100$$

The maximum percent differences for the supported frames is given in the following table.

**Table 42-24. Faster Receiver Maximum Tolerance**

| payload bits | max baudrate difference | tx <sub>STOP</sub> | rx <sub>STOP</sub> |
|--------------|-------------------------|--------------------|--------------------|
| 8            | 4.63%                   | 144                | 151                |
| 9            | 4.19%                   | 160                | 167                |
| 13           | 3.03%                   | 224                | 231                |

#### 42.5.4.2 Slower Receiver Tolerance

In this case the receiver has a slower baud rate than the transmitter, thus the stop bit sampling is still running while the next start bit is already transmitted. To ensure the correct, noise and framing error free reception of the stop bit, the samples RS8, RS9, and RS10 must be located in the transmitted stop bit as shown in the following figure.

**Figure 42-25. Slower Receiver**

## Functional Description

The maximum tolerance that ensures error free reception can be calculated with the assumption that RS11 is sampled in the transmitted start bit and RS10 is sampled in the last stop bit.

For a frame with  $n$  payload bits and  $s$  stop bits, the transmitter starts the transmission of the next start bit

$$t_{xSTART} = (n + s + 1) \cdot 16 \cdot RT_{TR}$$

after the start of the transmission of the previous start bit.

For a frame with  $n$  payload bits and  $s$  stop bits, the receiver samples the RS10 sample of the last stop bit

$$r_{xSTOP} = (n + s) \cdot 16 \cdot RT_{RE} + 9 \cdot RT_{RE}$$

after the successful qualification of the start bit.

To ensure error free reception of the last stop bit, the transmitter must start the transmission of the start bit after the receiver samples RS10.

$$r_{xSTOP} < t_{xSTART}$$

The maximum percent difference between the receiver baud rate and the transmitter baud rate is:

$$\Delta \text{baudrate} \leq \left( \frac{t_{xSTART} - r_{xSTOP}}{t_{xSTART}} \right) \times 100$$

The maximum percent differences for the supported frames is given in the following table.

**Table 42-25. Slower Receiver Maximum Tolerance**

| payload bits | stop bits | max baudrate difference | $r_{xSTOP}$ | $t_{xSTART}$ |
|--------------|-----------|-------------------------|-------------|--------------|
| 8            | 1         | 4.37%                   | 153         | 160          |
| 9            | 1         | 3.97%                   | 169         | 176          |
| 9            | 2         | 3.57%                   | 185         | 196          |
| 13           | 2         | 2.73%                   | 249         | 256          |

## 42.5.5 SCI Mode

### 42.5.5.1 SCI Mode Configuration

The application must configure the following bits and fields in order to achieve correct SCI operation.

- enable *SCI* Mode
  - LIN Control Register 1 (eSCI\_LCR1)[LIN]:= 0
- select *baud rate*
  - Baud Rate Register (eSCI\_BRR)[SBR]
- select *receiver input* mode
  - Control Register 1 (eSCI\_CR1)[LOOPS]
  - Control Register 1 (eSCI\_CR1)[RSRC]
- select *frame format*
  - Control Register 1 (eSCI\_CR1)[M]
  - Control Register 1 (eSCI\_CR1)[PE]
  - Control Register 1 (eSCI\_CR1)[WAKE]
  - Control Register 3 (eSCI\_CR3)[M2]
- select *parity type*
  - Control Register 1 (eSCI\_CR1)[PT]

### 42.5.5.2 Transmitter

The transmitter supports the transmission of all frame types defined in [Table 42-19](#), of all break characters defined in [Table 42-21](#), and of all idle characters defined in [Table 42-22](#).

#### 42.5.5.2.1 Transmitter States and Transitions

The transmitter has four basic states which are shown and described in [Table 42-26](#). The state transitions that can be triggered by the application commands are shown in [Table 42-27](#). The state transitions that can be triggered by the module are shown [Table 42-28](#). The state diagram of the transmitter is shown in [Figure 42-26](#).

Figure 42-26. Transmitter State Diagram

The current state of the transmitter can be determined by the TE control bit in the Control Register 1 (eSCI\_CR1) and the TACT status bit in Interrupt Flag and Status Register 1 (eSCI\_IFSR1).

Table 42-26. Transmitter States

| State | Indication   |                  | Description                                                          |
|-------|--------------|------------------|----------------------------------------------------------------------|
|       | eSCI_CR1[TE] | eSCI_IFSR1[TACT] |                                                                      |
| Idle  | 0            | 0                | Transmitter is <i>disabled</i> and <i>no</i> transmission is running |
| Ready | 1            | 0                | Transmitter is <i>enabled</i> and <i>no</i> transmission is running  |
| Run   | 1            | 1                | Transmitter is <i>enabled</i> and transmission is running            |
| Stop  | 0            | 1                | Transmitter is <i>disabled</i> and transmission is running           |

The application triggers a transition described in Table 42-27 when it issues a command by writing to the TE bit in the Control Register 1 (eSCI\_CR1). The transition is triggered only if the conditions are fulfilled. As a result of the transition the state of the transmitter is changed as shown in Figure 42-26 and the action given in Table 42-27 is executed.

Table 42-27. Transmitter Application Transitions

| Transition | Command         | Precondition   | Action  | Description                                           |
|------------|-----------------|----------------|---------|-------------------------------------------------------|
| EN         | eSCI_CR1[TE]:=1 | eSCI_CR1[TE]=0 | iPRE:=1 | Transmitter is <i>enabled</i> by application command. |
| DIS        | eSCI_CR1[TE]:=0 | eSCI_CR1[TE]=1 |         | Transmitter is <i>disabled</i> by application command |

The module transition shown in Table 42-28 are triggered when the described condition or event occurs. The send break bit SBK in the Control Register 1 (eSCI\_CR1) is checked for the start condition. The internal commit bit iCMT, the transmitter active bit TACT in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1), the TDRE, and the TC flag in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) are changed as a action result of the transition.

**Table 42-28. Transmitter Module Transitions**

| Transition | Condition                                              | Action                                          | Description                                                                                                                                                |
|------------|--------------------------------------------------------|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| start      | (State=Ready)<br>and<br>(SBK=1 or iPRE=1 or<br>iCMT=1) | TACT:=1                                         | Start of transmission of data frame or special character when data are available or character transmission request is pending.                             |
| done       | State=Run<br>and<br>last stop bit transmitted          | TACT:=0<br>TC:=<br>(SBK=0 & iPRE=0 &<br>iCMT=0) | Finished transmission of data frame or special character and transmitter still enabled.<br><br>Transmission is complete if no transmit request is pending. |
| halt       | State=Stop<br>and<br>last stop bit transmitted         | TACT:=0<br>TC:=1<br>iCMT:=0                     | Finished transmission of data frame or special character and transmitter was disabled.                                                                     |

#### 42.5.5.2.2 Frame and Character Transmission

The transmitter starts the transmission of a data frame or special character when the condition for the *start* transition as described in [Table 42-28](#) is fulfilled. There are three source for data or character transmission. The priority among these source are specified in the following table. All three sources can be available at one point in time.

**Table 42-29. Transmit Source Priority**

| Priority    | Indication      | Transmission Source                 |
|-------------|-----------------|-------------------------------------|
| (highest) 0 | iPRE=1          | Preamble.                           |
| 1           | eSCI_CR1[SBK]=1 | Break character.                    |
| (lowest) 2  | iCMT=1          | SCI Data Register (eSCI_SDR) frame. |

#### 42.5.5.2.3 CPU Controlled SCI Data Frame Transmission

The transmission of a data frame is started when the transmitter is in its Ready state and only the commit bit iCMT is set.

As the first step, the content of the SCI Data Register (eSCI\_SDR) is transferred into the internal transmitter shift register. When this transfer is finished, the internal commit bit iCMT is cleared and the transmit data register empty flag TDRE in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set. If the transmit interrupt enable bit TIE in the Control Register 1 (eSCI\_CR1) is also set, the TDRE flag generates a transmitter interrupt request.

The transmitter shift register then shifts a frame out through the TXD output signal, which is prefaced with a start bit and appended with the parity bit, if configured, and the configured number of stop bits.

When the last stop bit has been transmitted and the application has not disabled the transmitter, the transmitter returns to the Ready state via the *done* transition. If no frame or character transmit request is pending, the transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set.

If the application has disabled the transmitter while the frame is transmitted and stop bit has been transmitted, the transmitter goes into the Idle state via the *halt* transition. The transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set and the internal commit bit iCMT is cleared.

#### **42.5.5.2.4 DMA Controlled SCI Data Frame Transmission**

In this mode, the eSCI module handles the generation of Data Frames internally.

When new data is required for transmission, the module generates the transmit DMA request and the DMA controller delivers the required data via write accesses to SCI Data Register (eSCI\_SDR). The write access to the low byte of SCI Data Register (eSCI\_SDR) triggers the transmission of the data. The write access to the high byte of SCI Data Register (eSCI\_SDR) triggers no internal operation.

The application requests the eSCI module to enter this mode by setting the TXDMA bit in the Control Register 2 (eSCI\_CR2). From this point in time, the module starts the generation of DMA requests and frame transmission. Before entering this mode, the application should perform the following actions:

1. Configure the module for SCI mode.
2. Enable the transmitter by setting TE in Control Register 1 (eSCI\_CR1) to 1.
3. Setup the DMA controller channel and provide frame data in system memory

A block diagram which presents an overview of the DMA Controlled Date Frame Transmission is shown in the following figure.

**Figure 42-27. DMA Controlled SCI Data Frame generation**

#### 42.5.5.2.5 Parity Generation

The eSCI module generates the parity bit in transmitted data frame when the parity enable bit PE in the Control Register 1 (eSCI\_CR1) is set. The parity type bit PT in the Control Register 1 (eSCI\_CR1) defines whether the odd or even parity is generated.

#### 42.5.5.2.6 Preamble Transmission

The transmission of a preamble is started when the transmitter is in Ready state, the internal iPRE bit, which is not visible to the application, is set, and the SBK in the Control Register 1 (eSCI\_CR1) is clear.

After the transmission of the stop bit and if the application has not disabled the transmitter, the transmitter returns to the Ready state via the *done* transition. If no frame or character transmit request is pending, the transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set.

If the application has disabled the transmitter while the preamble is transmitted and if the stop bit has been transmitted, the transmitter goes into the Idle state via the *halt* transition. The transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set and the internal commit bit iCMT is cleared.

#### 42.5.5.2.7 Break Character Transmission

The transmission of a break character is started when the transmitter is in Ready state and the send break character bit SBK in the Control Register 1 (eSCI\_CR1) is set. After the transmission of the break character and if the application has not disabled the transmitter,

the transmitter returns to the Ready state via the *done* transition and restarts the transmission. As long as SBK bit remains set, the transmitter continues to send break characters.

When the application has cleared the SBK bit or has disabled the transmitter, the transmitter continues to transmit the current break character and after it has finished the transmission of this break character it transmits a stop bit. The stop bit at the end of a break character sequence guarantees the recognition of the start bit of the next data frame.

After the transmission of the stop bit and if the application has not disabled the transmitter, the transmitter returns to the Ready state via the *done* transition. If no frame or character transmit request is pending, the transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set.

If the application has disabled the transmitter while the break character is transmitted and if the stop bit has been transmitted, the transmitter goes into the Idle state via the *halt* transition. The transfer complete flag TC in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set and the internal commit bit iCMT is cleared.

### 42.5.5.3 Receiver

The receiver supports the reception of all data frame types defined in [Table 42-19](#) and [Table 42-20](#), of all break character defined in [Table 42-21](#), and of all idle characters defined in [Table 42-22](#).

#### 42.5.5.3.1 Receiver States and Transitions

The receiver has four basic states which are shown and described in [Table 42-30](#). The state transitions that can triggered by the application commands are shown in [Table 42-31](#). The state transitions that can triggered by the module are shown in [Table 42-32](#). The state diagram of the transmitter is shown in the following figure.

Figure 42-28. Receiver State Diagram

The current state of the receiver can be determined by the RE and RWU bit in the Control Register 1 (eSCI\_CR1) and the RACT status bit in Interrupt Flag and Status Register 1 (eSCI\_IFSR1).

**Table 42-30. Receiver States**

| State   | Indication |      |     | Description                                                    |
|---------|------------|------|-----|----------------------------------------------------------------|
|         | RE         | RACT | RWU |                                                                |
| Idle    | 0          | 0    | 0   | Receiver is <i>disabled</i> and <i>no</i> reception is running |
| Ready   | 1          | 0    | 0   | Receiver is <i>enabled</i> and <i>no</i> reception is running  |
| Run     | 1          | 1    | 0   | Receiver is <i>enabled</i> and reception is running            |
| Wake-up | 1          | -    | 1   | Receiver is in wake-up mode                                    |

The application triggers a transition described in [Table 42-31](#) when it issues a command by writing to the RE bit in the Control Register 1 (eSCI\_CR1). The transition is triggered only if the conditions are fulfilled. As a result of the transition, the state of the receiver is changed as shown in the preceeding figure and the action given in [Table 42-31](#) is executed.

**Table 42-31. Receiver Application Transition**

| Transition | Command | Condition | Action | Description                                        |
|------------|---------|-----------|--------|----------------------------------------------------|
| EN         | RE:=1   | RE=0      |        | Receiver is <i>enabled</i> by application command. |
| DIS        | RE:=0   | RE=1      |        | Receiver is <i>disabled</i> by application command |
| SLP        | RWU:=1  | RE=1      |        | Receiver is set into wake-up mode                  |

The module transitions shown in [Table 42-32](#) are triggered when the described event occurs.

**Table 42-32. Receiver Module Transition**

| Transition | Condition                                                                 | Action  | Description                                          |
|------------|---------------------------------------------------------------------------|---------|------------------------------------------------------|
| start      | (State=Ready,Run)<br>and<br>(start bit qualified)                         | RACT:=1 | Start of reception of data frame or break character. |
| done       | (State=Run)<br>and<br>(start bit not verified or idle character received) | RACT:=0 | Start Bit not Verified or Idle Character received.   |
| wake0      | (State=Wake-up)<br>and<br>(idle character received)                       | RWU:=0  | Wake-up Idle Character received.                     |
| wake1      | (State=Wake-up)                                                           | RWU:=0  | Wake-up address frame received.                      |

Table 42-32. Receiver Module Transition

| Transition | Condition                       | Action | Description |
|------------|---------------------------------|--------|-------------|
|            | and<br>(address frame received) |        |             |

42.5.5.3.2 Receiver Input Mode Selection

This section describes the three receiver input modes supported by the eSCI module. The modes are selected by the LOOPS and RSRC control bits in the Control Register 1 (eSCI\_CR1).

42.5.5.3.3 Dual Wire Mode

In Dual Wire Mode, the eSCI uses the TXD pin for transmitting and the RXD pin for data receiving.

Figure 42-29. Dual Wire Mode

42.5.5.3.4 Single Wire Mode

In Single Wire Mode, the RXD pin is disconnected from the eSCI module and the TXD pin is used for both receiving and transmitting.

Figure 42-30. Single Wire Mode

In this device, the TXDIR bit (eSCI\_CR2[TXDIR]) does not determine whether the TXD pin is going to be used as an input or an output. The relevant pad control register in the System Integration Unit must be programmed for input or output.

### 42.5.5.3.5 Loop Mode

In Loop Mode, the input of the receiver is driven by the output of the transmitter. The RXD pin is disconnected from the eSCI module.

Figure 42-31. Loop Mode

### 42.5.5.3.6 Frame and Character Reception

The receiver is started when it is in Ready or Wake-up state and on the selected receiver input (see [Receiver Input Mode Selection](#)) an active signal is sampled. The receiver enters the Run or Wake-up state. The received bits are recovered by the bit sampling described in [Bit Sampling](#). During the reception, the received bits are shifted into the internal shift register.

### 42.5.5.3.7 Break Character Detection

The receiver does not provide any means to detect the reception of a break character. Instead, break characters are processed as data frames. Due to the received 0 at the stop bit location, the reception of a break character causes at least a framing error. The error reporting is performed as described in [Reception Error Reporting](#).

### 42.5.5.3.8 Idle Character Detection

The Idle character detection starts after the reception of the last stop bit.

### 42.5.5.3.9 CPU Controlled SCI Data Frame Reception

This section describes the reception process when the receiver is in the Run state.

When the required number of frame bits have been received, the payload bits of the received frame are transferred into SCI Data Register (eSCI\_SDR) if the RDRF flag is 0. The receive data register full flag RDRF in Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set. If the receive interrupt enable bit RIE in the Control Register 1 (eSCI\_CR1) is set, the RDRF interrupt request is generated.

If an idle character has been detected, the IDLE flag in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set. If the idle line interrupt enable bit ILIE in the Control Register 1 (eSCI\_CR1) is set, the IDLE interrupt request is generated.

If any of the receiver errors described in [Reception Error Reporting](#) have occurred, that corresponding flags will be set.

If the application is disabled the receiver, by clearing the receiver enable bit RE in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1), the current frame is discarded and no flags will be updated.

#### **42.5.5.3.10 DMA Controlled SCI Data Frames Reception**

In this mode, the eSCI module controls the reception of SCI Data frames automatically and utilizes the connected DMA channels. A block diagram which presents an overview of the DMA Controlled SCI Data Frame reception is shown in the following figure. The RX DMA channel is used to transfer the received frame data into the memory.

When new data is received, the module generates the receive DMA request and the DMA controller retrieves the provided data from the SCI Data Register (eSCI\_SDR). The read access from the low byte of the SCI Data Register (eSCI\_SDR) signals the end of the DMA cycle for the current data and triggers the reception of new data. The read access from the SCI Data Register (eSCI\_SDR) triggers no internal action.

The application requests the eSCI module to enter this mode by setting the RXDMA bit in the Control Register 2 (eSCI\_CR2). From this point in time, the module start the generation of DMA requests and frame transmission and reception. Before entering this mode, the application should perform the following actions:

1. Configure the module for SCI mode.
2. Enable the receiver by setting RE in Control Register 1 (eSCI\_CR1) to 1.
3. Setup the DMA controller channel.

**Figure 42-32. DMA Controlled SCI Data Frame Reception**

#### 42.5.5.3.11 Receiver Overrun

When the eSCI module has received a frame and attempts to transfer the payload data of the received frame into the SCI Data Register (eSCI\_SDR) but neither the application nor the DMA controller has SCI Data Register (eSCI\_SDR) since its last update, the overrun flag OR in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set. The data contained in SCI Data Register (eSCI\_SDR) are not changed and the received data are lost.

#### 42.5.5.3.12 Wake-up Frame Reception

This section describes the reception process when the receiver is in the Wake-up state.

When the required number of frame bits have been received, the payload bits of the received frame are transferred into SCI Data Register (eSCI\_SDR) if the RDRF flag is 0.

If the *address-mark* wake-up mode is selected and the received frame has the address bit set, the receive data register full flag RDRF in Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set. If the receive interrupt enable bit RIE in the Control Register 1 (eSCI\_CR1) is set, the RDRF interrupt request is generated. The RWU bit is cleared, and the receiver enters the Run state via the wake1 transition.

If the *idle line* wake-up mode is selected and the receiver has detected an idle character, The RWU bit is cleared, and the receiver enters the Ready state via the wake0 transition.

If any of the receiver errors described in [Reception Error Reporting](#) have occurred, the corresponding flags will be set.

### 42.5.5.3.13 Bit Sampling

The receiver samples the selected receiver input (see [Receiver Input Mode Selection](#)) with the receiver clock RCLK. The bit sampling for start bit detection is shown in [Figure 42-33](#), the bit sampling for data and stop bit reception is shown in [Figure 42-34](#). The samples indicated by dashed arrows are not used by the receiver. The received data bits are transferred into the internal shift register after the data strobing. If noise or framing errors are detected, this is flagged as described in [Reception Error Reporting](#).

### 42.5.5.3.14 Bit Synchronization

To adjust for baud rate mismatch, a synchronization of the cyclic receive sample counter RSC is performed during start bit reception as described in [Start Bit Sampling](#).

### 42.5.5.3.15 Start Bit Sampling

**Figure 42-33. Start Bit Sampling and Strobing**

The sampling of the start bit consists of three phases, the start bit qualification, the start bit verification, and the start bit noise detection.

#### 42.5.5.3.15.1 Start Bit Qualification

To adjust for baud rate mismatch, the cyclic receive sample counter RSC is re-synchronized after a successful start bit qualification.

A start bit is successfully qualified if

- the start qualification is active, and
- a low sample is read, and
- the low sample was preceded by three consecutive high samples.

The start bit qualification becomes active

- after module reset, or
- after receiver disable and subsequent enable, or
- after the 7-th sample if the start bit verification failed, or
- after the 10-th sample of last stop bit of the preceding frame (example shown in [Figure 42-33](#)).

The start bit qualification becomes inactive

- after successful start bit qualification.

#### 42.5.5.3.15.2 Start Bit Verification

After the successful start bit qualification the receiver starts to verify the start bit by a two out of three samples majority voting.

A start bit is verified if at least two out of the three sample RSC3, RSC5, and RSC7 are sampled low. Noise is detected when exactly one out of the three samples is high. In this case, the noise flag eSCI\_IFSR1[NF] is set. The result of the start bit verification is summarized in [Table 42-33](#).

**Table 42-33. Start Bit Verification Result**

| [RSC3, RSC5, RSC7] | Start Bit Verified | Verification Noise Detected |
|--------------------|--------------------|-----------------------------|
| 000                | Yes                | No                          |
| 001                | Yes                | Yes                         |
| 010                | Yes                | Yes                         |
| 100                | Yes                | Yes                         |
| 011                | No                 | No                          |
| 101                | No                 | No                          |
| 110                | No                 | No                          |
| 111                | No                 | No                          |

If the start bit verification was *not successful*, the receiver activates the start bit qualification. If the start bit verification was *successful*, the receiver continues sampling to perform data noise detection on the samples at RSC8, RSC9, and RSC10. The result of the start bit data noise detection is summarized in [Table 42-34](#). If noise is detected, the noise flag eSCI\_IFSR1[NF] is set.

**Table 42-34. Start Bit Noise Detection**

| [RSC8, RSC9, RSC10] | Noise Detected |
|---------------------|----------------|
| 000                 | No             |
| 001                 | Yes            |
| 010                 | Yes            |
| 100                 | Yes            |
| 011                 | Yes            |
| 101                 | Yes            |
| 110                 | Yes            |
| 111                 | Yes            |

#### 42.5.5.3.16 Data Bit Sampling

**Figure 42-34. Data and Stop Bit Sampling and Strobming**

To determine the value of a data bit and to detect noise, a two out of three majority voting is performed on the samples RSC8, RSC9, and RSC10. The following table summarizes the results of the data bit sample. The receiver detects the number of data bit according to the selected frame format. If noise is detected, the noise flag eSCI\_IFSR1[NF] is set.

**Table 42-35. Data Bit Sampling**

| [RSC8, RSC9, RSC10] | Data Bit Value | Noise Detected |
|---------------------|----------------|----------------|
| 000                 | 0              | No             |
| 001                 | 0              | Yes            |
| 010                 | 0              | Yes            |
| 100                 | 0              | Yes            |
| 011                 | 1              | Yes            |
| 101                 | 1              | Yes            |
| 110                 | 1              | Yes            |
| 111                 | 1              | No             |

### 42.5.5.3.17 Stop Bit Verification

The reception of a valid stop bit is verified if at least two out of the sample RSC8, RSC9, and RSC10 are sampled high. If this is not the case, a framing error is detected. Noise is detected if not all of the samples are of the same value. In this case, the noise flag eSCI\_IFSR1[NF] is set. The result of the stop bit verification is summarized in the following table.

**Table 42-36. Stop Bit Verification**

| [RSC8, RSC9, RSC10] | Stop Bit Verified | Framing Error Detected | Noise Detected |
|---------------------|-------------------|------------------------|----------------|
| 000                 | No                | Yes                    | No             |
| 001                 | No                | Yes                    | Yes            |
| 010                 | No                | Yes                    | Yes            |
| 100                 | No                | Yes                    | Yes            |
| 011                 | Yes               | No                     | Yes            |
| 101                 | Yes               | No                     | Yes            |
| 110                 | Yes               | No                     | Yes            |
| 111                 | Yes               | No                     | No             |

### 42.5.5.3.18 Parity Checking

The eSCI module calculates the parity of a received character and checks it versus the received parity bit in the received data frame when the parity enable bit PE in the Control Register 1 (eSCI\_CR1) is set. The parity type bit PT in the Control Register 1 (eSCI\_CR1) defines whether to check for odd or even parity generation. If a parity error is detected, it is reported as described in [Reception Error Reporting](#).

## 42.5.5.4 Reception Error Reporting

The receiver can detect four error types: parity errors, framing errors, noise errors, and the overrun error.

The receiver reports the errors detected during frame reception at the end of the reception of the last stop bit of a frame. For error reporting the receiver utilizes the OR, NF, FE, and PF flags in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1).

If the receiver has detected an overrun as described in [Receiver Overrun](#), only the OR flag is set. All other error flags are not updated.

If the receiver has detected noise as described in [Bit Sampling](#), the NF flag is set.

If the receiver has *not* detected an overrun and has detected a framing error as described in [Bit Sampling](#), the FE flag is set.

If the receiver has *not* detected an overrun and has detected a parity error as described in [Parity Checking](#), the PF flag is set.

### 42.5.5.5 Multiprocessor Communication

The multiprocessor communication allows one processor to send blocks of frames to other processors on the same serial link. To avoid the received data interrupt for frames not intended for the processor, the eSCI receiver can be put into the Wake-up state. If the receiver is in the Wake-up state, the eSCI will still load the received data into the SCI Data Register (eSCI\_SDR), but will not set the RDRF flag and consequently not request the RDRF interrupt.

The receiver leaves the Wake-up state and clears the RWU bit in the Control Register 1 (eSCI\_CR1) when the wake-up pattern configured by WAKE bit in Control Register 1 (eSCI\_CR1) is received. The eSCI module supports two types of wake-up patterns, the idle-line wakeup pattern and the address-mark wake-up pattern.

#### 42.5.5.5.1 Idle-Line Wake Up

The idle-line wake-up mode is selected when the WAKE bit in Control Register 1 (eSCI\_CR1) is 0. In this mode, the receiver leaves the wake-up state when an idle character is detected as described in [Idle Character Detection](#). The next received frame is the address frame that contains address information which can be evaluated by the application. If the application decides not to receive the frame block, it can set the RWU bit in the Control Register 1 (eSCI\_CR1) and return the receiver to the wake-up state.

Figure 42-35. Idle-Line Wake Up

#### 42.5.5.5.2 Address-Mark Wake Up

The address-mark wake-up mode is selected when the WAKE bit in Control Register 1 (eSCI\_CR1) is 1. If the WAKE bit is set, the address bit is added to the frame format. In this mode, the receiver leaves the wake-up state when a data frame with the address bit value of 1 was received. This frame is the address frame and contains address

information which can be evaluated by the application. If the application decides not to receive the frame block, it can set the RWU bit in the Control Register 1 (eSCI\_CR1) and return the receiver to the wake-up state. All data frames that belong to the frame block must have the address bit cleared.

**Figure 42-36. Address-Mark Wake Up**

## 42.5.6 LIN Mode

The eSCI provides support for the LIN protocol. It can be used to automate most tasks of a LIN master. In conjunction with the DMA interface it is possible to transmit entire LIN frames and sequences of LIN frames as well as to receive data from LIN slaves without application intervention. There is no special support for LIN slave mode.

### 42.5.6.1 LIN Mode Configuration

The application must configure the following bits and fields in order to achieve correct LIN operation. The configuration of bits and fields not mentioned in this section depend on the connected LIN slaves and the current application.

- enable *LIN* Mode
  - LIN Control Register 1 (eSCI\_LCR1)[LIN]:= 1
- select *RXD* pin as receiver input
  - Control Register 1 (eSCI\_CR1)[LOOPS]:= 0
  - Control Register 1 (eSCI\_CR1)[RSRC]:= 0
- select *LIN byte fields* as used frame format
  - Control Register 1 (eSCI\_CR1)[M]:= 0
  - Control Register 1 (eSCI\_CR1)[PE]:= 0
  - Control Register 1 (eSCI\_CR1)[WAKE]:= 0
  - Control Register 3 (eSCI\_CR3)[M2]:= 0

- select *break character length* of 13 bit as required by LIN 2.0
  - Control Register 2 (eSCI\_CR2)[BRCL]:= 1
- select transmission stop on *bit error* detection
  - Control Register 2 (eSCI\_CR2)[BESTP]:= 1
- select transmission DMA stop on *bit error* detection
  - Control Register 2 (eSCI\_CR2)[BSTP]:= 1
- enable both *transmitter* and *receiver*
  - Control Register 1 (eSCI\_CR1)[TE]:= 1
  - Control Register 1 (eSCI\_CR1)[RE]:= 1

## 42.5.6.2 LIN frame formats

The term LIN frame refers to a sequence of LIN byte fields preceded by a break character, both are described in [Frame Formats](#). The eSCI module allows to generate LIN frames for LIN slaves of LIN standards 1.3 and 2.0.

### 42.5.6.2.1 LIN byte field reception

The reception of a LIN byte field starts with the successful start bit qualification and is finished with the reception of the 16-th sample of the stop bit when no start bit qualification pattern has been detected. If a start bit qualification pattern has been detected at or after the 10-th sample of the stop bit, the reception ends at this sample. An ongoing reception is indicated by the RACT status bit in Interrupt Flag and Status Register 1 (eSCI\_IFSR1).

The RACT flag is set if all of the following conditions are fulfilled:

1. the receiver is enabled (eSCI\_CR1[RE] = 1), and
2. the LIN task is not in reset (eSCI\_LCR1[LRES] = 0), and
3. the start bit qualification pattern has been received (see [Start Bit Sampling](#)).

The RACT flag is cleared if at least one of the following conditions is fulfilled,

1. the receiver is disabled (eSCI\_CR1[RE] = 0), or
2. the LIN task is in reset (eSCI\_LCR1[LRES] = 1), or

3. the start bit verification fails at sample 7 according to [Table 42-33](#), or
4. the 16-th sample of the stop bit has been received and no start bit qualification pattern has been detected at or after the 10-th sample.

#### 42.5.6.2.2 Standard LIN frames

A standard LIN frame, shown in the following figure consists of a break character, a sync field, an ID field, zero or more data fields, and a checksum field. The data fields and the checksum field are generated by the LIN master for TX LIN frames and generated by the LIN slave for RX LIN frames. The header fields will always be generated by the LIN master.

**Figure 42-37. Standard LIN frame format**

#### 42.5.6.2.3 CRC Enhanced LIN frames

The CRC Enhanced LIN frames shown in the following figure contain two additional CRC byte fields. These fields are located between the last data field and the Checksum field. The value of the CRC is calculated on the same byte fields as the Checksum is calculated on. The polynomial used for the CRC calculation is defined by LIN CRC Polynomial Register (eSCI\_LPR). The eSCI module generates the CRC fields for TX frames and checks the CRC fields for RX frames if the CRC bit in the LIN Transmit Register (eSCI\_LTR) was written with a value of 1.

**Figure 42-38. CRC Enhanced LIN frame format**

The CRC Enhanced LIN frames are not part of the LIN standard.

#### 42.5.6.3 LIN TX Frame generation

The eSCI module supports two modes of LIN TX Frame generation, the CPU controlled mode and the DMA controlled mode. In the CPU controlled mode, the application provides the required frame configuration and frame data by subsequent CPU write accesses to the LIN Transmit Register (eSCI\_LTR). In the DMA controlled mode, the DMA controller provides the required frame configuration and frame data in response to DMA requests generated by the eSCI module.

### 42.5.6.3.1 CPU Controlled LIN TX Frame generation

In this mode, the application initiates the generation of an LIN TX Frame and provides the data to be transmitted by a sequence of subsequent CPU write accesses to the LIN Transmit Register (eSCI\_LTR). When the eSCI module has processed the data written into LIN Transmit Register (eSCI\_LTR), the TXRDY interrupt flag in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) will be set.

The application should clear the TXRDY interrupt flag *before* writing data into the LIN Transmit Register (eSCI\_LTR) because the eSCI module will set the TXRDY one clock cycle after the write access.

The first data written to the LIN Transmit Register (eSCI\_LTR) provides the Identifier and Identifier Parity fields. The second data written defines the number of data bytes to be transmitted. The third data written defines the CRC and checksum generation. The TD bit has to set to 1 in order to invoke the LIN TX frame generation. The value of the TO field is ignored by the eSCI module for LIN TX frames.

After the third data was written the generation of a LIN TX frame is started. Firstly, a break field is transmitted, then the synch field and the protected identifier field.

All subsequent write accesses to the LIN Transmit Register (eSCI\_LTR) provide data bytes to be transmitted via the LIN bus. A data byte field will be transmitted as soon as data are available. After the last data byte, defined by the value written to the LEN field, was send out, the configured CRC and checksum fields will be send out.

After the transmission of the checksum field of the LIN TX frame, the write access counter for the LIN Transmit Register (eSCI\_LTR) is reset and the FRC interrupt flag in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) is set.

### 42.5.6.3.2 DMA Controlled LIN TX Frame generation

In this mode, the eSCI module controls the generation of an LIN TX Frame. When new data is required for transmission, the eSCI module generates the transmit DMA request and the DMA controller delivers the required data. The application requests the eSCI module to enter this mode by setting the TXDMA bit in the Control Register 2 (eSCI\_CR2). From this point in time, the module starts the generation of DMA requests and initiates the frame transmission. Before entering this mode, the application should perform the following actions:

1. Configure the module for LIN mode.
2. Enable the transmitter by setting TE in Control Register 1 (eSCI\_CR1) to 1.
3. Setup the DMA controller channel and provide frame data in system memory.

A block diagram which presents an overview of the DMA Controlled LIN TX Frame is shown in the following figure. The content of the fields in the memory is the same as described in LIN Transmit Register (eSCI\_LTR) - LIN TX frame generation.

**Figure 42-39. DMA Controlled LIN TX Frame generation**

#### 42.5.6.4 LIN RX frame generation

The eSCI module supports two modes of LIN RX Frame generation and reception, the CPU controlled mode and the DMA controlled mode. In the CPU controlled mode, the application provides the required data by subsequent CPU write accesses to the LIN Transmit Register (eSCI\_LTR) and retrieves the received data by subsequent CPU read accesses to the LIN Receive Register (eSCI\_LRR). In the DMA controlled mode, the DMA controller provides the required frame configuration data in response to DMA requests generated by the eSCI module and transfers the received frame data to the memory in response to DMA requests generated by the eSCI module.

##### 42.5.6.4.1 CPU Controlled LIN RX Frames generation

In this mode, the application initiates the generation of a LIN RX Frame by a sequence of subsequent CPU write accesses to the LIN Transmit Register (eSCI\_LTR). When the eSCI module has processed the data written into LIN Transmit Register (eSCI\_LTR), the TXRDY interrupt flag in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) will be set.

The application should clear the TXRDY interrupt flag *before* writing data into the LIN Transmit Register (eSCI\_LTR) because the eSCI module will set the TXRDY one clock cycle after the write access.

The first data written to the LIN Transmit Register (eSCI\_LTR) provides the Identifier and Identifier Parity fields. The second data written defines the number of data bytes requested from the LIN slave. The third data written defines the CRC and checksum generation. The TD bit has to set to 0 to invoke the RX frame generation. The TO field defines the upper part of the timeout value. The fourth byte written defines the lower part of the timeout value.

After the fourth byte was written the generation of a LIN RX frame is started. Firstly, a break field is transmitted, then the synch field and the protected identifier field. After the transmission of the protected identifier, the eSCI module starts to receive the frame data transmitted by the LIN slave. When the module has received a complete byte field, the received data are transferred into the LIN Receive Register (eSCI\_LRR) and the receive data ready flag RXRDY in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) is set.

The application can retrieve the received data by subsequent read access from LIN Receive Register (eSCI\_LRR) after checking the RXRDY flag. The application should clear the RXRDY flag immediately after reading the LIN Receive Register (eSCI\_LRR).

After the reception of the configured number of data from the slave, the module starts the reception of the configured CRC and Checksum byte fields. These data are not transferred into the LIN Receive Register (eSCI\_LRR). The CRC and Checksum checking is performed internally. In case of errors, they will be reported as described in [LIN Error Reporting](#).

After the reception of the checksum field of the LIN RX frame, the FRC interrupt flag in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) is set.

#### 42.5.6.4.2 DMA Controlled LIN RX Frames generation

In this mode, the eSCI module controls the generation of LIN RX frame header and the reception of the frame data automatically and utilizes the two connected DMA channels. A block diagram which presents an overview of the DMA Controlled LIN RX Frame generation and reception is shown in [Figure 42-40](#). The content of the header fields in the memory is the same as described in LIN Transmit Register (eSCI\_LTR) - LIN RX frame generation. The TX DMA channel is used to fetch the LIN RX frame header and control information. The RX DMA channel is used to transfer the received frame data into the memory.

When new data is required for transmission, the module generates the transmit DMA request and the DMA controller delivers the required data. When new data is received, the module generates the receive DMA request and the DMA controller retrieves the provided data.

The application requests the eSCI module to enter this mode by setting the RXDMA bit in the Control Register 2 (eSCI\_CR2). From this point in time, the module starts the generation of DMA requests and frame transmission and reception. Before entering this mode, the application should perform the following actions:

1. Configure the module for LIN mode.
2. Enable transmitter and receiver by setting TE and RE in Control Register 1 (eSCI\_CR1) to 1.
3. Setup the two DMA controller channels and provide frame header data in system memory.

**Figure 42-40. DMA Controlled LIN RX Frame generation and reception**

### 42.5.6.5 LIN Error Reporting

This section describes error checking and the signaling of detected errors in LIN mode.

#### 42.5.6.5.1 Physical Bus Error Detection

If the receiver input is sampled 0 for at least 31 sample clock cycles after the start of the transmission of a LIN frame, the physical bus error flag PBERR in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) will be set.

### 42.5.6.5.2 Unrequested Activity Detection

If an unrequested byte is received (i.e. a byte which is not part of an RX frame) which is not recognized as a wake-up or break character, the bit error flag BERR in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set. In addition the RXRDY flag will also be set, the LINRX register must be read before normal operations can proceed.

### 42.5.6.5.3 Standard Bit Error Detection

The standard bit error detection is enabled when the fast bit error detection control bit FBR in the Control Register 2 (eSCI\_CR2) is 0. The standard bit error detection is performed after each LIN byte field transmission.

During the transmission of the LIN frame header and LIN frame data, the receiver is running and receives the signal values on the serial bus. After the complete transmission and the related reception of a LIN byte field, the eSCI compares the data that was transmitted and the data that has been received. If they do not match, the bit error interrupt flag BERR in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set.

### 42.5.6.5.4 Fast Bit Error Detection

Fast Bit Error Detection has been designed to allow flagging of LIN bit errors while they occur, rather than flagging them after a byte transmission has completed (see [Figure 42-41](#)).

**Figure 42-41. Fast Bit Error Detection on a LIN Bus**

If fast bit error detection bit FBR in the Control Register 2 (eSCI\_CR2) is set, the eSCI will compare the transmitted and the received data stream while the transmitter is active (not idle). Once a mismatch between the transmitted data and the received data is detected, the bit error flag BERR will be set.

To adjust to different bus loads the sample point at which the incoming bit is compared to the one which was transmitted can be selected with the BESM bit in the Control Register 2 (eSCI\_CR2). If eSCI\_CR2[BESM] = 1, the comparison will be performed with sample RS13, otherwise with RS9 (see [Figure 42-42](#)) (also see [Bit Sampling](#)).

**Figure 42-42. Timing Diagram Fast Bit Error Detection**

### Note

To calculate the exact position of the sample point with regard to the RX pin, the delays through the pads and the two Bus Clock cycle delay through the input synchronizer also needs to be taken into account.

#### 42.5.6.5.5 Slave-Not-Responding-Error Detection

The Slave-Not-Responding-Error is defined in [LIN Specification Package Revision 1.3; December 12, 2002](#); 6 ERROR AND EXCEPTION HANDLING. The LIN specification requires that a NO\_RESPONSE\_ERROR has to be detected if a message frame is not fully completed within the maximum length  $T_{\text{FRAME\_MAX}}$  by any slave task upon transmission of the SYNCH and IDENTIFIER fields. The maximum frame length  $T_{\text{FRAME\_MAX}}$  is defined in [LIN Specification Package Revision 1.3; December 12, 2002](#); 3.3 LENGTH OF MESSAGE FRAME AND BUS SLEEP DETECT, as

$$T_{\text{FRAME\_MAX}} = (10 \cdot N_{\text{DATA}} + 45) \cdot 1.4$$

where  $N_{\text{DATA}}$  is the number of data byte fields of the message frame.

The STO interrupt flag in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) will be set, if an LIN RX frame was not fully received in the amount of time specified in the timeout value field TO in the LIN Transmit Register (eSCI\_LTR). The time period starts with the falling edge of the transmitted LIN break character and is specified in units of transmit bits.

To achieve LIN compliant Slave-Not-Responding-Error detection, the timeout value TO in the LIN Transmit Register (eSCI\_LTR) field has to be set to  $T_{\text{FRAME\_MAX}}$  when a LIN RX frame is initiated.

#### 42.5.6.5.6 Checksum Error Detection

If the checksum enable bit CSE in the LIN Transmit Register (eSCI\_LTR) was set, the checksum checking is performed based on the received checksum byte. The checksum mode is selected by the CSM bit in the LIN Transmit Register (eSCI\_LTR). If the value received in the checksum bytes did not match the calculated checksum, the checksum error flag CKERR in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) will be set.

#### 42.5.6.5.7 CRC Error Detection

The CRC checking is performed on the two received CRC bytes CRC1 and CRC2 if the CRC Enhanced LIN frame format was selected by the CRC bit in the LIN Transmit Register (eSCI\_LTR). If the value received in the two CRC bytes did not match the calculated CRC pattern, the CRC error flag CERR in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) will be set.

#### 42.5.6.5.8 Overflow Detection

When the receiver has received the next byte field, which should be transferred into the LIN Receive Register (eSCI\_LRR), but neither the application nor the RX DMA channel have read data from this register since the last update, the received data overflow flag OVFL in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) will be set. In this case the content of the LIN Receive Register (eSCI\_LRR) is not changed. The data received most recently are lost.

### 42.5.6.6 LIN Wake Up

The section describes the LIN Wake Up behavior of the eSCI module.

#### 42.5.6.6.1 LIN Wake-Up Request Generation

The eSCI module can cause the LIN bus to exit the sleep mode by sending a wake-up signal frame, which consists of a wake-up signal 0x80 (consisting of 8 dominant bits followed by 1 recessive bit), followed by the wake-up delimiter period as defined by the WUD field in the LIN Control Register 1 (eSCI\_LCR1), followed by Idle time which is  $n$  bits, where  $n \geq 0$ . This Idle time depends on the time until next frame is started by the software.

**Figure 42-43. LIN Wake-Up Signal Frame**

The application triggers the transmission of a wake-up signal frame by writing 1 to the LIN bus wake-up trigger WU in the LIN Control Register 1 (eSCI\_LCR1).

The LIN Specification 2.0 requires the generation of LIN wake-up signals as dominant pulses longer than 250  $\mu$ s and shorter than 5 ms. To achieve this, the eSCI module has to be programmed to a baud rate between 32 kBaud and 1.6 kBaud. With each of these baud rate settings, the wake-up signal is transmitted as a dominant pulse longer than 250  $\mu$ s and shorter than 5 ms.

#### 42.5.6.6.2 LIN Wake-Up Request Detection

The eSCI module detects a LIN wake-up requests when

1. one of the characters 0x00, 0x80, or 0xC0 has been received,
2. followed by zero or more low bits,
3. followed by at least one high bit, and
4. no LIN frame transmission or reception is started or running during the reception above

If a LIN wake-up request has been detected, the LIN wake-up flag LWAKE in the Interrupt Flag and Status Register 2 (eSCI\_IFSR2) will be set after the reception of the first high bit.

The LIN Specification 2.0 requires the detection of LIN wake-up requests as dominant pulses longer than 150  $\mu$ s. To achieve this, the eSCI module has to be programmed to the maximum baud rate that is not greater than 43.77 kBaud. With this baud rate setting, any dominant pulse longer than 150  $\mu$ s is decoded as at least 7 dominant bits (one start and 6 data bits) and consequently as one of the characters 0xC0, 0x80, or 0x00.

#### 42.5.6.7 LIN Protocol Engine Stop and Reset

The LIN protocol engine is stopped and reset when the application sets the LRES control bit in the LIN Control Register 1 (eSCI\_LCR1) to 1. In this case, the LIN protocol engine will stop immediately. No new transmissions or receptions are initiated, the LIN serial

bus is driven with the recessive value 1. Additionally to the stop and reset of the LIN protocol engine the receiver and transmitter modules are stopped and reset as well, and the receive and transmit DMA requests are deasserted.

In order to start the LIN Protocol Engine with idle transmitter and receiver processes, the LRES bit should be asserted until all of the status bits DACT, WACT, LACT, TACT, and RACT in the Interrupt Flag and Status Register 1 (eSCI\_IFSR1) are cleared. These status bits are cleared within one bit time after assertion of the LRES bit.

## 42.5.7 Interrupts

This section describes the interrupt sources and interrupt request generation.

### 42.5.7.1 Interrupt Flags and Enables

All interrupt sources, interrupt flags, and interrupt enable bits are listed in the following table. This table indicates the operational modes, where the interrupt flags can be set by the eSCI module.

**Table 42-37. eSCI Interrupt Flags and Interrupt Enable Bits**

| Interrupt Source      | Operational Mode | Interrupt Flag    | Interrupt Enable Bit |
|-----------------------|------------------|-------------------|----------------------|
| Transmitter           | SCI              | eSCI_IFSR1[TDRE]  | eSCI_CR1[TIE]        |
| Transmitter           | SCI, LIN         | eSCI_IFSR1[TC]    | eSCI_CR1[TCIE]       |
| Receiver              | SCI              | eSCI_IFSR1[RDRF]  | eSCI_CR1[RIE]        |
| Receiver              | SCI              | eSCI_IFSR1[IDLE]  | eSCI_CR1[ILIE]       |
| Receiver              | SCI              | eSCI_IFSR1[OR]    | eSCI_CR2[ORIE]       |
| Receiver              | SCI, LIN         | eSCI_IFSR1[NF]    | eSCI_CR2[NFIE]       |
| Receiver              | SCI, LIN         | eSCI_IFSR1[FE]    | eSCI_CR2[FEIE]       |
| Receiver              | SCI              | eSCI_IFSR1[PF]    | eSCI_CR2[PFIE]       |
| Receiver              | LIN              | eSCI_IFSR1[BERR]  | eSCI_CR2[BERRIE]     |
| Receiver              | LIN              | eSCI_IFSR2[RXRDY] | eSCI_LCR1[RXIE]      |
| Transmitter           | LIN              | eSCI_IFSR2[TXRDY] | eSCI_LCR1[TXIE]      |
| Receiver              | LIN              | eSCI_IFSR2[LWAKE] | eSCI_LCR1[WUIE]      |
| Receiver              | LIN              | eSCI_IFSR2[STO]   | eSCI_LCR1[STIE]      |
| Receiver              | LIN              | eSCI_IFSR2[PBERR] | eSCI_LCR1[PBIE]      |
| Receiver              | LIN              | eSCI_IFSR2[CEERR] | eSCI_LCR1[CIE]       |
| Receiver              | LIN              | eSCI_IFSR2[CKERR] | eSCI_LCR1[CKIE]      |
| Receiver              | LIN              | eSCI_IFSR2[FRC]   | eSCI_LCR1[FCIE]      |
| Receiver              | LIN              | eSCI_IFSR2[UREQ]  | eSCI_LCR2[URIE]      |
| Transmitter, Receiver | LIN              | eSCI_IFSR2[OVFL]  | eSCI_LCR2[OFIE]      |

### 42.5.7.2 Interrupt Request Generation

The eSCI module provides one hardware interrupt request signal to the systems interrupt controller. This interrupt request signal is asserted if and only if at least one of the interrupt flags and the corresponding interrupt enables are set to 1. Otherwise the interrupt line is deasserted.

## 42.6 Application Information

### 42.6.1 SCI Data Frames Separated by Preamble

To separate SCI data frame with preambles with minimum idle line time, use this sequence between messages:

1. write to SCI Data Register (eSCI\_SDR)
  - this sets the internal iCMT bit which requests the data transmission
2. wait until TDRE in Interrupt Flag and Status Register 1 (eSCI\_IFSR1) is set
  - this indicates the start of transmission; the iCMT bit was cleared
3. clear and subsequently set the TE bit in Control Register 1 (eSCI\_CR1)
  - this sets the internal iPRE bit which requests the preamble transmission
4. write to SCI Data Register (eSCI\_SDR)
  - this sets the internal iCMT bit which requests the data transmission

The priority scheme of the transmitter which is described in [Table 42-29](#) ensures that the preamble is transmitted before the data frame.

# Chapter 43

## Resets

### 43.1 Overview

This device supports the following system reset sources:

- Power-on reset (at power up)
- External reset (from RESET pin)
- Fault Collection and Control Unit (FCCU) reset
- FCCU Output Supervision Unit (FOSU) reset
- Dual core reset
- JTAG reset
- Self Test Control Unit (STCU) reset
- Software system reset
- Life cycle manipulation reset

A reset event caused by any of the above sources will trigger a reset cycle with the assertion of internal reset signals as well as the assertion of the RSTOUT pin. Software may set the SIU\_SRCR[SER] bit to 1 to assert the RSTOUT pin without causing an internal reset cycle. This action is referred to as a software external reset. After the reset cycle completes, software may learn the source of the last reset cycle by looking at the Reset Status Register (SIU\_RSR) in the SIU. The SIU\_RSR register is updated for all reset sources except JTAG and life cycle manipulation reset.

Power-on reset is the most comprehensive form of reset. It affects all modules without exception. Other sources of reset do not affect special hardware that needs to be active during the reset cycle, like for example the state machine of the reset controller. Some modules are affected by all reset sources, but are released from reset state before other modules during the execution of the reset cycle. This reset releasing sequence allows device configuration data to be read from flash memory and applied to the system before the completion of the reset cycle and prior the cores starting code execution.

When the reset cycle completes, the RSTOUT pin is negated. In parallel, the CSE security engine starts execution of the secure boot, and Core 0 starts execution. Core 1 and the associated checker core are kept in reset state until software running on Core 0 configures its reset vector and enables it to start code execution. Reset vectors and core resets are configured by the SIU\_RSTVEC0 and SIU\_RSTVEC1 registers.

The reset cycle can be extended by the assertion of the RESET pin. This is useful to allow JTAG communication to be established during the reset cycle, so that debugging configuration may be done before the cores start executing.

## 43.2 Reset sequence

The following figure illustrates the reset flow.

Figure 43-1. Internal reset flow diagram

When power-up is the source of the reset cycle, the following sequence of events takes place:

1. A power-on reset (POR) signal resets everything while power supplies are ramping up.
2. When supply rails are within acceptable (yet still untrimmed) voltage ranges, the POR signal is negated, the RSTOUT pin is asserted, and an internal reset signal is asserted to all modules.

**NOTE**

Some components are exceptions to this internal reset assertion. They include the reset controller, flash memory, and DCF clients (ERROR function and Reset escalation), all of which are affected only by POR.

3. The reset controller waits for 4 clock cycles so that the reset signal can propagate through the registers, then it negates the reset signals going to the STCU, FCCU and PASS, because these modules need to be active during the reset cycle.
4. The reset controller waits until the flash memory finishes its initialization, then negates the reset signal going to the SSCM module.
5. The SSCM reads device configuration and trimming data from DCF records stored in flash memory and applies the configuration data to the system. Refer to the DCF chapter for more information.
6. When the SSCM is done, the reset controller waits until the RESET pin is negated and then starts a timer that counts for a pre-determined number of clock cycles, which depends on the reset source (see [RSTOUT](#)).
7. If reset escalation is enabled, the reset cycle proceeds with reset escalation evaluation. A reset escalation counter is incremented at the end of every non-POR reset cycle. If the counter exceeds the number programmed in the RET field of SIU\_RCR, then the device is locked permanently into a reset state which can only be undone by a power-up cycle. To avoid reaching the reset escalation threshold, software must reset the escalation counter by servicing the SIU\_RCR register (write something to the RET field; writing zero disables the reset escalation process).
8. If the device was not locked at reset state by the reset escalation process, the STCU may take control of clocks and resets of the device to execute self-test diagnostics. Self-test is executed during the reset cycle when the following conditions are satisfied:
  - The reset cycle was initiated from power-up or RESET pin or FOSU reset
  - STCU execution is enabled by DCF configuration
  - JCOMP pin is not asserted and debug mode is not engaged

After the self-test is finished, the STCU records the test results and then triggers a new internal reset cycle via an STCU reset request. This new reset cycle will not trigger a self-test execution.

9. If the STCU did not execute, then the reset cycle reaches its normal termination flow, the SIU\_RSR register is updated, the RSTOUT pin is negated, and the internal reset signals are negated.

Reset cycles initiated by sources other than power-up, RESET pin, or FOSU do not affect all modules. For a reset cycle initiated by the STCU, the STCU itself is not reset, so that diagnostic results from the previous reset cycle are preserved.<sup>1</sup> Other sources of internal reset will not reset the STCU, FCCU, FOSU and PASS modules (they have information that needs to be preserved through the reset cycle).

## 43.3 Reset pins

### 43.3.1 RESET

The RESET pin is an active low input. The RESET pin must be asserted by an external device during power-up or whenever an external reset is required.

The RESET pin has hysteresis, and the hysteresis is always enabled.

The reset controller provides a glitch detector connected to the RESET pin. If the reset controller detects that the RESET pin is asserted for more than two peripheral clock cycles, the event is latched. After the latch is set, if the RESET pin is negated before 10 clock cycles is reached, the reset controller sets the RGF bit without affecting any of the other bits in the reset status register (SIU\_RSR). The latch is cleared when the RGF bit is set or a valid reset is recognized. The RGF bit remains set until cleared by a software or the RESET signal asserts for 10 clock cycles.

### 43.3.2 RSTOUT

The RSTOUT pin is an active low output that uses a push/pull configuration. The RSTOUT pin is driven low by the MCU for all internal and external reset sources.

The time interval between RESET pin negation and RSTOUT pin negation is deterministic, but it depends on the reset source, as shown in the following table. The actual time interval is the value in [Table 43-1](#) plus 4 clock cycles.

The RSTOUT pin can also be asserted by a write to the SER bit of the System Reset Control Register (SIU\_SRCR); however, an internal reset cycle is not initiated under this circumstance. The duration of RSTOUT assertion caused by setting the SER bit depends on whether the clock source is the IRC or not, as given in the following table.

---

1. The FCCU needs to be reset after a self-test run, because FCCU logic is part of the LBIST tests.

**Table 43-1. Clock Cycles for Different Reset Sources**

| Source <sup>1</sup> | Description                          | Number of clock cycles     |
|---------------------|--------------------------------------|----------------------------|
| PORS                | Power-on reset                       | 2400                       |
| ERS                 | External reset (RESET pin)           | 2410                       |
| FOSURS              | FOSU reset                           | 2430                       |
| FCCURS              | FCCU reset                           | 2460                       |
| CPURS               | Simultaneous core 0 and core 1 reset | 2490                       |
| STCURS              | STCU reset                           | 2500                       |
| SSRS                | Software system reset                | 2510                       |
| SERF <sup>2</sup>   | Software external reset              | 2520 (IRC) / 17200 (other) |

1. Bits of the SIU\_RSR register.

2. RSTOUT duration depends on the clock source: if IRC, duration is 2520; for all others, duration is 17200.

## 43.4 Reset sources

### 43.4.1 Power-on reset

The internal power-on reset signal is asserted when voltage and temperature monitors indicate that the device temperature and/or power supply voltages have reached values outside normal operating ranges. Control and configuration registers for temperature and voltage monitors are located within the Power Management Control (PMC) digital interface module.

POR is the highest priority reset and if POR is detected while any other reset is being processed, after reset cycle completion SRS will have just the PORS set.

#### 43.4.1.1 Voltage monitors

The following out-of-range voltage events can trigger a power-up reset cycle:

- POR: below absolute minimum value required for starting device wake-up process
- Low voltage Detection (LVD): below minimum power supply voltage specification
- High Voltage Detection (HVD): above maximum power supply voltage specification

A power-up reset cycle is triggered unconditionally when supply voltages fall below POR thresholds. LVD and HVD events can also trigger a power-up cycle if enabled in the PMC module. LVD/HVD events are also routed from the PMC to the FCCU to be handled there.

LVD/HVD events which are enabled to trigger reset will cause a POR reset cycle. When the reset cycle finishes, the PORS flag is set in the SIU\_RSR register. If LVD/HVD are routed to the FCCU, and the FCCU is enabled to generate reset from these sources, then an FCCU reset cycle is triggered. When the FCCU reset cycle finishes, the FCCURS bit is set in the SIU\_RSR register. The FCCU reset cycle will not reset the FCCU itself, therefore information about the LVD/HVD events can still be recovered from the FCCU registers.

See the the PMC chapter and the device data sheet for information on monitored voltages and threshold values.

### 43.4.1.2 Temperature monitors

The following table identifies the temperatures for which out-of-range temperature events can trigger a power-up reset cycle:

**Table 43-2. Temperature events configurable to cause POR**

| Temperature | Temperature Sensor name | PMC name      | Out-of-range event                                       |
|-------------|-------------------------|---------------|----------------------------------------------------------|
| -40°C       | Low temperature         | Temperature 0 | Temperature is below this threshold                      |
| 150°C       | High temperature 1      | Temperature 2 | Temperature is above this threshold                      |
| 165°C       | High temperature 2      | n/a           | No event: This device does not support 165°C monitoring. |

These events trigger a power-up cycle if enabled in the PMC module. Alternatively, the PMC can be configured to route the temperature events to the FCCU to be handled there.

Temperature events that are enabled to trigger a reset cause a POR cycle. When the reset cycle finishes, the PORS flag is set in the SIU\_RSR register. If the temperature events are routed to the FCCU, and the FCCU is enabled to generate reset from these sources, then an FCCU reset cycle is triggered. When the FCCU reset cycle finishes, the FCCURS bit is set in the SIU\_RSR register. The FCCU reset cycle will not reset the FCCU itself, so information about the LVD/HVD events can still be recovered from the FCCU registers.

See the detailed descriptions of the Temperature Sensor and PMC modules as well as the device Data Sheet for information about monitored temperatures and threshold values.

### 43.4.2 External reset

Assertion of the RESET pin triggers an internal reset cycle. The reset cycle will be sustained as long as RESET is kept asserted. When RESET is negated, the reset controller initiates a timer that counts for a predetermined number of clock cycles, as shown in [Table 43-1](#), before resuming the reset cycle.

If the RESET pin was the source reset, or if it was asserted during the last reset cycle, then the ERS bit is asserted in the SIU\_RSR register.

If POR is the current reset source being processed, then a RESET pin is detected, after reset cycle completion SRS will have PORS and ERS set.

If the Reset pin is the current reset source being processed, then if any other reset is detected (except POR), after reset cycle completion SRS will have just ERS set and PORS will keep its previous value.

### 43.4.3 FCCU reset

The Fault Collection and Control Unit collects failure events coming from different sub-systems within the device. One of the possible reactions to a failure event is the triggering of an internal reset cycle.

Failure sources include:

- All failure indication signals from modules within the MCU
- Logic and signals monitored by the FCCU itself
- Software-initiated failure indications
- External failure input.

Available failure reactions are:

- Assertion of an interrupt (maskable or nonmaskable)
- Resetting the MCU
- Changing the state of the failure indication pins, ERRORn
- No reaction

The FCCU itself is not affected by an FCCU reset. The FCCU is reset when the reset source is one of the following:

- Power-up
- RESET pin
- FOSU reset
- STCU reset

When the reset cycle that was initiated by the FCCU finishes, the FCCURS bit is asserted in the SIU\_RSR register. Since the FCCU itself is not reset when the reset source is an FCCU reset, information about the failure that caused reset is still available in the FCCU module to be read by software.

Refer to the FCCU chapter for information on failure sources that can generate a reset cycle.

#### 43.4.4 FOSU reset

As the FCCU is a central component in reacting to errors, it is itself supervised. This supervision is provided by the FCCU Output Supervision Unit (FOSU). The FOSU receives failure indications at the same time as the FCCU. Unless the respective failure is switched off, the FOSU will observe the outputs of the FCCU (IRQ, RESET, error pins). If the FCCU does not react within a predefined timing window, the FOSU assumes the FCCU has failed and causes a reset cycle.

A FOSU reset cycle resets the FCCU and the FOSU itself. The FOSU is reset when the reset source is one of the following:

- Power-up
- RESET pin
- FOSU reset
- STCU reset

When the FOSU reset cycle finishes, the FOSURS bit is asserted in the SIU\_RSR register.

#### 43.4.5 Dual core reset

Core 0 and Core 1 Reset Vector Registers described in the SIU chapter allow software executing on either core to place the other core in reset by setting the RST bit in the appropriate Reset Vector Register. Any attempt to reset both cores by setting both RST bits will result in an immediate internal reset.

When the reset cycle that was initiated by this reset source finishes, the CPURS bit is asserted in the SIU\_RSR register.

#### 43.4.6 JTAG reset

An internal reset cycle is initiated when JTAG is enabled and either the EXTEST, CLAMP, or HIGHZ instructions are executed by the JTAG controller. Since these instructions affect the state of the package pins, the state of the RSTOUT pin is determined by the JTAG instruction itself. The reset status bits in the SIU\_RSR are not affected by this reset source.

### **43.4.7 Software system reset**

A software system reset occurs when software asserts the SSR bit in the System Reset Control Register (SIU\_SRCR), triggering an internal reset cycle and the assertion of the RSTOUT pin. Once the reset cycle begins, the SSR bit is automatically cleared. When the reset cycle finishes, the SSRS bit is set in the SIU\_RSR register.

### **43.4.8 Software external reset**

A write of one to the SER bit in the SIU\_SRCR causes the external RSTOUT pin to be asserted for a predetermined number of clock cycles (refer to [RSTOUT](#)). The SER bit automatically clears after the clock counting expires. A software external reset does not cause an internal reset cycle. Only the RSTOUT pin is affected. The SERF bit in the SIU\_RSR is set, but no other status bits are affected. The SERF bit in the SIU\_RSR is not automatically cleared after the RSTOUT clock cycles expire, and remains set until cleared by software or another reset besides the software external reset occurs.

During a software external reset, the e200z7 cores will continue to execute instructions, timers that are enabled will continue to operate, and interrupt requests will continue to be processed. It is the responsibility of the application to ensure devices connected to RSTOUT are not accessed during a software external reset, and to determine how to manage MCU resources when using the software external reset.

### **43.4.9 STCU reset**

When the reset cycle is triggered by a power-up event or by the assertion of the RESET pin or a FOSU reset, and if enabled by DCF configuration, the Self-Test Control Unit executes a series of hardware self tests based on shifting pseudo-random data into the device registers and then comparing the resulting signature with a golden reference stored in flash memory. It also triggers the execution of self-test hardware within the embedded

memories. By the end of the self-test runs, the device is left with random data in its registers; therefore, the STCU sends a signal to the reset controller to trigger a new reset cycle.

The STCU itself is not affected by STCU reset cycle; therefore, test results are preserved to be read by software after the reset cycle finishes. The FCCU is also one of the structures included in the STCU tests; therefore, it also needs to be reset after the execution of STCU diagnostics.

When the reset cycle that was initiated by this reset source finishes, the STCURS bit is asserted in the SIU\_RSR register.

### 43.4.10 Life cycle manipulation reset

When SSCM loads information from UTest memory corresponding to the life cycle slots and that information includes invalid programmed values, a life cycle manipulation reset occurs. See [SSCM security reset and LC state](#) for further details.

## 43.5 Reset configuration

During reset, the SSCM reads various configuration and trimming data from flash memory and applies them to the device before the reset cycle finishes. See the DCF chapter for a complete list of DCF records. Following is a list of main functions configured by DCF records and information in other locations in UTest flash memory:

- Pull up/down of external I/O pins
- Boot mode (internal, serial, EBI, auto-baud)
- Crystal oscillator trimming and configuration
- RC oscillator trimming
- Trimming for voltage regulators and power supply monitors
- ADC trimming
- Temperature sensor trimming
- Flash access control bits and passwords
- Security, life cycle, and censorship
- STCU configuration

### 43.5.1 Weak pull up/down configuration

Initial pull up/down configuration of external I/O pins is available in the Miscellaneous DCF record, which is read by the SSCM from UTEST flash memory during reset and applied to the pad drivers.

As an alternative to the DCF record method, a legacy mode is available that uses the WKPCFG pin to do the same configuration. For all resets except a software external reset, the WKPCFG pin is applied at the assertion of the internal reset signal and latched upon negation of reset. Legacy mode is used when the legacy bit is asserted in the Miscellaneous DCF record.

Either coming from the DCF record or from the WKPCFG pin, the pull configuration is stored in the WKPCFG bit in the Reset Status Register.

### 43.5.2 Boot configuration

Configuration data required by the boot code is available in the Miscellaneous DCF record, which is read by the SSCM from UTEST flash memory during the reset cycle. As an alternative to the DCF record method, a legacy mode is available in which the boot configuration data is latched from package pins at the end of the reset cycle. Either coming from the DCF record or from package pins, the boot configuration data is placed in the Reset Status Register (SIU\_RSR) to be read by the boot code.

The boot configuration data in SIU\_RSR is also affected by the security life cycle of the component. If the life cycle has reached the “in field” state, then boot mode is forced to be internal only. See the table below and also refer to the SIU\_RSR description in the SIU chapter.

**Table 43-3. Boot configuration data**

| Mode (LEG bit in Misc DCF record) | SIU_RSR fields                     |                                    |
|-----------------------------------|------------------------------------|------------------------------------|
|                                   | BOOTCFG <sup>1</sup>               | ABR                                |
| Normal (LEG=0)                    | Loaded from bits 14–15 of Misc DCF | Loaded from bit 13 of Misc DCF     |
| Legacy (LEG=1)                    | Latched from BOOTCFG[0:1] pins     | Latched from EVTO pin <sup>2</sup> |

1. BOOTCFG is forced to 0b00 (internal boot) if life cycle is “in-field.”

2. Latching from EVTO works as follows. If no debug tool is attached to the device and EVTO is held at low logic level during reset, the ABR bit reset state is logic one. Otherwise it is zero.

## 43.6 Boot sequence

When the reset cycle finishes, the following sequence of events takes place:

1. In parallel, immediately after reset is negated, the Cryptographic Services Engine (CSE) starts running its secure boot code, and core 0 starts executing boot code from address 0xFFFF\_FFFC.
3. Core 1 is held in reset state until software writes a boot vector in SIU\_RSTVEC1 and then negates SIU\_HLT1[CORE1] or SIU\_RSTVEC1[RST1]. When either of these bits is negated, core 1 starts executing code at the address specified by the boot vector.
4. Execution of the checker core is controlled by the LOCKSTEP\_EN bit of the Miscellaneous DCF Client. If disabled, the checker core is kept in reset state after the end of the reset cycle even if core 1 starts executing code. When the checker core is disabled, RCCU error checking is also disabled. Enabling or disabling checker core execution requires a reset cycle to take effect.

# Chapter 44

## System Boot

### 44.1 Overview

The Boot Assist Module (BAM) is a 4-KB block of read-only memory, containing the boot program code for the MCU. The BAM program supports the following boot modes:

- Boot from internal flash memory
- Serial boot via SCI or CAN interface with optional baud-rate detection (available if the device life cycle is not “in-field”)
- Boot from a memory connected to the MCU development bus (EBI)<sup>1</sup> with multiplexed or separate address and data lines (available if the device life cycle is not “in-field”)

On the MPC5775E device, only Core0 is enabled out of reset; therefore, the BAM program is executed by Core0 after the reset cycle finishes. Depending on the boot mode, the program initializes the appropriate minimum MCU resources to start user application code. Note that the BAM is pure software; therefore, all registers and resources accessed and modified by the BAM can also be accessed by customer software.

### 44.2 Features

- Initial MMU setup with minimum address translation for all internal MCU resources
- MMU configuration to boot user application, compiled as Classic PowerPC Book E code or as NXP VLE code
- Passes control to user application code in the internal flash memory or external memory device
- Automatic switch to serial boot mode if internal or external flash is blank or invalid
- Serial boot by loading user program via CAN bus or eSCI to the internal SRAM
  - Not available at “in-field” device life cycle

---

1. EBI not available on all packages.

- Only public password protection is used
- Optional automatic detection of the host SCI or CAN speed
- Boot from an external memory device, connected to the EBI
  - Not available at “in-field” device life cycle
  - Option to boot from 16-bit memory device with separate data and address lines
  - Option to boot from 32/16-bit memory device with multiplexed data and address lines
- Controls MCU core Watchdog Timer and/or the Software Watchdog Timer (SWT)

## 44.3 Modes of operation

### 44.3.1 Normal boot

Core 0 is released from reset immediately at the end of the reset cycle and it begins execution of the BAM code from the reset vector contained in the SIU\_RSTVEC0 register.

### 44.3.2 Parallel secure boot

The Cryptographic Service Engine (CSE) and Core0 are released from reset at the same time. Core0 starts executing the BAM code in parallel with CSE execution. The BAM code is ignorant of the result of the secure boot code execution; it always continues with its own code execution.

### 44.3.3 Debug mode

The BAM program is not executed when the MCU exits reset in OnCE debug mode. Before accessing the MCU resources, use the development tool to initialize the MCU.

### 44.3.4 Internal boot mode

BAM looks for customer code at predefined locations in flash memory, then starts execution of that code from flash.

### 44.3.5 Serial boot mode

BAM loads customer code into internal SRAM using the eSCI or CAN serial interface, then executes that program. The program can then control:

- Downloading of data, and
- Erasing and programming of the internal or external flash memory

### 44.3.6 Development bus boot mode

This boot mode is intended for packaged versions of the device that have the development bus pinned out. The development bus (EBI) boot mode can be used for application code development.

## 44.4 Memory Map

The BAM occupies 16 KB of memory space, 0xFFFF\_C000 to 0xFFFF\_FFFF. The actual code size of the BAM program is less than 4 KB and starts at 0xFFFF\_F000, repeating itself every 4 KB in the BAM address space. The CPU starts the BAM program execution at its reset vector from address 0xFFFF\_FFFC.

The BAM exits to user code at 0xFFFF\_FFF8. The last instruction the BAM executes is a BLR. The link register is pre-loaded with the user application start address. The value of the start address depends on the boot mode:

- Booting from internal or external flash memory—32-bit word following a valid RCHW holds the start address value
- Serial boot—set according to the serial boot protocol

The following table shows the BAM address map.

**Table 44-1. BAM memory map**

| Address                   | Description                   |
|---------------------------|-------------------------------|
| 0xFFFF_C000 – 0xFFFF_EFFF | BAM program mirrored          |
| 0xFFFF_F000 – 0xFFFF_FFFF | BAM program                   |
| 0xFFFF_FFFC               | MCU reset vector              |
| 0xFFFF_FFF8               | BAM last executed instruction |

## 44.5 Functional Description

### 44.5.1 BAM program flow chart

The following figure shows the BAM program flow.

Figure 44-1. BAM program flow chart

## 44.5.2 BAM program operation

When Core0 is released from reset state, it fetches the boot vector corresponding to the BAM code from the SIU\_RSTVEC0 register. The first thing the BAM program does is to configure the MMU to allow access to all MCU internal resources, according to [Table 44-2](#). This MMU setup remains untouched through internal flash boot mode.

**Table 44-2. MMU configuration for internal flash boot**

| TLB entry | Region                      | Logical base address | Physical base address | Size   | Attributes    |
|-----------|-----------------------------|----------------------|-----------------------|--------|---------------|
| 0         | Peripheral Bridge B and BAM | 0xFFE0_0000          | 0xFFE0_0000           | 2 MB   | Guarded       |
|           |                             |                      |                       |        | Big endian    |
|           |                             |                      |                       |        | Global PID    |
|           |                             |                      |                       |        | Cache Inhibit |
| 1         | Internal flash              | 0x0000_0000          | 0x0000_0000           | 16 MB  | Not guarded   |
|           |                             |                      |                       |        | Big endian    |
|           |                             |                      |                       |        | Global PID    |
| 2         | EBI                         | 0x2000_0000          | 0x0000_0000           | 16 MB  | Not guarded   |
|           |                             |                      |                       |        | Big endian    |
|           |                             |                      |                       |        | Global PID    |
| 3         | Internal SRAM               | 0x4000_0000          | 0x4000_0000           | 512 KB | Not guarded   |
|           |                             |                      |                       |        | Big endian    |
|           |                             |                      |                       |        | Global PID    |
|           |                             |                      |                       |        | Cache Inhibit |
| 4         | Peripheral Bridge A         | 0xC3E0_0000          | 0xC3E0_0000           | 2 MB   | Guarded       |
|           |                             |                      |                       |        | Big endian    |
|           |                             |                      |                       |        | Global PID    |
|           |                             |                      |                       |        | Cache Inhibit |

The MMU regions are mapped with logical addresses the same as physical addresses except for the External Bus Interface (EBI). The logical EBI address space is mapped to physical address space of the internal flash memory. This allows code, written to run from external memory, to execute from internal flash memory.

After the MMU configuration, the BAM uses information from the read-only SIU\_RSR[BOOTCFG] field to decide what type of boot that it must do, according to [Table 44-3](#).

**Table 44-3. BOOTCFG field description**

| BOOTCFG[0:1] | Description                      |
|--------------|----------------------------------|
| 00           | Internal boot from flash memory  |
| 01           | Serial boot from eSCI or FlexCAN |

*Table continues on the next page...*

**Table 44-3. BOOTCFG field description (continued)**

| BOOTCFG[0:1] | Description                                             |
|--------------|---------------------------------------------------------|
| 10           | Non-muxed EBI boot (16-bit data, non-muxed address bus) |
| 11           | Muxed EBI boot mode (16-bit data, muxed address bus)    |

The BOOTCFG field is the only place that the BAM will look to determine what type of boot it should attempt. The value of the BOOTCFG field is loaded into the SIU\_RSR by internal hardware during reset, from one of the following possible sources:<sup>2</sup>

1. BOOTCFG pins
2. BOOTCFG field of the Miscellaneous DCF record
3. Fixed value 00 (Internal Boot)

Which of these sources is used depends on the life cycle and the legacy mode settings of the device.

Table 44-4 describes the source selection of the BOOTCFG field depending on the above settings.

**Table 44-4. BOOTCFG source selection**

| Life cycle              | Legacy mode?   | BOOTCFG source                            |
|-------------------------|----------------|-------------------------------------------|
| Different than In Field | Yes            | BOOTCFG pins                              |
|                         | No             | BOOTCFG field of Miscellaneous DCF record |
| In Field                | X <sup>1</sup> | Fixed to 00 (Internal Boot)               |

1. "X" means that the value of this entry has no effect on the determination of the BOOTCFG source.

For all cases presented where serial boot mode is available, a 64-bit public password is required. The password is 0xFEED\_FACE\_CAFE\_BEEF. After a match is detected, the BAM code goes on executing the serial boot flow. Otherwise, it stays on a loop until a reset is issued due to the watchdog settings.

The internal and EBI boot modes require no password, but it is still possible to have the flash memory inaccessible due to protection settings on the PASS module. Therefore, access to flash should be granted by not blocking the flash memory regions used by the BAM.

2. The BOOTCFG field is the only place that the BAM will look to determine what type of boot it should attempt. Other device settings affect the boot mode, but they are all factored in by the internal hardware when it loads BOOTCFG into the SIU\_RSR register.

### 44.5.3 Reset Configuration Half Word (RCHW)

The Reset Configuration Half Word defines boot options and must be programmed to predefined locations in the internal flash or at the beginning of the external flash device. The 32-bit word after the RCHW must be programmed with the user application's starting address. The BAM passes control to the user application at this starting address.

Table 44-6 provides possible RCHW locations in the internal flash. When booting from the external flash device, the RCHW must reside in the first 16-bit half word of the flash memory.

BOOT\_BLOCK\_ADDRESS

| 0 | 1 | 2 | 3 | 4   | 5   | 6   | 7   | 8                      | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
|---|---|---|---|-----|-----|-----|-----|------------------------|---|----|----|----|----|----|----|
|   |   |   |   | SWT | WTE | PS0 | VLE | 0                      | 1 | 0  | 1  | 1  | 0  | 1  | 0  |
|   |   |   |   |     |     |     |     | Boot Identifier = 0x5A |   |    |    |    |    |    |    |

**Table 44-5. RCHW field descriptions**

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–3                 | Reserved. These bit values are ignored when the halfword is read. Program to 0 for future compatibility.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 4<br>SWT            | Software watchdog timer enable. This bit determines if the software watchdog timer is enabled after passing control to the user application code.<br>0 Disable software watchdog timer<br>1 Enable software watchdog timer after reset. The time-out period is 392400 cycles of the Internal RC Oscillator.                                                                                                                                                                                                      |
| 5<br>WTE            | MCU core watchdog timer enable. This bit determines if the core software watchdog timer is enabled after passing control to the user application code.<br>0 Disable core software watchdog timer<br>1 Enable core watchdog timer after reset. The timeout period is $2.5 \times 2^{18}$ cycles of the CPU clock. <sup>1</sup>                                                                                                                                                                                    |
| 6<br>PS0            | Port size. Defines the width of the data bus connected to the memory on D_CS0. After system reset, the BAM changes D_CS0 to a 16-bit port to fetch the RCHW from either 16- or 32-bit external memories. Then the BAM reconfigures the EBI as a 16- or 32-bit port, depending on this bit.<br>0 32-bit D_CS0 port size<br>1 16-bit D_CS0 port size<br><b>NOTE:</b> Used in development bus boot modes only (that is, 496- and 516-pin packages). Do not clear this bit if the device only has a 16-bit data bus. |
| 7<br>VLE            | VLE Code Indicator. This bit configures the MMU entries 1–3 coded as Classic Book E instructions or as NXP VLE instructions.<br>0 User code executes as classic Book E code<br>1 User code executes as NXP VLE code                                                                                                                                                                                                                                                                                              |
| 8–15<br>BOOTID[0:7] | Boot identifier. This field serves two functions: <ul style="list-style-type: none"> <li>Indicates which block in flash memory contains the boot program</li> <li>Indicates if the flash memory is programmed (BOOTID = 0x5A) or invalid</li> </ul>                                                                                                                                                                                                                                                              |

1. Upon exiting reset, the CPU clock is connected to the Internal RC Oscillator at 16 MHz.

### 44.5.3.1 Application Start Address Register

Application Start Address Register, shown below, is the 32-bit word after the RCHW in the application code memory device (internal or external flash memory). The BAM uses the value from this location as a start address of the user application to pass control to.

BOOT\_BLOCK\_ADDRESS + 0x0000\_0004

|    |    |    |    |    |    |    |    |    |    |     |     |     |     |     |     |
|----|----|----|----|----|----|----|----|----|----|-----|-----|-----|-----|-----|-----|
| 0  | 1  | 2  | 3  | 4  | 5  | 6  | 7  | 8  | 9  | 10  | 11  | 12  | 13  | 14  | 15  |

### 44.5.4 Internal boot mode

Upon reset exit, when the BAM program starts running, the system clock is by default sourced by the Internal RC Oscillator (IRC). If internal boot mode was configured in the SIU\_RSR[BOOTCFG] field, the BAM program executes the following tasks:

1. Configures a machine check exception handler, since it will be accessing flash memory locations that may be corrupted and cause a bus error
2. Searches for a valid RCHW in predefined locations, as shown in the following table.

#### NOTE

In the search for a valid RCHW, the location with priority 0 has highest priority and the location with priority 4 has lowest priority.

**Table 44-6. Possible RCHW locations in internal flash memory**

| Priority | Address     |
|----------|-------------|
| 0        | 0x0080_0000 |
| 1        | 0x0002_0000 |
| 2        | 0x0003_0000 |
| 3        | 0x0000_0000 |
| 4        | 0x0001_0000 |

3. If a valid RCHW is not found, the BAM program checks for the life cycle state of the device (SSCM\_LCSTAT[LC]). For any life cycle other than In Field, the BAM program switches to the serial boot mode. Otherwise, the search for the RCHW will continue until SWT requests a reset.
4. If the BAM program finds a valid RCHW:

- `BOOT_BLOCK_ADDRESS` is the address (from [Table 44-6](#)) of the valid RCHW
- The BAM program fetches the application start address from `BOOT_BLOCK_ADDRESS + 0x4`
- The BAM branches to this start address (shown in [Application Start Address Register](#))
- The MMU TLB entries 1,2,3 are programmed with VLE attribute if the `RCHW[VLE] = 1`
- The watchdog timers are programmed as shown in the table below

**Table 44-7. Watchdog timeout settings**

| Core WD       |                                                                               | SWT           |                                                                  |
|---------------|-------------------------------------------------------------------------------|---------------|------------------------------------------------------------------|
| Clock source  | Condition                                                                     | Clock source  | Condition                                                        |
| IRC<br>16 MHz | Enabled if <code>RCHW[WTE] = 1</code><br>Timeout = $2.5 \times 2^{18}$ cycles | IRC<br>16 MHz | Enabled if <code>RCHW[SWT] = 1</code><br>Timeout = 392400 cycles |

### 44.5.5 Serial boot mode

When serial boot mode is detected, either because of the `BOOTCFG` configuration or because a valid RCHW word was not found in any of the expected locations in flash memory, the BAM program does the following:

1. Initializes the FlexCAN\_A RAM to avoid ECC errors
2. Uses message buffers in FlexCAN\_A for program stack and variables
3. Polls the `SIU_RSR[XOSC]` bit until it indicates that the oscillator has locked
4. Switches the clock source to the crystal oscillator by setting `SIU_SYSDIV[SYSCLKSEL] = 0x1`
5. Disables the core watchdog timer and sets the SWT timeout period to  $2.5 \times 2^{27}$  cycles
6. Waits for the host to send a 64-bit password by either the CAN or SCI
7. Receives start address, size of download code in bytes, and VLE bit
8. Receives the application code data
9. Disables the SWT and enables the core watchdog timer with a timeout period of  $2.5 \times 2^{28}$  CPU clock cycles
10. Branches to the loaded code at the start address

The MMU setup depends on how the BAM entered serial boot mode. If it attempted to boot from the development bus but switched to serial boot because it could not find a valid RCHW in Flash, the MMU is set up as for that mode (see [Table 44-13](#)). Otherwise, the MMU setup matches [Table 44-2](#).

Serial boot mode can run in two modes, depending on the state of the SIU\_RSR[ABR] bit:

- Standard serial boot mode—fixed baud rates derived from the MCU system frequency. EVTO pin is kept high during reset.
- Baud Rate Detection serial boot mode—allows communication with adaptable speed, based on measured baud rate of the host transmission. EVTO pin has to be driven low for this mode.

In enhanced mode, the SIU\_RSR[ABR] bit is loaded from the ABR bit of the Miscellaneous DCF record. In legacy mode, the latching of the EVTO pin status in the SIU\_RSR register is done following ways:

- If no debug tool is attached, then the state of EVTO pin is latched upon negation of system reset
- If a debug tool, using EVTO pin, is attached, the state of EVTO pin is latched upon enabling the Nexus module

The EVTO pin is pulled up by an internal pull-up. Actively driven low EVTO pin selects the Baud Rate Detection mode.

When Fixed Baud Rate mode is selected, the BAM program configures the RXD\_A pin to be the input of the eSCI\_A module, CNRX\_A pin as an input and CNTX\_A as an output of the CAN\_A module. When Baud Rate Detection Mode is selected, the BAM program configures RXD\_A and CNRX\_A pins as GPI inputs for polling their state by the CPU.

The SCI and CAN controller pin configuration summaries are shown in [Table 44-8](#).

**Table 44-8. CAN/eSCI pin configuration for CAN/eSCI fixed baud rate boot modes**

| Pins   | Reset Function | Initial Serial Boot Mode |                                         | Serial Boot Mode after a valid CAN message received |                                         | Serial Boot Mode after a valid eSCI message received |                                         |
|--------|----------------|--------------------------|-----------------------------------------|-----------------------------------------------------|-----------------------------------------|------------------------------------------------------|-----------------------------------------|
|        |                | Function                 | Pad Configuration                       | Function                                            | Pad Configuration                       | Function                                             | Pad Configuration                       |
| CNTX_A | GPIO           | CNTX_A                   | Push/Pull output, with medium slew rate | CNTX_A                                              | Push/Pull output, with medium slew rate | GPIO                                                 | —                                       |
| CNRX_A | GPIO           | CNRX_A                   | Input with pullup and hysteresis        | CNRX_A                                              | Input with pullup and hysteresis        | GPIO                                                 | —                                       |
| TXD_A  | GPIO           | GPIO                     | —                                       | GPIO                                                | —                                       | TXD_A                                                | Push/Pull output, with medium slew rate |
| RXD_A  | GPIO           | RXD_A                    | Input with pullup and hysteresis        | GPIO                                                | —                                       | RXD_A                                                | Input with pullup and hysteresis        |

The BAM configures the communication modules for reception with fixed baud rates as shown in [Table 44-9](#) and then waits for data reception. The watchdog timers are configured as shown in [Table 44-10](#).

**Table 44-9. Serial boot fixed baud rates**

| Crystal frequency (MHz) | Peripheral clock frequency (MHz) | Desired SCI baud rate (baud) | Actual SCI baud rate (baud)     | CAN baud rate <sup>1</sup> (baud) |
|-------------------------|----------------------------------|------------------------------|---------------------------------|-----------------------------------|
| $f_{xtal}$              | $f_{per} = 0.5 \times f_{xtal}$  | —                            | $f_{per} \div 416$ <sup>2</sup> | $f_{per} \div 40$ <sup>3</sup>    |
| 8                       | 4                                | 9600                         | 9615                            | 100K                              |
| 12                      | 6                                | 14400                        | 14423                           | 150K                              |
| 16                      | 8                                | 19200                        | 19230                           | 200K                              |
| 20                      | 10                               | 24000                        | 24038                           | 250K                              |
| 40                      | 20                               | 48000                        | 48076                           | 500K                              |

1. The CAN engine is clocked by the system clock.
2. The transmitter clock frequency, which is denoted by the bit time, is determined by the equation  $f_{CLK} = f_{sys} \div (16 \times SBR) = SCI_{BaudRate}$  where SBR is a constant defined on BAM code to provide the correct baud rate.
3. The Baud Rate Division Factor is defined as  $BRF = (PRES DIV + 1) \times \text{Number of Time Quanta}$ , where the number of time quanta is dependent on the SYN\_REG, Time Segment 1, and Time Segment 2 constants. See [Figure 1](#).

**Table 44-10. Watchdog timeout settings for serial boot**

| Core WD                   |                                                                                    | SWT           |                                                                                    |

| XOSC $\div$ 2<br>4–20 MHz | Disabled during boot<br>Enabled after boot<br>Timeout = $2.5 \times 2^{28}$ cycles | IRC<br>16 MHz | Enabled during boot<br>Disabled after boot<br>Timeout = $2.5 \times 2^{27}$ cycles |

If a message containing 8 bytes with ID 0x11 is received by the CAN controller first, the BAM program:

- Transitions to serial CAN boot mode
- Disables the eSCI
- Configures RXD\_A to its reset state
- Transitions to the CAN serial download protocol routine

If a byte from eSCI is received first, the BAM program:

- Transitions to the Serial SCI Boot sub-mode
- Disables CAN\_A module
- Configures CAN\_A's pins to their reset state
- Transitions to the SCI serial download protocol routine

### 44.5.5.1 CAN controller configuration in fixed baud rate mode

The CAN controller is configured to operate at a baud rate equal to system frequency divided by 40, using the standard 11-bit identifier format detailed in the CAN 2.0A specification. See [Table 44-9](#) for examples of baud rates. Only one message buffer 0 is used for all communications.

The bit timing is configured as shown in the following figure.

Note: 1 Time quanta = 4 System clock periods

**Figure 44-2. CAN bit timing**

The BAM program ignores CAN errors and all received messages are assumed to be good. Received messages are transmitted back. The host processor must compare the MCU transmissions with the sent data and restart the process if an error is detected.

### 44.5.5.2 SCI controller configuration in fixed baud rate mode

The eSCI is configured for 1 start bit, 8 data bits, no parity, 1 stop bit and operates at a baud rate equal to system clock divided by 416. See [Table 44-9](#) for examples of baud rates.

The BAM program ignores the eSCI errors. All data received is assumed to be good and is sent back through the TXD pin. The host processor must compare the MCU transmitted data with the sent data and restart the process if an error is detected.

### 44.5.5.3 Serial boot mode download protocol

The download protocol follows four steps:

1. Host sends 64-bit password.
2. Host sends start address, size of download code in bytes, and VLE bit.
3. Host sends the application code data.

4. The MCU switches to the loaded code at the start address.

The communication is done in half-duplex manner; any transmission from host is followed by the MCU transmission. The host computer should not send data until it receives echo from the MCU. All multi-byte data structures must be sent most-significant byte (MSB) first.

When the CAN is used for serial download, the data is packed into standard CAN messages in the following manner:

- A message with 0x11 ID and 8-byte length to send the password. The MCU transmits back the same data, but with ID of 0x1.
- A message with 0x12 ID and 8-byte length to send the start address, length, and the VLE mode bit. The MCU transmits back the same data, but with ID of 0x2.
- Messages with 0x13 ID are used to send the downloaded data. The MCU transmits back the same data with ID of 0x3.

When the SCI is used for serial download, the data must be sent on a byte-by-byte basis. The MCU transmits back the received bytes.

### NOTE

Since the MCU starts up with the system clock derived from the Internal RC Oscillator (IRC), it does not wait for the crystal oscillator to stabilize before finishing the reset sequence and negating the  $\overline{\text{RTSTOUT}}$  pin. The BAM program starts executing with the IRC clock, but it needs to switch to the crystal oscillator (XOSC) clock in case of serial boot. Before switching to the XOSC clock, the BAM program waits for the SIU\_RSR[XOSC] bit to be asserted, which is an indication that the crystal oscillator has settled. As a consequence, the external device that will upload the serial code needs to wait enough time after  $\overline{\text{RSTOUT}}$  negates to allow the crystal oscillator to stabilize. The exact time depends on the crystal used, but is typically less than 10 ms. On the other hand, the code must be uploaded before the SWT timeout expires. The SWT timeout is 21 seconds.

#### 44.5.5.4 Download protocol execution

The BAM program executes the serial boot according to the following steps:

1. Download 64-bit password.
  - The received 8-byte password is checked for validity. For a password to be valid, none of its four 16-bit half words must equal 0x0000 or 0xFFFF.
  - The password is compared to the fixed value of 0xFEED\_FACE\_CAFE\_BEEF.

- If the password check fails, the MCU stops responding. Assert RESET to force the MCU out of this state.
  - If the password check passes, the BAM transitions to the next step in the protocol.
2. Download start address, size of download, and VLE bit.

The BAM considers the next 8 bytes to contain a 32-bit start address, the VLE mode bit, and a 31-bit code length, as shown below.

- START\_ADDRESS defines where the received data is stored and where the MCU branches after the download is finished. The two least significant bits of the start address are ignored by the BAM program, thus the loaded code should be 32-bit word aligned.
  - CODE\_LENGTH defines how many data bytes to be loaded.
  - VLE instructs the MCU to program MMU entries 1–3 with VLE attribute. If it is 1, the downloaded code must be compiled to VLE instructions, if it is 0 the code contains classic Power Book E architecture instructions.
3. Download data.

Each byte of data received is stored in the MCU memory, starting at the START\_ADDRESS specified in the previous step. The data increments through memory until the number of bytes stored matches CODE\_LENGTH specified in the previous step.

The BAM program buffers incoming data, collecting up to 8 bytes. The buffered data is written to the RAM with 64-bit writes to prevent ECC errors, which may happen if the MCU RAM is protected by 64-bit ECC code.

Once the buffered data is written to the RAM, the BAM program refreshes the SWT.

### NOTE

Only system RAM supports 64-bit writes; therefore, attempting to download data to other RAM apart from system RAM causes errors.

If the start address of the downloaded data is not on an 8-byte boundary, the BAM writes 0x0 to the memory locations from the proceeding 8-byte boundary to the start address (maximum 4 bytes). The BAM also writes 0x0 to all memory locations from the last byte of data downloaded to the following 8 byte boundary (maximum 7 bytes). An additional 8 zero bytes are written to prevent possible ECC errors that may be caused by the CPU pre-fetching.

#### 4. Switch to the loaded code.

The BAM program waits for the last echo message transmission to complete, then the active communication controller is disabled. Its pins revert to GPIO inputs.

To provide compatibility with older devices, the BAM:

- Writes the core's time base registers (TBU and TBL) with 0x0
- Enables the core watchdog to cause a reset after a timeout period of  $2.5 \times 2^{28}$  CPU clock cycles
- Disables software watchdog (SWT)

The BAM code passes control to the loaded code at START\_ADDRESS, which was received in step 2 of the protocol.

### NOTE

The loaded code must periodically refresh the core watchdog timer or change the timeout period to a value that does not cause resets during normal operation.

#### 44.5.5.5 Baud rate detection procedure

When SIU\_RSR[ABR] is set, the BAM program enters into Baud Rate Detection mode.

The following additional steps are taken:

1. The baud rate detection routine is copied to the beginning of the system RAM from the BAM ROM to improve baud rate detection accuracy.
2. The CPU branches to the RAM.
3. The MCU configures the CNRX\_A and RXD\_A pins as general purpose inputs.
4. The MCU polls these GPIs until one of them goes low.

- If the CNRX\_A pin transitions first, the BAM program starts CAN baud rate detection routine, ignoring RXD\_A. After detecting the CAN baud rate, the BAM program transitions to the CAN download protocol routine described above.
- If the RXD\_A pin transitions first, the SCI baud rate detection and download protocol routines are called, ignoring any further CAN pins activity.

The host, executing the serial boot, should send a test frame so that the MCU can detect the host communication speed. When booting through the SCI, the host should send a zero byte as the test frame. When booting through the CAN, the host should send zero ID, zero length message as the test frame.

#### **44.5.5.5.1 SCI baud rate detection**

The host must send a zero byte to allow the MCU to detect the serial link baud rate. The host transmits one start bit, eight zero data bits, and one stop bit (the MCU does not echo it).

The MCU polls the RXD\_A pin for high-to-low transition and starts the e200 core Time Base counter (TB). Then the MCU polls for low-to-high transition on the pin and when it happens, the MCU turns off the TB counter. The TB content is used to calculate incoming signal baud-rate. The SCI baud rate is equal to the TB content divided by 288. (Measured over 9 bits with 16 system clocks per bit and the core frequency is two times higher than system frequency).

#### **44.5.5.6 CAN baud rate detection**

The host transmits a zero length message with zero 11 bit ID and MCU measures time over 40 bits, polling CNRX\_A pin for high and low, according to the sent data. The MCU does not acknowledge this message.

The CAN baud rate depends on the number of quantas per bit and serial clock frequency, which is defined by a prescaler. The CAN baud rate detection routine selects these parameters to maximize number of quantas per bit and achieve minimum difference between measured value and duration of the 40 CAN bits, to be programmed with selected pair of the parameters.

The CAN controller can be programmed with 8 to 25 number of quantas per bit. The bit timing parameters, which can be selected by the baud rate detection routine, are shown in the table below.

**Table 44-11. Lookup table for CAN bit timing**

| Time quanta per bit | Time segment 1 |       | Time Segment 2 | RJW |
|---------------------|----------------|-------|----------------|-----|
|                     | PROPSEG        | PSEG1 | PSEG2          |     |
| 8                   | 1              | 3     | 3              | 2   |
| 9                   | 2              | 3     | 3              | 2   |
| 10                  | 3              | 3     | 3              | 2   |
| 11                  | 4              | 3     | 3              | 2   |
| 12                  | 3              | 4     | 4              | 2   |
| 13                  | 4              | 4     | 4              | 3   |
| 14                  | 5              | 4     | 4              | 3   |
| 15                  | 6              | 4     | 4              | 4   |
| 16                  | 7              | 4     | 4              | 3   |
| 17                  | 8              | 4     | 4              | 3   |
| 18                  | 7              | 5     | 5              | 4   |
| 19                  | 8              | 5     | 5              | 4   |
| 20                  | 7              | 6     | 6              | 4   |
| 21                  | 8              | 6     | 6              | 4   |
| 22                  | 7              | 6     | 6              | 4   |
| 23                  | 8              | 6     | 6              | 4   |
| 24                  | 7              | 7     | 7              | 4   |
| 25                  | 8              | 7     | 7              | 4   |

Maximum and minimum speeds of the serial communication modules are defined by the MCU system frequency and shown in the table below.

**Table 44-12. Maximum and minimum detectable baud rates (crystal oscillator as reference clock source)**

| $F_{xtal}$ (MHz) | $F_{sys} = 0.5 \times F_{xtal}$ (MHz) | Max baud rate for CAN <sup>1</sup> (bps) | Min CAN baud rate ( $F_{sys}/25/256$ ) (bps) | Max baud rate for SCI ( $F_{sys}/160$ ) (bps) | Min baud rate for SCI ( $F_{sys}/160/2^{13}$ ) (bps) |
|------------------|---------------------------------------|------------------------------------------|----------------------------------------------|-----------------------------------------------|------------------------------------------------------|
| 8                | 4                                     | 1M                                       | 625                                          | 25K                                           | 3.0                                                  |
| 12               | 6                                     |                                          | 937.5                                        | 37.5K                                         | 4.6                                                  |
| 16               | 8                                     |                                          | 1250                                         | 50K                                           | 6.1                                                  |
| 20               | 10                                    |                                          | 1562.5                                       | 62.5K                                         | 7.6                                                  |
| 40               | 20                                    |                                          | 3125                                         | 125K                                          | 15.2                                                 |

1. Limited by 1 Mbps by CAN standard.

## 44.5.6 Booting from the development bus

If the MCU boots in one of the Development Bus boot modes, the BAM program:

- Reprograms the MMU entries for EBI and internal flash (see [Table 44-13](#))
- Sets up the EBI and development bus pins
- Tries to read RCHW from logical address 0x2000\_0000

If the valid RCHW is read from that address, the BAM program:

- Reads the user application code start address from 0x2000\_0004 address
- Parses RCHW
- Sets up watchdogs
- Updates EBI, SRAM, and internal flash MMU entries (1–3), according to RCHW[VLE]
- Passes control to the user code

If no valid RCHW was read, BAM switches to serial boot mode.

**Table 44-13. MMU configuration for development bus boot modes**

| TBL entry | Region         | Logical base address | Physical base address | Size  | Attributes                              |
|-----------|----------------|----------------------|-----------------------|-------|-----------------------------------------|
| 1         | Internal flash | 0x0000_0000          | 0x2000_0000           | 16 MB | Not guarded<br>Big endian<br>Global PID |
| 2         | EBI            | 0x2000_0000          | 0x2000_0000           | 16 MB | Not guarded<br>Big endian<br>Global PID |

### 44.5.6.1 EBI configuration for separate address and data development bus boot mode

The BAM program sets up EBI related registers as shown in the table below.

**Table 44-14. Development bus/EBI register settings for separate address data lines mode**

| Register    | Function | Value       | Comments                                                             |
|-------------|----------|-------------|----------------------------------------------------------------------|
| EBI_CAL_BR0 | —        | 0x2000_0803 | Sets the base address to 0x2000_0000, 16-bit wide bus, burst Inhibit |
| EBI_CAL_OR0 | —        | 0xFF80_00F0 | Set 15 wait states, 8MB                                              |

*Table continues on the next page...*

**Table 44-14. Development bus/EBI register settings for separate address data lines mode (continued)**

| Register              | Function                         | Value  | Comments                                           |
|-----------------------|----------------------------------|--------|----------------------------------------------------|
| SIU_PCR259–SIU_PCR293 | D_ADD[12:30],<br>D_ADD_DAT[0:15] | 0x0440 | Set pads to 20pf drive strength                    |
| SIU_PCR305–SIU_PCR307 | D_ADD[9:11]                      |        |                                                    |
| SIU_PCR256            | D_CS0                            | 0x443  | Set pads to 20pf drive strength and pull-up enable |
| SIU_PCR295            | D_WE0                            |        |                                                    |
| SIU_PCR297            | D_OE                             |        |                                                    |
| SIU_PCR298            | D_TS                             |        |                                                    |

RCHW[PS0] must be programmed to 1, since the development bus does not support 32-bit port size in that sub-mode.

#### 44.5.6.2 EBI configuration for multiplexed address and data development bus boot mode

The BAM program sets up EBI related registers as shown in the table below.

**Table 44-15. Development bus/EBI register settings multiplexed mode**

| Register                                                  | Function         | Value       | Comments                                                                                  |
|-----------------------------------------------------------|------------------|-------------|-------------------------------------------------------------------------------------------|
| The following registers are programmed when RCHW[PS0] = 1 |                  |             |                                                                                           |
| EBI_MCR                                                   | —                | 0x0000_0806 | AD multiplexed mode, small port size use D16–31                                           |
| EBI_CAL_BR0                                               | —                | 0x2000_0883 | Sets the base address to 0x2000_0000, 16-bit wide bus, AD multiplexed mode, burst Inhibit |
| EBI_CAL_OR0                                               | —                | 0xFF80_00F0 | Set 15 wait states, 8 MB                                                                  |
| SIU_PCR259–SIU_PCR262                                     | D_ADD[12:15],    | 0x440       | Set pads to 20 pf drive strength                                                          |
| SIU_PCR305–SIU_PCR307                                     | D_ADD[9:11]      |             |                                                                                           |
| SIU_PCR263–SIU_PCR277                                     | D_ADD_DAT[16:30] | 0x840       | Set pads to 20 pf drive strength                                                          |
| SIU_PCR257                                                | D_ADD_DAT[31]    |             |                                                                                           |
| SIU_PCR278–SIU_PCR293                                     | D_ADD_DAT[0:15]  | 0x440       | Set pads to 20 pf drive strength                                                          |
| SIU_PCR256                                                | D_CS0            | 0x443       | Set pads to 20 pf drive strength and pullup enable                                        |
| SIU_PCR295                                                | D_WE0            |             |                                                                                           |
| SIU_PCR297                                                | D_OE             |             |                                                                                           |
| SIU_PCR298                                                | D_TS             |             |                                                                                           |
| SIU_PCR299                                                | D_ALE            |             |                                                                                           |
| The following register is reprogrammed when RCHW[PS0] = 0 |                  |             |                                                                                           |
| EBI_CAL_BR0                                               | —                | 0x2000_0083 | Sets the base address to 0x2000_0000, 32-bit wide bus, AD multiplexed mode, burst Inhibit |

If the boot memory device is 32 bits wide, the RCHW must be programmed in two first half-words of the memory because when the MCU tries to read RCHW, the EBI is configured to use data lines 16–31 for 16-bit port accesses.

# Chapter 45

## System Status and Configuration Module (SSCM)

### 45.1 Chip-specific SSCM information

This chip has one instance of the SSCM. The SSCM is part of the reset and boot subsystem.

#### 45.1.1 SSCM and UTEST flash memory

The SSCM loads data stored in multiple locations of the UTEST portion of flash memory.

##### 45.1.1.1 Life Cycle (LC) slots

To determine the chip's Life Cycle status, the SSCM reads and interprets the LC slots according to the [Life Cycle](#) information. The SSCM\_LCSTAT[LC] field presents the results of the determination. The following table shows the LC slots' locations in UTEST flash memory.

**Table 45-1. Life Cycle slots in UTEST flash memory**

| Start address | End address | Bytes | Description                           |
|---------------|-------------|-------|---------------------------------------|
| 0040_0200h    | 0040_020Fh  | 16    | Life Cycle slot 0 - MCU Production    |
| 0040_0210h    | 0040_021Fh  | 16    | Life Cycle slot 1 - Customer Delivery |
| 0040_0220h    | 0040_022Fh  | 16    | Life Cycle slot 2 - OEM Production    |
| 0040_0230h    | 0040_023Fh  | 16    | Life Cycle slot 3 - In Field          |
| 0040_0240h    | 0040_024Fh  | 16    | Life Cycle slot 4 - Failure Analysis  |

### 45.1.1.2 System configuration data in DCF records and UTEST\_OFFSET location

Some DCF records in UTEST flash memory store data for system configuration. The SSCM scans these DCF records to provide information about the current state and configuration of the system.

On this chip, the UTEST\_OFFSET location at which the SSCM looks for DCF records is 0040\_0300h.

The following table summarizes these records. See the DCF Records chapter for additional details.

**Table 45-2. DCF records in UTEST flash memory scanned by SSCM**

| Address    | Purpose                                                                                                                     |
|------------|-----------------------------------------------------------------------------------------------------------------------------|
| 0040_0300h | STCU2 configuration<br>PASS configuration<br>Tamper Detect configuration<br>Miscellaneous configurations, such as boot mode |

### 45.1.1.3 Sources of errors flagged by SSCM\_STATUS[CER]

When set to 1, the **CER** field in the **SSCM System Status (SSCM\_STATUS)** register indicates that the SSCM has detected a configuration error during reset while loading initial system configuration.

On this chip, this field is set to 1 in these cases:

- When the process of loading any STCU2 DCF record encounters one of the conditions that generates a transfer error listed in the STCU2's [IPS bus interface](#) description
- When a DCF record that has the parity attribute is loaded without parity alignment

For a list of DCF clients and the corresponding DCF records on this chip, see [Table 5-6](#).

## 45.1.2 SSCM security reset and LC state

The SSCM provides a security mechanism to prevent device manipulation while loading the configuration data from dedicated slots in UTEST flash memory.

The SSCM ensures that the Life Cycle slots are correctly programmed and that at least one LC slot is valid. The Life Cycle state can only progress forward. Any attempt to move the LC state backward causes a security reset. This reset occurs in the cases where "System Reset" is the result of the scenarios in [Table 45-14](#).

### 45.1.3 SSCM\_ERROR[PAE] and abort responses to illegal accesses

The SSCM\_ERROR register's PAE field controls the abort responses to some illegal accesses to off-platform peripherals.

#### NOTE

This field has no effect on on-platform peripherals or on peripheral slots that are not allocated.

PAE, when set to 1, generates a transfer error in either of these cases of illegal accesses:

- The CPU tries to access any non-existing peripheral.
- The global module enable memory space is accessed.

Regardless of the PAE field, these cases always generate a transfer error:

- An access is attempted to a halted off-platform module.
- An accessed off-platform peripheral reports a transfer error.

## 45.2 Introduction

### 45.2.1 Overview

The System Status and Configuration Module (SSCM) is pictured in the figure below.

Figure 45-1. SSCM block diagram

## 45.2.2 Glossary

The table below shows a glossary of terms used through out the text.

Table 45-3. Glossary

| Term   | Definition                                                                                                                                                              |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0011b  | Binary numbers                                                                                                                                                          |
| 0Fh    | Hexadecimal numbers                                                                                                                                                     |
| Pin    | External physical connection.                                                                                                                                           |
| Signal | Electronic construct whose state or change in state conveys information.                                                                                                |
| X      | In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary coded X001b, the state of the first bit is a don't care. |
| y      | y is used for a place holder of 1 hex digit for unknown values.                                                                                                         |

## 45.2.3 Features

The SSCM includes these distinct features:

- System Configuration and Status
  - Device Mode and System Status
  - Decodes the Device Life Cycle
- Peripheral abort enable/disable

### 45.2.4 Modes of operation

The SSCM operates identically in all system modes.

## 45.3 External signal description

The SSCM has no external pins.

## 45.4 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

The table below shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

#### NOTE

All registers are accessible via 8-bit, 16-bit or 32-bit reads and/or writes. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, the STATUS register is accessible by a 16-bit read or write, SSCM Base + 02h, but performing a 16-bit access to SSCM Base + 0003h is illegal (that is, you should not make any transfer that is not aligned to burst size boundary).

#### NOTE

SSCM does not generate transfer errors in all memory holes.

**NOTE**

Reserved IPS register access is prohibited.

**SSCM memory map**

| Address offset (hex) | Register name                                  | Width (in bits) | Access | Reset value | Section/ page |
|----------------------|------------------------------------------------|-----------------|--------|-------------|---------------|
| 0                    | SSCM System Status (SSCM_STATUS)               | 16              | R      | See section | 45.4.1/2206   |
| 6                    | SSCM Error Configuration Register (SSCM_ERROR) | 16              | R/W    | 0000h       | 45.4.2/2208   |
| 34                   | Life Cycle Status Register (SSCM_LCSTAT)       | 32              | R      | See section | 45.4.3/2209   |

**45.4.1 SSCM System Status (SSCM\_STATUS)**

The System Status register reflects the current state of the system.

Address: 0h base + 0h offset = 0h

|       |          |     |     |       |      |    |          |    |
|-------|----------|-----|-----|-------|------|----|----------|----|
| Bit   | 0        | 1   | 2   | 3     | 4    | 5  | 6        | 7  |
| Read  | 0        | CER | MER | NXEN1 | NXEN | 1  | Reserved | 0  |
| Write |          | w1c | w1c |       |      |    |          |    |
| Reset | 0        | 0   | 0   | *     | *    | 1  | *        | 0  |
| Bit   | 8        | 9   | 10  | 11    | 12   | 13 | 14       | 15 |
| Read  | Reserved |     |     | 1     | 0    | 0  | 0        |    |
| Write |          |     |     |       |      |    |          |    |
| Reset | *        | *   | *   | 1     | 0    | 0  | 0        | 0  |

\* Notes:

- Reserved field: Each bit of this field can reset to 0 or 1.
- Reserved field: This field can reset to 0 or 1.
- NXEN field: Reset value depends on the device status after leaving reset.
- NXEN1 field: Reset value depends on the device status after leaving reset..

**SSCM\_STATUS field descriptions**

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                            |

| 14–15<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                               |

### 45.4.2 SSCM Error Configuration Register (SSCM\_ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Address: 0h base + 6h offset = 6h

|       |   |   |    |    |    |    |     |          |
|-------|---|---|----|----|----|----|-----|----------|
| Bit   | 0 | 1 | 2  | 3  | 4  | 5  | 6   | 7        |
| Read  | 0 |   |    |    |    |    |     |          |

## 45.5 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

### 45.5.1 DCF mechanism

The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST\_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.

Each record is 64 bits in length. [Table 45-8](#) shows the DCF start record. The start record must be placed at UTEST\_OFFSET to indicate to the device that the following data records should be processed.

**Table 45-8. DCF start record**

|            |
|------------|
| 0:31       |
| 05AA 55AFh |
| 0:31       |
| 0000 0000h |

The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - See [Table 45-9](#). In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

**Table 45-9. Format of a DCF data record**

|             |            |      |      |
|-------------|------------|------|------|
| 0:31        |            |      |      |
| WDATA[31:0] |            |      |      |
| 0:14        | 15:29      | 30   | 31   |
| CS[14:0]    | ADDR[16:2] | PRTY | STOP |

The stop record indicates that processing should stop. The general format of the stop record is shown in [Table 45-10](#). Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

**Table 45-10. DCF stop record**

|      |    |
|------|----|
| 0:30 | 31 |
| rsvd | 1  |

*Table continues on the next page...*

**Table 45-10. DCF stop record (continued)**

|      |
|------|
| 0:31 |
| rsvd |

If  $n$  data records are to be stored in UTEST, the data structure must be as shown in [Table 45-11](#).

**Table 45-11. Series of DCF records in UTEST**

| ADDR<br>offset | DATA        |            |      |        |
|----------------|-------------|------------|------|--------|
| 00h            | 05AA 55AFh  |            |      |        |
| 04h            | 0000 0000h  |            |      | STOP=0 |
| 08h            | WDATA[31:0] |            |      |        |
| 0Ch            | CS[14:0]    | ADDR[16:2] | PRTY | STOP=0 |
| 10h            | WDATA[31:0] |            |      |        |
| 14h            | CS[14:0]    | ADDR[16:2] | PRTY | STOP=0 |
| ...            | ...         |            |      |        |
| $8n - 1 + 0h$  | reserved    |            |      |        |
| $8n - 1 + 4h$  | reserved    |            |      | 1      |
| $8n + 0h$      |             |            |      |        |
| $8n + 4h$      |             |            |      |        |

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in [Figure 45-5](#).

**Figure 45-5. Appending DCF records**

In this case, a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing, and so on.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0000\_0001h then the PRTY field needs to be set to 1, so that the total number of 1s is even.)

### NOTE

When programming DCF records, ensure that programming is not interrupted and can complete without error.

## 45.5.2 Life Cycle

The SSCM will determine the Life Cycle (LC) of the device by reading the LC slots from the UTEST flash memory. The read operation is done during the reset phase with normal timings and it is protected by operating monitors. In addition, a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- MCU Production
- Customer Delivery
- OEM Production
- In Field
- Failure Analysis

Life cycle can only be moved in the direction shown below:

**Figure 45-6. Life cycle sequence**

The LC is written into 5 slots, 128 bits each, at fixed locations in the UTEST flash memory block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- the valid field
- the invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 statuses as seen in [Table 45-12](#).

**Table 45-12. LC slot status**

| LC slots              |                         | LC slot value |
|-----------------------|-------------------------|---------------|
| Valid field (64 bits) | Invalid field (64 bits) |               |
| Erased                | Erased                  | Erased        |
| Marked                | Erased                  | Active        |
| Marked                | Marked                  | Inactive      |
| Any other values      |                         | Illegal       |

"Marked" in this case means that the value has been programmed with the bit pattern 55AA\_50AF\_55AA\_50AFh. "Erased" is detected by the bit pattern FFFF\_FFFF\_FFFF\_FFFFh. [Table 45-13](#) shows how the slots are arranged in memory.

**Table 45-13. LC slots in memory**

| Offset | LC slot word   |
|--------|----------------|
| 00h    | Valid[31:0]    |
| 04h    | Valid[63:32]   |
| 08h    | Invalid[31:0]  |
| 0Ch    | Invalid[63:32] |

The Life Cycle is determined as shown in [Table 45-14](#)

**NOTE**

"Erased" means the slot returns all 1s.

**Table 45-14. LC slots**

| LC slot 0<br>MCU Production | LC slot 1<br>Customer Delivery | LC slot 2<br>OEM Production | LC slot 3<br>In Field | LC slot 4<br>Failure Analysis | Resulting life cycle |
|-----------------------------|--------------------------------|-----------------------------|-----------------------|-------------------------------|----------------------|
| <b>Active</b>               | Erased                         | Erased                      | Erased                | Erased                        | MCU Production       |
| Inactive                    | <b>Active</b>                  | Erased                      | Erased                | Erased                        | Customer Delivery    |
| Inactive                    | Inactive                       | <b>Active</b>               | Erased                | Erased                        | OEM Production       |
| Inactive                    | Inactive                       | Inactive                    | <b>Active</b>         | Erased                        | In Field             |
| Inactive                    | Inactive                       | Inactive                    | Inactive              | <b>Active</b>                 | Failure Analysis     |
| Erased                      | Erased                         | Erased                      | Erased                | Erased                        | System Reset         |
| Illegal <sup>1</sup>        | Illegal                        | Illegal                     | Illegal               | Erased                        | In Field             |

1. Any value programmed other than shown in table above for Erased, Active, and Inactive would be treated as illegal.

**NOTE**

When programming Life Cycle, ensure that programming is not interrupted and can complete without error.

**NOTE**

Any other combination of values will result in a system reset.

**NOTE**

No one should program “ILLEGAL” even if able to do that.  
Device behavior is not guaranteed for these combinations.

## **45.6 Initialization and application information**

### **45.6.1 Reset**

The reset state of each individual bit appears in the detailed register descriptions.

## **45.7 Additional safety measures**

### **45.7.1 Spurious reset protection**

The SSCM implements protection against spurious module resets (for example, resets which only effect the SSCM, but not other modules) by gating the state machines status with the expected status of the system reset controller logic. If a spurious reset occurs, the SSCM will not interfere with the flash memory bus or overwrite configuration registers. However, internal SSCM status will be lost.

# Chapter 46

## Power Management

### 46.1 Overview

The MPC5775E microcontroller includes a robust power management infrastructure that enables applications to select among various operational modes and to monitor internal voltages for high- and low-voltage conditions. The monitoring capability is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller can leave RESET.

The power management infrastructure consists of a Power Management Unit (PMU), which itself consists of a digital portion and an analog portion of a Power Management Controller (PMC).

**Figure 46-1. Power management overview**

For details about any module, see the chapter dedicated to the module.

## 46.2 Functional description

The analog portion of the PMC provides a linear voltage regulator (LDO) and a switching mode regulator (SMPS) to generate the internal digital core supply and monitors various internal regulating points and supply voltages of the chip for functional safety purposes. The analog portion of the PMC includes an additional regulator for the flash memory block to provide the necessary 3.3 V source to the flash memory module.

The digital portion of the PMC contains the registers and digital logic to generate a power-on reset (POR) in response to particular voltage detection (VD) events and to execute a self test of the analog block. The PMC digital logic also contains the controls for PMC analog outputs to be sensed with the ADC module. In addition, the PMC digital logic contains the enable signals and other register controls for the Temperature Sensor modules.

The PMC connects to the Fault Collection and Control Unit (FCCU) and the flash memory controller. The on-chip ADCs receive signals from the PMC for diagnostic purposes.

## 46.3 Power modes

MPC5775E does not support ultra-low power modes that require power gating or separate power domains. The core logic implements stop and low frequency power saving modes, which may result in core current steps. To avoid undershoots or overshoots that trigger LVD or HVD events, ramp frequency changes smoothly.

## 46.4 External supply

The chip provides a bypass option that allows the core supply and flash memory supply to be supplied from an external source.

## 46.5 Power management supply description

See the product Data Sheet for supply descriptions.

## 46.6 Voltage monitoring

The PMC senses functional reset and supply voltages continuously to keep the chip in a safe operating range. When the voltage exceeds or falls below the limits defined by recommended electrical operating conditions, the PMC triggers a reset or, alternatively, an interrupt. See the PMC\_REE and PMC\_LVD\_HVD\_INTR\_ENB registers' descriptions for more information.

# Chapter 47

## Power Management Controller (PMC)

### 47.1 Introduction

The Power Management Controller (PMC) consists of two blocks: an analog power management block and a digital controller for the analog block.

The PMC digital controller contains the registers and digital logic to generate a POR in response to voltage-threshold events detected by the analog block. The PMC digital logic also contains:

- the controls for PMC analog outputs to be sensed with the ADC module.
- the enable signals and other registers for the Temperature Sensors.

#### NOTE

Temperature Sensor 0 and Temperature Sensor 1 each monitor two temperatures: temperature 0 refers to  $-40^{\circ}\text{C}$ , and temperature 2 refers to  $150^{\circ}\text{C}$ . Register field notation such as TEMP1\_0 designates Temperature Sensor 1's monitoring of temperature 0, or  $-40^{\circ}\text{C}$ .

#### 47.1.1 Features

The PMC module provides:

- 16 MHz clock frequency
- 32-bit IPS bus interface
- Memory-mapped configuration, control, and status registers
- Built-in self test for LVD and HVD during non-functional User mode

- Automatic loading of factory-defined trim/control information during POR for HVDs, LVDs, regulators, and voltage bandgap (via the DCF interface)
- Automatic loading of factory-defined trim configuration and control information to the analog PMC block
- Configuration and monitoring of the two Temperature Sensors
- Interrupt or POR generation for HVDs and LVDs (based on the configuration)
  - Option to generate interrupt, POR, or no action in response to:
    - LVD\_CORE\_COLD
    - HVD\_CORE
    - HVD\_HV
    - HVD\_FLASH
  - Automatic POR generation (except during PMC self test) in response to:
    - POR098\_c
    - LVD\_CORE\_HOT
    - POR\_HV
    - LVD\_HV
    - LVD\_FLASH
    - LVD\_IO
- Interrupt or POR generation for Temperature Sensors (based on the configuration)
- Fault injection to the FCCU for LVDs, HVDs, Temperature Sensors, and self test via IPS interface
- Precision LVD (low-voltage detection) and HVD (high-voltage detection)
- Bandgap voltage reference for:
  - LVDs and HVDs
  - ADC voltage reference channel
- FCCU: Software-triggered fault injection for LVDs, HVDs, Temperature Sensors, and LVD self test
- Self test logic for the LVDs and HVDs

## 47.2 Memory Map and Registers

Attempts to access 32-bit spaces starting at offset D4h result in a transfer error.

For *undocumented* 32-bit spaces at offsets lower than D4h:

- The reset value of the 32-bit space at offset B0h is 0000\_0080h.
- The reset value of every other 32-bit space is 0000\_0000h.
- Reads of and writes to these locations do not generate a transfer error, but the locations are reserved. Any writes to these locations must write the reset value.

47.2.1 Temperature Sensor Interrupt Enable Register (PMC\_TS\_IER)

This configuration register contains a set of Interrupt Enable bits, each of which corresponds to a bit in the Temperature Event Status Register (ESR\_TD). These bits indicate whether an interrupt occurs when the temperature event occurs. A 0 indicates that no interrupt is to be sent, and a 1 indicates that an interrupt is to occur when the detected temperature event occurs. Enable these bits by writing 1 to the TS\_EN field of this register. After TS\_EN is 1, this register's Interrupt Enable bits can be read or written at any time.

Address: 0h base + 88h offset = 88h

## 47.2.3 Temperature Reset Event Enable register (PMC\_REE\_TD)

This register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event can cause a reset to be generated when the selected temperature passes the trigger event.

**NOTE**

These bits can be loaded from a DCF record in the UTEST portion of the flash memory. When they are loaded from a DCF record, they cannot be changed by a register write.

47.2.4 Temperature Reset Event Selection Register (PMC\_RES\_TD)

This register controls whether the temperature sensor detect signal event causes a POR or no reset. If the desired flag bit is enabled, the temperature sensor event causes either a POR or no reset to be generated when the selected temperature passes the trigger event.

Address: 0h base + 94h offset = 94h

47.2.6 Temperature Sensor Fault Injection Register (PMC\_TS\_FIR)

This FCCU Fault Injection register enables user software to artificially generate FCCU faults corresponding to TEMP SENS. Writing 1 to one of these bits generates a single cycle pulsed fault to the FCCU block. The bit clears to 0 automatically in the next cycle.

Address: 0h base + A4h offset = A4h

**PMC\_TS\_FIR field descriptions**

### 47.2.7 Voltage Detect User Mode Test Register (PMC\_SELF\_TEST\_UM\_VD\_REG)

This register is used for testing LVDs and HVDs during user mode.

#### NOTE

A PMC self test of any or all LVDs and HVDs can be interrupted by these reset sources and thereby become corrupted:

- Writing 1 to SIU\_SRCR[SSR]
- JTAG reset
- FCCU reset

Due to this corruption, the PMC or FCCU might report incorrectly that a PMC self test of any or all LVDs and HVDs failed.

If software detects one of these reset sources when exiting reset and the PMC or FCCU reports a failed PMC self test of any or all LVDs and HVDs, execute the PMC self test again to confirm the failure.

## Memory Map and Registers

Address: 0h base + B4h offset = B4h

47.2.8 FCCU Fault Injection Register (PMC\_FIR)

This FCCU Fault Injection register enables user software to artificially generate FCCU faults corresponding to various events, namely LVD, HVD, TEMP SENS and Self Test. A write of 1 to these bits generates a single-cycle pulsed fault to the FCCU block. This bit is automatically cleared to 0 in the next cycle.

Address: 0h base + B8h offset = B8h

### 47.2.9 LVD/HVD Interrupt Enable Control Register (PMC\_LVD\_HVD\_INTR\_ENB)

This register enables/disables interrupts of PMC VD events.

#### NOTE

Writes to this register must occur in two steps:

1. Set PMC\_ENABLE in this register to 1.
2. In another write operation, program the other fields of the register.

Address: 0h base + BCh offset = BCh

47.2.10 LVD/HVD Event Status Register  
(PMC\_LVD\_HVD\_EVENT\_STATUS)

This status register contains the latched status of the voltage detect events. These bits indicate the state of the voltage detect events, including whether a voltage level event has occurred at any time in the past but has not been cleared (via writing 1). These bits are read-only, and they are cleared by writing 1 to the corresponding ESR register bit.

Address: 0h base + C0h offset = C0h

**47.2.12 Reset Event Enable Register (PMC\_REE)**

This Reset Event Enable Register controls whether or not the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a POR to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash memory during the boot sequence. If the bits loaded from flash memory are programmed to be enabled (set), these bits cannot be disabled (cleared).

**NOTE**

This register is cleared on POR or a reset due to RESET pin assertion or FOSU failure indication.

**CAUTION**

Except when they occur during a PMC self test, the following VD events *always* result in a POR. The result of these VD events cannot be programmed:

- POR098\_c
- LVD\_CORE\_HOT
- POR\_HV
- LVD\_HV
- LVD\_FLASH
- LVD\_IO

Address: 0h base + D0h offset = D0h

## 47.3 Functional description

### 47.3.1 Analog PMC interface

The digital block uses the analog PMC interface to configure factory-defined trim values for the regulators and LVDs that are in the analog block.

### 47.3.2 Temperature Sensor interface logic

The digital PMC block provides control and configuration information, including module enables, to the two Temperature Sensors.

### 47.3.3 POR phase gates

The interface with the SIU module is used during the power-on sequence and startup. It provides various phase gates, thereby enabling the SIU to properly complete the reset sequence.

It also provides reset sources based on LVD and HVD events and their enable/disable control through the REE register.

The temperature sensor provides another reset source, based on the under/over temperature events and their control through the REE\_TD and RES\_TD registers.

### 47.3.4 Flash memory interface to DCF

During power up, trim values for the regulators, LVDs, and HVDs are read from flash memory by the SSCM and then provided to the digital PMC via the DCF interface.

The reset event enable (REE) configurations that are stored in flash memory are also provided to the PMC via the DCF interface. These REE configurations are used, by default, to configure which programmable voltage detection (VD) events generate a POR.

### 47.3.5 FCCU interface

The digital block generates various fault indications to the FCCU block:

- Separate, corresponding, active-high fault indications are generated whenever an LVD or HVD defect is detected in the analog block.
- A fault indication is generated when a self test task results in a failure.
- A fault condition is generated whenever over-temperature or under-temperature events occur in the temperature sensor.

The figure below show the exact logic for the generation fault indications to FCCU block.

**Figure 47-13. Fault generation to FCCU**

See [FCCU Fault Injection Register \(PMC\\_FIR\)](#) for details.

### 47.3.6 LVD/HVD self test mechanism

The PMC implements an LVD/HVD self test mechanism for use in satisfying safety goals. The digital block assists and controls the analog block during execution of the self test.

Currently, three self test modes are supported by the analog block. Select the mode using the SELF\_TEST\_UM\_VD\_REG[ST\_MODE] field.

The self test status and result are provided in the SELF\_TEST\_UM\_VD\_REG register's ST\_DONE and ST\_RESULT fields, respectively.

### **NOTE**

Self tests must execute with the FM\_PER\_CLK frequency at 8 MHz.

#### **47.3.6.1 Default mode**

The self test always occurs during startup (power on). The self test starts after the SSCM has completed reads from the flash memory. A counter is provided that starts from zero and increments by one after a factory-defined time gap. The counter value is the source for the self test output signal, which is provided to the analog block.

Meanwhile, the LVD/HVD indication from the analog block is latched in the SELF\_TEST\_UM\_VD\_REG register. At the end of the self test, after all of the LVDs/HVDs have been tested, the SELF\_TEST\_UM\_VD\_REG[ST\_DONE] status bit is set to 1 and all bits in the SELF\_TEST\_UM\_VD\_REG register are read to see if the value of each is 1.

- If one or more bits is not set to 1, a fault indication to the FCCU block is generated, and the SELF\_TEST\_UM\_VD\_REG[ST\_RESULT] field is set to 0.
- If each of the register bits is set to 1, the test is considered passed, the SELF\_TEST\_UM\_VD\_REG[ST\_RESULT] bit is set to 1, and no fault indications are provided to the FCCU.

### **NOTE**

The total run time of the self test is 300  $\mu$ s (factory-defined default).

#### **47.3.6.2 Software-triggered self test**

This mode is entered by software by writing 01b to the SELF\_TEST\_UM\_VD\_REG[ST\_MODE] field. The complete self test, as is performed in default mode, is executed. The difference is that the self test in this mode is initiated by the host while the self test in default mode is started automatically during power on.

### 47.3.6.3 Single voltage detect test

This mode is entered by software writing 10b to the SELF\_TEST\_UM\_VD\_REG[ST\_MODE] field. The test completes after the prescribed time gap has elapsed (factory-defined default is 20  $\mu$ s). The PASS/FAIL result is then updated based on whether or not the corresponding VD output trips.

#### NOTE

During execution of the VD self test, all of the LVD and HVD outputs—including PORs, which are also under self test—are masked. Therefore, they have no effect on POR generation or any reset and/or fault generation.

# Chapter 48

## JTAG Controller (JTAGC)

### 48.1 Chip-specific JTAGC information

This chip has one instance of the JTAGC module.

#### 48.1.1 JTAG ID

The JTAG ID depends on the version of the chip.

**Table 48-1. JTAG ID by chip version**

| Maskset | JTAG ID    |
|---------|------------|
| 3N45H   | 1837_701Dh |

For details, see [Device identification register](#).

### 48.2 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

#### 48.2.1 Block diagram

The following is a simplified block diagram of the JTAG Controller (JTAGC) block. Refer to [Register description](#) for more information about the JTAGC registers.

**Figure 48-1. JTAG (IEEE 1149.1) block diagram**

## 48.2.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
  - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to [Table 48-5](#) for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS\_AUX\_x instructions
- JTAG\_PASSWORD register
- Bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

## 48.2.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

### 48.2.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

### 48.2.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [JTAGC block instructions](#).

### 48.2.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

## 48.3 External signal description

The JTAGC consists of a set of signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

**Table 48-2. JTAG signal properties**

| Name  | I/O    | Function         | Reset State         |
|-------|--------|------------------|---------------------|
| TCK   | Input  | Test Clock       | Weak pulldown       |
| TDI   | Input  | Test Data In     | Weak pullup         |
| TDO   | Output | Test Data Out    | High Z <sup>1</sup> |
| TMS   | Input  | Test Mode Select | Weak pullup         |
| JCOMP | Input  | JTAG Compliancy  | Weak pulldown       |

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

### 48.3.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

### 48.3.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 48.3.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [TAP controller state machine](#).

### 48.3.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

### 48.3.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

## 48.4 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

### 48.4.1 Instruction register

The JTAGC block uses a 5-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 00001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

|        |                  |   |   |   |   |
|--------|------------------|---|---|---|---|
|        | 4                | 3 | 2 | 1 | 0 |
| R      | 0                | 0 | 0 | 0 | 1 |
| W      | Instruction Code |   |   |   |   |
| Reset: | 0                | 0 | 0 | 0 | 1 |

Figure 48-2. Instruction register

### 48.4.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

### 48.4.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

|       |                            |    |    |    |    |    |    |    |                            |    |    |    |    |    |                            |    |
|-------|----------------------------|----|----|----|----|----|----|----|----------------------------|----|----|----|----|----|----------------------------|----|
|       | 31                         | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23                         | 22 | 21 | 20 | 19 | 18 | 17                         | 16 |
| R     | Part Revision Number       |    |    |    |    |    |    |    | Design Center              |    |    |    |    |    | Part Identification Number |    |
| W     |                            |    |    |    |    |    |    |    |                            |    |    |    |    |    |                            |    |
| Reset | PRN                        |    |    |    |    |    |    |    | DC                         |    |    |    |    |    | PIN                        |    |
|       | 15                         | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7                          | 6  | 5  | 4  | 3  | 2  | 1                          | 0  |
| R     | Part Identification Number |    |    |    |    |    |    |    | Manufacturer Identity Code |    |    |    |    |    |                            | 1  |
| W     |                            |    |    |    |    |    |    |    |                            |    |    |    |    |    |                            |    |
| Reset | PIN (contd.)               |    |    |    |    |    |    |    | MIC                        |    |    |    |    |    |                            | 1  |

The following table describes the device identification register functions.

Table 48-3. Device identification register field descriptions

| Field | Description                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------------------|
| PRN   | Part Revision Number. Contains the revision number of the part. Value is 0x0 for masksets 1N45H and 2N45H, 0x1 for maskset 3N45H. |
| DC    | Design Center. Indicates the design center. Value is 0x20.                                                                        |
| PIN   | Part Identification Number. Contains the part number of the device. 0x377.                                                        |

Table continues on the next page...

| Field     | Description                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------|
| MIC       | Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x00E.           |
| IDCODE ID | IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1. |

#### 48.4.4 JTAG\_PASSWORD register

The JTAG\_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE\_JTAG\_PASSWORD instruction is active. The default reset value of the JTAG\_PASSWORD register is 256'b0. The JTAG\_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE\_JTAG\_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG\_PASSWORD is 256 'b0.

The following table describes the JTAG\_PASSWORD register functions.

**Table 48-4. JTAG\_PASSWORD register field descriptions**

| Field         | Description                                                                               |
|---------------|-------------------------------------------------------------------------------------------|
| JTAG_PASSWORD | JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security. |

#### 48.4.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary

scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

## 48.5 Functional description

This section explains the JTAGC functional description.

### 48.5.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

### 48.5.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to [ACCESS\\_AUX\\_x instructions](#).

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

**Figure 48-3. Shifting data through a register**

### 48.5.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the

TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 48-4. IEEE 1149.1-2001 TAP controller finite state machine**

### 48.5.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

### 48.5.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

## 48.5.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

**Table 48-5. General 5-bit JTAG instructions**

| Instruction            | Code[4:0] | Instruction Summary                                                                                                                                     |
|------------------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| IDCODE                 | 00001     | Selects device identification register for shift                                                                                                        |
| SAMPLE/PRELOAD         | 00010     | Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation                                           |
| SAMPLE                 | 00011     | Selects boundary scan register for shifting and sampling without disturbing functional operation                                                        |
| EXTEST                 | 00100     | Selects boundary scan register and applies preloaded values to output pins.<br><br><b>NOTE:</b> Execution of this instruction asserts functional reset. |

| Factory debug reserved | 01111             | Intended for factory debug only                                                                                                              |
| BYPASS                 | 11111             | Selects bypass register for data operations                                                                                                  |
| Reserved <sup>1</sup>  | All other opcodes | Decoded to select bypass register                                                                                                            |

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

The ACCESS\_AUX instructions are described in the chip configuration debug information.

#### 48.5.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

#### 48.5.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- The SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- The PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

### 48.5.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

### 48.5.4.4 EXTEST External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

### 48.5.4.5 ENABLE\_JTAG\_PASSWORD instruction

The ENABLE\_JTAG\_PASSWORD instruction selects the JTAG\_PASSWORD register for connection as the shift path between TDI and TDO.

### 48.5.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

### 48.5.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a

single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

#### **48.5.4.8 ACCESS\_AUX\_x instructions**

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS\_AUX\_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

#### **48.5.4.9 BYPASS instruction**

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

### **48.5.5 Boundary scan**

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

## 48.6 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

## 49.3 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backwards compatible with IEEE P1149.1. This standard is also known as "Compact JTAG" or "CJTAG".

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths

- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

### 49.3.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- **Compliant**
  - Compliant with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
  - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- **Extended**
  - Compatible with the IEEE 1149.1 standard
  - Four-pin operation using the "Standard Protocol" — IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
  - Additional test/debug functions
- **Advanced**
  - Two-pin operation using the "Advanced Protocol" — signaling where TCK(C) and TMS(C) signals transfer control/data information
  - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

### 49.3.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
  - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
  - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
  - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors..
  - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
  - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

### 49.3.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in the following table. Signal names that end in “C” are associated with expanded functionality (beyond the functionality provided by the IEEE 1149.1 standard).

The table uses the following notation:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the following pins:

- TCKC
- TDIC
- TDOC
- TMSC
- nTRST

**Table 49-2. TAP.7 signal list**

| Signal name                      | Description      | Class |    |    |    |    |
|----------------------------------|------------------|-------|----|----|----|----|
|                                  |                  | T4    | T3 | T2 | T1 | T0 |
| TCK/TCKC                         | Test clock       | MC    | M  | M  | M  | M  |
| TMS/TMSC                         | Test mode select | MC    | M  | M  | M  | M  |
| TDI/TDIC                         | Test data input  | OC    | MC | M  | M  | M  |
| TDO/TDOC                         | Test data output | OC    | MC | M  | M  | M  |
| nTRST                            | Test reset       | O     | O  | O  | O  | O  |
| Mandatory signal count (minimum) |                  | 2     | 4  | 4  | 4  | 4  |

### 49.3.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in the following figure. It is described with the hardware layers listed below:

- **STL – System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP. 7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

Figure 49-1. TAP.7 Controller Architecture

### 49.3.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in the following figure.

Figure 49-2. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and

vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in the following table.

**Table 49-3. Class/protocol relationship**

| Class          | Protocol  |           |           |
|----------------|-----------|-----------|-----------|
|                | Standard  | Control   | Advanced  |
| <b>T0 – T2</b> | Mandatory | Optional  | N/A       |
| <b>T3</b>      | Mandatory | Mandatory | N/A       |
| <b>T4</b>      | Mandatory | Mandatory | Mandatory |

The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

#### 49.3.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

#### 49.3.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMSC signaling sequences.

### 49.3.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

## 49.4 Operating models

The following figure illustrates a simplified view of the CJTAG operating model.

Figure 49-3. CJTAG operating model

## 49.5 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

### 49.5.1 T0 functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

### 49.5.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

### 49.5.3 T2 functions

- “Super Bypass” function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

### 49.5.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

### 49.5.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

## 49.6 Ancillary services

### 49.6.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options

- Escape sequences
- TAPC state machine

## 49.6.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset. (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST\_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC.

Figure 49-4. Conceptual view of the EPU reset logic and state machines

### 49.6.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS\_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

### 49.6.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS\_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

### 49.6.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST\_PD pin).

#### 49.6.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

#### 49.6.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST\_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

#### 49.6.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

#### 49.6.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

Figure 49-5. Reset state machine

**Table 49-4. Reset state descriptions**

| Reset state |                        | Description                                        |
|-------------|------------------------|----------------------------------------------------|
| ARA         | Async. Reset Asserted  | An async. reset has occurred or is occurring       |
| ARC         | Async. Reset Completed | An async. reset has occurred and has been released |
| No Reset    | No Reset               | No Reset                                           |
| T3 Reset    | Type-3 Reset           | A Type-3 reset request has been processed.         |

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS\_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in the following table.

**Table 49-5. Reset effects**

| Reset  | CLTAPC | Pin-Hi-Z | State Machines other than CSM | Control State Machine (CSM) | TAPC SM State | Escape Sequence Detection | Power Control State |
|--------|--------|----------|-------------------------------|-----------------------------|---------------|---------------------------|---------------------|
| Type-5 | Yes    | –        | –                             | –                           | –             | –                         | –                   |
| Type-4 | –      | Yes      | Yes                           | –                           | –             | –                         | –                   |
| Type-3 | Yes    | Yes      | Yes                           | Yes                         | Yes           | –                         | –                   |
| Type-2 | Yes    | Yes      | Yes                           | Yes                         | Yes           | Yes                       | –                   |
| Type-1 | Yes    | Yes      | Yes                           | Yes                         | Yes           | Yes                       | –                   |
| Type-0 | Yes    | Yes      | Yes                           | Yes                         | Yes           | Yes                       | Yes                 |

## 49.6.3 Start-up Options

### 49.6.3.1 Overview

The TAP.7 start-up options are shown in the following table. The only startup option currently supported by the CJTAG module is 1149.1 Compliant.

**Table 49-6. Start-up Options**

| Start-up Option          | Description                                         |
|--------------------------|-----------------------------------------------------|
| <b>1149.1 Compliant</b>  | TAP.1 signal functionality, the CLTAPC is coupled   |
| <b>1149.1 Compatible</b> | TAP.7 signal functionality, the CLTAPC is decoupled |

*Table continues on the next page...*

**Table 49-6. Start-up Options (continued)**

| Start-up Option                      | Description                                                                                                                                                                               |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1149.1 Protocol Compatible</b>    | No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.                                                                                                                 |
| <b>Offline-at-Start-up (Dormant)</b> | The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to <i>Run-Test/Idle</i> |

### 49.6.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine.
- The TDIC and TDOC pins are present and provide the TDI and TDO function.
- The CLTAPC is coupled at start-up.

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

**Table 49-7. Reset values for TAP.7 startup options**

| Start-up Option  | Type-0 – Type-3 Reset? | Default TAP.7 and TAP.7 controller characteristics |                |               |        |                       |
|------------------|------------------------|----------------------------------------------------|----------------|---------------|--------|-----------------------|
|                  |                        | TAP.7 Controller online                            | CLTAPC Coupled | SGC Reg. == 1 | SCNFMT | Initial TMSC pin bias |
| 1149.1 Compliant | x                      | Yes                                                | Yes            | Yes           | JScan0 | PU                    |

### 49.6.4 RSU operation

The RSU uses TCKC and TMSC with the control protocol for configuration control.

### 49.6.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP.7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in the following figure.

Figure 49-6. Conceptual view of technology selection mechanism

### 49.6.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

### 49.6.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges) – Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges) – Resets all technologies (generates a Type-3 TAP.7 TAPC reset)

The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

#### 49.6.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.

#### 49.6.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occur with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

### 49.6.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

### Figure 49-7. Falling edge TAP controller state machine

## 49.7 EPU (Extended Protocol Unit) Operation

### 49.7.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

### 49.7.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

### 49.7.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

### 49.7.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

### 49.7.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths

6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control levels.

#### 49.7.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

#### 49.7.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

### 49.7.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called "**TAP.7 ZBSs**". ZBSs that are intended for other uses are henceforth called "**Other ZBSs**". Two TAP.7 registers enable the STL's use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP.7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

## 49.7.2 EPU Registers

### 49.7.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose. These commands store a single global register. Global registers manage TAP.7 TAPC functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN\_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

### 49.7.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one at a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers. There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back..

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- **Read-only** – Configuration and register read back.

**Table 49-8. TAP.7 controller register list (managed with commands)**

| Register type | Global/local | Width | Register mnemonic | Name                     |
|---------------|--------------|-------|-------------------|--------------------------|
| Control       | Global       | 1     | ECL               | Exit Control Level       |
|               |              | 1     | SUSPEND           | Suspend                  |
|               |              | 1     | ZBSINH            | ZBS Detect Inhibit       |
|               |              | 5     | SCNFMT            | Scan Format              |
|               |              | 1     | SSDE              | SSD Enable               |
|               |              | 2     | DLYC              | Delay control            |
|               |              | 2     | RDYC              | Ready Control            |
| Options       | Local        | 1     | TRESET            | Test Reset               |

M = Mandatory register

O = Optional register

### 49.7.2.3 Register Descriptions

#### 49.7.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

#### 49.7.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the "System Path" (STL) is used.

**1** – Suspend use of control levels. Enables "System Path."

**0** – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

#### 49.7.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

**1** – Inhibit ZBS detection.

**0** – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

#### 49.7.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

**Table 49-9. Scan Format Register Values**

| TAPC.7 Class | SCNFMT | Description                                                                                                                                                                                                                                  |

Table continues on the next page...

**Table 49-9. Scan Format Register Values (continued)**

| TAPC.7 Class | SCNFMT        | Description                                                                                                                                                                                                                                         |
|--------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | 01111         | <b>OScan7</b> <ul style="list-style-type: none"> <li>• TAP.1 components</li> <li>• No TDI in non-shift states</li> <li>• No TDO in any state</li> </ul>                                                                                             |
|              | 10000         | <b>MScan</b> <ul style="list-style-type: none"> <li>• Data rate dependent components</li> <li>• Multi TAP.7 communication</li> <li>• Directed CID assignment</li> <li>• Virtually any IP with compliant or non-compliant 1149.1 behavior</li> </ul> |
|              | 10001 – 11111 | <b>Reserved</b>                                                                                                                                                                                                                                     |

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

#### 49.7.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

**0** – Scan selection directives are not enabled.

**1** – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

#### 49.7.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0

Bits 18-17 of the "Global Register."

#### 49.7.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

#### 49.7.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

**0** – The nSYS\_TRST and SYS\_TMS signals presented to the STL is not influenced by this bit.

**1** – The nSYS\_TRST presented to the STL is asserted and the SYS\_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS\_TRST and the SYS\_TMS logic 1 value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0.
- A stay in the Run-Test/Idle state of two or more SYS\_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

#### 49.7.2.3.9 Auxiliary Pin Function Control (APFC[1:0])

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

**0x** – TDI and TDO have JTAG function.

**1x** – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

#### 49.7.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

#### 49.7.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

#### 49.7.2.3.12 Sampling Edge (SEEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

## Register Descriptions

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0

### 49.7.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as "0".

**Table 49-10. RDBACK register format**

| Bit   | Width | Register Mnemonic | Name                             |
|-------|-------|-------------------|----------------------------------|
| 4:0   | 5     | SCNFMT            | Scan Format                      |
| 6:5   | 2     | PWRMODE           | Power-control Modes              |

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

**49.7.3 EPU Commands**

There are two command types:

- Two Part Commands
- Three Part Commands

Any number of two-part and three part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

### 49.7.3.1 Two Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two). The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.

### 49.7.3.2 Three Part Commands

Some commands are used to send and/or receive data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

### 49.7.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of Shift-DR states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in the following figure.

**Figure 49-8. DR\_Scan sequence used for command creation**

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a **Control-Register Scan** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two part commands, but only three three-part commands, each having a special purpose.

### 49.7.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in the following table.

**Table 49-13. – TAP.7 controller command list**

| Command class          | Opcode count | Mnemonic | Name                        | TAP.7 class |   |   |   |
|------------------------|--------------|----------|-----------------------------|-------------|---|---|---|
|                        |              |          |                             | 1           | 2 | 3 | 4 |
| Store                  | 0x00         | STMC     | Store Miscellaneous Control | M           | M | M | M |

|                        | 0x0B         | CIDD     | De-allocate Controller ID   | -           | - | M | M |
| Reserved               | 0x0C–0x1F    | Reserved | Reserved                    | -           | - | - | - |

1. Enumerate commands are not currently supported by the CJTAG module.

#### 49.7.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing an external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

### 49.7.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

### 49.7.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

## 49.7.3.5 Command Definitions

### 49.7.3.5.1 Store Commands

#### 49.7.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 49-14. Store Miscellaneous Control

| STMC   |         | Store Miscellaneous Control |          |   |   |                            |
|--------|---------|-----------------------------|----------|---|---|----------------------------|
| Opcode | Operand | bbb                         |          | x | y | Description                |
| 00000  | bbb x y | 000                         | StateCtl | 0 | 0 | NOP                        |
|        |         |                             |          | 0 | 1 | ExitCmdLev(ECL)            |
|        |         |                             |          | 1 | 0 | Exit/Suspend (SUSPEND) = 1 |
|        |         |                             |          | 1 | 1 | ZBS Inhibit (ZBSINH) = 1   |
|        |         | 001                         | ScanCtl  | 0 | - | SGC = y                    |
|        |         |                             |          | 1 | - | CGM = y                    |

**49.7.3.5.2 Select Commands**

This section describes the select commands with their operands.

**49.7.3.5.2.1 Make Conditional Group Member (MCM)**

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

**Table 49-18. Make Conditional Group Member (MCM)**

| MCM    |         | Conditional Group Member |                                                                                                   |
|--------|---------|--------------------------|---------------------------------------------------------------------------------------------------|
| Opcode | Operand | m                        | Description                                                                                       |
| 00110  | m iiii  | 0                        | CGM bit of the non-targeted controller is cleared                                                 |
|        |         | 1                        | CGM bit of the targeted controller is set.<br>CGM bit of a non-targeted controller is unaffected. |

**49.7.3.5.2.2 Make Scan Group Candidate (MSC)**

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

**Table 49-19. Make Scan Group Candidate (MSC)**

| MSC    |         | Make Scan Group Candidate |                                                                                                   |
|--------|---------|---------------------------|---------------------------------------------------------------------------------------------------|
| Opcode | Operand | m                         | Description                                                                                       |
| 00111  | m iiiii | 0                         | SGC bit of the non-targeted controller is cleared                                                 |
|        |         | 1                         | SGC bit of the targeted controller is set.<br>SGC bit of a non-targeted controller is unaffected. |

### 49.7.3.5.3 Scan Commands

#### 49.7.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

**Table 49-20. Scan Bit (SCNB)**

| SCNB   |         |         | Scan Bit |                                                        |            |
|--------|---------|---------|----------|--------------------------------------------------------|------------|
| Opcode | Operand | CR-Scan | yyyyy    | Description                                            | R/W        |
| 01000  | yyyyy   | -       | 0        | Scan Group Candidate (SGC)                             | Write only |
|        |         | -       | 1        | Conditional Group Member (CGM)                         | Write only |
|        |         | -       | 2        | CNFG[0]                                                | Read only  |
|        |         | -       | 3        | CNFG[1] (not implemented)                              | Read only  |
|        |         | -       | 4        | CNFG[2] (not implemented)                              | Read only  |
|        |         | -       | 5        | CNFG[3] (not implemented)                              | Read only  |
|        |         | -       | 6        | Functional reset requested (FRESETR) (not implemented) | Read only  |
|        |         | -       | 7        | Series topology detect                                 | Write only |
|        |         | -       | 15 – 8   | Reserved                                               | Read only  |

#### 49.7.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

**Table 49-21. Scan String (SCNS)**

| SCNS   |         |         | Scan String |                           |           |
|--------|---------|---------|-------------|---------------------------|-----------|
| Opcode | Operand | CR-Scan | yyyyy       | Description               | R/W       |
| 01001  | yyyyy   | -       | 0           | RDBACK[0] Register [31:0] | Read only |

*Table continues on the next page...*

**Table 49-21. Scan String (SCNS)**  
(continued)

| SCNS   |         |         | Scan String |                                             |           |
|--------|---------|---------|-------------|---------------------------------------------|-----------|
| Opcode | Operand | CR-Scan | yyyyy       | Description                                 | R/W       |
|        |         | -       | 1           | RDBACK[1] Register [31:0] (not implemented) | Read only |
|        |         | -       | 2           | CNFG[0] Register [31:0]                     | Read only |
|        |         | -       | 3           | CNFG[1] Register [31:0] (not implemented)   | Read only |
|        |         | -       | 4           | CNFG[2] Register [31:0] (not implemented)   | Read only |
|        |         | -       | 5           | CNFG[3] Register [31:0] (not implemented)   | Read only |
|        |         | -       | 6 - 7       | Reserved (read logic 0)                     | Read only |
|        |         | -       | 31 - 8      | Private – available for customization       |           |

#### 49.7.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in the following figure:

**Figure 49-9. EPU operating states**

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in the following table. The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

**Table 49-22. ZBS use state characteristics with both TAP.7 and other ZBS use**

| ZBSINH | SUSPEND | EPU operating State | ZBS use by: | Until                                   |
|--------|---------|---------------------|-------------|-----------------------------------------|
| 0      | 0       | RUNNING             | EPU         | Command allocates to STL                |
| 0      | 1       | SUSPENDED           | STL         | ZBS sequence allocates to EPU           |
| 1      | 0       | STOPPED             | STL         | Test-Logic-Reset state allocates to EPU |
| 1      | 1       | Not possible        |             |                                         |

### 49.7.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path
- **Bit** – Supports set and test bit operations (a 1-bit shift register)
- **String** – Support 32-bit reads or 32-bit writes
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

## 49.8 APU (Advanced Protocol Unit) Operation

### 49.8.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMS signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (i.e., ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Two groups of scan formats (MScan and OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan Scan Format is broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a

special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.

The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

**Figure 49-10. Conceptual block diagram of the APU functions**

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMS pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMS pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

## 49.8.2 Operation

The conceptual view of the APU operation is shown in the following figure.

Figure 49-11. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMS pin.

APU operating states:

- **BPA** – **By**Pass **A**ctive
- **CPA** – **C**hange **P**acket **A**ctive
- **SPA** – **S**can **P**acket **A**ctive

#### 49.8.2.1 BPA

The *BPA* state allocates the use of the TMS pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

### 49.8.2.2 CPA

The *CPA* state allocates the use of the TMS pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

### 49.8.2.3 SPA

The *SPA* state allocates the use of the TMS pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

## 49.8.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMS pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

## 49.8.4 Signal behaviors

The TCKC signal:

- The test clock

The TMS signal:

- An input when the Standard Protocol is used
- Bi-directional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
  - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
  - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

## 49.8.5 APU Functions

### 49.8.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (e.g., a narrow TAP.7 or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

### 49.8.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in . There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

**Figure 49-12. Scan Packet Sequence**

A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS\_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO\_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

**Figure 49-13. Serialization and De-serialization of Scan Packet Information**

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats.)

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.

With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug

applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

### 49.8.5.3 Control Process Active (CPA) Function

While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

**Figure 49-14. CPA State Entry from BPA State with Continued Online Operation**

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

Figure 49-15. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while

the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

**Figure 49-16. CPA State Entry from the BPA State with Offline Operation**

**Figure 49-17. CPA State Entry from the SPA State with Offline Operation**

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

## 49.8.6 Configuration Change Packets (CP)

A Change Packet (CP) is composed of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.

- **Body** – Two or more bits representing one or more CP directives
  - **00** – CP\_END
  - **01** – CP\_NOP (extends the body by 1-bit)
  - **10** – CP\_NOP (extends the body by 1-bit)
  - **11** – CP\_RES (Generate a Type-3 TAP.7 controller reset coincident with the postamble bit.
- **Postamble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Postamble. This can be as simple as four logic zero values.

### 49.8.7 Scan Packet

A Scan Packet defines the period of TAP.7 pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof)
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

### 49.8.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

### 49.8.8.1 Payload Element Content

#### 49.8.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain an input bit frame, an output bit frame, or both. When an input bit frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

### 49.8.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in the following table.

**Table 49-23. Factors determining the SP payload content**

| Scan format | Payload content determined by the: |        |
|-------------|------------------------------------|--------|
|             | TAPC state                         | Header |
| MScan       | –                                  | –      |
| OScan       | Yes                                | –      |

### 49.8.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMS pin. The TMS pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMS pin for the first n-1 bits and may drive the TMS pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY\_NOP, DLY\_END, and DLY\_RES).

### 49.8.8.3 Scan Formats

#### 49.8.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is

required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in [Table 49-24](#) and [Table 49-26](#). The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

#### 49.8.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

**Table 49-24. MScan scan format use case summary**

| Scan format | Supporting                    | Performance | Flexibility | TCKC source         |
|-------------|-------------------------------|-------------|-------------|---------------------|
| MScan       | STL Stalls                    | Least       | Best        | External tool or TS |
|             | Test                          |             |             |                     |
|             | Non-compliant behavior STL IP |             |             |                     |

*Table continues on the next page...*

**Table 49-24. MScan scan format use case summary (continued)**

| Scan format | Supporting                     | Performance | Flexibility | TCKC source |
|-------------|--------------------------------|-------------|-------------|-------------|
|             | Multi-chip debug communication |             |             |             |
|             | Controller ID Allocation       |             |             |             |

### Table 49-25. MScan Scan Packet content

|       |                                 |     |     |     |     |     |  |                             |     |     |     |     |     |
|-------|---------------------------------|-----|-----|-----|-----|-----|--|-----------------------------|-----|-----|-----|-----|-----|
|       | Non-shift TAP controller states |     |     |     |     |     |  | Shift TAP controller states |     |     |     |     |     |
| MScan | nTDI                            | TMS | PC0 | RDY | PC1 | TDO |  | nTDI                        | TMS | PC0 | RDY | PC1 | TDO |

### Figure 49-18. MScan Transaction

### 49.8.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

Figure 49-19. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, and EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods fo this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in the following table.

**Table 49-26. OScan scan format use case summary**

| Scan Format | Supporting                   | Performance  | Flexibility  | TCKC Source         |
|-------------|------------------------------|--------------|--------------|---------------------|
| OScan0      | Stalls                       | <div>↓</div> | Best         | External tool       |
| OScan1      | Test                         |              | <div>↑</div> |                     |
| OScan2      | Debug Performance            |              |              |                     |
| OScan3      | Debug Downloads (input only) | Best         | <div>↑</div> | External tool or TS |
| OScan4      | Stalls                       | <div>↓</div> |              |                     |
| OScan5      | Test                         |              |              |                     |
| OScan6      | Debug Performance            |              |              |                     |
| OScan7      | Debug Downloads (input only) | Best         |              |                     |

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

**Table 49-27. OScan Scan Format "Payload"**

| Scan Format | Non-shift TAP controller states |     |     |     |        | Shift TAP controller states |     |     |     |
|-------------|---------------------------------|-----|-----|-----|--------|-----------------------------|-----|-----|-----|
| OScan0      | nTDI                            | TMS | RDY | TDO |        | nTDI                        | TMS | RDY | TDO |
| OScan1      | nTDI                            | TMS | –   | TDO |        | nTDI                        | TMS | –   | TDO |
| OScan2      | –                               | TMS | –   | –   |        | nTDI                        | TMS | –   | TDO |
| OScan3      | –                               | TMS | –   | –   |        | nTDI                        | TMS | –   | –   |
| OScan4      | nTDI                            | TMS | RDY | TDO |        | nTDI                        | –   | RDY | TDO |
| OScan5      | nTDI                            | TMS | –   | TDO |        | nTDI                        | –   | –   | TDO |
| OScan6      | –                               | TMS | –   | –   | Note 1 | nTDI                        | TMS | –   | TDO |
|             |                                 |     |     |     | Note 2 | nTDI                        | –   | –   | TDO |
| OScan7      | –                               | TMS | –   | –   |        | nTDI                        | –   | –   | –   |

Note 2: Following Shift-xR Scan Packet

## 49.9 Functional Description

This section combines the information given in the Ancillary Services, EPU Operation, and APU Operation sections into a single reference for performing common TAP.7 tasks.

### 49.9.1 Switching from Standard Protocol to Advanced Protocol

Upon exit of Type-0 to Type-4 reset, the CJTAG begins operation in Standard Protocol 4-pin mode. The following steps are required to move from Standard Protocol 4-pin mode to Advanced Protocol (either 4-pin or 2-pin) mode.

The first step required to move to the Advanced Protocol is to change the CJTAG control level to control level 2 via zero-bit scans (ZBS), as described in [Control levels](#).

After the control level is set to control level 2, TAP.7 commands can be executed as described in [EPU Commands](#). Execution of the Store Scan Format (STFMT) to set the scan format to any OSCAN0-7 or MSCAN format begins the switch from the Standard Protocol to the Advanced Protocol.

Once the STFMT command is executed selecting an Advanced Protocol scan format, the CJTAG transitions to the intermediate Control Protocol mode. The Control Protocol uses TMS inputs to control Configuration Change Packets as described in [Control Process Active \(CPA\) Function](#) and [Configuration Change Packets \(CP\)](#). Loading a change packet body value of 00 (CP\_END) results in the switch to the Advanced Protocol.

If Advanced Protocol 2-pin operation is desired, the APFC register should be written to a value of 10 or 11 prior to the execution of the STFMT command that selects an advanced scan format. The APFC register is written via the Store Conditional 2-bit (STC2) command described in [Store Conditional 2-bit \(STC2\)](#).

# Chapter 50

## JTAG Data Communication (JDC)

### 50.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

### 50.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.

The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JOUT\_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JIN\_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JIN\_IPS register, and when new data has been written to the JOUT\_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (MSR), and also provided to a JTAG register (JOUT) for tool visibility.

There is a single bus interface to port register data out to the JTAGC, and a single bus interface to port data in from the JTAGC. The architecture is shown in the following figure.

### Figure 50-1. JDC block diagram

## 50.3 Memory mapped registers

Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

## JDC memory map

| Address offset (hex) | Register name                            | Width (in bits) | Access | Reset value | Section/<br>page            |

| Field        | Description    |
|--------------|----------------|
| 0–31<br>Data | JOUT_IPS data. |

50.3.4 JTAG Input Data Register (JDC\_JIN\_IPS)

Data written to the JTAG input data register (JIN) via the JTAG port is held in the JIN\_IPS register, where it can be read via IPS. This register is reset by system functional reset.

Address: 0h base + Ch offset = Ch

JDC\_JIN\_IPS field descriptions

| Field        | Description   |
|--------------|---------------|
| 0–31<br>Data | JIN_IPS data. |

50.4 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JIN\_IPS register. The other JTAG register captures data from the JOUT\_IPS register and ready status from the MSR to be shifted out via the JTAG port.

50.4.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT\_IPS register upon execution of the JOUT\_READ JTAG instruction. It also holds the JIN\_RDY and JOUT\_RDY status bits. This register is reset by system power-on reset and JTAG reset. The following figure shows the format of the JOUT register.

1. The reset value of the JOUT register is 34'b0.

The JOUT register is described in the following table.

**Table 50-6. JOUT JTAG register field descriptions**

| Field         | Description                       |
|---------------|-----------------------------------|
| JOUT_IPS Data | Data value from JOUT_IPS register |
| JIN_RDY       | State of JIN_RDY bit from MSR     |
| JOUT_RDY      | State of JOUT_RDY bit from MSR    |

## 50.4.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN\_WRITE JTAG instruction. The JIN data is later captured in the JIN\_IPS register to be read via IPS. This register is reset by system power-on reset and JTAG reset. The following figure shows the format of the JIN register.

1. The reset value of the JIN register is 32'b0.

The JIN register is described in the following table.

**Table 50-7. JIN JTAG register field descriptions**

| Field    | Description                                                                                                              |
|----------|--------------------------------------------------------------------------------------------------------------------------|
| JIN Data | Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction. |

## 50.5 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT\_IPS register sets the JOUT\_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT\_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT\_READ

instruction with a JOUT\_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT\_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT\_READ instruction. Clearing the JOUT\_RDY bit indicates to software that a new data value can be written to the JOUT\_IPS register.

- A JTAG write to the JIN register via execution of the JIN\_READ JTAG instruction updates the contents of the JIN\_IPS register upon exit of the Update-DR state. An update of the JIN\_IPS register sets the JIN\_RDY flag bit, indicating new data is available to be read via IPS. The state of the JIN\_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN\_RDY flag bit is cleared upon software read of the JIN\_IPS register. A JTAG read of the JOUT register with a JIN\_RDY value of logic 0 indicates new data can be written to the JIN register.

## 50.5.1 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

### 50.5.1.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

**Table 50-8. JTAG instructions**

| Instruction | Code[4:0]         | Instruction Summary                                                                                                                          |
|-------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Reserved    | 00001             | Factory debug reserved                                                                                                                       |
| JOUT_READ   | 00010             | Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active. |
| JIN_WRITE   | 01110             | Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.                    |
| BYPASS      | 11111             | Selects bypass register for data operations                                                                                                  |
| Reserved    | All other opcodes | Decoded to select bypass register                                                                                                            |

# Chapter 51

## Nexus Development Interface (NDI)

### 51.1 Overview

The NDI integrates seven individual Nexus modules that provide the chip's development support interface.

All seven Nexus modules are connected to the Nexus Port Controller (NPC). The following table lists the modules.

**Table 51-1. Nexus modules of NDI**

| Nexus modules                                                                                                         | For detailed information, see                                                               |
|-----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| Two Nexus e200z7 core interfaces (NZ7C3): one each for Core0 and Core1                                                | <i>e200z759n3 Core Reference Manual</i> (document number e200z759n3CRM)                     |
| Two Nexus eTPU development interfaces (NDEDI and NSEDI)                                                               | <a href="#">Nexus eTPU Development Interface (NDEDI)</a>                                    |
| Two Nexus crossbar eDMA interfaces (NXDM): one each for eDMA_A and eDMA_B<br>One Nexus crossbar SIPI interface (NXSI) | <a href="#">Nexus eDMA Interface (NXDM)</a> and <a href="#">Nexus SIPI Interface (NXSI)</a> |

The chip has no debug capability for the CSE module. CSE is not traceable.

#### NOTE

In each core, simultaneous access to debug control registers by software and Nexus hardware is not possible. When debug registers are allocated to Nexus hardware, they cannot be accessed by software.

## 51.2 Nexus clients for TAP access

After the NDI is out of the reset state: To grant the NDI ownership of the TAP, a specific instruction must be loaded in the JTAG Controller (JTAGC) module. Each Nexus client has its own JTAGC instruction opcode for ownership of the TAP, granting that client read/write access to the TAP's registers. The following table shows the JTAGC instruction opcode for each Nexus client. After the JTAGC opcode for a client has been loaded, the client is enabled by loading its NEXUS-ENABLE instruction.

**Table 51-2. JTAG client select instructions**

| JTAGC instruction         | Opcode | Description                                                                  |
|---------------------------|--------|------------------------------------------------------------------------------|
| ACCESS_AUX_NPC            | 10000  | Enables access to the NPC TAP controller                                     |
| ACCESS_AUX_ONCE           | 10001  | Enables access to the primary OnCE TAP controller (Core0)                    |
| ACCESS_AUX_eTPU           | 10010  | Enables access to the eTPU Nexus TAP controller (ETPU A/B)                   |
| ACCESS_AUX_NXDM           | 10011  | Enables access to the eDMA Nexus TAP controller (eDMA_A)                     |
| Reserved                  | 10100  | Not used                                                                     |
| ACCESS_AUX_SIPI           | 10101  | Enables access to the SIPI Nexus TAP controller                              |
| ACCESS_AUX_eTPU_Secondary | 10110  | Enables access to secondary ETPU Nexus TAP controller (ETPU C)               |
| ACCESS_AUX_NXDM_B         | 10111  | Enables access to the second eDMA Nexus TAP controller (eDMA_B)              |
| Reserved                  | 11000  | Not used                                                                     |
| ACCESS_AUX_ONCE_1         | 11001  | Enables access to the secondary OnCE TAP controller (Core1)                  |
| ACCESS_AUX_PAR            | 11010  | Enables parallel access to both OnCE TAP controllers (Core0 and Core1)       |
| ACCESS_AUX_MULTI          | 11100  | Enables serial access to both OnCE TAP controllers (Core0 followed by Core1) |
| ACCESS_AUX_JDC            | 11101  | Enables access to the JDC TAP controller                                     |
| Reserved                  | 11110  | Not used                                                                     |
| BYPASS                    | 11111  | Selects bypass register for data operations                                  |

## 51.3 Debug break and cross-triggering

This chip supports central break control among the cores and debug modules such as eTPU, eDMA, and Watchdog, allowing synchronous restart control for all cores when exiting debug mode.

**Figure 51-1. Debug break and cross-triggering logic**

### 51.3.1 Break control

Multiple modules on the chip, including the Nexus trace blocks, have debug features that allow them to request device-wide breaks to enter debug mode. All debug mode entry requests are combined (logically ORed) together, and the result produces the debug requests to the cores and peripherals.

The cross-triggering logic generates these debug request signals:

- Debug Request signal (active high) for all non-core peripherals
- External Debug Request (active high) for requesting an external debug event to cores

### 51.3.2 Cross-triggering control

Cross-triggering provides the ability to select whether modules enter debug mode upon receiving halt request signals from Nexus modules. In response to debug mode entry, some modules can be programmed to halt operation or to continue normal operation. This cross-triggering feature is implemented through debug control bits in the modules. The cores and peripherals can be programmed selectively with their respective control bits.

### 51.3.3 Synchronous restart control

The cross-triggering logic implements a feature that enables all debug peripherals—cores and peripherals that are put in the debug state—to restart synchronously, as follows:

1. The debugging tool sequentially scans the CPUSCR for each core to restore the proper processor state.
2. The debugging tool scans into the main chip TAP controller the instruction whose execution selects all core TAP controllers in parallel.
3. To enable any combination of cores to exit debug mode synchronously: The debugging tool simultaneously scans into each core's TAP instruction register (OCMD) the 10-bit sequence 180h, which sets both the GO and EX fields to 1 and clears RS[0:6] field to 0.
4. If a core exits debug mode, it sets a flag OnCE go+exit command.
5. When the OR of the core OnCE go+exit command signals is asserted, all other selected non-cores and peripherals in debug synchronously exit debug mode.

## **51.4 Nexus eDMA Interface (NXDM) and Nexus SIPI Interface (NXSI)**

The e200z7 eDMA Nexus module (NXDM) and SIPI module (NXSI) comply with the Class 3 defined data trace feature of the IEEE-ISTO 5001-2003 standard.

### **51.4.1 Introduction**

The NXDM can be programmed to trace data accesses for the eDMA module on the system bus. The NXSI can be programmed to trace data accesses for the SIPI module on the system bus. This eDMA module and SIPI module as well as the Nexus module are components of the e200z7 platform. All output messages and register accesses are compliant with the protocol defined in the IEEE-ISTO 5001 standard.

#### **NOTE**

The auxiliary port and its signals, such as MCKO, MSEO[1:0], MDO[15:0] and others, are referenced. The device NPC module arbitrates the access of the single auxiliary port. The functions of the NXDM and SIPI modules are described without the interaction of the NPC, as if Nexus has a dedicated auxiliary port, to simplify the description.

#### **51.4.1.1 Block Diagrams**

Figure 51-2 shows a block diagram of the NXDM. The block diagram of the NXSI is the same.

Figure 51-2. NXDM and NXSI Block Diagram

### 51.4.1.2 Features

Features include the following:

- Data trace via data write messaging (DWM) and data read messaging (DRM). This provides the capability for the development tool to trace reads and/or writes through the eDMA and SIPI modules to (selected) internal memory resources.
- Watchpoint messaging via the auxiliary pins.
- Watchpoint trigger enable of data trace messaging (DTM).

- Registers for data trace, watchpoint generation, and watchpoint trigger.
- All features controllable and configurable via the JTAG port.
- Power management.
  - Low power design
  - Dynamic power management of FIFOs and control logic

### 51.4.2 External Signal Description

The NXDM and NXSI modules use the same pins and pin protocol as the JTAG Controller and NPC modules.

#### 51.4.2.1 Rules for Output Messages

The NXDM and NXSI modules observe the same rules for output messages as the NPC.

#### 51.4.2.2 Auxiliary Port Arbitration

The NXDM and NXSI modules arbitrate for the shared Nexus port. This arbitration is handled by the NPC based on prioritized requests from the NXDM, NXSI, and the other Nexus clients sharing the port.

### 51.4.3 NXDM and NXSI Programmers Model

This section describes the programmers model. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See the JTAGC module details for more information about Nexus register access.

#### 51.4.3.1 NXDM and NXSI Nexus Register Map

Table 51-3. NXDM and NXSI Register Map

| Nexus Register                           | Nexus Access Opcode | Read/Write | Read Address | Write Address |
|------------------------------------------|---------------------|------------|--------------|---------------|
| Client Select Control (CSC) <sup>1</sup> | 0x1                 | R          | 0x02         | -             |

Table continues on the next page...

**Table 51-3. NXDM and NXSI Register Map (continued)**

| Nexus Register                                    | Nexus Access Opcode | Read/Write | Read Address | Write Address |
|---------------------------------------------------|---------------------|------------|--------------|---------------|
| Port Configuration Register (PCR) <sup>1</sup>    | Refer to NPC        | R/W        | -            | -             |

| Development Control 2 (DC2_n)                     | 0x3                 | R/W        | 0x05         | 0x06          |
| Watchpoint Trigger (WT_n)                         | 0xB                 | R/W        | 0x16         | 0x17          |
| Data Trace Control (DTC_n)                        | 0xD                 | R/W        | 0x1A         | 0x1B          |
| Data Trace Start Address 1 (DTSA1_n)              | 0xE                 | R/W        | 0x1C         | 0x1D          |
| Data Trace Start Address 2 (DTSA2_n)              | 0xF                 | R/W        | 0x1E         | 0x1F          |
| Data Trace End Address 1 (DTEA1_n)                | 0x12                | R/W        | 0x24         | 0x25          |
| Data Trace End Address 2 (DTEA2_n)                | 0x13                | R/W        | 0x26         | 0x27          |
| Breakpoint/Watchpoint Control Register 1 (BWC1_n) | 0x16                | R/W        | 0x2C         | 0x2D          |
| Breakpoint/Watchpoint Control Register 2 (BWC2_n) | 0x17                | R/W        | 0x2E         | 0x2F          |
| Breakpoint/Watchpoint Address Register 1 (BWA1_n) | 0x1E                | R/W        | 0x3C         | 0x3D          |
| Breakpoint/Watchpoint Address Register 2 (BWA2_n) | 0x1F                | R/W        | 0x3E         | 0x3F          |
| Reserved                                          | 0x20-0x3F           | -          | 0x40-0x7E    | 0x41-0x7F     |

1. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level Nexus3 controller (NPC), not in the NXDM or NXSI module. The device's CSC register is readable through Nexus3; the PCR is shown for reference only.

### 51.4.3.2 NXDM and NXSI Registers

Detailed register definitions for the NXDM and NXSI implementation are as follows:

#### 51.4.3.2.1 Development Control Register DC1

The development control registers control the basic development features of the NXDM and NXSI modules.

|       |     |         |    |    |    |    |    |     |    |    |    |    |    |    |    |    |
|-------|-----|---------|----|----|----|----|----|-----|----|----|----|----|----|----|----|----|
|       | 31  | 30      | 29 | 28 | 27 | 26 | 25 | 24  | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 |

1. The EOC bits in DC1 must be programmed to trigger  $\overline{\text{EVTO}}$  on watchpoint occurrence for the EWC bits to have any effect.

### 51.4.3.2.3 Watchpoint Trigger Register (WT)

The watchpoint trigger register allows the watchpoints defined internally to the NXDM and NXSI modules to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages.

| 19-0         | Reserved, read as 0.                                                                                                                                                                                     |

**NOTE**

The WT bits ONLY enable data trace if the tm bits within the development control register (DC) have not already been set to enable data trace.

**51.4.3.2.4 Data Trace Control Register (DTC)**

The data trace control register controls whether DTM Messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXDM and NXSI modules.

**Figure 51-7. Data Trace Start Address Registers (DTSA1, DTSA2)**

### 51.4.3.2.6 Data Trace End Address Registers 1 and 2 (DTEA1 and DTEA2)

The data trace end address registers define the end addresses for each trace channel.

**Figure 51-8. Data Trace Start Address Registers (DTEA1, DTEA2)**

Table 51-8 illustrates the range that is selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

**Table 51-8. Data Trace Address Range Options**

| Programmed Values | Range Control Bit Value | Range Selected          |
|-------------------|-------------------------|-------------------------|
| DTSA < or = DTEA  | 0                       | DTSA → ← DTEA           |
| DTSA < or = DTEA  | 1                       | ← DTSA DTEA →           |
| DTSA > DTEA       | -                       | Invalid range, no trace |

**NOTE**

DTSA must be less than (or equal to) DTEA to guarantee correct data write/read traces. When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

**51.4.3.2.7 Breakpoint / Watchpoint Control Register 1 (BWC1)**

Breakpoint/watchpoint control register 1 controls attributes for generation of NXDM and NXSI watchpoint number 1.

**Figure 51-9. Break / Watchpoint Control Register 1 (BWC1)****Table 51-9. BWC1 Field Description**

| Field | Description                                                     |
|-------|-----------------------------------------------------------------|
| 31-30 | Breakpoint/watchpoint #1 enable                                 |

| 15<br>BWT2    | Breakpoint/watchpoint #2 type<br>0 Invalid value<br>1 Watchpoint #2 on data accesses                                                                                    |
| 14-0          | Reserved, read as 0.                                                                                                                                                    |

#### 51.4.3.2.9 Breakpoint/Watchpoint Address Registers 1 and 2 (BWA1 and BWA2)

The breakpoint/watchpoint address registers are compared with bus addresses to generate internal watchpoints.

**Figure 51-11. Breakpoint / Watchpoint Address Registers (BWA1, BWA2)**

#### 51.4.3.2.10 Unimplemented Registers

Unimplemented registers are those with client select and index value combinations other than the ones listed in [Table 51-3](#). For unimplemented registers, the NXDM and NXSI modules drive TDO to zero during the "SHIFT-DR" state. The modules also transmit an error message with the invalid access opcode encoding.

#### 51.4.3.2.11 Programming Considerations ( $\overline{\text{RESET}}$ )

If Nexus3 register configuration is to occur during system reset (as opposed to debug mode), all NXDM configuration should be completed between the negation of JCOMP and system reset de-assertion, after the JTAG DID register has been read by the tool.

### 51.4.3.2.12 IEEE 1149.1 (JTAG) Test Access Port

The NXDM and NXSI modules use the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. See the JTAGC module details for more information about the JTAG interface.

The NXDM and NXSI modules implement a 4-bit instruction register (IR). The valid instructions and method for register access are outlined in the JTAGC module details.

#### 51.4.3.2.12.1 NXDM and NXSI JTAG DID Register

This JTAG DID register that is included in the NXDM and NXSI modules provides key development attributes to the development tool concerning the NXDM and NXSI blocks. The register is accessed through the standard JTAG IR/DR paths. Refer to the PMC chapter.

**Figure 51-12. NXDM and NXSI JTAG DID Register**

**Table 51-11. NXDM and NXSI JTAG DID Field Descriptions**

| Field                     | Description                                                                       |
|---------------------------|-----------------------------------------------------------------------------------|
| 31-28<br>PRN <sup>1</sup> | Embedded part revision number (0x0)                                               |
| 27-22<br>DC               | Freescale design center ID number (0x1F)                                          |
| 21-12<br>PIN              | NXDM and NXSI module part identification number, defines the features set. (0x60) |
| 11-1<br>MIC               | Manufacturer identity code<br>0x00E Freescale                                     |
| 0                         | Fixed per JTAG 1149.1<br>1 Always set                                             |

1. The revision number is initially 0 and could change in the future.

51.4.3.2.12.2 Enabling the NXDM and NXSI TAP Controllers

Assertion of a power-on-reset signal or assertion of the JCOMP pin resets all TAP controllers on the device. Upon exit from the test-logic-reset state, the IR value is loaded with the JTAG DID. When the NXDM or NXSI TAP is accessed, this information helps the development tool obtain information about the Nexus module it is accessing, such as version, sequence, feature set, and so forth.

51.4.3.2.12.3 NXDM and NXSI Register Access via JTAG

Access to Nexus register resources is enabled by loading a single instruction (NEXUS\_ACCESS) into the JTAG Instruction Register (IR). This IR is part of the IEEE 1149.1 TAP controller within the NXDM and NXSI modules.

After the JTAG NEXUS\_ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in [Table 51-3](#).

Reading/writing of a Nexus register then requires two (2) passes through the data-scan (DR) path of the JTAG state machine.

- 1. The first pass through the DR selects the Nexus register to be accessed by providing an index (refer to [Table 51-3](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG data register (DR). [Figure 51-13](#) shows the format of this register.
- 2. The second pass through the DR then shifts the data in or out of the JTAG port, lsb first.
  - a. During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the capture-DR state.
  - b. During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the update-DR state.

Figure 51-13. JTAG DR for NEXUS Register Access

Table 51-12. DR Read/Write Encoding

| Nexus Register Index | Description |
|----------------------|-------------|
| Read/Write (R/W)     | 0 Read      |

**Table 51-12. DR Read/Write Encoding**

| Nexus Register Index | Description |
|----------------------|-------------|
|                      | 1 Write     |

## 51.4.4 Functional Description

### 51.4.4.1 Enabling NXDM and NXSI Operation

The NXDM (and NXSI) module is enabled by loading a single instruction (ACCESS\_AUX\_TAP\_DMA or ACCESS\_AUX\_TAP\_NXSI) into the JTAG instruction register (IR), and then loading the corresponding OnCE OCMD register with the NEXUS\_ACCESS instruction. After it is enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the test-logic-reset state. This state can be reached by the assertion of the JCOMP pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a power-on reset (POR) event occurs.

If the NXDM (and NXSI) module is disabled, no trace output is provided, and the module disables (drive inactive) auxiliary port output pins (MDO[15:0], MSEO[1:0], MCKO). Nexus registers are not be available for reads or writes.

### 51.4.4.2 TCODEs Supported by NXDM and NXSI

The NXDM and NXSI pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages. The NXDM and NXSI blocks currently support the public TCODEs seen in [Table 51-13](#).

**Table 51-13. Public TCODEs Supported**

| Message Name                            | Packet Size<br>Bits |     | Packet Name | Packet Type | Packet Description                                         |
|-----------------------------------------|---------------------|-----|-------------|-------------|------------------------------------------------------------|
|                                         | Min                 | Max |             |             |                                                            |
| Data Trace - Data Write Message         | 6                   | 6   | TCODE       | Fixed       | TCODE number = 5                                           |
|                                         | 4                   | 4   | SRC         | Fixed       | Source processor identifier (multiple Nexus configuration) |
|                                         | 3                   | 3   | DSZ         | Fixed       | Data size (refer to <a href="#">Table 51-15</a> )          |
|                                         | 1                   | 32  | U-ADDR      | Variable    | Unique portion of the data write value                     |
|                                         | 1                   | 64  | DATA        | Variable    | Data write value                                           |

| 00111              | Invalid value                                        |
| 01000              | Data Trace and Watchpoint overrun                    |
| 01001-11111        | Invalid value                                        |

**Table 51-15. Data Trace Size (DSZ) Encodings (TCODE = 5, 6, 13, 14)**

| DTM Size Encoding | Transfer Size            |
|-------------------|--------------------------|
| 000               | Byte                     |
| 001               | Halfword (two bytes)     |
| 010               | Word (four bytes)        |
| 011               | Doubleword (eight bytes) |
| 100-111           | Invalid value            |

#### 51.4.4.2.1 Data Trace

This section deals with the data trace mechanism supported by the NXDM and NXSI modules. Data trace is implemented via data write messaging (DWM) and data read messaging (DRM).

#### 51.4.4.2.2 Data Trace Messaging (DTM)

XDM and NXSI data trace messaging is accomplished by snooping the NXDM and NXSI data bus, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXDM (and NXSI) module traces all data access that meet the selected range and attributes.

#### NOTE

Data trace is ONLY performed on DMA or SIPI accesses to the system bus.

51.4.4.2.3 DTM Message Formats

The NXDM (and NXSI) block supports five types of DTM Messages - data write, data read, data write synchronization, data read synchronization and error messages.

51.4.4.2.3.1 Data Write and Data Read Messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. Data write message and data read message information is messaged out in the following format:

Figure 51-14. Data Write/Read Message Format

51.4.4.2.3.2 DTM Overflow Error Messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. After it is emptied, an error message is queued. The error encoding indicates which types of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (00010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (01000).

Error information is messaged out in the following format:

Figure 51-15. Error Message Format

### 51.4.4.2.3.3 Data Trace Synchronization Messages

A data trace write/read w/ sync. message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (refer to [Table 51-16](#)):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.
- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.
- Upon assertion of the Event In ( $\overline{\text{EVTI}}$ ) pin, the first data trace message is a synchronization message if the eic bits of the dc register have enabled this feature.
- Upon data trace write/read after the previous dtm message was lost due to an attempted access to a secure memory location.
- Upon data trace write/read after the previous dtm message was lost due to a collision entering the fifo between the dtm message and any of the following: error message, or watchpoint message.

Data trace synchronization messages provide the full address (without leading zeros) and insure that development tools fully synchronize with data trace regularly.

Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read w/ sync. messages is as follows:

**Figure 51-16. Data Write/Read w/ Sync Message Format**

Exception conditions that result in data trace synchronization are summarized in [Table 51-16](#)."

**Table 51-16. Data Trace Exception Summary**

| Exception Condition                 | Exception Handling                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System Reset Negation               | At the negation of JTAG reset (JCOMP), queue pointers, counters, state machines, and registers within the NXDM and NXSI module are reset. If data trace is enabled, the first data trace message is a data write/read w/ sync. message.                                                                                                                                                                           |
| Data Trace Enabled                  | The first data trace message (after data trace has been enabled) is a synchronization message.                                                                                                                                                                                                                                                                                                                    |
| Exit from Low Power/Debug           | Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read w/ sync. message.                                                                                                                                                                                                                                                                                     |
| Queue Overrun                       | An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. After it is emptied, an error message is queued. The error encoding indicates the types of messages that attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read w/ sync. message. |
| Periodic Data Trace Synchronization | A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read w/ sync. message is queued. The periodic data trace message counter then resets.                                                                                                                                                                                                                   |
| Event In                            | If the nexus module is enabled, an EVTI assertion initiates a data trace write/read w/ sync. message upon the next data write/read (if data trace is enabled and the eic bits of the dc register have enabled this feature).                                                                                                                                                                                      |
| Attempted Access to Secure Memory   | Any attempted read or write to secure memory locations temporarily disable data trace & cause the corresponding DTM to be lost. A subsequent read/write queues a data trace read/write with sync. message.                                                                                                                                                                                                        |
| Collision Priority                  | All messages have the following priority: Error → WPM → DTM. A DTM message which attempts to enter the queue at the same time as an error message, or watchpoint message is lost. A subsequent read/write queues a data trace read/write with sync. message.                                                                                                                                                      |

#### 51.4.4.2.4 DTM Operation

##### 51.4.4.2.4.1 Enabling Data Trace Messaging

Data trace messaging can be enabled in one of two ways.

- Setting the DC1[TM] field to enable data trace
- Using the WT[DTS] field to enable data trace on watchpoint hits

##### 51.4.4.2.4.2 DTM Queueing

NXDM and NXSI implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

**NOTE**

If multiple trace messages must be queued at the same time, watchpoint messages have the highest priority (WPM → DTM).

**51.4.4.2.4.3 Relative Addressing**

The relative address feature is compliant with IEEE-ISTO Nexus 5001-2003 and is designed to reduce the number of bits transmitted for addresses of data trace messages. Relative addressing is the same as described for the NZ7C3.

**51.4.4.2.4.4 Data Trace Windowing**

Data write/read messages are enabled via the RWT1(2) field in the data trace control register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA registers and by the RC1(2) field in the DTC. All eDMA or SIPI initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

**51.4.4.2.4.5 System Bus Cycle Special Cases****Table 51-17. System Bus Cycle Special Cases**

| Special Case                               | Action                         |
|--------------------------------------------|--------------------------------|
| System bus cycle aborted (DABORT asserted) | Cycle ignored                  |
| System bus cycle with data error           | Data Trace Message discarded   |
| System bus cycle completed without error   | Cycle captured and transmitted |
| System bus cycle is an instruction fetch   | Cycle ignored                  |

**51.4.4.2.5 Data Trace Timing Diagrams (Eight MDO configuration)**

Data trace timing for the NXDM and NXSI is the same as for the NZ7C3.

**51.4.4.3 Watchpoint Support**

The NXDM and NXSI module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2003.

Watchpoint messages can be generated using the NXDM and NXSI defined internal watchpoints.

51.4.4.3.1 Watchpoint Messaging

Enabling watchpoint messaging is accomplished by setting the watchpoint messaging enable bit, DC1[WEN]. Using the BWC1 and BWC2 registers, two independently controlled internal watchpoints can be initialized. When a DMA or SIPI access address matches on BWA1 or BWA2, a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the TCODE. When either of the two possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number.

Figure 51-17. Watchpoint Message Format

Table 51-18. Watchpoint Source Description

| Watchpoint Source (4 bits) | Watchpoint Description              |
|----------------------------|-------------------------------------|
| XXX1                       | Invalid value                       |
| XX1X                       | Invalid value                       |
| X1XX                       | Internal Watchpoint #1 (BWA1 match) |
| 1XXX                       | Internal Watchpoint #2 (BWA2 match) |

51.4.4.3.2 Watchpoint Error Message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. After it is emptied, an error message is queued. The error encoding indicates which types of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (00110). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (01000).

Error information is messaged out in the following format (refer to [Figure 51-18](#)).

Figure 51-18. Error Message Format

# Chapter 52

## Nexus Port Controller (NPC)

### 52.1 Chip-specific NPC information

The NPC connects to several other Nexus modules that compose the chip's Nexus Development Interface (NDI).

For more information, see the chip-level details about debug and development support.

#### 52.1.1 DID register reset value

The reset value of the [Nexus Device ID \(DID\) Register](#) depends on the chip version.

The PRN, PIN, and DC parameters define the chip-specific values of correspondingly named fields in the DID register. The following table provides their values.

**Table 52-1. Reset values of PRN, DC, and PIN fields of DID register**

| DID field | Device-specific value                                   |
|-----------|---------------------------------------------------------|
| PRN       | 0h for masksets 1N45H and 2N45H<br>1h for maskset 3N45H |
| DC        | 20h                                                     |
| PIN       | 377h                                                    |

#### 52.1.2 NPC MDO pins

The number of available Message Data Out (MDO) pins varies by NPC mode of operation. The following table shows the number of MDO pins available in full-port mode and reduced-port mode.

Table 52-2. MDO pins available by NPC mode of operation

| Mode              | Number of available MDO pins |
|-------------------|------------------------------|
| Full-port mode    | 16                           |
| Reduced-port mode | 12                           |

52.2 Introduction

The following figure is a block diagram of the Nexus Port Controller (NPC) block.

Figure 52-1. Nexus Port Controller Block Diagram

52.2.1 Overview

On a system-on-a-chip device, there are often multiple blocks that require development support. Each of these blocks implements a development interface based on the IEEE-ISTO 5001-2001 standard. The blocks share input and output ports that interface with the development tool. The NPC controls the usage of the input and output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

## 52.2.2 Features

The NPC block performs the following functions:

- Controls arbitration for ownership of the Nexus Output Port
- Nexus Device Identification Register and Messaging
- Generates MCKO enable and frequency division control signals
- Generates a Nexus DDR mode status indication output signal
- Controls sharing of  $\overline{\text{EVTO}}$
- Generates an MCKO clock gating control signal to enable gating of MCKO when the auxiliary output port is idle
- Control of the device-wide debug mode
- Generates asynchronous reset signal for Nexus blocks based on JCOMP input, censorship status, and power-on reset status
- Selectable mode for transmission of processor status information on MDO Auxiliary Output Port pins
- System clock status indication via MDO[0] following power-on reset
- Provides Nexus support for censorship mode

## 52.2.3 Modes of operation

The NPC block uses the JCOMP input, the censorship status signal and an internal power-on reset indication as its primary reset signals. Upon exit of reset, the mode of operation is determined by the Port Configuration Register (PCR) settings.

### 52.2.3.1 Reset

The NPC block is asynchronously placed in reset when either power-on reset is asserted, JCOMP is not set for Nexus access, the device enters censored mode, or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Following negation of power-on reset, the NPC remains in reset until the system clock achieves lock. The NPC is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The output port pins are negated
- The TDI, TMS, and TCK TAP inputs are ignored (when in power-on reset, censored mode or JCOMP not set for NPC operation only)
- Registers default back to their reset values

### **52.2.3.2 Disabled-Port Mode**

In disabled-port mode, output pin port enable signals are negated, thereby disabling message transmission. Any debug feature that generates messages can not be used. The primary features available are class 1 features and read/write access to the registers. Class 1 features include the ability to trigger a breakpoint event indication through EVTO.

### **52.2.3.3 Full-Port Mode**

Full-port mode (FPM) is entered by asserting the MCKO\_EN and FPM bits in the PCR. In All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

### **52.2.3.4 Reduced-Port Mode**

Reduced-port mode (RPM) is entered by asserting the MCKO\_EN bit and negating the FPM bit in the PCR. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific.

### **52.2.3.5 Censored Mode**

In censored mode, it should not be possible to read the contents of internal Flash externally. The NPC and all other Nexus blocks are held in reset when in censored mode , preventing Nexus read/write to memory mapped resources and the transmission of Nexus trace messages.

### 52.2.3.6 Nexus Double Data Rate Mode

Nexus double data rate (DDR) mode is enabled by asserting the DDR\_EN bit in the PCR. DDR mode is only supported for MCKO\_DIV settings of sys\_clk/2, sys\_clk/4 and sys\_clk/8. In double data rate mode, message data is updated between each edge (both rising and falling) of MCKO, effectively doubling the message throughput of single data rate mode.

## 52.3 External signal description

### 52.3.1 Overview

The NPC pin interface provides for the transmission of messages from Nexus blocks to the external development tools and for access to Nexus client registers. The NPC pin definition is outlined in the following table. Pull information for the JTAG signals can be found in the JTAG chapter.

**Table 52-3. NPC Signal Properties**

| Name   | Port      | Function                                | Reset State         |
|--------|-----------|-----------------------------------------|---------------------|
| EVTO_B | Nexus     | Event Out pin                           | 0b1                 |
| JCOMP  | JTAG      | JTAG Compliancy and TAP Sharing Control | —                   |
| MDO    | Auxiliary | Message Data Out pins                   | 0 <sup>1</sup>      |
| MSEO   | Auxiliary | Message Start/End Out pins              | 0b11                |
| TCK    | JTAG      | Test Clock Input                        | —                   |
| TDI    | JTAG      | Test Data Input                         | —                   |
| TDO    | JTAG      | Test Data Output                        | High Z <sup>2</sup> |
| TMS    | JTAG      | Test Mode Select Input                  | —                   |

1. Following a power-on reset, MDO[0] remains asserted until power-on reset is exited and the system clock achieves lock.
2. TDO output buffer enable is negated when the NPC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented on TDO at the SoC level.

### 52.3.2 Detailed signal descriptions

This section describes each of the signals listed in [Table 52-3](#) in more detail. Note that the JTAG test clock (TCK) input from the pin is not a direct input to the NPC. The NPC requires two separate input clocks for TCK clocked logic, one for posedge (rising edge TCK) logic and one for negedge (falling edge TCK) logic. Both clocks are derived from the pin TCK, and generated external to the NPC.

### 52.3.2.1 EVTO\_B — Event Out

Event Out ( $\overline{\text{EVTO}}$ ) is an output pin that is asserted upon breakpoint occurrence to provide breakpoint status indication. The  $\overline{\text{EVTO}}$  output of the NPC is generated based on the values of the individual  $\overline{\text{EVTO}}$  signals from all Nexus blocks that implement the signal.

### 52.3.2.2 JCOMP — JTAG Compliancy

The JCOMP signal provides the ability to share the TAP. The NPC TAP controller remains in reset until it is enabled using the JCOMP signal.

### 52.3.2.3 MDO — Message Data Out

Message Data Out (MDO) are output pins used for uploading OTM, BTM, DTM, and other messages to the development tool. The development tool should sample MDO on the rising edge of MCKO. The width of the MDO bus used is determined by reset configuration.

### 52.3.2.4 MSEO\_B — Message Start/End Out

Message Start/End Out ( $\overline{\text{MSEO}}$ ) is an output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool should sample  $\overline{\text{MSEO}}$  on the rising edge of MCKO.

### 52.3.2.5 TCK — Test Clock Input

Test Clock Input (TCK) pin is used to synchronize the test logic and control register access through the JTAG port.

### 52.3.2.6 TDI — Test Data Input

Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK.

### 52.3.2.7 TDO — Nexus Test Data Output

Test Data Output (TDO) pin transmits serial output for instructions and data. TDO is three-stateable and is actively driven in the SHIFT-IR and SHIFT-DR controller states. TDO is updated on the falling edge of TCK and sampled by the development tool on the rising edge of TCK.

### 52.3.2.8 TMS — Test Mode Select

Test Mode Select Input (TMS) pin is used to sequence the IEEE 1149.1-2001 TAP controller state machine. TMS is sampled on the rising edge of TCK.

## 52.4 Register definition

This section provides a detailed description of the NPC registers accessible to the end user. Individual bit-level descriptions and reset states of the registers are included.

The following table shows the NPC registers by index values. The registers are not memory-mapped and can only be accessed via the TAP. The NPC block does not implement the client select control register because the value does not matter when accessing the registers.

Note that the bypass and instruction registers have no index values. These registers are not accessed in the same manner as Nexus client registers. Refer to the individual register descriptions for more detail.

**Table 52-4. NPC registers**

| Index | Register                          |
|-------|-----------------------------------|
| 0     | Device ID Register (DID)          |
| 127   | Port Configuration Register (PCR) |

### 52.4.1 Register descriptions

This section consists of NPC register descriptions.

### 52.4.1.1 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS instruction or any unimplemented instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

### 52.4.1.2 Instruction register

The NPC block uses a 4-bit instruction register as shown in the following table. The instruction register is accessed via the SELECT\_IR\_SCAN path of the tap controller state machine, and allows instructions to be loaded into the block to enable the NPC for register access (NEXUS\_ENABLE) or select the bypass register as the shift path from TDI to TDO (BYPASS or unimplemented instructions).

Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in synchronous loading of the BYPASS instruction. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the BYPASS instruction. During the Capture-IR TAP controller state, the instruction register is loaded with the value of the previously executed instruction, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

|        |                                 |   |   |   |
|--------|---------------------------------|---|---|---|
|        | 3                               | 2 | 1 | 0 |
| R      | Previous Instruction Opcode     |   |   |   |
| W      | Instruction Opcode              |   |   |   |
| Reset: | BYPASS Instruction Opcode (0xF) |   |   |   |

### 52.4.1.3 Nexus Device ID (DID) Register

The device identification register, shown in the following figure, allows the part revision number, design center, part identification number, and manufacturer identity code of the part to be determined through the output port.

**Table 52-7. DID field descriptions**

| Bit   | Name    | Description                                                                                                                     |
|-------|---------|---------------------------------------------------------------------------------------------------------------------------------|
| 31:28 | PRN     | Part Revision Number<br>These bits contain the revision number of the part                                                      |
| 27:22 | DC      | Design Center<br>These bits indicate the device design center                                                                   |
| 21:12 | PIN     | Part Identification Number<br>These bits contain the part number of the device                                                  |
| 11:1  | MIC     | Manufacturer Identity Code<br>These bits contain the reduced Joint Electron Device Engineering Council (JEDEC) ID for NXP, 0xE. |
| 0     | Bit [0] | IDCODE Register ID<br>Bit [0] identifies this register as the device identification register and not the bypass register        |

## 52.4.1.4 Port Configuration Register (PCR)

| Register index: 127 |          |                 |                 |          |    |    |          |          |          |    |    |    |          |    |    |              |
|---------------------|----------|-----------------|-----------------|----------|----|----|----------|----------|----------|----|----|----|----------|----|----|--------------|
|                     | 31       | 30              | 29              | 28       | 27 | 26 | 25       | 24       | 23       | 22 | 21 | 20 | 19       | 18 | 17 | 16           |
| R                   | FPM      | MCK<br>O_G<br>T | MCK<br>O_E<br>N | MCKO_DIV |    |    | Reserved | DDR_EN   | Reserved | 0  | 0  | 0  | Reserved |    | 0  | 0            |
| W                   |          |                 |                 |          |    |    |          |          |          |    |    |    |          |    |    |              |
| Reset               | 0        | 0               | 0               | 0        | 0  | 0  | 0        | 0        | 0        | 0  | 0  | 0  | 0        | 0  | 0  | 0            |
|                     | 15       | 14              | 13              | 12       | 11 | 10 | 9        | 8        | 7        | 6  | 5  | 4  | 3        | 2  | 1  | 0            |
| R                   | Reserved | 0               | 0               | 0        | 0  | 0  | Reserved | Reserved | 0        | 0  | 0  | 0  | 0        | 0  | 0  | PSTA<br>T_EN |
| W                   |          |                 |                 |          |    |    |          |          |          |    |    |    |          |    |    |              |
| Reset               | 0        | 0               | 0               | 0        | 0  | 0  | 0        | 0        | 0        | 0  | 0  | 0  | 0        | 0  | 0  | 0            |

The PCR, shown in the figure above, is used to select the NPC mode of operation, enable MCKO and select the MCKO frequency, and enable or disable MCKO gating. This register should be configured as soon as the NPC is enabled.

### NOTE

The mode or clock division must not be modified after MCKO has been enabled. Changing the mode or clock division while MCKO is enabled can produce unpredictable results.

**Table 52-9. PCR field descriptions**

| Bit | Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                    |

## 52.5 Functional Description

### 52.5.1 NPC reset configuration

The NPC is placed in disabled mode upon exit of reset. If message transmission via the output port is desired, a write to the PCR is then required to enable the NPC and select the mode of operation. Asserting MCKO\_EN places the NPC in enabled mode and enables MCKO. The frequency of MCKO is selected by writing the MCKO\_DIV field. Asserting or negating the FPM bit selects full-port or reduced-port mode, respectively.

The following table describes the NPC reset configuration options.

**Table 52-11. NPC reset configuration options**

| Power On Reset status asserted? | JCOMP asserted high | MCKO_EN bit of the Port Configuration Register | FPM bit of the Port Configuration Register | Configuration     |
|---------------------------------|---------------------|------------------------------------------------|--------------------------------------------|-------------------|
| yes                             | x                   | X                                              | X                                          | Reset             |
| no                              | no                  | X                                              | X                                          | Reset             |
| no                              | yes                 | 0                                              | X                                          | Disabled          |
| no                              | yes                 | 1                                              | 1                                          | Full-Port Mode    |
| no                              | yes                 | 1                                              | 0                                          | Reduced-Port Mode |

### 52.5.2 Auxiliary Output Port

The auxiliary output port is shared by each of the Nexus modules on the device. The NPC communicates with each of the Nexus modules and arbitrates for access to the port.

#### 52.5.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the  $\overline{\text{MSEO}}$  functions. The  $\overline{\text{MSEO}}$  pins are used to signal the end of variable-length packets and the end of messages. They are not required to indicate the end of fixed-length packets. MDO and  $\overline{\text{MSEO}}$  are sampled on the rising edge of MCKO.

The following figure illustrates the state diagram for  $\overline{\text{MSEO}}$  transfers. All transitions not included in the figure are reserved, and must not be used.

Figure 52-2.  $\overline{\text{MSEO}}$  Transfers (for 2-bit  $\overline{\text{MSEO}}$ )

### 52.5.2.2 Output Messages

In addition to sending out messages generated in other Nexus blocks, the NPC can also output the device ID message contained in the device ID register on the MDO pins. The device ID message can also be sent out serially through TDO.

Figure 52-3 describes the device ID output message that the NPC can transmit on the auxiliary port. The TCODE is the first packet transmitted.

| Message Name      | Min. Packet Size (bits) | Max Packet Size (bits) | Packet Type | Packet Name | Packet Description    |
|-------------------|-------------------------|------------------------|-------------|-------------|-----------------------|
| Device ID Message | 6                       | 6                      | fixed       | TCODE       | Value = 1             |
|                   | 32                      | 32                     | fixed       | ID          | DID register contents |

Figure 52-3. NPC output messages

### 52.5.2.3 Rules of Message

- A variable-sized field within a message must end on a port boundary. (Port boundaries depend on the number of MDO pins active with the current reset configuration.)
- A variable-sized field may start within a port boundary only when following a fixed-length field.
- Super-fields must end on a port boundary.
- When a variable-length field is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary.
- Multiple fixed-length packets may start and/or end on a single clock.
- When any packet follows a variable-length packet, it must start on a port boundary.
- The field containing the TCODE number is always transferred out first, followed by subsequent fields of information.
- Within a field, the lowest significant bits are shifted out first. The following figure shows the transmission sequence of a message that is made up of a TCODE followed by two fields.

Figure 52-4. Transmission Sequence of Messages

### 52.5.3 IEEE 1149.1-2001 (JTAG) TAP

The NPC block uses the IEEE 1149.1-2001 test access port (TAP) for accessing registers. Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers as well. TAP signals include TCK, TDI, TMS, and TDO. There may also be other blocks on the MCU that use the TAP and implement a TAP controller.

Refer to the IEEE 1149.1-2001 specification for further detail on electrical and pin protocol compliance requirements.

The NPC implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1-2001 state machine shown in [Figure 52-6](#). The Nexus controller state machine is defined by the IEEE-ISTO 5001-2001 standard. It is shown in [Figure 52-7](#).

The instructions implemented by the NPC TAP controller are listed in the following table. The value of the NEXUS-ENABLE instruction is 0b0000. Each unimplemented instruction acts like the BYPASS instruction. The size of the NPC instruction register is 4 bits.

**Table 52-12. Implemented Instructions**

| Instruction Name | Private/Public | Opcode | Description                                                                       |
|------------------|----------------|--------|-----------------------------------------------------------------------------------|
| NEXUS-ENABLE     | public         | 0x0    | Activate Nexus controller state machine to read and write NPC registers.          |
| BYPASS           | private        | 0xF    | NPC BYPASS instruction. Also the value loaded into the NPC IR upon exit of reset. |

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

**Figure 52-5. Shifting Data Into Register**

### 52.5.3.1 Enabling the NPC TAP controller

Assertion of the power-on reset signal or entry into censored mode or setting JCOMP to a value other than the NPC enable encoding resets the NPC TAP controller. When not in power-on reset or censored mode, the NPC TAP controller is enabled by driving JCOMP with the NPC enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

NOTE: The value shown adjacent to each state transition in this figure represents the value of TMS at the time of a rising edge of TCK.

**Figure 52-6. IEEE 1149.1-2001 TAP Controller State Machine**

### 52.5.3.2 Retrieving device IDCODE

The Nexus TAP controller does not implement the IDCODE instruction. However, the device identification message can be output by the NPC through the output port or shifted out serially by accessing the Nexus Device ID register through the TAP.

Transmission of the device identification message on the auxiliary output port MDO pins occurs immediately after a write to the PCR, if the NPC is enabled for auxiliary port mode. Transmission of the device identification message serially via the TAP is achieved by performing a read of the register contents as described in [Selecting a Nexus Client Register](#).

### 52.5.3.3 Loading NEXUS-ENABLE Instruction

Access to the NPC registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in [Figure 52-7](#), transitions to the REG\_SELECT state. The Nexus controller has three states: idle, register select, and data access. [Table 52-13](#) illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

**Figure 52-7. NEXUS Controller State Machine**

**Table 52-13. Loading NEXUS-ENABLE instruction**

| Clock | TMS | IEEE 1149.1 State | Nexus State | Description                                      |
|-------|-----|-------------------|-------------|--------------------------------------------------|
| 0     | 0   | RUN-TEST/IDLE     | IDLE        | IEEE 1149.1-2001 TAP controller in idle state    |
| 1     | 1   | SELECT-DR-SCAN    | IDLE        | Transitional state                               |
| 2     | 1   | SELECT-IR-SCAN    | IDLE        | Transitional state                               |
| 3     | 0   | CAPTURE-IR        | IDLE        | Internal shifter loaded with current instruction |

*Table continues on the next page...*

**Table 52-13. Loading NEXUS-ENABLE instruction  
(continued)**

| Clock  | TMS | IEEE 1149.1 State | Nexus State | Description                                                                                                                   |
|--------|-----|-------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| 4      | 0   | SHIFT-IR          | IDLE        | TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction. |
| 3 TCKS |     |                   |             |                                                                                                                               |

| 9      | 1   | UPDATE-IR         | IDLE        | NEXUS-ENABLE loaded into instruction register                                                                                 |
| 10     | 0   | RUN-TEST/IDLE     | REG_SELECT  | Ready to be read/write Nexus registers                                                                                        |

### 52.5.3.4 Selecting a Nexus Client Register

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows development tool access to all Nexus registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus Controller defaults to the REG\_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following table. The read/write control bit is set to 1 for writes and 0 for reads.

| MSB                  | LSB |
|----------------------|-----|
| 7-bit register index | R/W |

**Figure 52-8. IEEE 1149.1 Controller Command Input**

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the JTAG shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register.

**Table 52-14. Write to a 32-Bit Nexus Client Register**

| Clock   | TMS | IEEE 1149.1 State | Nexus State | Description                                                                                          |
|---------|-----|-------------------|-------------|------------------------------------------------------------------------------------------------------|
| 0       | 0   | RUN-TEST/IDLE     | REG_SELECT  | IEEE 1149.1-2001 TAP controller in idle state                                                        |
| 1       | 1   | SELECT-DR-SCAN    | REG_SELECT  | First pass through SELECT-DR-SCAN path                                                               |
| 2       | 0   | CAPTURE-DR        | REG_SELECT  | Internal shifter loaded with current value of controller command input.                              |
| 3       | 0   | SHIFT-DR          | REG_SELECT  | TDO becomes active, and write bit and 6 bits of register index shifted in.                           |
| 7 TCKs  |     |                   |             |                                                                                                      |
| 11      | 1   | EXIT1-DR          | REG_SELECT  | Last bit of register index shifted into TDI                                                          |
| 12      | 1   | UPDATE-DR         | REG_SELECT  | Controller decodes and selects register                                                              |
| 13      | 1   | SELECT-DR-SCAN    | DATA_ACCESS | Second pass through SELECT-DR-SCAN path                                                              |
| 14      | 0   | CAPTURE-DR        | DATA_ACCESS | Internal shifter loaded with current value of register                                               |
| 15      | 0   | SHIFT-DR          | DATA_ACCESS | TDO becomes active, and outputs current value of register while new value is shifted in through TDI  |
| 31 TCKs |     |                   |             |                                                                                                      |
| 47      | 1   | EXIT1-DR          | DATA_ACCESS | Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.                     |
| 48      | 1   | UPDATE-DR         | DATA_ACCESS | Value written to register                                                                            |
| 49      | 0   | RUN-TEST/IDLE     | REG_SELECT  | Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register. |

## 52.5.4 Nexus JTAG Port Sharing

Each of the individual Nexus blocks on the device implements a TAP controller for accessing its registers. When Nexus has ownership of the TAP, only the block whose NEXUS-ENABLE instruction is loaded has control of the TAP. This allows the interface to all of these individual TAP controllers to appear to be a single port from outside the device. If no register is selected as the shift path for a Nexus block, that block acts like a single-bit shift register, or bypass register.

## 52.5.5 MCKO Control

MCKO is an output clock to the development tools used for the timing of  $\overline{\text{MSE0}}$  and MDO pin functions. MCKO is derived from the system clock and its frequency is determined by the value of the MCKO\_DIV field in the PCR. Possible operating frequencies include system clock, one-half system clock, one-quarter system clock, and one-eighth system clock speed.

The NPC also generates an MCKO clock gating control output signal. This output can be used by the MCKO generation logic to gate the transmission of MCKO when the auxiliary port is enabled but not transmitting messages. The setting of the MCKO\_GT bit inside the PCR determines whether or not MCKO gating control is active. The MCKO\_GT bit resets to a logic 0. In this state gating of MCKO is disabled. To enable gating of MCKO, the MCKO\_GT bit in the PCR is written to a logic 1.

### 52.5.6 $\overline{\text{EVTO}}$ Sharing

The NPC block controls sharing of the  $\overline{\text{EVTO}}$  output between all Nexus clients that produce an  $\overline{\text{EVTO}}$  signal. The NPC assumes incoming  $\overline{\text{EVTO}}$  signals will be asserted for one system clock period. After receiving a single clock period of asserted  $\overline{\text{EVTO}}$  from any Nexus client, the NPC latches the result, and drives  $\overline{\text{EVTO}}$  for one MCKO period on the following clock. When there is no active MCKO, such as in disabled mode, the NPC drives  $\overline{\text{EVTO}}$  for two system clock periods.  $\overline{\text{EVTO}}$  sharing is active as long as the NPC is not in reset.

### 52.5.7 Nexus Reset Control

The JCOMP input that is used as the primary reset signal for the NPC is also used by the NPC to generate a single-bit reset signal for other Nexus blocks. If JCOMP is negated, an internal reset is asserted, indicating that all Nexus modules should be held in reset. Internal Nexus reset is also asserted when the device is in censored mode.

### 52.5.8 System Clock Locked Indication

Following a power-on reset, MDO[0] can be monitored to provide the lock status of the system clock. MDO[0] is driven to a logic 1 until the system clock achieves lock after exiting power-on reset. Once the system clock is locked, MDO[0] is negated and tools may begin Nexus configuration. Loss of lock conditions that occur subsequent to the exit of power-on reset and the initial lock of the system clock do not cause a Nexus reset, and therefore do not result in MDO[0] driven high.

## 52.6 Initialization/Application Information

### 52.6.1 Accessing NPC tool-mapped registers

To initialize the TAP for Nexus register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Load the TAP controller with the NEXUS-ENABLE instruction

To write control data to NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select the register with a pass through the SELECT-DR-SCAN path in the TAP controller state machine.
2. Write the register value with a second pass through the SELECT-DR-SCAN path. Note that the prior value of this register is shifted out during the write.

To read status and control data from NPC tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear the write bit to select register with a pass through SELECT-DR-SCAN path in the TAP controller state machine.
2. Read the register value with a second pass through the SELECT-DR-SCAN path. Data shifted in is ignored.

See the IEEE-ISTO 5001-2001 standard for more detail.

# Chapter 53

## Nexus eTPU Development Interface (NDEDI)

### 53.1 Chip-specific NDEDI information

This chip contains two Nexus eTPU Development Interface modules.

- A dual NDEDI covers eTPU\_A and eTPU\_B. The NDEDI's ENGINE1 corresponds to eTPU\_A and ENGINE2 corresponds to eTPU\_B.
- A single Nexus eTPU Development Interface (NSEDI) covers eTPU\_C. The single interface has the same features as the NDEDI but is for a single eTPU engine.

Each interface also includes a coherent dual-parameter controller (CDC) for coherent access to eTPU parameters. In each interface, the eTPU modules and CDC unit appear as separate Nexus clients.

#### 53.1.1 NDEDI/NSEDI device-specific parameters

The following table provides the chip-specific parameter values of the NDEDI module and NSEDI module. Each parameter has a placeholder "variable" name that appears in the detailed NDEDI description.

**Table 53-1. Device-specific parameters**

| Parameter                  | Variable name | Description                                                                                                                          | NDEDI value | NSEDI value |
|----------------------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------|-------------|-------------|
| Full-Port Mode MDO pins    | N             | Number of MDO pins used for message transmission in full-port mode: This value is the same for all Nexus blocks sharing the port.    | 16d         | 16d         |
| Reduced-Port Mode MDO pins | J             | Number of MDO pins used for message transmission in reduced-port mode: This value is the same for all Nexus blocks sharing the port. | 12d         | 12d         |
| SRC Packet size            | K             | Number of bits used for the SRC packet in messages                                                                                   | 4d          | 4d          |

*Table continues on the next page...*

**Table 53-1. Device-specific parameters (continued)**

| Parameter                  | Variable name   | Description                                                                 | NDEDI value | NSEDI value |
|----------------------------|-----------------|-----------------------------------------------------------------------------|-------------|-------------|
| HIST Packet size           | H               | Number of bits used for the HIST packet in messages                         | 26d         | 26d         |
| Queue size                 | Q_SIZE          | Depth of the event queue used to store events before transmission           | 32d         | 32d         |
| Stall Threshold            | STALL_THRESHOLD | Number of spots within the queue used as a threshold to delay the processor | 7d          | 7d          |
| ENGINE1 SRC value          | ENGINE1_SRC     | SRC packet value for messages generated by ENGINE1                          | 2h          | Ah          |
| ENGINE2 SRC value          | ENGINE2_SRC     | SRC packet value for messages generated by ENGINE2                          | 3h          | —           |
| CDC SRC value              | CDC_SRC         | SRC packet value for messages generated by the CDC                          | 4h          | Ch          |
| Manufacturer ID            | DID_MIC         | Manufacturer code used in the DID register                                  | Eh          | Eh          |
| Design Center ID           | DID_DC          | Design center code used in the DID register                                 | 20h         | 20h         |
| Part Revision Number       | DID_PRN         | Part revision number used in the DID register                               | 4h          | 4h          |
| Part Identification Number | DID_PIN         | Part identification number used in the DID register                         | 224h        | 124h        |

## 53.2 Introduction

The Nexus ETPU Development Interface (NDEDI) provides real-time development capabilities for the ETPU system including two engines and the coherent dual-parameter controller (CDC) in compliance with the IEEE-ISTO 5001-2002 standard. The NDEDI interfaces to the ETPU via dedicated trace busses. The main development features supported are breakpoint/watchpoint configuration, debug mode register access, enter debug mode at reset negation or during normal execution, single stepping of instructions, branch trace, data trace, ownership trace, and watchpoint trace. Combined, these features make the interface for each engine compliant with Class 3 of the IEEE-ISTO 5001-2002 standard.

Both engines have their own Nexus register sets that allows trace to be set up independently for each of them. The only exception to this is the data trace address range registers that are shared. All the registers are accessed via the JTAG port. Output messages between the engines and other sources are differentiated by the value of the SRC packet in the output messages.

The NDEDI block is combined with similar blocks for other intelligent peripherals, a read/write access block, and a Nexus Port Controller block to provide the complete IEEE-ISTO 5001-2002 interface for a system-on-a-chip design. The JTAG port and Nexus auxiliary port pins are shared by all of the Nexus based blocks on the chip.

### 53.3 Features

The NDEDI block is compliant with the IEEE-ISTO 5001-2002 standard, and implements the following features:

- Full duplex pin interface for medium and high visibility throughput
  - Pin interface shared among all Nexus-based development interfaces on the device
  - One of two modes selected during reset: full-port mode (FPM) and reduced-port mode (RPM)
- Auxiliary Output Port
  - 1 MCKO (Message Clock Out) pin
  - MDO (Message Data Out) port (port size is SoC specific)
  - 2  $\overline{\text{MSEO}}$  (Message Start/End Out) pins
  - 1  $\overline{\text{EVTO}}$  (Event Out) pin
- Auxiliary Input Port
  - 1  $\overline{\text{EVTI}}$  (Event In) pin
- IEEE 1149.1 (JTAG) Test Access Port (TAP)
  - Support for optional Multi-JTAG TAP Linking Module (TLM)
  - 4 pins (TDI, TDO, TMS, and TCK)
  - Reset input  $\overline{\text{TRST}}$  driven by either the Nexus Port Controller or an external pin
- ETPU Development Support
  - IEEE-ISTO 5001-2002 standard class 3 compliant for both engines
  - Read/Write registers in debug mode
  - Ability to enter debug mode at reset negation or during normal execution

- Ability to single step an instruction and re-enter debug mode
- Breakpoint and Watchpoint Configuration
- Execute external microcode instructions in debug mode providing indirect read/write accesses to ETPU registers
- Read the microprogram counter in debug mode
- Change the microprogram counter by executing external microcode instructions in debug mode
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This allows the development tool to trace reads and writes to selected shared parameter RAM (SPRAM) address ranges
  - Four data trace windows with programmable address ranges and access attributes are provided. Data trace windowing reduces the requirement on the auxiliary port bandwidth by constraining the number of trace locations. The four trace window address ranges are shared among the dual engines and the ETPU Coherent Dual-Parameter Controller (CDC)
- Ownership Trace via Ownership Trace Messaging (OTM). OTM provides visibility of which channel is being serviced. An ownership trace message is transmitted to indicate when a new channel service request is scheduled, allowing the development tools to trace task flow. A special OTM is sent when the engine enters in idle, meaning that all requests were serviced and no new requests are yet scheduled
- Program Trace via Branch Trace Messaging (BTM). BTM displays program flow discontinuities (start, jump, return, etc....), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced
  - Public messages are used for jump, and return instructions
  - Private messages are used to indicate special ETPU cases not covered by public messages. These messages include the writes to the channel register, the start of a channel service and the trace enabling after a watchpoint hit
  - Branch/Predicate History is kept on direct branches (taken and not taken) and predicated instructions (executed or not executed) to minimize the number of messages transmitted
- Watchpoint Messaging (WPM) via the auxiliary port. WPM provides visibility of the occurrence of the ETPUs' watchpoints

- Event Queue Interface. The Event Queue array is located external to the NDEDI block to separate hard and soft IP. The depth of the Event Queue is specified in the SoC Guide
- Read/Write Access functions are provided on the device level by a block separate from the NDEDI block

## 53.4 Modes of operation

### 53.4.1 Reset

The NDEDI block is placed in reset when Nexus is reset, or the TAP controller state machine is in the Test-Logic-Reset state. Holding TMS high for 5 consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Nexus reset results in asynchronous entry into the reset state. The NDEDI is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state
- The auxiliary output port pins are negated
- The auxiliary output port enable outputs are negated
- The TDI, TMS, and TCK TAP inputs are ignored
- Registers default back to their reset values

Note that the NDEDI is not reset by the system reset signal. The system reset signal is used though to make ETPU entering in debug mode from reset condition and to synchronize Program Trace and Data Trace messages.

### 53.4.2 Disabled-port mode

In disabled-port mode, auxiliary output pin port enable signals are negated, thereby disabling message transmission. Thus, the NDEDI class 3 features are not available in this mode. The primary features available are class 1 features and read/write access to the registers.

### 53.4.3 Full-port mode

Full-port mode (FPM) is determined by the chip Nexus configuration. See the chip-specific NPC information. In full-port mode, the block is enabled and the FPM port enable is asserted indicating that all available MDO pins are to be used for message transmission. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific. Refer to the SoC guide for this information.

### 53.4.4 Reduced-port mode

Reduced-port mode (RPM) is determined by the chip Nexus configuration. See the chip-specific NPC information. In reduced-port mode, the block is enabled and the RPM port enable is asserted indicating that only a subset of the MDO pins are to be used for message transmission. All trace features are enabled or can be enabled by writing the configuration registers via the TAP. The number of MDO pins available is device-specific. Refer to the SoC guide for this information.

### 53.4.5 Stop mode

The NDEDI supports the IPI Green-Line Interface stop mode mechanism. When a request is made to enter stop mode, the NDEDI block waits for the ETPU to acknowledge the stop condition so no trace information is lost. The NDEDI then completes transmitting all pending messages, emptying the Event Queue. Finally, NDEDI transmits a debug status message to indicate it is entering stop mode, and if Program Trace is enabled it will send a correlation message. Refer to [Functional description](#) for further information about the messages. After this is completed, the request to enter stop mode is acknowledged. No breakpoint requests are sent to the engines while they are in stop mode. After the acknowledgement, the system clock input may be shut off by the clock driver on the device. While the clocks are shut off, the development tool must not access NDEDI registers via the JTAG test access port.

## 53.5 External signal description

The following section describes the External Signal description.

## 53.5.1 Overview

The NDEDI pin provides interface for the transmission of messages and for accessing Nexus registers. The NDEDI pin definition is outlined in the following table.

**Table 53-2. NDEDI signal properties**

| Name                            | Port      | Function                         | Reset State | Pull <sup>1</sup> |
|---------------------------------|-----------|----------------------------------|-------------|-------------------|
| EVT $\overline{\text{I}}$       | Auxiliary | Event In pin                     | —           | Up                |
| EVT $\overline{\text{O}}$       | Auxiliary | Event Out pin                    | 1           | —                 |
| MCKO                            | Auxiliary | Message Clock Out pin (from NPC) | —           | —                 |
| MDO[J-1:0]<br>or<br>MDO[N-1:0]  | Auxiliary | Message Data Out pins            | 0           | —                 |
| MSE $\overline{\text{O}}$ [1:0] | Auxiliary | Message Start/End Out pins       | 0b11        | —                 |
| TCK                             | TAP       | Test Clock Input                 | —           | —                 |
| TDI                             | TAP       | Test Data Input                  | —           | Up                |
| TDO                             | TAP       | Test Data Output                 | 0           | —                 |
| TMS                             | TAP       | Test Mode Select Input           | —           | Up                |
| TRST                            | TAP       | Test Reset Input                 | —           | Up                |

1. The pull is not implemented in this block. Refer to the SoC guide for more details.

## 53.5.2 Detailed signal descriptions

This section describes each of the signals listed in the preceding table in more detail.

### 53.5.2.1 $\overline{\text{EVTI}}$ - Event In

Event In ( $\overline{\text{EVTI}}$ ) is used to initiate program and data trace synchronization messages or to generate a breakpoint.  $\overline{\text{EVTI}}$  is edge-sensitive for synchronization and breakpoint generation.

### 53.5.2.2 $\overline{\text{EVTO}}$ - Event Out

Event Out ( $\overline{\text{EVTO}}$ ) is an output pin to development tools comprising exact timing for a single watchpoint or breakpoint occurrence.  $\overline{\text{EVTO}}$  is asserted for 1 MCKO clock<sup>1</sup>.

1. NDEDI asserts The EVTO indication for 1 system clock.

### 53.5.2.3 MCKO - Message Clock Out

Message Clock Out (MCKO) is an output clock to the development tools used for the timing of MDO and  $\overline{\text{MSEO}}$  pin functions. The frequency of MCKO is determined by the NPC block. Refer to the NPC BG for more information.

The MCKO signal is generated external to the NDEDI block but is included in this document for functional clarity. An input is provided to this block to keep logic synchronized to MCKO.

### 53.5.2.4 MDO - Message Data Out

Message Data Out (MDO) are output pins used for uploading messages to the development tool. The development tool must sample MDO on the rising edge of MCKO. The width of the MDO bus is determined by the Nexus full port mode configuration. See the chip-specific NPC information for further information.

### 53.5.2.5 MSEO[1:0] - Message Start/End Out

Message Start/End Out ( $\overline{\text{MSEO}}$ ) is an output pin that indicates when a message on the MDO pins has started, when a variable length packet has ended, or when the message has ended. The development tool must latch  $\overline{\text{MSEO}}$  on the rising edge of MCKO.

### 53.5.2.6 TCK - Test Clock Input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the JTAG port.

### 53.5.2.7 TDI - Test Data Input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

### 53.5.2.8 TDO - Test Data Output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is actively driven in the 'SHIFT-IR' and 'SHIFT-DR' states of the JTAG state machine. TDO changes on the falling edge of TCK and is sampled on the rising edge of TCK.

### 53.5.2.9 TMS - Test Mode Select

Test Mode Select (TMS) is an input pin used to sequence the JTAG state machine. TMS is sampled on the rising edge of TCK.

### 53.5.2.10 $\overline{\text{TRST}}$ - Test Reset Input

The Test Reset Input is used to asynchronously reset the NDEDI block and initialize the JTAG controller. This signal can be generated in the Nexus Port Controller or driven by an external pin. Refer to the SoC Guide for more information.

## 53.6 Register definition

This section provides a detailed description of all NDEDI registers accessible to the development tool. Individual bit-level descriptions and reset states of each register are included.

The following table shows the NDEDI registers by client select and index values. These registers are not memory-mapped and can only be accessed via the TAP.

**Table 53-3. NDEDI Registers**

| CS                               | Index | Register                                                     |
|----------------------------------|-------|--------------------------------------------------------------|
| Client-Independent Registers     |       |                                                              |
| X                                | 0     | Device Identity (DID)                                        |
| X                                | 1     | Client Select Control (CSC)                                  |
| ENGINE1 Control/Status Registers |       |                                                              |
| ENGINE1_SRC                      | 2     | ENGINE1 Development Control (NDEDI_ENGINE1_DC)               |
| ENGINE1_SRC                      | 4     | ENGINE1 Development Status (NDEDI_ENGINE1_DS)                |
| ENGINE1_SRC                      | 11    | ENGINE1 Watchpoint Trigger (NDEDI_ENGINE1_WT)                |
| ENGINE1_SRC                      | 13    | ENGINE1 Data Trace Control (NDEDI_ENGINE1_DTC)               |
| ENGINE1_SRC                      | 22    | ENGINE1 Breakpoint/Watchpoint Control 1 (NDEDI_ENGINE1_BWC1) |
| ENGINE1_SRC                      | 23    | ENGINE1 Breakpoint/Watchpoint Control 2 (NDEDI_ENGINE1_BWC2) |

*Table continues on the next page...*

**Table 53-3. NDEDI Registers (continued)**

| CS                                                  | Index | Register                                                     |
|-----------------------------------------------------|-------|--------------------------------------------------------------|
| ENGINE1_SRC                                         | 24    | ENGINE1 Breakpoint/Watchpoint Control 3 (NDEDI_ENGINE1_BWC3) |
| ENGINE1_SRC                                         | 30    | ENGINE1 Breakpoint/Watchpoint Address 1 (NDEDI_ENGINE1_BWA1) |
| ENGINE1_SRC                                         | 31    | ENGINE1 Breakpoint/Watchpoint Address 2 (NDEDI_ENGINE1_BWA2) |
| ENGINE1_SRC                                         | 38    | ENGINE1 Breakpoint/Watchpoint Data 1 (NDEDI_ENGINE1_BWD1)    |
| ENGINE1_SRC                                         | 39    | ENGINE1 Breakpoint/Watchpoint Data 2 (NDEDI_ENGINE1_BWD2)    |
| ENGINE1_SRC                                         | 64    | ENGINE1 Program Trace Channel Enable (NDEDI_ENGINE1_PTCE)    |
| ENGINE1_SRC                                         | 69    | ENGINE1 Microinstruction Debug Register (NDEDI_ENGINE1_INST) |
| ENGINE1_SRC                                         | 70    | ENGINE1 Microinstruction Program Counter (NDEDI_ENGINE1_MPC) |
| ENGINE1_SRC                                         | 71    | ENGINE1 Channel Flag Status Register(NDEDI_ENGINE2_CSFR)     |
| ENGINE2 Control/Status Registers                    |       |                                                              |

### 53.6.1 Register descriptions

This section consists of NDEDI register descriptions. The ENGINE1 and ENGINE2 registers are shown in the preceding table. To simplify the document, the description of registers with the same content is only given once instead of being repeated for each ENGINE. This is denoted in the text as ENGINE<sub>x</sub> where ENGINE<sub>x</sub> can be replaced by either ENGINE1 or ENGINE2.

#### 53.6.1.1 Device Identity Register (DID)

The DID register contains the unique identification information.

Client Select: X

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CS    | <p>Client Select</p> <p>The value of the CS field determines which client is accessed.</p> <p>The number of bits implemented for the CS field (K) is MCU dependent, and is the same number of bits as the size of the SRC field transmitted with messages. Refer to the SoC Guide for the size on a particular MCU.</p> <p>The value written to the CSC register to access a client register is the same value as the SRC field a client uses in its messages. For example, to access an NDEDI ENGINE1 register, the CSC register is written with a value of ENGINE1_SRC.</p> |

53.6.1.3 ENGINE<sub>x</sub> Development Control Register (NDEDI\_ENGINE<sub>x</sub>\_DC)

The NDEDI\_ENGINE<sub>x</sub>\_DC register controls various trace and debug features as described below.

When a field is set to a reserved value the behavior defaults to the reset values behavior.

Client Select: ENGINE<sub>x</sub>\_SRC

Register index: 2

Figure 53-3. ENGINE<sub>x</sub> Development Control Register (NDEDI\_ENGINE<sub>x</sub>\_DC)

**Table 53-6. NDEDI\_ENGINEx\_DC field descriptions**

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CHW   | <p>ENGINEx CHAN Register Write Trace</p> <p>The CHW bit enables the tracing of writes to the CHAN register in the ENGINEx execution unit. CHAN register write tracing requires the channel being serviced to have program trace enabled.</p> <p>0 = Tracing not enabled for ENGINEx CHAN writes.</p> <p>1 = Tracing enabled for ENGINEx CHAN writes</p>                                                                                                                                                                                                                                           |
| PINS  | <p>Stop Pins in Debug Mode</p> <p>The PINS bit controls whether the ENGINEx pins are sampled when the ENGINEx enters debug mode. When PINS is set, the pins are not sampled during debug mode or when executing a forced instruction from the microinstruction register. The pins are sampled during single steps.</p> <p>0 = Sample pins in the halted state</p> <p>1 = Stop sampling pins in the halted state</p>                                                                                                                                                                               |
| CLKS  | <p>Stop TCR Clocks</p> <p>The CLKS bit controls whether the TCR clocks from ENGINEx stop running when the ENGINEx enters debug mode. When CLKS is set, TCR is not updated during debug mode or when executing a forced instruction from the microinstruction register. TCR is updated during single steps.</p> <p>0 = Do not stop TCRs during debug mode</p> <p>1 = Stop TCRs during debug mode</p>                                                                                                                                                                                               |
| CBT   | <p>Client Breakpoint Timing</p> <p>The CBT bit controls the timing of an ENGINEx halt due to an external breakpoint source or due to a breakpoint at the twin engine. For this bit to matter, CBI or HTWIN must be set to 1.</p> <p>0 = Halt at the end of the current microcycle</p> <p>1 = Halt at the completion of the current instruction thread</p>                                                                                                                                                                                                                                         |
| HTWIN | <p>HTWIN — Halt on Twin Engine Breakpoint</p> <p>Along with CBT, the HTWIN bit controls the action taken on breakpoints occurrences at the twin engine. If the Twin Engine that is causing a breakpoint exit debug state, the ENGINEx shall resume its operation. If the HTWIN bit is cleared while the ENGINEx is in debug state due to a Twin Engine Breakpoint, the ENGINEx shall resume its operation. This bit must not be cleared when the engine is neither halted nor stopped.</p> <p>0 = Do not halt for breakpoints in the twin Engine</p> <p>1 = Halt for twin Engine's breakpoint</p> |
| EBC   | <p>EVT<math>\overline{O}</math> Breakpoint Controller</p> <p>The EBC bit controls the generation of EVT<math>\overline{O}</math> due to any of the following breakpoint types: Exit of System Reset, DBR assertion, SW, TWIN Engine, EVTI, MISC Error, Illegal Instruction, Single Step or External.</p> <p>0 = Breakpoint status indication is not output on EVT<math>\overline{O}</math></p> <p>1 = Breakpoint status indication is output on EVT<math>\overline{O}</math></p>                                                                                                                  |
| CBR   | <p>Clear Breakpoint Request</p> <p>Writing this bit to one clears breakpoint requests caused by the following conditions:</p> <ul style="list-style-type: none"> <li>• Exit of system reset</li> <li>• Internal breakpoint (due to: instruction address match, accesses to the SPRAM, channel service and writes to the CHAN register)</li> <li>• Single Step breakpoint</li> </ul>                                                                                                                                                                                                               |

**Table 53-6. NDEDI\_ENGINEx\_DC field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | <ul style="list-style-type: none"> <li>• EVTI assertion</li> <li>• Halt instruction at the engine</li> <li>• MISC miscompare</li> <li>• Illegal instruction at the engine.</li> </ul> <p>Asserting this bit causes it to clear one clock later. This means that the development tool can never read this bit with a value other than zero.</p> <p>The ETPU must always execute the first instruction after exiting a breakpoint condition, in such a way that it does not halt twice at the same position.</p> <p>The breakpoints caused by external/system debug request or twin engine are not cleared by the assertion of this bit. This bit must not be asserted when the engine is not halted.</p> <p>0 = No action<br/>1 = Clear breakpoint requests</p>                                                                                                                                                                                                                                                                                                                                                                                            |
| CBI   | <p>Client Breakpoint Input</p> <p>Along with CBT, the CBI bit controls the action taken on breakpoints from external sources.</p> <p>The breakpoint condition caused by the external source is only cleared if CBI equals 0 or if the external breakpoint is negated. This bit must not be cleared when the engine is neither halted nor stopped.</p> <p>0 = Do not halt for other clients' breakpoints<br/>1 = Halt for other clients' breakpoints</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DBE   | <p>Debug Enable</p> <p>DBE enables debug mode. When DBE is asserted, the occurrence of any of the following events will cause the processor to enter debug mode:</p> <ul style="list-style-type: none"> <li>• DBR assertion</li> <li>• Twin Engine breakpoint</li> <li>• External breakpoint</li> <li>• Exit of system reset</li> <li>• Internal breakpoint (due to: instruction address match, accesses to the SPRAM, channel service and writes to the CHAN register)</li> <li>• Single Step breakpoint</li> <li>• EVTI assertion</li> <li>• Halt instruction at the engine</li> <li>• MISC miscompare</li> <li>• Illegal instruction at the engine.</li> </ul> <p>No breakpoints will occur if DBE is not asserted. If this bit is negated while in debug mode a request to resume the processor operation will be sent to the engine. This bit must not be cleared when the engine is either halted nor stopped.</p> <p>This bit is necessary to use features such as single stepping and breakpoints, but does not affect neither watchpoint, program trace nor data trace operations.</p> <p>0 = Debug mode disabled<br/>1 = Debug mode enabled</p> |

**Table 53-6. NDEDI\_ENGINEx\_DC field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DBR   | <p>Debug Request</p> <p>Mechanism to allow development tool to request processor to enter debug mode. When written, and DBE equals 1 this bit forces the ENGINEx to enter debug mode.</p> <p>The engine will not exit debug mode while this bit is asserted and DBE equals 1.</p> <p>0 = Exit debug mode if there are no pending breakpoint sources</p> <p>1 = Request debug mode</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| OVC   | <p>OVC — Overrun Control</p> <p>The NDEDI can be programmed to stall the ENGINEx operation avoiding errors related to that engine due to full Event Queue. The ENGINEx can't be stalled neither in the middle of an atomic sequence of accesses to the SPRAM nor in the middle of the Time Slot Transition(TST). Please refer to the ETPU BG for further information.</p> <p>The overrun control field controls how the NDEDI reacts when the Queue is about to get full. If programmed to delay the processor, the NDEDI asserts the request to delay the processor when the Event Queue has only STALL_THRESHOLD available positions, and negates the delay request as soon as there are STALL_THRESHOLD + 1 available positions.</p> <p>The request to delay the processor does not affect neither the other engine nor the CDC operations. Therefore, in some extreme cases an overrun message may be generated even with OVC configured to delay the processor. If an error event happens, the processor will be delayed until the Event Queue is enabled for storing snapshots again, which will happen as the Event Queue gets empty.</p> <p>If the OVC field is changed to 0b011 while the Event Queue has less than STALL_THRESHOLD available positions the NDEDI will automatically assert the stall request. If the OVC field is changed to a value other than 0b011 while the ENGINEx is in STALL state, the NDEDI will automatically negate the stall request.</p> <p>A breakpoint request prevails over the request to delay the processor. Thus, if a breakpoint request happens at the same time of a stall request, the ETPU will enter in HALT state instead of STALL state.</p> <p>OVC values:</p> <p>000b = Generate overrun message</p> <p>001b–010b = Reserved</p> <p>011b = Stall Processor to prevent overruns for ENGINEx</p> <p>100b–111b = Reserved</p> |
| EIC   | <p>ENGINEx <math>\overline{\text{EVTI}}</math> Control</p> <p>The <math>\overline{\text{EVTI}}</math> control (EIC) field can be configured for synchronization or breakpoint generation. ### 53.6.1.4 ENGINEx Development Status Register (NDEDI\_ENGINEx\_DS)

The NDEDI\_ENGINEx\_DS register shows the status of various conditions that impact development support. All status bits are dynamic and do not require clearing. If the Class 3 is enabled, any time the value of any bit in this register changes, a Debug Status Event is queued, and then will generate a Debug Status Message. If the Event Queue is not enabled to store snapshots while a DS event should be queued, then an error event is queued as soon as the Event Queue is enabled for storing snapshots.

DS register dynamically tracks the debug condition status even when several of them are simultaneously asserted. For instance, if EVTI and external debug are asserted at the same time, ETPU will enter in debug mode and NDEDI will assert the bits EBP(EVTI) and CBP. Then, if CBR is asserted the EBP bit will be cleared but the CBP bit will continue to be active since the external debug request is still on.

In some extreme cases NDEDI may not signalize more than one breakpoints condition at the same address. Please refer to [Multiple breakpoint conditions at the same address](#) for more details about this limitation.

1. A hardware breakpoint is a breakpoint configured by BWC1, BWC2 or BWC3.

### 53.6.1.5 ENGINE<sub>x</sub> Watchpoint Trigger Register (NDEDI\_ENGINE<sub>x</sub>\_WT)

The NDEDI\_ENGINE<sub>x</sub>\_WT register allows traces to be enabled and/or disabled on the occurrence of a watchpoint. If the same watchpoint is programmed to enable and disable a trace, the occurrence of the watchpoint toggles the current value of the trace flags. If one watchpoint occurs to enable trace and a different watchpoint occurs to disable trace at the same time the current value of the trace flags will also be toggled. Trace enable flags from triggers (PTEF and DTEF) are ORed with the appropriate bit in the TM field of the DC register and sent to the trace blocks.

### 53.6.1.7 ENGINEx Breakpoint/Watchpoint Control 1/2 Register (NDEDI\_ENGINEx\_BWC1/2)

The ENGINEx Breakpoint/Watchpoint Control 1 Register is used to configure ENGINEx breakpoint/watchpoint 1 along with the NDEDI\_ENGINEx\_BWA1 and NDEDI\_ENGINEx\_BWD1 registers.

The ENGINEx Breakpoint/Watchpoint Control 2 Register is used to configure ENGINEx breakpoint/watchpoint 2 along with the NDEDI\_ENGINEx\_BWA2 and NDEDI\_ENGINEx\_BWD2 registers.

These registers are responsible for configuring the hardware breakpoints/watchpoints 1 and 2. And every field of this register is related to these breakpoints only. When a field is set to a reserved value the behavior defaults to the reset values behavior.

The register can be configured for breakpoint/watchpoint based on data write values, instruction address and data read or write addresses.

When a hardware breakpoint occurs the program execution is halted before the instruction is executed. This means that data access breakpoints occur before the SPRAM access actually takes place.

The data accesses that occur within the Time Slot Transition (TST) do not generate a hardware breakpoint. Thus, it is not expected that the ETPU system signalize these transactions to the NDEDI interface.

Client Select: ENGINEx\_SRC

Register index: 22

## Register definition

53.6.1.8 ENGINEx Breakpoint/Watchpoint Address 1/2 Register (NDEDI\_ENGINEx\_BWA1/2)

The ENGINEx Breakpoint/Watchpoint Address 1 Register is used to configure ENGINEx hardware breakpoint/watchpoint 1 along with the NDEDI\_ENGINEx\_BWC1 and NDEDI\_ENGINEx\_BWD1 registers. It is used for data access and instruction fetches breakpoints.

The ENGINEx Breakpoint/Watchpoint Address 2 Register is used to configure ENGINEx hardware breakpoint/watchpoint 2 along with the NDEDI\_ENGINEx\_BWC2 and NDEDI\_ENGINEx\_BWD2 registers. It is used for data access and instruction fetches breakpoints.

| BWA   | Breakpoint/Watchpoint Address<br>The BWA field is used to compare address operands (address of instruction or data).<br>The BWA field represent a word addressable address.<br>The most significant two bits are ignored for address of data comparisons because the SPRAM address space is only 14 bits. |

### 53.6.1.9 ENGINEx Breakpoint/Watchpoint Data 1/2 Register (NDEDI\_ENGINEx\_BWD1/2)

The ENGINEx Breakpoint/Watchpoint Data 1 Register is used to configure the ENGINEx hardware breakpoint/watchpoint 1 along with the NDEDI\_ENGINEx\_BWC1 and NDEDI\_ENGINEx\_BWA1 registers. It is used for data access breakpoints only.

The ENGINEx Breakpoint/Watchpoint Data 2 Register is used to configure the ENGINEx hardware breakpoint/watchpoint 2 along with the NDEDI\_ENGINEx\_BWC2 and NDEDI\_ENGINEx\_BWA2 registers. It is used for data access breakpoints only.

| BWD   | Breakpoint/Watchpoint Data<br><br>The BWD field is used to compare data operands whether in a SPRAM write access. Depending on the size of the access, only certain bits of BWD are compared against the data written to the SPRAM. <a href="#">Table 53-13</a> shows which bits of BWD are compared against the data written to the SPRAM. |

Table 53-13. Bits compared against BWD

| Operation size | Bits compared                    |
|----------------|----------------------------------|
| 8-bits         | 8 most significant bits of BWD   |
| 24-bits        | 24 least significant bits of BWD |
| 32-bits        | All bits from BWD                |

### 53.6.1.10 ENGINEx Program Trace Channel Enable Register (NDEDI\_ENGINEx\_PTCE)

The NDEDI\_ENGINEx\_PTCE register enables program tracing for each of the 32 ENGINEx channels. There is one enable bit per channel. And the bit corresponding to the serviced channel is the only bit tested for enabling program trace. For these bits to have any effect, program trace must also be enabled in the TM field of the DC register or via a watchpoint trigger.

Client Select: ENGINEx\_SRC

Register index: 64

### 53.6.1.11 ENGINEx Breakpoint/Watchpoint Control 3 Register (NDEDI\_ENGINEx\_BWC3)

The ENGINEx Breakpoint/Watchpoint Control 3 Register is used to configure miscellaneous ENGINEx hardware breakpoint/watchpoint sources. This is a vendor-defined register with different fields than BWC1 and BWC2.

When a field is set to a reserved value the behavior defaults to the reset values behavior.

### 53.6.1.12 ENGINEx Microinstruction Debug Register (NDEDI\_ENGINEx\_INST)

The NDEDI\_ENGINEx\_INST register is used for forcing a microinstruction on the microinstruction register. This register must only be accessed while the ENGINEx is halted. Writes to this register are ignored if accessed while the ENGINEx is not halted.

Client Select: ENGINEx\_SRC

Register index: 69

|        |              |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

**Figure 53-15. ENGINEx Microinstruction Debug Register (NDEDI\_ENGINEx\_INST)**

Writes to the register in debug mode force the execution of an arbitrary instruction. This is used to retrieve information about internal status, set internal flag values among other things during debug mode. Some fields of this microinstruction may be ignored, for instance an END instruction will be ignored. For further information about the arbitrary instruction refer to the ETPU BG Section 4.10.2.7.

Reads from the register returns 0.

### 53.6.1.13 ENGINE<sub>x</sub> Microprogram Counter Debug Register (NDEDI\_ENGINE<sub>x</sub>\_MPC)

The NDEDI\_ENGINE<sub>x</sub>\_MPC register is used for reading the microprogram counter value. This register is only meaningful while the ENGINE<sub>x</sub> is halted. If accessed while the ENGINE<sub>x</sub> is not halted, reads return zero. Writes to this register are always ignored.

Client Select: ENGINE<sub>x</sub>\_SRC

Register index: 70

### 53.6.1.14 ENGINE<sub>x</sub> Channel Flag Status Register (NDEDI\_ENGINE<sub>x</sub>\_CFSR)

The NDEDI\_ENGINE<sub>x</sub>\_CFSR register provides read-only access to the flags of the channel being serviced by ENGINE<sub>x</sub>. Reads to this register when ENGINE<sub>x</sub> is out of halt mode return zero., Transition Detection and Match Recognition flags are available in two versions: One reflecting the Branch Condition Selection (BCC), TDL1/2 and MRL1/2, and an ‘internal’ version, ITDL1/2 and IMR1/2, reflecting the flag value within the channel logic.

Client Select: ENGINE<sub>x</sub>\_SRC

Register index: 71

### 53.6.1.16 Data Trace Address Range 0 Register (NDEDI\_DTAR0)

The NDEDI\_DTAR0 register defines a data trace address range. The address range is shared by the two ENGINES and the CDC. All three of these clients can independently enable the range for reads and/or writes. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 0.<sup>2</sup>

Notice that the combination of the start and end addresses for data trace into one register does not follow the standard's recommended method of having separate registers for start and end addresses.

Client Select: ENGINE1\_SRC or ENGINE2\_SRC or CDC\_SRC

Register index: 65

2. If RC0 equals 1 for a determined source all accesses from that source will have the address value acknowledged.

Register definition

Figure 53-19. Data Trace Address Range 0 Register (NDEDI\_DTAR0)

Table 53-20. NDEDI\_DTAR0 field descriptions

| Field | Description                                                                                      |
|-------|--------------------------------------------------------------------------------------------------|
| DTSA0 | Data Trace Start Address 0<br>The DTSA0 field is the start address for ETPU data trace window 0. |
| DTEA0 | Data Trace End Address 0<br>The DTEA0 field is the end address for ETPU data trace window 0.     |

53.6.1.17 Data Trace Address Range 1 Register (NDEDI\_DTAR1)

The NDEDI\_DTAR1 register defines a data trace address range. The address range is shared by the two ENGINES and the CDC. All three of these clients can independently enable the range for reads and/or writes. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 1.<sup>3</sup>

Notice that the combination of the start and end addresses for data trace into one register does not follow the standard's recommended method of having separate registers for start and end addresses.

Client Select: ENGINE1\_SRC or ENGINE2\_SRC or CDC\_SRC

Register index: 66

3. If RC1 equals 1 for a determined source all accesses from that source will have the address value acknowledged.

**Figure 53-20. Data Trace Address Range 1 Register (NDEDI\_DTAR1)****Table 53-21. NDEDI\_DTAR1 field descriptions**

| Field | Description                                                                                      |
|-------|--------------------------------------------------------------------------------------------------|
| DTSA1 | Data Trace Start Address 1<br>The DTSA1 field is the start address for ETPU data trace window 1. |
| DTEA1 | Data Trace End Address 1<br>The DTEA1 field is the end address for ETPU data trace window 1.     |

### 53.6.1.18 Data Trace Address Range 2 Register (NDEDI\_DTAR2)

The NDEDI\_DTAR2 register defines a data trace address range. The address range is shared by the two ENGINES and the CDC. All three of these clients can independently enable the range for reads and/or writes. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 2.<sup>4</sup>

Notice that the combination of the start and end addresses for data trace into one register does not follow the standard's recommended method of having separate registers for start and end addresses.

Client Select: ENGINE1\_SRC or ENGINE2\_SRC or CDC\_SRC

Register index: 67

4. If RC2 equals 1 for a determined source all accesses from that source will have the address value acknowledged.

Register definition

Figure 53-21. Data Trace Address Range 2 Register (NDEDI\_DTAR2)

Table 53-22. NDEDI\_DTAR2 field descriptions

| Field | Description                                                                                      |
|-------|--------------------------------------------------------------------------------------------------|
| DTSA2 | Data Trace Start Address 2<br>The DTSA2 field is the start address for ETPU data trace window 2. |
| DTEA2 | Data Trace End Address 2<br>The DTEA2 field is the end address for ETPU data trace window 2.     |

53.6.1.19 Data Trace Address Range 3 Register (NDEDI\_DTAR3)

The NDEDI\_DTAR3 register defines a data trace address range. The address range is shared by the two ENGINES and the CDC. All three of these clients can independently enable the range for reads and/or writes. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 3.<sup>5</sup>

Notice that the combination of the start and end addresses for data trace into one register does not follow the standard's recommended method of having separate registers for start and end addresses.

Client Select: ENGINE1\_SRC or ENGINE2\_SRC or CDC\_SRC

Register index: 68

5. If RC3 equals 1 for a determined source all accesses from that source will have the address value acknowledged.

**Figure 53-22. Data Trace Address Range 3 Register (NDEDI\_DTAR3)****Table 53-23. NDEDI\_DTAR3 field descriptions**

| Field | Description                                                                                           |
|-------|-------------------------------------------------------------------------------------------------------|
| DTSA3 | ETPU Data Trace Start Address 3<br>The DTSA3 field is the start address for ETPU data trace window 3. |
| DTEA3 | ETPU Data Trace End Address 3<br>The DTEA3 field is the end address for ETPU data trace window 3.     |

## 53.6.2 Unimplemented Registers

Unimplemented registers are those with client select and index value combinations other than those listed in [Table 53-3](#). NDEDI will treat unimplemented registers like the JTAG BYPASS instruction.

## 53.7 Functional description

This section describes the functional description.

### 53.7.1 NDEDI reset configuration

This section describes the reset configuration of NDEDI.

### 53.7.1.1 Enabling NDEDI Class 1 operation

The NDEDI Class 1 features are always enabled after exiting the JTAG Test-Logic-Reset state. But they are disabled while the JTAG is in this state. Thus, allowing low power mode for a production part. The registers are always reset while in the JTAG Test-Logic-Reset state.

### 53.7.1.2 Enabling NDEDI Class 3 operation

When NDEDI input `nex_mcko_en` is asserted the NDEDI Classes 1 and 3 are enabled after exiting the JTAG Test-Logic-Reset state, otherwise the NDEDI Class 3 features will be disabled, entering in the Disable-Port Mode, thus no trace output will be provided, and auxiliary port output pins will be disabled (driven inactive or used for an alternate function if sharing pins).<sup>6</sup>

## 53.7.2 Auxiliary output port

This section describes the Auxiliary output ports.

### 53.7.2.1 Output Message Protocol

The protocol for transmitting messages via the auxiliary port is accomplished with the  $\overline{\text{MSEO}}$  functions.  $\overline{\text{MDO}}$  and  $\overline{\text{MSEO}}$  must be sampled by the development tool on the rising edge of  $\text{MCKO}$ .

The following figure illustrates the state diagram for  $\overline{\text{MSEO}}$  transfers. All transitions not included in the figure are reserved, and are never generated by the NDEDI block.

---

6. Class 1 features are still available in Disable-Port Mode.

Figure 53-23. MSEO Transfers

### 53.7.2.2 Output messages

The following table describes the messages that the NDEDI can transmit on the auxiliary port.

Table 53-24. NDEDI messages

| Message Name            | Min. Packet Size (bits) | Max Packet Size (bits) | Packet Type | Packet Name | Packet Description                       |
|-------------------------|-------------------------|------------------------|-------------|-------------|------------------------------------------|
| Debug Status Message    | 6                       | 6                      | fixed       | TCODE       | Value = 0                                |
|                         | K                       | K                      | fixed       | SRC         | Client that is the source of the message |
|                         | 32                      | 32                     | fixed       | STATUS      | Value of the Development Status register |
| Ownership Trace Message | 6                       | 6                      | fixed       | TCODE       | Value = 2                                |
|                         | K                       | K                      | fixed       | SRC         | Client that is the source of the message |

Table continues on the next page...

**Table 53-24. NDEDI messages (continued)**

| Message Name                             | Min. Packet Size (bits) | Max Packet Size (bits) | Packet Type | Packet Name | Packet Description                                                                                     |
|------------------------------------------|-------------------------|------------------------|-------------|-------------|--------------------------------------------------------------------------------------------------------|

The following table describes the Error Code encodings for the error messages generated by the NDEDI block.

**Table 53-25. Error Codes Encodings(ECODE)**

| Error Code | Description                                                                                          |
|------------|------------------------------------------------------------------------------------------------------|
| 0b00000    | Ownership trace overrun                                                                              |
| 0b00001    | Program trace overrun                                                                                |
| 0b00010    | Data trace overrun                                                                                   |
| 0b00110    | Watchpoint Overrun                                                                                   |
| 0b00111    | Program and/or Data and/or Ownership Trace Overrun                                                   |
| 0b01000    | Program Trace and/or Data Trace and/or Ownership Trace and/or Watchpoint Overrun                     |
| 0b11000    | Debug Status Overrun                                                                                 |
| 0b11001    | Debug Status Overrun and/or Program and/or Data and/or Ownership Trace Overrun                       |
| 0b11010    | Debug Status and/or Program Trace and/or Data Trace and/or Ownership Trace and/or Watchpoint Overrun |

The following table describes the Resource Code encodings for the resource full messages.

**Table 53-26. Resource Codes Encodings**

| Resource Code | Resource                                | DATA Packet Count | DATA Packet Value                                                                                                                                                                                                               |
|---------------|-----------------------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0b0000        | Program Trace, Sequential Counter       | 1                 | Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit. The value that causes the counter to fill is always the same and can be determined without sending the value |
| 0b0001        | Program Trace, Branch/Predicate History | 1                 | Branch/Predicate Instruction History. This packet is terminated by a stop bit set to 1 after the last history bit                                                                                                               |

Message formatting is performed by the message formatter block. Raw messages read from the message queues are independent of the number of MDO pins implemented.

The following table shows the various message formats and the location of variable length packets. Notice that for variable-length packets, the transmitted size of the packet is determined from the range of the least significant bit to the most significant non-zero-valued bit (i.e. most significant 0 value bits are not transmitted).

**Table 53-27. Message Packet Sizes**

| Message                                  | TCODE | Packet #1 | Packet #2              | Packet #3                       | Packet #4                         | Packet #5 | Packet #6 | Min. Size <sup>1</sup> (bits) | Max Size <sup>2</sup> (bits) |
|------------------------------------------|-------|-----------|------------------------|---------------------------------|-----------------------------------|-----------|-----------|-------------------------------|------------------------------|
| Debug Status Message                     | 0     | Fixed = K | Fixed = 32             | NA                              | NA                                | NA        | NA        | 38+K                          | 38+K                         |
| Ownership Trace Message                  | 2     | Fixed = K | Fixed = 16             | NA                              | NA                                | NA        | NA        | 22+K                          | 22+K                         |
| Data Trace, Data Write Message           | 5     | Fixed = K | Fixed <sup>3</sup> = 2 | Variable<br>Min = 1<br>Max = 14 | Variable<br>Min = 1<br>Max = 32   | NA        | NA        | 10+K                          | 54+K                         |

1. Minimum information size. The actual number of bits transmitted depends on the number of MDO pins.
2. Maximum information size. The actual number of bits transmitted depends on the number of MDO pins.
3. Packet is fixed and NDEDI always transmits 2 bits, but other sources sharing the auxiliary port may have a different packet size{ndedi\_msg\_checker, ndedi\_dt\_rnd}. Packet size can always be determined by the value of the SRC packet.  
{Statement}

The double edges in the preceding table indicate the starts and ends of messages. The shaded edges in the preceding figure indicate the end of a variable length packet which is not also the end of the message. Packets without shaded areas between them are grouped into super packets and are transmitted together without end-of-packet indications between them.

#### 53.7.2.2.1 Rules of messaging

- A variable-length packet within a message must end on a port boundary (Port boundaries depend on the number of MDO pins active with the current reset configuration)
- A variable-length packet may start within a port boundary only when following a fixed-length packet.
- Superblocks must end on a port boundary
- When a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest order bit so that it can end on a port boundary
- Multiple fixed-length packets may start and/or end on the same clock
- When any packet follows a variable-length packet, it must start on a port boundary
- The packet containing the TCODE number is always transferred out first, followed by subsequent packets of information
- Within a packet, the least significant bits are shifted out first. The following figure shows the transmission sequence of a message that is made up of a TCODE followed by two packets

**Figure 53-24. Transmission Sequence of Messages**

#### 53.7.2.2.2 Examples

The following are examples of branch trace and data trace messages.

Functional description

The following figure illustrates how the indirect branch with history public message is transmitted. *Notice that the example uses a 4-bit MDO port* . For this example, 4 bits are shifted out in the I-CNT packet, 5 bits are shifted out in the HIST packet, and 11 bits are shifted out for the UADDR packet. Notice also that T0, S0, H0, I0, and A0 are the least significant bits where:

- Tx= TCODE packet bits (Fixed)
- Sx= SRC packet bits (Fixed)
- Hx = HIST packet bits (Variable)
- Ix= I-CNT packet bits (Variable)
- Ax= UADDR packet bits (Variable)

| Clock | MDO[3:0] |     |    |      | MSEO[1:0] | State               |

Figure 53-27. Data Write with Sync Message (16 pins)

### 53.7.2.2.3 Temporal Ordering of Transmitted Messages

All Messages are sent out in the sequence their related event actually occurred. The ETPU interface with the NDEDI provides the ETPU signals to be monitored and captured. At the occurrence of any event that would cause a message, a snapshot of all information needed by the Message Formatter to generate a message is queued. Doing so, several events from either Engines or CDC can be queued at the same time.

Whenever the auxiliary port is idle, the Event Queue is read and the appropriate messages are formatted. Then, NDEDI sends a request for the auxiliary port, and as soon as the auxiliary port is granted the message is sent. If more than one messages are to be sent, the Message Formatter respects the following priority: Messages related to Error, Debug Status, Watchpoints, Program Trace and Data Trace. A request for the auxiliary port is sent for every messages within the snapshot.

NDEDI maintain temporal ordering of messages relative to ENGINE1, ENGINE2 and CDC, but not relative to messages generated by other clients sharing the auxiliary port.

The Time Slot Transition (TST) is considered to be an active state, and since data are accessed at the SPRAM, it is possible that Data Trace Events are recognized within TST.

<sup>7</sup> For further information about TST, please refer to the ETPU BG.

## 53.7.3 IEEE 1149.1 (JTAG) Input Port

The NDEDI block uses the IEEE 1149.1 TAP for accessing registers. This port is shared among all TAP controllers on the MCU. This sharing is controlled by the value in the instruction register and client select control register.

The NDEDI implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1 state machine shown in [Figure 53-29](#) . The Nexus controller state machine, shown in [Figure 53-30](#), is defined by the IEEE-ISTO 5001-2002 standard.

The instructions implemented by the NDEDI TAP controller are listed in the following table. If any other instruction is received it will be treated as a BYPASS.

---

7. Due to ETPU operation, speculative accesses may also happen within TST and will be traced.

**Table 53-28. Implemented Instructions**

| Instruction Name | Private/<br>Public | Opcode  | Description                                                                                    |
|------------------|--------------------|---------|------------------------------------------------------------------------------------------------|
| NEXUS-ENABLE     | public             | 4'b0000 | Activate Nexus controller state machine to read and write NDEDI registers                      |
| BYPASS           | public             | 4'b1111 | Implements a single shift register stage providing a minimum serial length between TDI and TDO |

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

**Figure 53-28. Shifting Data Into Register**

### 53.7.3.1 Enabling the NDEDI TAP Controller

Assertion of the  $\overline{\text{TRST}}$  input resets all TAP controllers on the MCU. The controllers are loaded with the BYPASS instruction upon exit of the 'TEST-LOGIC-RESET' JTAG controller state. Loading the NEXUS-ENABLE instruction grants access to Nexus debug. NDEDI acts as BYPASS by loading any other instruction. The TDO bit is driven with the value of the instruction register while in 'SHIFT\_IR' state.

Figure 53-29. IEEE 1149.1 16-State Finite State Machine

### 53.7.3.2 Loading NEXUS-ENABLE Instruction

Access to the NDEDI registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. The current instruction value is loaded into the IEEE 1149.1 shifter in the 'CAPTURE-IR' state. The instruction is shifted in via the 'SELECT-IR-SCAN' path and loaded in the 'UPDATE-IR' state. At this point, the Nexus controller state machine, shown in the following figure, transitions to the 'REG\_SELECT' state. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 53-30. Nexus Controller State Machine

Table 53-29. Loading NEXUS-ENABLE instruction

| Clo<br>ck | TM<br>S | IEEE 1149.1 State | Nexus<br>State | Description                                                                                                                |
|-----------|---------|-------------------|----------------|----------------------------------------------------------------------------------------------------------------------------|

| 14        | 0       | RUN-TEST/IDLE     | REG_SEL<br>ECT | NEXUS-ENABLE ready to be read                                                                                              |

### 53.7.3.3 Selecting an IEEE 1149.1 Register

When the NEXUS-ENABLE instruction is loaded in the NDEDI TAP controller instruction register, the input port allows development tool access to all NDEDI registers. Each register has a 7-bit address index. Some clients have registers with the same index as registers in other clients. Therefore, to access the registers of a particular client, the Client Select Control register must be set for that client.

All register access is performed via the 'SELECT-DR-SCAN' path. The Nexus state machine defaults to the register select state when enabled. Accessing a register requires two passes through the 'SELECT-DR-SCAN' path: one pass to select the register and the second pass to read/write the register.

The first pass through the 'SELECT-DR-SCAN' path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in the following figure. The read/write control bit is set to 1 for writes and 0 for reads. The current value of the Controller Command Input is captured into the IEEE 1149.1 shifter during the 'CAPTURE-DR' state while the Nexus controller state machine is in the 'REG\_SELECT' state.

**Figure 53-31. IEEE 1149.1 Controller Command Input**

The second pass through the 'SELECT-DR-SCAN' path is used to read or write the register data by shifting in the data (LSB first) during the 'SHIFT-DR' state. When reading a register, the current register value is loaded into the IEEE 1149.1 shifter during the 'CAPTURE-DR' state. When writing a register, the value is loaded from the IEEE 1149.1 shifter to the register during the 'UPDATE-DR' state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

The following table illustrates a sequence which writes a 32-bit value to a register

**Table 53-30. Writing to a Register**

| Clock | TM S | IEEE 1149.1 State | Nexus State | Description                                                            |
|-------|------|-------------------|-------------|------------------------------------------------------------------------|
| 0     | 0    | RUN-TEST/IDLE     | REG_SELECT  | IEEE 1149.1 controller in idle state                                   |
| 1     | 1    | SELECT-DR-SCAN    | REG_SELECT  | First pass through 'SELECT-DR-SCAN' path                               |
| 2     | 0    | CAPTURE-DR        | REG_SELECT  | Internal shifter loaded with current value of controller command input |

*Table continues on the next page...*

**Table 53-30. Writing to a Register (continued)**

| Clock   | TMS | IEEE 1149.1 State | Nexus State | Description                                                                                           |
|---------|-----|-------------------|-------------|-------------------------------------------------------------------------------------------------------|
| 3       | 0   | SHIFT-DR          | REG_SELECT  | TDO becomes active, and write bit and 6 bits of register index shifted in                             |
| 7 TCKs  |     |                   |             |                                                                                                       |
| 12      | 1   | EXIT1-DR          | REG_SELECT  | Last bit of register index shifted into TDI                                                           |
| 13      | 1   | UPDATE-DR         | REG_SELECT  | Controller decodes and selects register                                                               |
| 14      | 1   | SELECT-DR-SCAN    | DATA_ACCESS | Second pass through 'SELECT-DR-SCAN' path                                                             |
| 15      | 0   | CAPTURE-DR        | DATA_ACCESS | Internal shifter loaded with current value of register                                                |
| 16      | 0   | SHIFT-DR          | DATA_ACCESS | TDO becomes active, and outputs current value of register while new value is shifted in through TDI   |
| 31 TCKs |     |                   |             |                                                                                                       |
| 48      | 1   | EXIT1-DR          | DATA_ACCESS | Last bit of current value shifted out TDO. Last bit of new value shifted in TDI                       |
| 49      | 1   | UPDATE-DR         | DATA_ACCESS | Value written to register                                                                             |
| 50      | 0   | RUN-TEST/IDLE     | REG_SELECT  | Controller returned to idle state. It could also return to 'SELECT-DR-SCAN' to write another register |

### 53.7.4 Microcode Development Support

The NDEDI contains a number of hardware hooks that aid in the development of microcode for the ETPUs. This features described in this section make the ETPUs compliant with Nexus Class 1 features.

The main features provided are the abilities to:

- Read and write ETPU internal registers in debug mode
- Read and write SPRAM in debug mode
- Enter a debug mode at reset negation
- Enter a debug mode during normal execution
- Single step instructions and re-enter debug mode
- Stop program execution on instruction/data breakpoints or channel service breakpoints and enter debug mode
- Set breakpoints or watchpoints

Functional description

- Execute external microcode instruction in debug mode
- Read/write the microprogram counter register value in debug mode

Refer to [Initialization/Application Information](#) on how the following functions provide the features listed above.

53.7.5 Debug Status

The NDEDI module provides the Debug Status via the auxiliary port, as defined by the IEEE-ISTO 5001-2002 standard.

53.7.5.1 Messaging

The NDEDI block provides debug status messaging using IEEE-ISTO 5001-2002 standard-defined public messages. When the development status register changes, a debug status change event is sent to the Event Queue. If the debug status change condition occurs while the Event Queue is not enabled for storing snapshots, a debug status overrun message is generated.

The debug status message has the format shown in the following figure.

Figure 53-32. Debug Status Message Format

The DS packet correspond to the ENGINE<sub>x</sub> DS register value described in [Figure 53-4](#).

53.7.5.2 Error Messages

A debug status overrun error event is queued if a debug status event occurs while the Event Queue is not enabled for storing snapshots. The error event is stored as soon as the Event Queue is enabled which happens when the queue gets empty.

The error message has the format shown in the following figure.

**Figure 53-33. Debug Status Error Message Format**

### 53.7.5.3 Synchronization

Upon the exit of debug mode, the next program and data trace messages are synchronization messages. The exit of debug mode by one of the Engines causes data and program synchronization for that Engine only.

### 53.7.5.4 Timing Diagrams

Note that all of the following timing diagrams assume a 3-bit SRC size and a 16-bit MDO port. The state variable is not a signal, but instead is derived from  $\overline{\text{MSEO}}$ . It is included for clarity. Refer to [Figure 53-23](#) for  $\overline{\text{MSEO}}$  state diagram.

The following abbreviations are used for the state variable in the diagrams:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

**Figure 53-34. Debug Status Message**

Functional description

Figure 53-35. Debug Status Overrun Error Message

### 53.7.6 Ownership Trace

Ownership trace provides a macroscopic view of the ETPU program flow. This is done by generating an ownership trace event at the start of each channel service and whenever an engine becomes idle.

Each engine within the ETPU system generates ownership traces independently, and the events are queued in the order in which they occur.

#### 53.7.6.1 Messaging

Ownership trace information is transmitted via the auxiliary port using an ownership trace message (OTM).

Ownership trace information is transmitted in the format shown in the following figure.

Figure 53-36. Ownership Trace Message Format

Notice that the channel number and entry points number in the preceding figure are concatenated to form the variable length PROCESS packet defined by the IEEE-ISTO 5001-2002 standard.

### 53.7.6.2 OTM Flow

A channel generates an ownership trace message when service starts if ownership trace is enabled for the ETPU via the development control register. If ownership trace is enabled and an engine becomes idle, NDEDI will transmit a special OTM with the PROCESS packet set to 0.

### 53.7.6.3 Timing Diagram

The following figure shows an example of an ownership message being transmitted on the auxiliary port. The diagram assumes a 3-bit SRC size and a 16-bit MDO port. The state variable is not a signal but instead, it is derived from  $\overline{\text{MSEO}}$ . It is included for clarity. Refer to [Figure 53-23](#) for  $\overline{\text{MSEO}}$  state diagram.

The following abbreviations are used for the state variable in the diagrams:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

**Figure 53-37. Ownership Trace Message**

### 53.7.7 Program Trace

This section details the program trace mechanism supported by the NDEDI for the dual Engine system. Program trace is implemented via a combination of Branch Trace Messaging (BTM) and Ownership Trace Messaging (OTM) as per the IEEE-ISTO 5001-2002 standard definition.

### 53.7.7.1 Branch Trace Messaging

Branch trace messaging facilitates program trace by providing the following types of information:

- Messages for the start of channel services, each containing the full address of the first instruction to execute and history and sequential count information left over from the previously traced channel service. This message is always synchronizing
- Messages to indicate that the Program Trace was enabled in the middle of a thread or after the Queue is enabled for storing snapshots and it was previously disabled due to queue overrun. It includes the address of the enable point, the value of the serviced channel and the CHAN reg value only if it differs from the serviced channel value
- Messages to indicate that the internal history buffer has filled and been reset. The current value of the history buffer is included in each of these messages
- Messages to indicate that the internal sequential instruction counter has overflow and been reset. The current value of the history buffer is included in each of these messages
- Messages for taken indirect branches, each including a branch/predicate instruction<sup>8</sup> history packet, sequential instruction count, and the unique portion of the branch target address. Indirect branch messages that are generated with pending synchronization event include the full branch target address (instead of the unique portion of the address)
- Messages to indicate the entry into debug mode, the entry into low power mode, or the end of channel service with no new service pending
- Messages for writes to the CHAN register, indicating the value assigned to the register

The address packet of a program trace address excludes the 2 least significant bits of the byte address because they are zero for all instruction addresses.

### 53.7.7.2 Branch Trace Message Formats

There are seven types of messages used by the ETPU for branch tracing. These types are shown in the following table.

---

8. Predicate Instructions depend on the AS/CE field within ETPU instructions.

**Table 53-31. ETPU BTM Messages**

| Message                                              | Synchronizing | Public/Private |
|------------------------------------------------------|---------------|----------------|
| Resource Full Message                                | No            | Public         |
| Indirect Branch with History Message                 | No            | Public         |
| Indirect Branch with History Synchronization Message | Yes           | Public         |
| Program Trace Correlation Message                    | No            | Public         |
| Channel Start Service Message                        | Yes           | Private        |
| Channel Trace Enable Message                         | Yes           | Private        |
| Channel Register Write Message                       | No            | Private        |

The occurrence of any of the following conditions requires subsequent synchronization:

- Exit of system reset
- Exit of low power mode
- Exit of debug mode
- Write to the Development Control Register or the Program Trace Channel Enable Register<sup>9</sup>
- 255 branch trace messages of the same are queued without synchronization
- Assertion of the Event In ( $\overline{\text{EVTI}}$ ) pin, depending on how the development control register is configured
- A watchpoint occurrence<sup>10</sup>
- A queue overrun

The message that follows any of these synchronizing events will be a synchronizing message if it is not a Resource Full Message or a Channel Register Write Message which have no synchronizing information. If the ETPU reaches the idle the next program trace message will be a Channel Start Service Message or a Channel Trace Enable Message, that are synchronizing.

#### 53.7.7.2.1 Resource Full Messages

The resource full message is generated when the branch/predicate history buffer is full or the sequential instruction counter overflows.

9. Only the Source that have the register written will generate a synchronization message.

10. A Watchpoint occurrence for one Engine generates synchronization message for that Engine only.

For messages caused by the branch/predicate history buffer filling, the current value of that buffer is transmitted as part of the resource full message. This information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch history for a message. The HIST value is reset by this message, and the I-CNT value is reset as a result of a bit being added to the history buffer.

For messages caused by sequential instruction counter overflow, the HIST packet is also transmitted. This occurrence indicates that exactly 256 sequential instructions have been executed without a history bit being recorded or a message (other than CHAN\_WRITE) being generated. The HIST and I-CNT values are reset by this message.

The resource full message has the format shown in the following figure.

**Figure 53-38. Resource Full Message Format**

### 53.7.7.2.2 Indirect Branch with History Messages

The indirect branch with history message is generated on a taken indirect branch with no synchronization event pending. The program trace indirect branch with history message has the format shown in the following figure.

**Figure 53-39. Indirect Branch with History Message Format**

### 53.7.7.2.3 Indirect Branch with History Synchronization Messages

The indirect branch with history synchronization message is generated on a taken indirect branch with a synchronization event pending.

The program trace indirect branch with history synchronization message has the format shown in the following figure.

**Figure 53-40. Indirect Branch with History Synchronization Message Format**

#### 53.7.7.2.4 Program Trace Correlation Message

The program trace correlation message is generated at the end of an ETPU channel service if there is no new service, if there is a new service which channel is not enabled for tracing, if program trace is disabled in the middle of a thread being traced, upon entry into debug mode, or upon entry into low power mode.

The message contains the history and sequential instruction count information generated during the previous traced service since the last message generation.

The correlation message also contains an event code that indicates the event responsible for the generation of the message. Event code encodings are shown in the following table.

**Table 53-32. Event Code Encodings**

| EV-CODE    | Description                                      |
|------------|--------------------------------------------------|
| 0b0000     | Entry into Debug Mode                            |
| 0b0001     | Entry into Low Power Mode                        |
| 0b0010     | Program Trace disabled in the middle of a thread |
| 0b1110     | End Channel Service (no new service)             |
| all others | Reserved                                         |

The program trace correlation message has the format shown in the following figure.

**Figure 53-41. Program Trace Correlation Message Format**

#### 53.7.7.2.5 Channel Start Service Message

The channel start service message is generated at the start of an ETPU channel service. The message contains the history and sequential instruction count information generated during the previous traced service since the last message generation. The message also contains the address of the first instruction of the current service.

The program trace channel start service message has the format shown in the following figure.

**Figure 53-42. Channel Start Service Synchronization Message Format**

### 53.7.7.2.6 Channel Trace Enable Message

If the program trace is enabled in the middle of a thread or after the Queue is enabled for storing snapshots and it was previously disabled due to queue overrun, the Channel Trace Enable Message is sent indicating to the development tool the number of the channel being serviced and the address of the current instruction.<sup>11</sup> If the CHAN register value differs from the serviced channel, the CHAN field is sent at the end of the message indicating the current CHAN register value.<sup>12</sup>

The program trace channel trace enable message has the format shown in the following figure.

**Figure 53-43. Channel Trace Enable Synchronization Message Format**

### 53.7.7.2.7 Channel Register Write Messages

The channel register write message is generated when the CHAN register is written to by the microcode. This message is not necessary to reconstruct program flow and generation is enabled/disabled by the CHW bit in the ENGINE<sub>x</sub> development control register. Program trace must be enabled for this message to be generated.

The channel register write message has the format shown in the following figure

11. The message does not contains the history and sequential instruction count information since the trace of this channel was disabled until there.

12. Usually the CHAN register equals the serviced channel.

**Figure 53-44. Channel Register Write Message Format**

### 53.7.7.3 Branch Trace Messaging Operation

Figure 53-45 and Figure 53-46 show the basic flow used to generate branch trace messages for the ETPUs. The following acronyms are used in the figures:

- CHAN - CHAN register in ETPU execution unit
- S-CHAN - Channel being serviced
- HIST - Nexus shift register whose value is transmitted in the HIST packet of many BTMs
- I-CNT - Nexus sequential instruction counter whose value is transmitted in the HIST packet of many BTMs
- CWE - Channel Write Event
- IHE - Indirect Branch with History Event
- IHS - Indirect Branch with History Synchronization Event
- CSE - Channel Start Service Event
- CTE - Channel Trace Enable Event
- RFE - Resource Full Event
- PCE - Program Trace Correlation Event

Figure 53-45. Branch Trace Message Generation (Part 1)

Figure 53-46. Branch Trace Message Generation (Part 2)

### 53.7.7.3.1 Relative Addressing

The relative address feature is compliant with the IEEE-ISTO 5001-2002 standard recommendations and is designed to reduce the number of bits transmitted for addresses of program trace messages.

The address transmitted for a determined source is relative to the address of the previous branch trace message sent for that source. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant '1' in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address. The following figure shows how a relative address is generated and how it can be used to recreate the original address.

Engine 1: Current Address (A1) = 0x65DC,  
 Engine 2: Current Address (B1) = 0x7238

Next Message Relative to Engine 1: Address (A2) = 0x1AF8

### ***Address Generation:***

A1 = 110 0101 1101 11 00  
 A2 = 001 1010 1111 10 00  
 A1 ^ A2 = 111 1111 0010 01 00

Address Message (M1) = 111 1111 0010 01

### ***Address Recreation:***

A1 ^ M1 = A2  
 A1 = 110 0101 1101 11 00  
 ME1 = 111 1111 0010 01  
 A1 ^ ME1 = 001 1010 1111 10 00 = A2

Next Message Relative to Engine 2: Address (B2) = 0x54C8

### ***Address Generation for Engine 2.***

B1 = 111 0010 0011 10 00  
 B2 = 101 0100 1100 10 00  
 B1 ^ B2 = 010 0110 1111 00 00

Address Message (ME2) = 10 0110 1111 00

### ***Address Recreation:***

B1 ^ M1 = B2  
 B1 = 111 0010 0011 10 00  
 ME2 = 10 0110 1111 00  
 B1 ^ ME2 = 101 0100 1100 10 00 = B2

**Figure 53-47. Relative Address Generation and Recreation**

#### **53.7.7.3.2 Enabling Program Trace**

Program trace for the ETPU is enabled on a channel-by-channel basis. This selective enabling allows the tool more control over how much information gets transmitted.

For program trace information to be generated for a channel, the appropriate bit in the program trace channel enable register must be set and program trace must be enabled via the TM field in the DC register or via a watchpoint trigger.

Any combination of channels can be enabled for trace at the same time by configuring the program trace channel enable register. See [ENGINEx Program Trace Channel Enable Register \(NDEDI\\_ENGINEx\\_PTCE\)](#) for more details.

Note that since the registers may be changed in the middle of a thread, program trace may be enabled or disabled in the middle of a thread.

If program trace for a determined channel is enabled in the middle of a service routine, a Channel Trace Enable Message is sent to the development tool indicating the number of the channel being serviced and the address of the current instruction. Otherwise, normal program trace begins only on the following service for that channel.

If program trace for a determined channel is disabled in the middle of a service routine, a Program Correlation Message is sent to the development tool indicating that the trace is disabled and informing the HIST and I-CNT values.

### **53.7.7.3.3 Branch/Predicate Instruction History**

The HIST packet provides a history of direct branch and predicated instruction execution used for reconstructing the program flow. This packet is implemented as a left-shifting shift register. The register is always pre-loaded with a value of 1. This bit acts as a stop bit so the tool can determine which bit is the end of the history information. The pre-loaded 1 bit itself is not part of the history information but is transmitted with the packet.

A value of 1 is shifted into the HIST packet on a taken direct branch (conditional or unconditional) and on a predicate instruction whose predicate condition was evaluated as true. A value of 0 is shifted into the HIST packet on a not taken direct branch and on a predicate instruction whose predicate condition was evaluated as false.

A direct branch is a branch whose target address is hard-coded into the microcode instruction at compile time. An indirect branch is a branch whose target address depends on run time conditions. The indirect branches in the ETPU are return from subroutine, dispatch jump, and dispatch call.

For the ETPU, predicated instructions are those that execute ALU operations conditionally based on the value of the C, Z, or N flags. This conditional execution is controlled by the value of the AS/CE packet in the ETPU microcode instruction formats A3, B4, B5, and B6.

### 53.7.7.3.4 Sequential Instruction Count

The I-CNT packet, present in many of the program trace messages, represents the number of ETPU microcode instructions executed since the start of channel service, last taken direct branch, last not-taken direct branch, last taken indirect branch, or last predicated instruction.<sup>13</sup> In other words, I-CNT is reset whenever it is transmitted within a message or a bit is recorded to HIST.

When a sequential instruction is executed and the current I-CNT value is 255, a resource full message is transmitted to tell the tool that the I-CNT has reached a value of 256. The current HIST packet is transmitted as part of this message and reset inside the NDEDI. The HIST and I-CNT information in the resource full message are combined with information from subsequent messages to provide the development tool a full picture of the program flow.

If additional HIST bits are recorded between a resource full message for the I-CNT and the next program trace message, the I-CNT overflow can be ignored by the tool. In this case, the HIST packet transmitted by any resource full messages and the next program trace are concatenated to provide the full HIST information.

Multiple I-CNT resource full messages can be received between other program trace messages. In these cases, the HIST packets are concatenated, and the I-CNT values are added only when no HIST bits were recorded between the resource full messages.

### 53.7.7.3.5 Interleaved ENGINE1 and ENGINE2 messages

Both ENGINE1 and ENGINE2 can be enabled for program trace at the same time. Each Engine microcode instruction takes two system clocks to execute. The dual Engine system alternates instruction completion between ENGINE1 and ENGINE2, thus one module never completes an instruction in the same clock as the other.

The NDEDI block formats and queues ENGINE1 and ENGINE2 messages in the order they are generated. There is no way for the development tool to infer any other temporal information from the ETPU messages.

## 53.7.7.4 Timing Diagrams

Note that all of the following timing diagrams assume a 3-bit SRC size and either a 4-bit MDO port or a 16-bit MDO port. The state variable is not a signal, but instead is derived from `MSEO`. It is included for clarity. Refer to [Figure 53-23](#) for MSEO state diagram.

The following abbreviations are used for the state variable in the diagrams:

13. ETPU does not have a conditional indirect branch. Thus, there is no not-taken indirect branch.

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 53-48. Resource Full Message, I-CNT Overflow

Figure 53-50. Indirect Branch with History Message

**Figure 53-51. Indirect Branch with History Synchronization Message****Figure 53-52. Program Trace Correlation Message****Figure 53-53. Channel Start Service Message****Figure 53-54. Channel Trace Enable Message with the same value for CHAN and S-CHAN**

## Functional description

**Figure 53-55. Channel Trace Enable Message with different values for CHAN and S-CHAN**

**Figure 53-56. Channel Register Write Message**

## 53.7.8 Data Trace

Dual Engines perform loads and stores to the Shared Parameter RAM (SPRAM). The NDEDI block gathers information about these accesses on a dedicated bus. The NDEDI block traces all SPRAM accesses that meet the selected address range and attributes. This includes accesses from either Engines as well as Coherent Dual-Parameter Controller (CDC) accesses. SPRAM accesses can have data sizes of 8, 24, and 32 bits. The NDEDI block supports all three data sizes.

Whenever performing 8-bits accesses, the ETPU accesses the 8 most significant bits of the word addressed, while the 24-bits accesses are accomplished by accessing the 24 least significant bits. Thus, since the ETPU system uses the Big Endian convention and since the ETPU data addresses are byte-relative the two least significant bits of the transmitted address follows the convention shown in the following table.

**Table 53-33. Two least significant bits for Data Trace Addresses**

| Value | Access                        |
|-------|-------------------------------|
| 0b00  | ETPU 8-bit or 32-bit accesses |
| 0b01  | ETPU 24-bit accesses          |
| 0b1x  | Are not meaningful for ETPU   |

### 53.7.8.1 Data Trace Message Formats

There are four types of Data Trace Messages (DTMs):

- Data Write Message
- Data Read Message
- Data Write with Synchronization Message
- Data Read with Synchronization Message

All of the data trace messages contain a SIZE packet. The following table shows the decoding for this packet.

**Table 53-34. Data Trace SIZE Packet Decodings**

| SIZE Packet | Access Size    |
|-------------|----------------|
| 0b00        | Not Meaningful |
| 0b01        | 24 bits        |
| 0b10        | 8 bits         |
| 0b11        | 32 bits        |

#### 53.7.8.1.1 Data Write Message

The data write message contains the data write value and the address of the target location relative to the address of the previous data trace message from the same source.

The data write message has the format shown in the following figure.

**Figure 53-57. Data Write Message Format**

#### 53.7.8.1.2 Data Read Message

The data read message contains the data read value and the address of the target location relative to the address of the previous data trace message from the same source.

The data read message has the format shown in the following figure.

## Functional description

**Figure 53-58. Data Read Message Format**

### 53.7.8.1.3 Data Trace Synchronization Messages

The occurrence of any of the following conditions requires the following data trace message to be synchronizing:

- Exit of system reset
- Exit of low power mode
- Exit of debug mode
- Write to the development control register or data trace control register<sup>14</sup>
- Write to any of the ETPU data trace address range registers
- Exit of NDEDI reset
- 255 data trace messages of the same source are queued without synchronization
- Assertion of the Event In ( $\overline{\text{EVTI}}$ ) pin, depending on how the development control register is configured
- A watchpoint occurrence<sup>15</sup>
- A queue overrun

Data trace synchronization messages provide the full addresses (without leading zeros) and ensure that the development tools fully synchronize with data trace regularly. Each synchronization message provides a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted.

There are two types of data trace synchronization messages: data write synchronization and data read synchronization.

#### 53.7.8.1.3.1 Data Write Synchronization Message

The data write synchronization message has the format shown in the following figure.

14. Only the Source that have the register written will generate a synchronization message.

15. A Watchpoint occurrence for one Engine generates synchronization message for that Engine only.

**Figure 53-59. Data Write Synchronization Message Format****53.7.8.1.3.2 Data Read Synchronization Message**

The data read synchronization message has the format shown in the following figure.

**Figure 53-60. Data Read Synchronization Message Format****53.7.8.2 Data Trace Operation**

Data tracing is performed by snooping a dedicated ETPU/Nexus interface for SPRAM read and write cycles. Data trace functions are enabled by setting the appropriate fields in the following registers:

- ENGINE1 Development Control (NDEDI\_ENGINE1\_DC) Register
- ENGINE2 Development Control (NDEDI\_ENGINE2\_DC) Register
- ENGINE1 Data Trace Control (NDEDI\_ENGINE1\_DTC) Register
- ENGINE2 Data Trace Control (NDEDI\_ENGINE2\_DTC) Register
- CDC Data Trace Control (NDEDI\_CDC\_DTC) Register
- ETPU Data Trace Address Range 0 (NDEDI\_ETPU\_DTAR0) Register
- ETPU Data Trace Address Range 1 (NDEDI\_ETPU\_DTAR1) Register
- ETPU Data Trace Address Range 2 (NDEDI\_ETPU\_DTAR2) Register
- ETPU Data Trace Address Range 3 (NDEDI\_ETPU\_DTAR3) Register

For details on register configuration, refer to [Register descriptions](#).

The dual Engines and CDC data tracing share the same Data Trace Address Range Registers. This enables usage of more address ranges for one client when the others are not being traced, or monitoring a certain range regardless of which client accesses the range.

The ETPU provides information to the NDEDI block when the access is actually being performed. The NDEDI does not have to track a bus protocol or check for error conditions on the accesses, since SPRAM does not generate errors. Any access signaled by the ETPU/NDEDI interface completes without error. Data trace flow is depicted in the following figure.

Figure 53-61. ETPU/CDC Data Trace Flow Diagram

### 53.7.8.2.1 Data Trace Windowing

Data trace windowing is provided so the development tool can decrease the auxiliary port usage by limiting the accesses that are traced.

Data trace windowing is achieved via the address range defined by the DTSA and the DTEA fields of the DTAR registers. These registers are shared by ENGINE1, ENGINE2, and the CDC. SPRAM accesses will be traced if their address fall in any of these ranges and the specific range is enabled in the data trace control register of the source making the access. Data read and/or data write trace may be enabled via the Read/Write Trace Control fields in the data trace control registers.

Data trace ranges are 32-bit aligned. This alignment is done by making the two least significant bits of the DTSA and DTEA fields read only. Since the two least significant bits of DTSA and DTEA are read only and default to different values, DTSA can never equal DTEA. The following figure shows the relationship between the DTSA and DTEA fields.

| Programmed Value | Ranged Selected                             |
|------------------|---------------------------------------------|
| DTSA < DTEA      | DTSA → ← DTEA                               |
| DTSA > DTEA      | All addresses are out of Range <sup>1</sup> |
| DTSA == DTEA     | Impossible <sup>2</sup>                     |

**Figure 53-62. Data Trace Address Range Options**

### 53.7.8.2.2 Relative Addressing

The relative address feature is compliant with the IEEE-ISTO 5001-2002 standard recommendations and is designed to reduce the number of bits transmitted for addresses of data read and data write messages.

The address transmitted for a determined source is relative to the address of the previous data trace message sent for that source. It is generated by XORing the new address with the previous address and then using only the results up to the most significant '1' in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address. The following figure shows how a relative address is generated and how it can be used to recreate the original address.

Previous Address (A1) = 0xC10, New Address (A2) = 0xF64

**Address Generation:**

A1 = 1100 0001 0000  
A2 = 1111 0110 0100  
A1 ^ A2 = 0011 0111 0100  
Address Message (M1) = 11 0111 0100

**Address Recreation:**

A1 ^ M1 = A2  
A1 = 1100 0001 0000  
M1 = 0011 0111 0100  
A1 ^ M1 = 1111 0110 0100 = A2

Figure 53-63. Relative Address Generation and Recreation1

53.7.8.3 Timing Diagrams

Note that all of the following timing diagrams assume a 3-bit SRC size and either a 4-bit MDO port or a 16-bit MDO port. The state variable is not a signal, but instead is derived from  $\overline{\text{MSEO}}$ . It is included for clarity. Refer to [Figure 53-23](#) for  $\overline{\text{MSEO}}$  state diagram.

The following abbreviations are used for the state variable in the diagrams:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 53-64. Data Write Message

Figure 53-65. Data Read Message

Figure 53-66. Data Write with Synchronization Message

Figure 53-67. Data Read with Synchronization Message

### 53.7.9 Watchpoint Trace

The NDEDI module provides ETPU watchpoint messaging via the auxiliary port, as defined by the IEEE-ISTO 5001-2002 standard.

### 53.7.9.1 Messaging

The NDEDI block provides watchpoint messaging using IEEE-ISTO 5001-2002 standard-defined public messages. When a watchpoint occurs, a watchpoint event is sent to the Event Queue. If the watchpoint condition occurs while the Event Queue is not enabled for storing snapshots, a watchpoint overrun message is generated.

The watchpoint message has the format shown in the following figure.

Figure 53-68. Watchpoint Hit Message Format

The values for the WPHIT packet are described in [Table 53-35](#) . Notice that WPHIT is never 0 because the message is only generated when a watchpoint has occurred.

Table 53-35. WPHIT Values

| Value     | Meaning                                    |
|-----------|--------------------------------------------|
| 0b1xxxxxx | ETPU Watchpoint 1 (based on BWC1 register) |
| 0bx1xxxxx | ETPU Watchpoint 2 (based on BWC2 register) |
| 0bxx1xxxx | Channel Register Write Watchpoint          |
| 0bxxx1xxx | Host Service Request Watchpoint            |
| 0bxxxx1xx | Link Register Watchpoint                   |
| 0bxxxxx1x | MRL Watchpoint                             |
| 0bxxxxxx1 | TDL Watchpoint                             |

### 53.7.9.2 Error Messages

A watchpoint overrun error event is queued if an watchpoint event occurs and the Event Queue is not enabled for storing snapshots. This event is queued as soon as the Event Queue gets empty.

The error message has the format shown in the following figure.

Figure 53-69. Watchpoint Overrun Error Message Format

### 53.7.9.3 Synchronization

Upon the occurrence of a watchpoint, the next program and data trace messages are synchronization messages. A watchpoint in one of the Engines causes data and program synchronization for that Engine only.

### 53.7.9.4 Timing Diagrams

Note that all of the following timing diagrams assume a 3-bit SRC size and a 16-bit MDO port. The state variable is not a signal, but instead is derived from  $\overline{\text{MSEO}}$ . It is included for clarity. Refer to [Figure 53-23](#) for  $\overline{\text{MSEO}}$  state diagram.

The following abbreviations are used for the state variable in the diagrams:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

**Figure 53-70. Watchpoint Message**

**Figure 53-71. Watchpoint Overrun Error Message**

## 53.7.10 ETPU Message Queue

The NDEDI implements an external Q\_SIZE location Queue that is shared by data trace, ownership trace, program trace, watchpoint, error and debug status events.

One single microcycle may generate a combination of data trace, ownership trace, program trace, watchpoint, error and debug status events. The data trace events related to one engine have different timing though, being generated at the system clock subsequent to the other events. Thus, since the ENGINE1 and ENGINE2 alternate instructions, a snapshot may contain data trace information regarding to one engine and other events information related to the other engine.

With the occurrence of one or more events at one specific cycle, a snapshot of the signals, that can give information about all events, is queued in only one location of the Queue. The information of the source which have generated the events is also queued at the same position, so the Message Formatter can reconstruct the messages of the occurred events. [Figure 53-72](#) shows the Event Queue Block Diagram.

The Queue operation is transparent to the user.

The Event Queue is read whenever there is at least one position of the FIFO occupied and there are no concurrent writes to the Queue. Thus, the appropriate message is formatted and a request to send the message is sent to the Nexus Port Controller (NPC). The request will be assigned a level based on the number of used positions in the Queue as shown in the following table.

**Table 53-36. MDO Request Level**

| Level | Used positions (q) as a fraction of the Queue size |
|-------|----------------------------------------------------|
| 0     | $q = 0$                                            |
| 1     | $1 \leq q < 0.5$                                   |
| 2     | $0.5 \leq q < 0.75$                                |
| 3     | $0.75 \leq q^1$                                    |

1. The MDO request will also be 3 whenever the Queue is disabled for storing new snapshots due to an overrun.

According to the request priority of the NDEDI and the other Nexus Blocks within the chip, the NPC will grant the Auxiliary port to the NDEDI, and as soon as the auxiliary port is granted, the NDEDI will send the message. If there are other pending messages in the same snapshot, a new request is sent and a new grant is expected from the NPC. The next snapshot is only read when there are no pending messages to be sent in the current snapshot and there are no concurrent write accesses to the Queue.

If more than one message event are to be sent, the Message Formatter sends first the Messages related to Debug Status, then the Messages related to Watchpoints, then the messages related to Program Trace and latest the Data Trace Messages.

If the Q\_SIZE position of the Queue is full and an event occurs, the Event Queue is disabled for storing any information. The MDO request level will be 3 until the last snapshot is sent. When the Queue gets empty, an Error event is queued containing information of all lost events. At this point, snapshots may be queued again.<sup>16</sup>

NDEDI keep temporal ordering of messages relative to ENGINE1, ENGINE2 and CDC, but not relative to messages generated by other clients sharing the auxiliary port.

**Figure 53-72. Event Queue**

### 53.7.10.1 Queue Control

The queue is able to perform a single read or write operation per system clock. Thus, since there are no buffers to neither traces nor watchpoint events, the Message Formatter can only read the Event Queue if no events happen at the same time.

### 53.7.10.2 Error Messages

A trace or watchpoint overrun error occurs when an event cannot be queued. The error code (ECODE) within the error message indicates what type of trace overrun has occurred and that messages might have been lost for any or all of these events. [Table 53-25](#) shows the error code encodings for the various overrun error conditions.

16. If ENGINE<sub>x</sub> is in stall condition, and an error happens, the ENGINE<sub>x</sub> operation will only be resumed after the Queue is empty.

When information is lost, the Event Queue is disabled and no events are queued until the Event Queue gets empty. After the Event Queue gets empty an error message is queued indicating which information was lost for each source. At this point the Queue is enabled for storing snapshots again.

If multiple sources lose information at the same time multiple error messages are sent. In this case, the message related to the Engine 1 will be sent first, then the message related to the Engine 2 and finally the Error message related to the CDC.

The error message has the format shown in the following figure.

Figure 53-73. Error Message Format

53.7.10.3 Timing Diagrams

Note that the following timing diagram assumes a 3-bit SRC size and a 16-bit MDO port. The state variable is not a signal, but instead is derived from  $\overline{\text{MSEO}}$ . It is included for clarity. Refer to [Figure 53-23](#) for  $\overline{\text{MSEO}}$  state diagram.

The following abbreviations are the values for the state variable in the diagram:

- ID = Idle
- SM = Start Message
- NT = Normal Transfer
- EP = End Packet
- EM = End Message

Figure 53-74. Error Messages (Program/Data/Ownership Trace Overrun)

Notice that three overrun messages are transmitted in the preceding figure. The first is an overrun indication for ENGINE1, the second is an overrun indication for ENGINE2, and the third is an overrun indication for the CDC.

## 53.8 Initialization/Application Information

The following section describes the Initialization/Application Information process.

### 53.8.1 Accessing NDEDI tool-mapped registers

To initialize the JTAG port for register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Retrieve Device ID if needed
3. Load the Nexus TAP controller with the NEXUS-ENABLE instruction

To write control data to NDEDI tool-mapped registers, the following sequence is required:

1. Write to the client select control register, if needed
2. Write the 7-bit register index and set the write bit to select register with a pass through the SELECT-DR-SCAN path in the JTAG state machine
3. Write the register value with a pass through the SELECT-DR-SCAN path. Notice that the prior value of this register is shifted out during the write

To read status and control data from NDEDI tool-mapped registers, the following sequence is required:

1. Write to the client select control register if needed
2. Write the 7-bit register index and clear write bit to select register with a pass through SELECT-DR-SCAN path
3. Read the register value with a pass through the SELECT-DR-SCAN path. Data shifted in is ignored

See [IEEE 1149.1 \(JTAG\) Input Port](#) for more detail.

## 53.8.2 Program Trace Reconstruction

This section details the program trace reconstruction mechanism supported by Nexus3 for the NDEDI. Program trace is implemented via Branch Trace Messaging (BTM) as per the Class 3 IEEE-ISTO 5001-2002 standard.

### 53.8.2.1 Branch Trace Messages

Branch Trace Messaging allows program trace by providing the following types of information:

- Messaging for start of program trace
  - Channel Start Message (CSM)
  - Channel Trace Enable Message (CTM)
- Branches with run-time target address (indirect branches)
  - Indirect Branch with History Message (IHM)
  - Indirect Branch with History and Synchronization Message (IHS)
- Discontinuity Information:
  - History including information of predicated instruction execution and information of all branches taken or not taken with compile-time target address. (direct branches)
  - Information of the amount of sequential instructions executed since the last branch. (ICNT)
    - Channel Start Message (CSM)
    - Indirect Branch with History and Synchronization Message (IHS)
    - Resource Full Message (RFM)
    - Program Correlation Message (PCM)
- Information of Program Trace End
  - Channel Start Message (CSM)
  - Program Correlation Message (PCM)
- Program trace overrun

- An Error Message will be issued if program trace information is lost due to FIFO overrun. The following error codes indicates program trace error: ECODE = 0b00001, 0b00111, 0b01000, 0b11001 and 0b11010

### 53.8.2.2 Assembly Code

The assembly code is necessary for gathering information about the direct branches location, target addresses for direct branches, predicated instructions location and "non-flush" indication.

The following eTPU instruction formats<sup>17</sup> can generate direct branches:

E1, E2, E3 and E4

The following eTPU instruction formats can be predicated:

A3, B4, B5 and B6 but only if AS/CE differs 0, 1 and 7.

The following eTPU instruction formats can be indirect branches:

A1 with RTN = 1, D1, D2, D3 and D4

The Branch instructions have the capability of executing one instruction before changing the flow to the target address. The instruction being executed before the change of flow is hereafter called "non flushed" instruction.

The following eTPU instruction formats can lead to "non flushed" instructions:

D1, D2, D3, D4, E1, E2, E3 and E4 if FLS = 1

The other formats will lead to sequential instructions.

### 53.8.2.3 Branch Indication

The branch indication within the eTPU/NDEDI system happens at the instruction execution instead of the branch target execution. Thus it is important to notice that the "non flushed" instruction will be stored in the subsequent HIST/ICNT information. It is also important to notice that a CTM message is not issued if program trace is enabled in a "non flushed" instruction. In this case a CTM will be issued in the subsequent instruction.

17. Please refer to the ETPU Block Guide for further information about the instructions format.

### 53.8.2.4 Code Reconstruction

The CSM and CTM messages indicate the starting program trace address. Thus, these messages must be used as a starting point in order to synchronize the reconstruction program with the Assembly code.

From the starting point, the program flow can be completely reconstructed unless an Error message is issued. If an Error message is issued, watchpoints must be used to enable/disable program trace reducing the number of program trace messages.

### 53.8.2.5 Program Reconstruction Examples

Follows a code example where the reconstruction can be performed with the generated messages.

The program reconstruction will be performed by using the following two components:

- A copy of the program. Ideally this would be a listing file from the assembler;
- The program trace messages sent to the development tool;

#### 53.8.2.5.1 Example 1

Follows the Example Code file:

```
234 FFFFFFFF format:F1.
235 010F64D1 format:A2 t2abd:"RAR", imm:578.
236 F7E846FF format:E4 j/c:"jump",bcc:"false",fls:"no_flush",bcf:"true",
    baf:567.
237 8AD4A218 format:B1 shf:"ror",cin:"no_carry",binv:"inv",t2abd:"P[31:24]",
    rw:"write",t4abs:"TRR",t4bbs:"BS=0,1st_2nd",src:">>1",p/d:"P",
    ccs:"flag_size",end:"yes",aid:24.
```

Follows the messages generated for a certain run example:

1. CSM (s=0x3) [S-CHAN=0x1e] [I-CNT=0x0000] [faddr=0x0234] [HIST=0x00000001];
2. PCM (s=0x3) [event=0x0] [I-CNT=0x01] [HIST=0x00000001];
3. CTM (s=0x3) [S-CHAN=0x001e] [faddr=0x0235] [CHAN=0x00000000];
4. PCM (s=0x3) [event=0x0] [I-CNT=0x00] [HIST=0x00000002];
5. CTM (s=0x3) [S-CHAN=0x001e] [faddr=0x0237] [CHAN=0x00000000];
6. CSM (s=0x3) [S-CHAN=0x11] [I-CNT=0x0001] [faddr=0x0443] [HIST=0x00000001];

## Reconstruction:

The reconstruction starts with CSM pointing to the 0x0234 address. Note that ICNT = 0x0 and HIST = 0x1 indicating that there was no previous thread being executed.

PCM with event = 0x0 indicates that eTPU entered in debug mode. ICNT = 0x01 and HIST = 0x1 means that there were no direct branches and only one sequential instruction. Thus, instruction at address 0x0234 was executed and then eTPU entered in debug mode.

The third message is CTM which indicates that Program Trace was enabled again (eTPU exited debug mode) at address 0x0235. Then, another PCM with event = 0x0 was issued indicating entry in debug mode. From the code it is possible to inquire that instruction at address 0x0235 is a sequential instruction and the instruction at address 0x0236 is a conditional jump with "no flush".

HIST = 0b10 indicates that the first branch after address 0x0235 was reached but not taken. ICNT = 0x0 indicates that no sequential instruction after the last branch was executed, thus, it is possible to conclude that the code entered in debug mode just after executing the instruction at address 0x0236.

The fifth message is CTM which indicates a new Program Trace enable at address 0x0237.

The next message refers to CSM, and it indicates that a new thread is starting at address 0x0443. HIST=0b1 and ICNT=0b1 refers to the old thread and states that one sequential instruction (at address 0x0237) was executed before starting the new thread. This is the expected behavior since the address 0x0237 contains a "end=yes" command.

### 53.8.2.5.2 Example 2

Follows the Example Code file:

```
336 CB5CE283 3083 format:D1 mrle:"match_off",psc:"high",fls:"flush",rw:"write",
    pscs:"opac2",flc:"flags=P[25:24]",circ:"nop",
    r/d:"dispatch_call",p/d:"P",rsiz:"24",aid:131,
    end:"no".
...
41B 00AF6531 3962 format:A2 t2abd:"RAR", imm:1065.
41C F32083BF 3965 format:E4 j/c:"jump",bcc:"LSR",fls:"no_flush",bcf:"false",
    baf:1053.
41D 11092F98 3968 format:A1 t2d:"DIOB",rtn:"nop",IMM:9608768.
41E 004F7757 3971 format:B3 shf:"<<1",cin:"use_carry",binv:"inv",t4bbs:"SR",rw:"read",
    t4abs:"AS[23:0]=0",t2abd:"MACH",src:">>1",p/d:"DIOB",
    ccs:"no_flags",zro:"clear",end:"yes",
    stc:"no_inc/dec".
```

Follows the messages generated for a certain run example:

1. CSM (s=0x3) [S-CHAN=0x0f] [I-CNT=0x0001] [faddr=0x0336]  
[HIST=0x0000000a];

2. IHM (s=0x3) [I-CNT=0x00] [uaddr=0x072d] [HIST=0x00000001];
3. CSM (s=0x3) [S-CHAN=0x14] [I-CNT=0x0003] [faddr=0x0345] [HIST=0x00000003];

#### Reconstruction:

The first CSM indicates that the thread will be started at the address 0x0336. The next message is an IHM with I-CNT = 0x0 and HIST = 0x1 indicating that no instructions were executed until the indirect branch. The message indicates u-addr = 0x072d, thus the target address of this instruction is 0x041b (0x0336 XOR 0x072d). Note that since the instruction at 0x0336 is a flush instruction, then the instruction at 0x0337 is not supposed to be executed.

The next message refers to CSM, and it indicates that a new thread is starting at address 0x0345. Since HIST = 0x3, either the next branch (after address 0x041b) was taken or the next predicated instruction (after address 0x041b) was executed. From address 0x041b the next branch instruction is located at 0x041c address, thus all instructions were executed until this address.

The instruction within the address 0x041c refers to a branch with no\_flush instruction to address 0x041d.

Since I-CNT = 0x3, it is expected that 3 sequential instructions are executed after the branch instruction.

The instruction within 0x041d will be executed since it is a non-flushed instruction, then it will be executed again since 0x041d is the target for the branch instruction executed before, and finally the instruction within the address 0x041e is executed. Note that the instruction within 0x041e contains a "end=yes" command which will finish the current thread.

### 53.8.3 Microcode Development Support

The following sections describe the steps required to perform various class 1 features with the NDEDI block.

#### 53.8.3.1 Read and Write SPRAM In Debug Mode

Reading and writing to the SPRAM is done through Nexus read/write access hardware external to the NDEDI block. Refer to the MCUs SoC Guide for details. SPRAM reads and writes are done the same in debug mode as they are in run mode.

### 53.8.3.2 Read and Write ETPU Internal Registers in Debug Mode

1. Select an area of the SPRAM to be used for dumping the register values
2. Read the current value of those SPRAM locations and store them
3. Write to the SPRAM as needed for writing internal ETPU registers
4. Execute external microcode that reads values from the SPRAM location and writes the values to registers or reads registers and writes the values to the SPRAM. See [Execute Forced Microcode Instruction in Debug Mode](#) for more details
5. Read the SPRAM as needed to retrieve register read values
6. Write the SPRAM back to the original values

### 53.8.3.3 Enter Debug Mode at the Negation of Reset

If the DBE field of the ETPU's Development Control register is asserted, NDEDI ETPU will enter debug mode as soon as the system reset is negated. Configure other bits as appropriate.

### 53.8.3.4 Enter Debug Mode During Normal Execution

To enter debug mode during normal execution, write the ETPU's Development Control register to set the DBE and DBR bits. Configure other bits as appropriate.

### 53.8.3.5 Stop Program Execution on a Breakpoint

There are four possibilities to stop the program execution on a Breakpoint:

1. Program execution halts at the end of the current microcycle when a synchronous breakpoint condition is reached. A synchronous breakpoint condition occurs due to the following breakpoints:
  - Breakpoint due to DBR assertion
  - Twin Engine breakpoint<sup>18</sup>

---

18. Depending on CBT value

- External breakpoint<sup>19</sup>
  - Breakpoint due to exit of system reset
  - breakpoint due to start of a channel service
  - Single Step breakpoint
  - breakpoint due to EVTI assertion
  - breakpoint due to MISC miscompare
2. Program execution stops at the beginning of the current microcycle when an asynchronous breakpoint condition is reached. An asynchronous condition occurs due to the following breakpoints:
    - breakpoint due to SPRAM access
    - breakpoint due to Illegal instruction
    - breakpoint due to CHAN register write
  3. Program execution stops at the end of the current thread if a twin breakpoint or an external source requests to enter in debug mode and the NDEDI is programmed to enter in debug mode only at the end of the current thread
  4. Whenever fetching an instruction, if the microprogram counter matches the BWA related to one of the breakpoint conditions programmed for breaking into an instruction fetch, the instruction is tagged indicating that it must not be executed. The microengine halts just before the execution of this instruction if it was supposed to be executed<sup>20</sup>.

See [Set Breakpoint or Watchpoints](#) and [Register descriptions](#) for details on configuring breakpoints.

#### 53.8.3.5.1 Multiple breakpoint conditions at the same address

The ETPU block must always execute the first instruction after exiting debug mode.

Assume that an engine is halted due to a synchronous breakpoint at a given address. As soon as the engine exits debug mode, the instruction at the given address will be executed anyway, even if other breakpoint conditions are matched, for instance tagged instructions or asynchronous breakpoints.

---

19. Depending on CBT value

20. Instructions flushed after a JUMP are not considered to be executed

Although the DS register doesn't signalize the other breakpoint conditions, the development tool can infer from the NDEDI registers and pre-loaded code if the engine is halted in one of these conditions.

### 53.8.3.6 Single Step Instructions and Re-Enter Debug Mode

To single step an instruction from shared code memory in debug mode, write to the Engine's Development Control register so the CBR bit is asserted, the DBR bit is cleared and the SS bit is asserted. Single stepping causes the Engine to exit debug mode for a microcycle where the TCRs, decrementors, and microprogram counter can update. Program Trace messages are generated within Single Step operation.

### 53.8.3.7 Set Breakpoint or Watchpoints

There are two main ETPU breakpoint/watchpoint sources that are independent of each other but have identical configuration registers. Each can be configured as either a breakpoint or watchpoint that detects reads and/or writes, compares data and/or address. Each can be configured to occur only on certain Channel services.

In addition, there is a breakpoint/watchpoint that can be configured to occur when the CHAN register is written to a certain value.

There are also four channel service breakpoint/watchpoints that can be configured to occur when a specific channel is serviced for one of the following reasons: host service request, link request, match detect, and transition detect.

Breakpoints cause the Engine to halt. Watchpoints cause a watchpoint hit message. All breakpoint/watchpoint sources can be configured to assert EVTO on an breakpoint/watchpoint occurrence.

Refer to [Register descriptions](#) for detailed descriptions of breakpoint/watchpoint registers.

### 53.8.3.8 Execute Forced Microcode Instruction in Debug Mode

To execute a forced instruction in debug mode, write the instruction into the Microinstruction debug register. This mechanism does not cause the Engine to exit debug mode so the microprogram counter is not updated (unless a branch instruction is executed) and the TCRs and decrementors are not updated if the CLKS bit is asserted in the Development Control Register. Executing instructions in this manner is useful for reading and writing internal Engine registers.

## Chapter 54

# Development Trigger Semaphore (DTS)

### 54.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

#### Note

When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2012 Nexus standards, which use the Nexus Auxiliary port.

### 54.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal—DTS Trigger Output (DTO). The registers are as follows:

- **DTS\_SEMAPHORE** register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding **DTS\_EN** bit is set in the **DTS\_ENABLE** register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.

- **DTS\_SEMAPHORE\_B** register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding **DTS\_EN\_B** bit is set in the **DTS\_ENABLE** register. This enables an external tool to detect an additional 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.
- **DTS\_STARTUP** register—This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- **DTS\_ENABLE** register—This register provides an enable/disable capability for the DTS feature.

The architecture is shown in the following figure.

**Figure 54-1. DTS block diagram**

The DTS Trigger Output (DTO) signal is connected to one of the EVTO inputs of the Nexus Port Controller (NPC). The other EVTO inputs are connected to the other Nexus modules in the device. DTO is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

### Note

When the DTS module is enabled ( $\text{DTS\_ENABLE}[\text{DTS\_EN}] = 0b1$  or  $\text{DTS\_ENABLE}[\text{DTS\_EN\_B}] = 0b1$ ), all other Nexus EVTO functions associated should be disabled by the tool and

EVTO becomes the DTO. Unlike the EVTO function that only asserts for one clock, the DTO function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

The following figure shows an example of the chain of events that begins with setting of a bit in the DTS\_SEMAPHORE register and the clearing of the register caused by a Nexus read.

Figure 54-2. DTO event sequence example

### 54.3 DTS device connections

The following figure shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

Figure 54-3. DTS device connections

The registers have limited access as described in [DTS register access](#). Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore registers is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool can clear bits in the semaphore registers (semaphore register bits are cleared automatically when read). Similarly, the DTS\_ENABLE and DTS\_STARTUP registers can only be written via a Nexus Read/Write Access.

### Note

Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

## 54.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in the following table. Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

**Table 54-1. DTS register access effects**

| Register        | 32-bit read                 |      |      |                        | 32-bit write     |           |           |                        |
|-----------------|-----------------------------|------|------|------------------------|------------------|-----------|-----------|------------------------|
|                 | RWA <sup>1</sup>            | Core | eDMA | Other crossbar masters | RWA <sup>1</sup> | Core      | eDMA      | Other crossbar masters |
| DTS_ENABLE      | Data                        | Data | Data | Data                   | Data             | No effect | No effect | No effect              |
| DTS_STARTUP     | Data                        | Data | Data | Data                   | Data             | No effect | No effect | No effect              |
| DTS_SEMAPHORE   | Data and Clear <sup>2</sup> | Data | Data | Data                   | No effect        | Bit OR    | Bit OR    | No effect              |
| DTS_SEMAPHORE_B | Data and Clear <sup>2</sup> | Data | Data | Data                   | No effect        | Bit OR    | Bit OR    | No effect              |

1. Nexus Read/Write access via an external tool

2. A read of the semaphore registers by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

### Note

The XBAR Master ID should not be confused with the Master Port number of the XBAR. See the Crossbar Switch (XBAR) chapter for details.

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

## 54.4 Memory mapped registers

Only certain types of accesses are allowed to the DTS registers. See the description for each register to determine the accesses that are allowed.

**DTS memory map**

| Address offset (hex) | Register name                         | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|---------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | Output Enable Register (DTS_ENABLE)   | 32              | R/W    | 0000_0000h  | <a href="#">54.4.1/2483</a> |
| 4                    | Startup Register (DTS_STARTUP)        | 32              | R/W    | 0000_0000h  | <a href="#">54.4.2/2484</a> |
| 8                    | Semaphore Register (DTS_SEMAPHORE)    | 32              | R/W    | FFFF_FFFFh  | <a href="#">54.4.3/2485</a> |
| C                    | Semaphore Extension (DTS_SEMAPHORE_B) | 32              | R/W    | FFFF_FFFFh  | <a href="#">54.4.4/2486</a> |

### 54.4.1 Output Enable Register (DTS\_ENABLE)

The DTS\_ENABLE register controls the DTS Trigger Output ( $\overline{D\bar{T}O}$ ) and whether  $\overline{D\bar{T}O}$  is active on the  $\overline{E\bar{V}\bar{T}O}$  output pin of the device. The DTS\_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

#### NOTE

Access to the DTS\_SEMAPHORE, DTS\_SEMAPHORE\_B, and DTS\_STARTUP registers are unaffected by the state of this register.

## 54.4.2 Startup Register (DTS\_STARTUP)

The DTS\_STARTUP register is used for tool detection and startup information exchange between external data acquisition tool and the embedded controller. DTS\_STARTUP register can be read by the core, the eDMA module and Nexus but can only be updated by a Nexus Read Write Access (RWA).

|       | software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access to update the contents of this register.<br><br>A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register. |

**54.4.3 Semaphore Register (DTS\_SEMAPHORE)**

The DTS\_SEMAPHORE register is used by software to assert the  $\overline{\text{DTO}}$  signal on the device  $\overline{\text{EVTO}}$  pin. A one in any bit of this register causes the  $\overline{\text{DTO}}$  signal on the  $\overline{\text{EVTO}}$  pin to be driven low. The intended use of this register is for the  $\overline{\text{DTO}}$  signal to notify tools that data is available. Individual bits are used to identify the specific data.

54.4.4 Semaphore Extension (DTS\_SEMAPHORE\_B)

The DTS\_SEMAPHORE\_B register is used by software to assert the  $\overline{DTO}$  signal on the device  $\overline{EVTO}$  pin. A one in any bit of this register causes the  $\overline{DTO}$  signal on the  $\overline{EVTO}$  pin to be driven low. The intended use of this register is for the  $\overline{DTO}$  signal to notify tools that data is available. Individual bits are used to identify the specific data.

Address: 0h base + Ch offset = Ch

DTS\_SEMAPHORE\_B field descriptions

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

54.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.

In this type of application the DTS\_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

## Note

It is the user's responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

The following table shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS\_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS\_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS\_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS\_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS\_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS\_SEMAPHORE register (the example shown in the figure above uses 0xAAAA\_AAAA—all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

Figure 54-8. DTS startup sequence example

# Chapter 55

## Fault Collection and Control Unit (FCCU)

### 55.1 Chip-specific FCCU information

The FCCU on this chip supports 46 non-critical faults (NCFs).

#### 55.1.1 FCCU register default values

The following table documents FCCU register default values that are specific to this chip. For the default values of all other FCCU registers, see [Register descriptions](#).

**Table 55-1. FCCU register default values**

| Register       | Default value           |
|----------------|-------------------------|
| FCCU_CFG       | 0000_0000h <sup>1</sup> |
| FCCU_NCF_CFG0  | FFFF_FFFFh              |
| FCCU_NCF_CFG1  | 0000_FFFFh              |
| FCCU_NCFS_CFG0 | 2200_2000h              |
| FCCU_NCFS_CFG1 | 0000_0000h              |
| FCCU_NCFS_CFG2 | 0000_0000h              |
| FCCU_NCF_E0    | 0000_5040h              |
| FCCU_NCF_E1    | 0000_0000h              |
| FCCU_NCF_TOE0  | 0000_0000h              |
| FCCU_NCF_TOE1  | 0000_0000h              |
| FCCU_NCF_TO    | 0000_FFFFh              |
| FCCU_CFG_TO    | 0000_0006h              |

1. FCCU\_CFG resets to 0000\_0000h after the chip resets the FCCU. After a Configuration-state timeout, the value of FCCU\_CFG is 0000\_0008h. For details, including the value of FCCU\_CFG after an OP31 operation, see [FCCU\\_CFG register event bit values by source \(N and C\)](#).

## 55.1.2 FOSU\_COUNT value

The FCCU Output Supervision Unit (FOSU) has a timer whose duration is the value FOSU\_COUNT. On this chip, the value is 8000 IRCOSC clock cycles.

## 55.1.3 FCCU fault inputs

The following table identifies the various fault input signals to the FCCU, how they can be tested, and the default reaction to each input after the FCCU itself is reset.

**Table 55-2. FCCU non-critical fault (NCF) mapping**

| NCF | Fault                 | Fault description                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Error reaction path check <sup>1</sup>                                                                  | Default reaction after reset |
|-----|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|------------------------------|
| 0   | TEMP_ERROR            | Event indication from temperature sensor. The fault is cleared by clearing the status in PMC_ESR_TD, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                                                                                                                                                                                                         | LBIST + TSNS_FAULT bit of Temperature Sensor Fault Injection Register (PMC_TS_FIR)                      | No reaction                  |
| 1   | LVD_ERROR             | Voltage out of range indication from LVDs. The fault is cleared by clearing the status in PMC_LVD_HVD_EVENT_STATUS, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                                                                                                                                                                                          | LVD assertion test by tap point manipulation + LVD_FAULT bit of FCCU Fault Injection Register (PMC_FIR) | No reaction                  |
| 2   | HVD_ERROR             | Voltage out of range indication from HVDs. The fault is cleared by clearing the status in PMC_LVD_HVD_EVENT_STATUS, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                                                                                                                                                                                          | HVD assertion test by tap point manipulation + HVD_FAULT bit of FCCU Fault Injection Register (PMC_FIR) | No reaction                  |
| 3   | DPMC_SELF_TEST        | Digital PMC initialization error during self test. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. The status gets cleared if the fault is not persistent.                                                                                                                                                                                                                                                                                       | LBIST+ STEST_FAULT bit of FCCU Fault Injection Register (PMC_FIR)                                       | No reaction                  |
| 4   | MEMORY_DCF_SAFETY_ERR | Indication of fault during timing/repair configuration initialization by SSCM of different memories. Faults can be caused by parity or triple-redundant errors in loaded configuration data. The status is cleared by clearing SSCM_STATUS[CERS], followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. The status gets cleared if the fault is not persistent. Additionally, this error will cause a MBIST failure. This channel bit is cleared in case of reset. | LBIST                                                                                                   | No reaction                  |
| 5   | SSCM_XFER_ERR         | SSCM transfer or parity error during DCF loading (trimming, STCU, and UTEST Miscellaneous <sup>2</sup> ). This fault is also asserted when there is a flash memory ECC double bit detection during flash memory reset reads or coherency checks done on the flash memory test row reads. The fault is                                                                                                                                                                          | Not testable (but wrong configuration can trigger other detection)                                      | No reaction                  |

*Table continues on the next page...*

**Table 55-2. FCCU non-critical fault (NCF) mapping (continued)**

| NCF | Fault                           | Fault description                                                                                                                                                                                                     | Error reaction path check <sup>1</sup>                                     | Default reaction after reset |

|     |                                 | cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. This channel bit is cleared in case of reset.                                                                 |                                                                            |                              |
| 6   | STCU_UF                         | STCU unrecoverable error during self-test. Fault is cleared by clearing STCU2_ERR_STAT[UFSF] followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                        | SW check of BIST MISR or Feedback loop via FCCU Fake bit                   | Reset                        |
| 7   | STCU_RF                         | STCU recoverable error during self-test. Fault is cleared by clearing STCU2_ERR_STAT[RFSF] followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                          | SW check of BIST MISR or Feedback loop via FCCU Fake bit                   | No reaction                  |
| 8   | STCU_LMBIST_USR_ERR             | Activation of LBIST or MBIST control during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. The status will clear if the fault is not persistent.                         | Feedback loop via FCCU Fake bit.                                           | No reaction                  |
| 9   | SPURIOUS_DEB_UG_SSCM_ACTIVATION | JTAG, NPC, or Debug functionality moved out of reset or SSCM activation during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                            | LBIST + Feedback loop via FCCU Fake bit                                    | No reaction                  |
| 10  | RCCU_0                          | Safety cores out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                   | LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input | No reaction                  |
| 11  | RCCU_1                          | Safety cores out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                   | LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input | No reaction                  |
| 12  | WDRS_DBRC0                      | Core 0 Watchdog Timer reset status (TSR[WRS]) and Core 0 Debug Reset Control (DBCR0[RST]). The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared in TSR[WRS].                         | LBIST + SW test by not triggering WD during startup                        | Reset                        |
| 13  | WDRS_DBRC1                      | Core 1 Watchdog Timer reset status (TSR[WRS]) and Core 1 Debug Reset Control (DBCR0[RST]). The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared in TSR[WRS].                         | LBIST + SW test by not triggering WD during startup                        | No reaction                  |
| 14  | SWTRS0                          | Software Watchdog A reset. The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared inside SWT_A.                                                                                        | LBIST + SW test by not triggering SWT during startup                       | Reset                        |
| 15  | SWTRS1                          | Software Watchdog B reset. The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared inside SWT_B.                                                                                        | LBIST + SW test by not triggering SWT during startup                       | No reaction                  |
| 16  | SWTINT0                         | Software Watchdog A interrupt request. The fault is cleared by clearing FCCU_NCF_Sn[NCFSm] after the status has been cleared inside SWT_A.                                                                            | LBIST + SW test by not triggering SWT during startup                       | No reaction                  |
| 17  | FLASH_INIT <sup>3</sup>         | Flash memory initiation error. This fault is intended for debug purposes only because, if such an error occurs, no code will run from flash memory. It is expected that this fault is read through development tools. | LBIST                                                                      | No reaction                  |

*Table continues on the next page...*

**Table 55-2. FCCU non-critical fault (NCF) mapping (continued)**

| NCF | Fault     | Fault description                                                                                                                                                                                                                                                                                                                                               | Error reaction path check <sup>1</sup>                                            | Default reaction after reset |
|-----|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------|
| 18  | SSCM_INIT | SSCM initiation error. DCFs might not have loaded properly.                                                                                                                                                                                                                                                                                                     | LBIST                                                                             | No reaction                  |
| 19  | PER_CE    | Indication of correctable errors in eTPU, M_CAN, and FlexCAN RAM Controllers. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. For proper eTPU SCM and SDM monitoring, eTPU_MESR_MECR[MECIE] must be set to 1.                                                                                                                     | Error injection in eTPU, FlexCAN, M_CAN + LBIST + Feedback loop via FCCU Fake bit | No reaction                  |
| 20  | PER_UCE   | Indication of uncorrectable errors in eTPU, M_CAN, and FlexCAN RAM Controllers. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. The eTPU combines uncorrectable errors and other sources in a single exception signal. The exact exception source must be determined with the help of the eTPU Global Exception.                  | Error injection in eTPU, FlexCAN, M_CAN + LBIST + Feedback loop via FCCU Fake bit | No reaction                  |
| 21  | FLS_CE    | Indication of correctable errors in flash memory. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                                                                                                                                 | LBIST                                                                             | No reaction                  |
| 22  | FLS_UCE   | Indication of uncorrectable errors in flash memory. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                                                                                                                               | LBIST                                                                             | No reaction                  |
| 23  | PLL_0     | PLL0 loss of lock. For this fault source to be asserted, the Loss of Lock Interrupt must be enabled by writing 1 to PLLDIG_PLL0CR[LOLIE]. Fault is cleared by clearing PLLDIG_PLL0SR[LOLF], followed by clearing FCCU_NCF_Sn[NCFSm].<br><br><b>NOTE:</b> Always configure this fault to generate a reset instead of an interrupt.                               | LBIST + Forced loss by PLL reconfiguration                                        | No reaction                  |
| 24  | PLL_1     | PLL1 loss of lock. For this fault source to be asserted, the Loss of Lock Interrupt must be enabled by writing 1 to PLLDIG_PLL1CR[LOLIE]. Fault is cleared by clearing PLLDIG_PLL1SR[LOLF], followed by clearing FCCU_NCF_Sn[NCFSm].<br><br><b>NOTE:</b> When PLL1 is used as a system clock: Configure this fault to generate a reset instead of an interrupt. | LBIST + Forced loss by PLL reconfiguration                                        | No reaction                  |
| 25  | CMU_0_OSC | Loss of XOSC clock. The fault is cleared by clearing CMU_ISR[OLRI] of CMU_0, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].<br><br><b>NOTE:</b> When XOSC is used as a system clock: Configure this fault to generate a reset instead of an interrupt.                                                                                       | LBIST                                                                             | No reaction                  |
| 26  | CMU_0_PLL | Exception from monitor CMU_0 (PLL0). The fault is cleared by clearing CMU_ISR[FHHI], CMU_ISR[FLLI], or both of CMU_0, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                                                                         | LBIST + Test by misconfiguration                                                  | No reaction                  |
| 27  | CMU_COMP  | Exception from monitors CMU_1, CMU_2, and CMU_3. The fault is cleared by clearing CMU_ISR[FHHI], CMU_ISR[FLLI], or both of CMU_n, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                                                             | LBIST + Test by misconfiguration                                                  | No reaction                  |

**Table 55-2. FCCU non-critical fault (NCF) mapping (continued)**

| NCF | Fault                                           | Fault description                                                                                                                                                                                                                     | Error reaction path check <sup>1</sup>                                            | Default reaction after reset |
|-----|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|------------------------------|
| 28  | CMU_OTHER                                       | Exception from monitors CMU_4 to CMU_8. The fault is cleared by clearing CMU_ISR[FHHI], CMU_ISR[FLLI], or both of CMU_n, followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                            | LBIST + Test by misconfiguration                                                  | No reaction                  |
| 29  | EDC_ECC_FLASH                                   | Indication of a hardware fault in the ECC of the flash memory resulting in corrupted ECC detection/correction. Fault is cleared by a dummy read of the flash memory followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. | LBIST                                                                             | No reaction                  |
| 30  | EDC_ECC_FLASH_C                                 | Indication of hardware fault in the Flash Memory Controller resulting in corrupted ECC detection/correction. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                | LBIST                                                                             | No reaction                  |
| 31  | ENC_ERR_FLASH                                   | Indication of hardware fault resulting in corrupted flash memory access. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                    | LBIST                                                                             | No reaction                  |
| 32  | ADDR_FDBK_ERROR_FLASH_C                         | Indication of an addressing error in the Flash Memory Controller resulting in corrupted flash memory access. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                | LBIST                                                                             | No reaction                  |
| 33  | XBAR Transaction Monitor                        | Indication by the Crossbar Integrity Checker (XBIC) of a corrupted transaction in the crossbar. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                             | LBIST + proper configuration of XBIC Error Injection Register (XBIC_EIR)          | No reaction                  |
| 34  | ADDR_FDBK_ERROR_PRAM + RAM_LWB_ERR <sup>4</sup> | Indication of an addressing error in system RAM or a write error in the RAM Controller resulting in corrupted RAM access. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                   | LBIST                                                                             | No reaction                  |
| 35  | SSCM_PASS_ERROR_CC_ERR                          | An ECC error occurred while SSCM or PASS was fetching data from flash memory.                                                                                                                                                         | LBIST                                                                             | No reaction                  |
| 36  | EDC_ERR_PRAM                                    | Indication of a fault in the RMW logic of the system RAM resulting in an incorrect RMW access and a potentially corrupted RAM word. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                         | LBIST                                                                             | No reaction                  |
| 37  | DFT1                                            | Test circuitry Group 1 activation. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                          | LBIST                                                                             | No reaction                  |
| 38  | DFT2                                            | Test circuitry Group 2 activation. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                          | LBIST                                                                             | No reaction                  |
| 39  | DFT3                                            | Test circuitry Group 3 activation. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                          | LBIST                                                                             | No reaction                  |
| 40  | DFT4                                            | Test circuitry Group 4 activation. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                                                                          | LBIST                                                                             | No reaction                  |
| 41  | Safety Core Machine Check Exception             | Safety Core exception indication. The fault is cleared by clearing the status in MCSR register of the Safety core followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                   | LBIST + willfully cause an exception (for example, access a non-existing address) | No reaction                  |

**Table 55-2. FCCU non-critical fault (NCF) mapping (continued)**

| NCF | Fault         | Fault description                                                                                                                                                                                | Error reaction path check <sup>1</sup>                                     | Default reaction after reset |
|-----|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|------------------------------|
| 42  | Lockstep mode | Indication of disabled Checker Core or RCCUs. Fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                          | LBIST                                                                      | No reaction                  |
| 43  | ERROR_IN_ERR  | Error input pin (external to the MCU) signaling an error condition. The fault is cleared by clearing the fault driving the pin followed by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm]. | External activation of EIN. External entity must pull the error input low. | No reaction                  |
| 44  | Unused        | —                                                                                                                                                                                                | —                                                                          | —                            |
| 45  | ERM_CE        | ERM module detected single ECC error. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                              | EIM + LBIST + Feedback loop via FCCU Fake bit                              | No reaction                  |
| 46  | ERM_UCE       | ERM module detected multiple ECC error. The fault is cleared by clearing the FCCU channel status, FCCU_NCF_Sn[NCFSm].                                                                            | EIM + LBIST + Feedback loop via FCCU Fake bit                              | No reaction                  |

1. All channels can use feedback loop via FCCU Fake bit.
2. TDM does not have parity error during DCF loading. For UTEST Miscellaneous, only the DCF clients for PMC Digital have parity detection.
3. This fault occurs after any flash memory programming. To avoid unexpected behavior, configure the reaction to this fault carefully if flash memory programming is executed.
4. Fault 34 might be asserted during MBIST and LBIST execution. Before running MBISTs, configure this channel to result in no reset reaction. If this channel becomes asserted during MBIST testing, simply clear the fault and take no further action.

### 55.1.4 Error signal flow diagram

\* This condition must be satisfied only when FCCU is configured for Bistable fault-output mode (FCCU\_CFG[FOM]).

**Figure 55-1. Error signal flow**

### 55.1.5 Restriction on configuring RESET and NMI reactions on same FCCU channel

Do not configure an FCCU channel to have both a RESET reaction (using the FCCU\_NCFS\_CFG $n$  register) and an NMI reaction (using the FCCU\_NMI\_EN $n$  register) at the same time. If the FCCU channel is serviced and the chip resets, the NMI interrupt address is undefined and halts the chip.

### 55.1.6 FCCU\_CFG register event bit values by source (N and C)

For each bit in the [Configuration \(FCCU\\_CFG\)](#) register, this table specifies the values of  $N$  and  $C$  for this chip. For information on how to interpret and use these values, see [FCCU\\_CFG register bit value sources \(N and C\) by event](#).

| Bit | N | C |

## 55.2 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect faults and to place the device into a safe state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault collection and control. The distinctive features of the module are:

- Redundant collection of hardware checker (for example, RCCU) results
- Redundant collection of fault information from safety relevant modules on the device
- Collection of test results
- Configurable fault control
- Configurable internal reactions for each NCF:
  - No reaction
  - IRQ
  - Functional reset
  - NMI
- External reactions via configurable output pins
- Watchdog timer for the reconfiguration phase
- Lockable configuration
- Nonvolatile memory interface (NVMCFG signals) for configuration loading
- One of the fault-output (EOUT) signals is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the error out protocol is configured to be a toggling protocol, for example, dual rail and time switching.

- After power on, the EOUT signals have high impedance.<sup>1</sup> They show operational state only after configuration by software.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time  $T_{min}$ , even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only).
- The actual maximum time is 5 CLKSAFE cycles.

The FCCU circuitry is checked at the start-up by the self-checking procedure. The FCCU is operative with the default configuration immediately after the completion of the self-checking procedure. Internal (functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable. The default configuration can be modified only in the CONFIG state. FCCU is designed to function when CLKSYS is faster than the CLKSAFE clocks.

## 55.2.1 Acronyms and abbreviations

| Term | Description                     |
|------|---------------------------------|
| CF   | Critical fault                  |
| CPU  | Central processing unit         |
| EOUT | Error out                       |
| FOSU | FCCU output supervision unit    |
| FSM  | Finite state machine            |
| INTC | Interrupt controller            |
| intf | Interface                       |
| IRQ  | Interrupt request               |
| NCF  | Noncritical fault               |
| NMI  | Nonmaskable interrupt           |
| NVM  | Nonvolatile memory              |
| RCC  | Redundancy control checkers     |
| RCCU | Redundancy control checker unit |
| SoC  | System-on-chip                  |
| STCU | Self-test control unit          |
| SW   | Software                        |

1. Actual value depends on device specific setting at pad level.

### 55.3 Main features

- Management of noncritical faults
- HW or SW fault recovery management
- Fault detection and collection
- Fault injection (fake faults)
- External reaction (fault state): EOUT signaling. Error indication via the pin(s) is controlled by the FCCU.
- Internal chip reactions (alarm state): interrupt request
- Internal chip reactions (fault state):
  - functional reset
  - NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Internal (to the FCCU) watchdog timer for the reconfiguration phase
- Configuration lock
- Nonvolatile memory interface (NVMCFG signals) for configuration loading

### 55.4 Block diagram

The following figure is a top-level diagram of the FCCU module.

Figure 55-2. FCCU block diagram

This table describes the FCCU submodules.

Table 55-3. FCCU submodules

| Submodule                              | Description                                                                                                                                                                         |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| REG intf                               | Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers                                                      |
| HNSHK blocks (master and slave blocks) | Includes the FSM's ability to support the handshake between the REG interface and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock) |
| FSM unit                               | Implements the main functions of the FCCU. The FSM also includes the: <ul style="list-style-type: none"><li>• Watchdog timer (WDG)</li><li>• Alarm timer (ALRT)</li></ul>           |
| FAULT intf                             | Implements the interface for the fault conditioning and management                                                                                                                  |
| EOUTx units                            | Implement the output stage to manage the EOUT interfaces                                                                                                                            |

## 55.5 Signal description

### 55.5.1 Signals

This table describes the signals on the boundary of FCCU.

| Signal                 | Direction | Function                                                                                                                                                                                                                                                                                                                                                                                 | Active level | Clock              |
|------------------------|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|--------------------|
| <b>Clock and reset</b> |           |                                                                                                                                                                                                                                                                                                                                                                                          |              |                    |
| CLKSYS                 | Input     | System Clock—Supplies the primary clock.                                                                                                                                                                                                                                                                                                                                                 | Rising edge  | —                  |
| CLKSAFE0               | Input     | Safe Clock 0—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE1 are often referred to as the same clock (CLKSAFE).                                                                                                                                                                                                                       | Rising edge  | —                  |
| CLKSAFE1               | Input     | Safe Clock 1—Supplies one of two 16 MHz clocks for use by various redundant submodules. This clock and CLKSAFE0 are often referred to as the same clock (CLKSAFE).                                                                                                                                                                                                                       | Rising edge  | —                  |
| <b>EOUT interface</b>  |           |                                                                                                                                                                                                                                                                                                                                                                                          |              |                    |
| EIN[1:0]               | Input     | Error Input—Provide the mechanism for FCCU to capture the states that off-chip logic drives on the associated EOUT[1:0] signals. (On the chip, the EOUT signals are connected to their corresponding EIN signals.) FCCU captures the states in the <a href="#">EIN1</a> and <a href="#">EIN0</a> fields.                                                                                 | —            | Asynchronous       |
| EOUT[1:0]              | Output    | Error Output—Indicate FCCU's condition (Faulty, Nonfaulty, or Configuration) to off-chip logic.                                                                                                                                                                                                                                                                                          | Programmable | CLKSAFE0, CLKSAFE1 |
| <b>FOSU interface</b>  |           |                                                                                                                                                                                                                                                                                                                                                                                          |              |                    |
| FIF                    | Output    | <p>FCCU In Fault—Indicates to the FOSU module, if present, that FCCU is recognizing a fault. FCCU asserts and then deasserts this signal in two cases:</p> <p><i>Case 1</i></p> <p>When the EOUT signals are programmed to be always low (<a href="#">FCCU_SET_CLEAR</a>), FCCU asserts this signal until the EOUT signals are programmed not to be always low.</p> <p><i>Case 2</i></p> | High         | CLKSAFE0, CLKSAFE1 |

Table continues on the next page...

## Put FCCU in Configuration or Normal state

| Signal                     | Direction | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Active level | Clock  |

|                            |           | <p>When the EOUT signals are programmed not to be always low (<a href="#">FCCU_SET_CLEAR</a>), FCCU asserts this signal when all of the following are true:</p> <ul style="list-style-type: none"> <li>FCCU enters Fault state as the result of a fault.</li> <li>If the fault is a noncritical fault, and the EOUT signals are in a fault-output mode (<a href="#">FOM</a>) other than Bistable, the associated <a href="#">EOUTENx</a> field is set to enabled.</li> </ul> <p>FCCU deasserts this signal when FCCU leaves Fault state.</p> |              |        |
| <b>Interrupt interface</b> |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |              |        |
| NMIOUT                     | Output    | Nonmaskable Interrupt Output—Sends a nonmaskable interrupt request to the processor core or cores when FCCU enters Fault state as the result of a noncritical fault for which NMI is enabled as the reaction ( <a href="#">FCCU_NMI_ENa[NMIENx]</a> ).                                                                                                                                                                                                                                                                                       | Low          | CLKSYS |
| <b>NVM interface</b>       |           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |              |        |
| NVMCFG[21:0]               | Input     | Nonvolatile Memory Configuration—Provide the values of certain bits in the <a href="#">Configuration (FCCU_CFG)</a> register when certain events occur. See <a href="#">Configuration (FCCU_CFG)</a> . Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See <a href="#">FCCU_CFG register bit value sources (N and C) by event</a> .                                                                                                                    | Static value | —      |
| SSCMDONE                   | Input     | SSCM Done—After an FCCU reset, indicates that the SSCM module is now driving any NVMCFG signals that are associated with a data record stored in nonvolatile (flash) memory.                                                                                                                                                                                                                                                                                                                                                                 | High         | CLKSYS |

## 55.6 Put FCCU in Configuration or Normal state

## 55.6.1 Introduction

You put FCCU in Configuration state to change its configuration. You put FCCU in Normal state to save changes to the configuration.

After you configure FCCU, you can lock its configuration to prevent accidental changes.

## 55.6.2 About changing states

When changing states, keep the following in mind:

- To put FCCU in Configuration state, FCCU must be in Normal state.
- After FCCU is reset, the configuration is temporarily locked. You must temporarily unlock the configuration before you can put FCCU in Configuration state.
- When FCCU is in Configuration state, FCCU doesn't actually save the changes you make to the configuration. To save changes to the configuration, you must manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (**TO**) expires (called a Configuration-state timeout), FCCU changes the value of the [Configuration \(FCCU\\_CFG\) register](#) to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see [FCCU\\_CFG register bit value sources \(N and C\) by event](#). For a list of configuration registers, see [Configuration registers](#).

## 55.6.3 About locking the configuration

When locking the configuration, keep the following in mind:

- If you attempt to lock the configuration while FCCU is in Configuration state, FCCU doesn't actually lock the configuration until FCCU leaves Configuration state—that is, either you put FCCU in Normal state, or FCCU puts FCCU in Normal state because the configuration-timer interval (**TO**) expires.
- After you permanently lock the configuration, you must reset FCCU before you can put FCCU in Configuration state.

## 55.6.4 Put FCCU in Configuration state

1. From Supervisor mode, temporarily unlock the configuration ([TRANSKEY](#)).
2. To determine FCCU's state, run the OP3 operation (see [Run an operation](#)).
3. Check the operation status ([OPS](#)).
  - If the operation status is Successful, go to step 4.
  - If the operation status is Aborted, go to step 2.

4. Check the FCCU status ([STATUS](#)).
  - If the FCCU status is Configuration, FCCU is in Configuration state. Stop.
  - If the FCCU status is Normal, go to step [5](#).
  - If the FCCU status is Alarm or Fault, go to step [7](#).
5. To put FCCU in Configuration state, run the OP1 operation (see [Run an operation](#)).
6. Check the operation status ([OPS](#)).
  - If the operation status is Successful, FCCU is in Configuration state. Stop.
  - If the operation status is Aborted, the configuration is probably permanently locked. Go to step [9](#).
7. Recover all faults.
8. Go to step [2](#).
9. Reset FCCU.

### 55.6.5 Put FCCU in Normal state

1. To determine FCCU's state, run the OP3 operation (see [Run an operation](#)).
2. Check the operation status ([OPS](#)).
  - If the operation status is Successful, go to step [3](#).
  - If the operation status is Aborted, go to step [1](#).
3. Check the FCCU status ([STATUS](#)).
  - If the FCCU status is Normal, FCCU is in Normal state. Go to step [8](#).
  - If the FCCU status is Configuration, go to step [4](#).
  - If the FCCU status is Alarm or Fault, go to step [6](#).
4. To put FCCU in Normal state, run the OP2 operation (see [Run an operation](#)).
5. Check the operation status ([OPS](#)).
  - If the operation status is Successful, FCCU is in Normal state. Go to step [8](#).
  - If the operation status is Aborted, go to step [4](#).
6. Recover all faults.
7. Go to step [1](#).
8. If you want to prevent changes to the configuration, lock it:
  - To require a key to unlock the configuration, from Supervisor mode, temporarily lock the configuration ([TRANSKEY](#)).
  - To require a reset of FCCU to unlock the configuration, from Supervisor mode, permanently lock the configuration ([PERMNTKEY](#)).

The configuration is permanently locked until FCCU is reset.

## 55.7 Run operations

### 55.7.1 Introduction

You run operations to perform actions such as putting FCCU in Configuration state or reading a timer. For a complete list of operations you can run, see [OPR](#).

### 55.7.2 About running operations

When running operations, keep the following in mind:

- FCCU ignores any operations initiated while the operation status is In Progress.
- Certain operations must be unlocked before you can initiate them. After you initiate them, they are again locked.

### 55.7.3 Run an operation

1. Check the operation status ([OPS](#)).
2. If the operation status is In Progress, go to step 1.
3. If the operation must be unlocked before you can initiate it, unlock the operation ([CTRLK](#)) using a 32-bit write.

#### NOTE

The [Control Key \(FCCU\\_CTRLK\)](#) register used in this step and the [Control \(FCCU\\_CTRL\)](#) register used in the next step must be written with consecutive instructions. Do not use read-modify-write instructions, such as bit-field instructions, to modify these registers.

4. Initiate the operation ([OPR](#)) using a 32-bit write.
5. Check the operation status ([OPS](#)).
6. If the operation status is In Progress, go to step 5.

The operation status is now Idle (OP15 only), Aborted, or Successful.

## 55.8 Functional description

### 55.8.1 Definitions

In general, the following definitions are applicable for the fault management:

- **HW recoverable fault:** the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is deasserted. That is, if logical 0 on the fault signal indicates fault, then the status flags are valid as long as the fault line stays at 0. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched external to the FCCU in the module where the fault occurred. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- **SW recoverable fault:** the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the fault is recoverable by itself when the fault condition gets corrected.

### 55.8.2 FSM description

FCCU functionality is depicted by the finite state machine (FSM) state diagram.

Basically four states are identified with the following meaning:

- **Configuration:** Used only to modify the configuration of FCCU from its default. A subset of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, timeout, noncritical fault masking) can be accessed in write mode only in Configuration state.

Configuration state is accessible only in Normal state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset which also resets the FCCU., The transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU\_TRANS\_LOCK register (that is, other than BCh). Key to lock FCCU permanently is FFh, written in the FCCU\_PERMNT\_LOCK register.

After the release of reset the state of the transient lock will be locked. The state of the permanent lock will be unlocked.

The locking feature only restricts the FSM movement into Configuration state. Once the user enters Configuration state and then tries to lock the configuration, the locking of configuration will be effective after FCCU moves to Normal state, it will not be effective in the current Configuration state.

The Configuration to Normal state transition can be executed by SW or automatically following a timeout condition of the watchdog. In case the timeout information and the SW request to mode change to Normal appears at the same time, watchdog timeout has the priority and hence the Configuration registers (those that are writable only in Configuration state) are reset to their default values. The movement to Normal is made.

The incoming faults, occurring during the configuration phase (Configuration state) are latched in order to process them when FCCU is moved into Normal state, according to the new configuration.

All pending faults that occur during Configuration state result in both of the following:

- Highest-priority state transition
- Interrupt generation (NMI or alarm IRQ)

If the state transition occurs, it gives the reset reaction corresponding to the worst case based on all the faults (pending or nonpending faults) that occurred during Configuration state.

- Normal: This is FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following state transitions occur on one of the following events:
  - unmasked noncritical faults with the timeout disabled → FCCU moves to Fault state
  - unmasked noncritical faults with the timeout enabled → FCCU moves to Alarm state
  - masked noncritical faults → FCCU stays in Normal state
- Alarm: FCCU moves into Alarm state when an unmasked noncritical fault occurs and the timeout is enabled. The transition to Alarm state goes along with an interrupt alarm, if enabled. By definition, this fault may be recovered within a programmable

timeout period, before it generates a transition to Fault state. The timeout is reinitialized if FCCU enters Normal state. The timeout restarts following the recovery from Fault state.

- Fault: FCCU moves into Fault state when one of the following condition occurs:
  - timeout related to a noncritical fault when FCCU is in Alarm state
  - unmasked noncritical faults with the timeout disabled

The transition from Normal/Alarm to Fault state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: functional reset
- Non Maskable Interrupt (NMI) is routed only to the Safety Core

After moving to Fault state, if there is either a previous pending fault or a new fault for which NMI is enabled, NMI generation takes place.

Multiple faults can occur at the same time. Consider the case where there is a fault for which Alarm state is enabled and IRQ is programmed along with a fault for which Alarm state is disabled. In that case, the FSM moves to Fault state, but with the generation of alarm IRQ for the fault which has IRQ enabled.

Figure 55-3. FCCU state diagram

### 55.8.3 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (noncritical) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a noncritical fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the noncritical faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been cleared (SW or HW recovery); otherwise the FCCU will move to the ALARM state (if any noncritical fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the noncritical faults that cause an ALARM to FAULT state transition. In this case the NCF timer is stopped until the FAULT state is recovered. If FCCU is in ALARM state and another fault comes, which has its alarm timeout enabled, then the alarm timer shall not reload and shall not start again.

## 55.8.4 STCU interface

The STCU interface includes:

- A set of signals resulting from the self-checking procedure connected externally at the FCCU.

The STCU fault signals are processed by the FCCU when the SoC is re-booted following the self-testing procedure. The STCU includes a status register that stores the self-testing results (flags).

- a mask that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self-testing procedure, depending on the STCU results, three cases are applicable:

1. STCU completes the self-testing procedure successfully. The SoC reboots and the FCCU is responsible for fault collection and indication.
2. STCU completes the self-testing procedure with low severity failures. The FCCU records the fault condition but does not, by default, trigger a reset cycle.
3. STCU completes the self-testing procedure with serious failures. The FCCU triggers a reset cycle in response to this fault input from the STCU. Because the fault condition survives reset, new reset cycles are subsequently triggered until the reset escalation feature takes control, freezing the chip in the reset state until a POR.

**Figure 55-4. STCU-FCCU (case 1)**

**Figure 55-5. STCU-FCCU (case 2)****Figure 55-6. STCU-FCCU (case 3)**

### 55.8.5 Nonvolatile memory interface

FCCU includes a nonvolatile memory interface (NVMCFG signals) that provides the values of certain bits in the [Configuration \(FCCU\\_CFG\)](#) register when certain events occur. See [Configuration \(FCCU\\_CFG\)](#). Whether any of these signals are actually connected to nonvolatile (flash) memory is chip-specific. Some or all of these signals may be driven by bits in a data record in nonvolatile (flash) memory or may be tied high (1) or low (0). See [FCCU\\_CFG register bit value sources \(N and C\) by event](#).

The timing diagram related to the NVM interface is given in [Figure 55-7](#).

Figure 55-7. NVM interface

## 55.8.6 EOUT interface

### 55.8.6.1 Introduction

You use the EOUT[1:0] signals to indicate FCCU's condition to off-chip logic. For information on the availability and names of these FCCU signals on the boundary of this chip, see the chip-specific FCCU information.

### 55.8.6.2 The FCCU conditions

There are three FCCU conditions:

| Condition     | Description                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Faulty        | The fault-output (EOUT) timer is running (see <a href="#">How the fault-output (EOUT) timer works</a> ).                                                                      |
| Nonfaulty     | All of the following are true: <ul style="list-style-type: none"> <li>• The fault-output (EOUT) timer is not running.</li> <li>• FCCU is in Alarm or Normal state.</li> </ul> |
| Configuration | All of the following are true: <ul style="list-style-type: none"> <li>• The fault-output (EOUT) timer is not running.</li> <li>• FCCU is in Configuration state.</li> </ul>   |

### 55.8.6.3 How the fault-output (EOUT) timer works

FCCU starts the fault-output (EOUT) timer when all of the following are true:

- The fault-output (EOUT) signals are not programmed to be always low ([FCCU\\_SET\\_CLEAR](#)).
- The fault-output (EOUT) timer isn't already running.
- FCCU enters Fault state as the result of a fault.

When the fault-output (EOUT) timer is already running and a new fault occurs:

- When FCCU is in Configuration state: FCCU doesn't restart the fault-output (EOUT) timer.
- When FCCU is in Normal state or Alarm state:
  - And Alarm state is enabled for the fault (noncritical): FCCU enters (or remains in) Alarm state but doesn't restart the fault-output (EOUT) timer.
  - And Alarm state is disabled for the fault (noncritical): FCCU enters Fault state and restarts the fault-output (EOUT) timer.
- When FCCU is in Fault state: FCCU restarts the fault-output (EOUT) timer.

FCCU stops and reinitializes the fault-output (EOUT) timer when all of the following are true:

- If the EOUT signals are in Bistable fault-output mode ([FOM](#)), T\_min (see [DELTA\\_T](#)) has expired.
- All faults that caused FCCU to enter or remain in Fault state since FCCU started the fault-output (EOUT) timer have been cleared, causing FCCU to return to Normal state.

#### 55.8.6.4 Prepare the EOUT signals to indicate FCCU's condition

- If the EOUT signals are in Bistable fault-output mode ([FOM](#)), make sure the EOUT signals are controlled by FCCU's finite state machine ([FCCU\\_SET\\_CLEAR](#)).
- Make sure the EOUT signals are active ([FCCU\\_SET\\_AFTER\\_RESET](#)).

#### NOTE

If the EOUT signals are in Bistable fault-output mode, you must deactivate and then reactivate the EOUT signals ([FCCU\\_SET\\_AFTER\\_RESET](#)) to correctly initialize them so they have opposite states.

#### 55.8.6.5 More about the EOUT interface

Different fault-output modes (protocols) for the fault-output (EOUT) interface are supported ([FCCU\\_CFG\[FOM\]](#)):

- Dual-Rail
- Time-Switching
- Bistable
- Test

You can further configure the fault-output modes using the following attributes:

| Attribute          | Field                        | Setting used in the example diagrams and tables that follow |
|--------------------|------------------------------|-------------------------------------------------------------|
| Switching mode     | <a href="#">FCCU_CFG[SM]</a> | Slow                                                        |
| Polarity selection | <a href="#">FCCU_CFG[PS]</a> | For the faulty indication, EOUT1 is high, and EOUT0 is low. |

The EOUT frequency is generated by dividing the CLKSAFE frequency by a fixed factor of  $2^{18}$ .

With a CLKSAFE frequency of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and CLKSAFE (which detects the edge transition of the EOUT protocol) in Dual-Rail or Time-Switching fault-output mode.

In case of a failure event or on software request for EOUT indication, the signal(s) are set to the faulty state for a minimum time  $T_{min}$ , even if software tries to release it before. If software configures the error pins to OK(1), and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and the error signals indicate NOK, such as an incoming fault is not masked when software has set the error signal to high. During the  $T_{min}$  by a non-software fault, the FCCU FSM moves independently of this signal state (low), and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in, and it is not possible to set the signals to OK by software moving FCCU to Configuration state, as long as this timer is running. No software intervention is needed to bring the signal from the low state.

Software can bring the pin back to OK state by clearing the faults and waiting for the  $T_{min}$  interval to expire, after which the FCCU automatically enters Normal state and the error signal indicates OK.

In case another failure event happens within  $T_{min}$  after a first one, the  $T_{min}$  counter is restarted.

### NOTE

The transition from Fault to Configuration state is not possible but is shown to display the behavior in all four states—reset, normal, error, and configuration.

### NOTE

FCCU remains in Normal state when a fault is disabled; therefore, NA (not applicable) appears in the following table.

### NOTE

The following table is valid only when the EOUT signals are active ([FCCU\\_SET\\_AFTER\\_RESET](#)).

**Table 55-4. FCCU error pin behavior on state transitions**

| Fault signaling state | Transition from Normal to Fault state |                  |           | Normal+Configuration states |                  |           | Transition from Normal to Alarm state |                  |           |
|-----------------------|---------------------------------------|------------------|-----------|-----------------------------|------------------|-----------|---------------------------------------|------------------|-----------|
|                       | with Fault disabled   enabled         |                  |           |                             |                  |           | with Fault disabled   enabled         |                  |           |
|                       | Internal error pin                    | Error pin enable | Error pad | Internal error pin          | Error pin enable | Error pad | Internal error pin                    | Error pin enable | Error pad |
| Disabled              | NA   OK                               | NA   1           | NA   OK   | OK                          | 1                | OK        | NA   OK                               | NA   1           | NA   OK   |
| Enabled               | NA   NOK                              | NA   1           | NA   NOK  | OK                          | 1                | OK        | NA   OK                               | NA   1           | NA   OK   |

**NOTE**

The first time FCCU is in Configuration state, the EOUT pads are in a high-impedance state; thereafter, their states reflect the programmed EOUT protocol.

**55.8.6.6 Dual-rail protocol**

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in [Table 55-5](#) and the related timing diagram is given in [Figure 55-8](#) and [Figure 55-9](#).

**Table 55-5. Dual-rail encoding**

| Logical state | Dual-rail encoding (output pins EOUT[1:0]) | Note        |
|---------------|--------------------------------------------|-------------|
| non-faulty    | 10                                         | toggling    |
| non-faulty    | 01                                         |             |
| faulty        | 00                                         | toggling    |
| faulty        | 11                                         |             |
| reset         | Hi impedance <sup>1</sup>                  | no toggling |
| configuration | same as NORMAL                             | toggling    |

1. Final value depends on the SoC setting at pad level.

As long as FCCU is in NORMAL or ALARM state, output will show "non-faulty" signal. Output pins EOUT[0:1] will toggle between 01 and 10 with a given frequency of 61 Hz.

In the RESET phase the output pins are set as "high impedance".

**Note**

[Figure 55-8](#) and [Figure 55-9](#) are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 55-8. Dual-rail protocol (slow switching mode)

Figure 55-9. Dual-rail protocol (fast switching mode)

### 55.8.6.7 Time-switching protocol

The encoding scheme is given in [Table 55-6](#) and the related timing diagram is given in [Figure 55-10](#).

Table 55-6. Time-switching encoding

| Logical state | Time-switching encoding (output pins EOUT[1:0]) | Note        |
|---------------|-------------------------------------------------|-------------|
| non-faulty    | 10                                              | toggling    |
| non-faulty    | 01                                              |             |
| faulty        | 10                                              | no toggling |
| reset         | high-Z <sup>1</sup>                             | no toggling |
| configuration | same as NORMAL                                  | toggling    |

1. Final value depends on device specific settings at pad level.

As long as FCCU is in NORMAL or ALARM state, outputs will show "non-faulty" signal. Output pins #0, #1 will toggle between 01 and 10 with frequency of 61 Hz.

In the FAULT state, the output pin EOUT[0] is set as low.

In Time Switching mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".<sup>2</sup>

**Note**

Figure 55-10 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

**Figure 55-10. Time-switching protocol**

**55.8.6.8 Bi-stable protocol**

The encoding scheme is given in Table 55-7 and the related timing diagram is given in Figure 55-11.

**Table 55-7. Bi-stable encoding**

| Logical state | Bi-stable encoding (output pins EOUT[1:0]) | Note        |
|---------------|--------------------------------------------|-------------|
| non-faulty    | 01                                         | no toggling |
| faulty        | 10                                         | no toggling |
| reset         | high-Z <sup>1</sup>                        | no toggling |
| configuration | same as NORMAL                             | no toggling |

1. Final value depends on device specific settings at pad level.

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, "no-faulty" state is indicated. In Bi-stable mode the second output (EOUT[1]) is the inverted signal of first output (EOUT[0]).

In the RESET phase the output pins are set as "high impedance".<sup>3</sup>

2. Actual value depends on device specific settings at pad level.

3. Actual value depends on device specific settings at pad level.

## Note

Figure 55-11 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

**Figure 55-11. Bi-stable protocol**

### 55.8.7 Error signal flow

See the chip-specific FCCU information for the diagram of the signal flow.

## 55.9 Register descriptions

The FCCU registers are listed in the table below. Any address offset not explicitly mentioned in this table is reserved.

The FCCU supports word (32-bit), half-word (16-bit), and byte (8-bit) read and write accesses.

Follow these register-access guidelines:

- Don't read from or write to any addresses that are not shown in the following table. Doing so may result in a transfer error.
- Don't write to any of the configuration registers unless FCCU is in Configuration state. Doing so results in a transfer error.
- Don't write to FCCU\_TRANS\_LOCK or FCCU\_PERMNT\_LOCK unless your code runs in Supervisor mode. Doing so results in a transfer error.

## Register descriptions

All the registers accessible in write mode only in CONFIG state are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU\_TRANS\_LOCK and FCCU\_PERMNT\_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible NCF failure source, a different reaction—including no reaction—is configurable through the use of NMI, IRQ, and reset selection registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by functional resets.

### FCCU memory map

| Address offset (hex) | Register name                                          | Width (in bits) | Access | Reset value                 | Section/ page                |

55.9.1 Control (FCCU\_CTRL)

Initiates and indicates the status of operations, indicates that FCCU successfully loaded configuration data from the NVMCFG signals, controls glitch-filter settings, and enables Debug mode.

Address: 0h base + 0h offset = 0h

| Field | Description                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | 01011 Reserved                                                                                                                                                                                                                                                                                                                                                                                                   |
|       | 01100 OP12—Do not initiate this operation; it is automatically initiated by FCCU. A <a href="#">Noncritical Fault Status (FCCU_NCF_Sn)</a> register status clear operation is in progress.                                                                                                                                                                                                                       |
|       | 01101 OP13—Clear the freeze status registers.                                                                                                                                                                                                                                                                                                                                                                    |
|       | 01110 OP14—Do not initiate this operation; it is automatically initiated by FCCU. A Configuration-state timeout is in progress. For more information, see <a href="#">Configuration registers</a> .                                                                                                                                                                                                              |
|       | 01111 OP15—Set the operation status (OPS) to Idle.                                                                                                                                                                                                                                                                                                                                                               |
|       | 10000 Reserved                                                                                                                                                                                                                                                                                                                                                                                                   |
|       | 10001 OP17—Update the <a href="#">X Timer (FCCU_XTMR)</a> register with the current value of the Alarm-state timer.                                                                                                                                                                                                                                                                                              |
|       | 10010 Reserved                                                                                                                                                                                                                                                                                                                                                                                                   |
|       | 10011 OP19—Update the <a href="#">X Timer (FCCU_XTMR)</a> register with the current value of the Configuration-state timer.                                                                                                                                                                                                                                                                                      |
|       | 10100 Reserved                                                                                                                                                                                                                                                                                                                                                                                                   |
|       | 10101–11110 Forbidden. Writing any of these values returns an operation status (OPS) of Aborted with no side effect.                                                                                                                                                                                                                                                                                             |
|       | 11111 OP31—Applies only immediately after you unlock the operation (CTRLK). Load configuration data from the NVMCFG signals to certain fields in the <a href="#">Configuration (FCCU_CFG)</a> register, but without resetting FCCU (for testing and debugging). See <a href="#">FCCU_CFG register bit value sources (N and C) by event</a> . The operation status (OPS) for this operation is always Successful. |

## 55.9.2 Control Key (FCCU\_CTRLK)

Writable only with a 32-bit write. Unlocks locked operations so you can initiate them (OPR). For information on how to unlock locked operations before you initiate them, see [Run an operation](#).

## NOTE

Reading from this register always returns the value 0000\_0000h.

Address: 0h base + 4h offset = 4h

|       | <p>Unlocks locked operations so you can initiate them (<a href="#">OPR</a>). For information on how to unlock locked operations before you initiate them, see <a href="#">Run an operation</a>. Operations not listed here are not locked and do not need to be unlocked.</p> <p><b>NOTE:</b> You must initiate an operation in the instruction that immediately follows the instruction that unlocks it; otherwise, the operation is again locked.</p> <p>9137_56AFh: Unlock OP1.</p> <p>825A_132Bh: Unlock OP2.</p> <p>29AF_8752h: Unlock OP31.</p> <p>Any other value: Do nothing.</p> |

**55.9.3 Configuration (FCCU\_CFG)**

Writable only when FCCU is in Configuration state. Specifies the global configuration for FCCU.

The values of the bits in this register are affected by writes as well as any of the following events:

- The chip resets FCCU.
- FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval ([TO](#)) expires. This is called a Configuration-state timeout.
- You run an OP31 operation.

For information on the sources of bit values for these events, see [FCCU\\_CFG register bit value sources \(N and C\) by event](#).

**NOTE**

If you specify a new value for any of the fields in this register that affect the EOUT signals while the fault-output (EOUT) timer is running (FCCU is indicating a fault on the EOUT signals), FCCU doesn't use the new settings you specified until after the fault-output (EOUT) timer expires (FCCU stops indicating a fault on the EOUT signals).

| 20<br>Reserved         | This field is reserved.<br>Always write the reset value to this field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 21<br>SM               | Fault-Output (EOUT) Switching Mode<br><br>For fault-output (EOUT) signaling, controls how quickly the signals switch between faulty and nonfaulty indication. Applies only to Dual-Rail and Time-Switching fault-output modes.<br><br>0 Slow: No EOUT frequency violation during the FCCU state transition (Normal to Fault or vice versa, and Configuration to Normal). The indication transition occurs after a maximum delay equal to the duration of the semiperiod of the EOUT frequency.<br>1 Fast: The indication transition (Normal to Fault or vice versa, and Configuration to Normal) occurs immediately. A pulse with the minimum duration corresponding to the CLKSAFE period can occur in this mode. It implies a frequency violation of the EOUT protocol. |
| 22<br>PS               | Fault-Output (EOUT) Polarity Selection<br><br>For fault-output (EOUT) signaling, controls the polarity of the signals for fault-output-mode indications that hold the signals low or high (versus toggling them or placing them in a high-impedance state). Applies only to Time-Switching fault-output mode (for faulty and configuration indications) and Bistable fault-output mode (for all indications).<br><br>0 For the faulty indication, EOUT1 is high, and EOUT0 is low.<br>1 For the faulty indication, EOUT1 is low, and EOUT0 is high.                                                                                                                                                                                                                       |
| 23–25<br>FOM           | Fault-Output (EOUT) Mode<br><br>For fault-output (EOUT) signaling, controls the protocol of the signaling.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## 55.9.4 Noncritical Fault Configuration (FCCU\_NCF\_CFGn)

Contains the configuration of noncritical faults in terms of fault-recovery management. The configuration depends on the type of signaling of a fault event. Hardware-recoverable faults should be configured only if a previous latching stage captures and holds the physical fault; otherwise, the fault can be lost. All other faults should be configured as software faults.

**NOTE**

These registers are writable only when FCCU is in Configuration state.

| Noncritical Fault Configuration<br>(FCCU_NCF_CFGn)<br>register (value of n) | Offset | NCFCx fields (value of x)       |                                   |

**55.9.5 Noncritical Fault State Configuration (FCCU\_NCFS\_CFGn)**

The FCCU\_NCFS\_CFGx registers contain the configuration of each noncritical fault in terms of fault reaction (functional reset request pulse) when it is the root cause for the FAULT state transition.

**NOTE**

These registers are writable only when the FCCU is in the CONFIG state.

Table 55-16 shows FCCU configuration register channels.

**Table 55-18. FCCU NCFS configuration register channels**

| Address offset | Register name  | Channel range (x) |
|----------------|----------------|-------------------|
| 4Ch            | FCCU_NCFS_CFG0 | NCFSCx[15:0]      |
| 50h            | FCCU_NCFS_CFG1 | NCFSCx[31:16]     |

## 55.9.6 Noncritical Fault Status (FCCU\_NCF\_Sn)

The FCCU\_NCF\_Sx register contains the latched fault indication collected from the noncritical fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the NCF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU\_NCF\_Ex register and the respective enable bit for the timeout is set in the FCCU\_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU\_NCF\_Ex register and the respective enable bit for the timeout is disabled in the FCCU\_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the timeout (FCCU\_TO register) is elapsed before recovering from the fault.

The timeout is stopped only when the FCCU returns in the NORMAL state.

The FCCU\_NCF\_Sx register is encoded respectively into the N2FF\_STATUS or A2FF\_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU\_NCF\_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU\_NCFK register.
2. Clear the status (flag) bit NCFSx => the opcode OP12 is automatically set into the FCCU\_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
4. Read the FCCU\_NCF\_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root .

### NOTE

There should not be any other operation in between the above steps.

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU\_NCF\_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the FCCU\_NCF\_Sx register.

In case of re-configuration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU\_NCF\_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following faults are ignored:

- to write a wrong key into the FCCU\_NCFK register
- to attempt to clear a HW recoverable fault

| Noncritical Fault<br>Status<br>(FCCU_NCF_Sn)<br>register (value of n) | Offset | NCFSx fields (value of x)          |                                      |

## 55.9.7 Noncritical Fault Key (FCCU\_NCFK)

The FCCU\_NCFK register implements the key access to clear the status flags of the FCCU\_NCF\_Sx register.

The status bits of the FCCU\_NCF\_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU\_NCFK register.
2. Clear the status (flag) bit NCFSx .

The key must be written for each FCCU\_NCF\_Sx clear operation.

The FCCU\_NCFK register is not readable; a 0000\_0000h value is always returned in case of read operation.

Address: 0h base + 90h offset = 90h

|--------------|------------------------------------|
| 0–31<br>NCFK | Noncritical fault key = AB34_98FEh |

## 55.9.8 Noncritical Fault Enable (FCCU\_NCF\_En)

The FCCU\_NCF\_En registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU\_NCF\_Sn register is set (for debugging purposes), only the reaction is masked.

### NOTE

These registers are writable only when the FCCU is in the CONFIG state.

### NOTE

Any enabled fault should be programmed to result in a defined action. For example, set up an ALARM IRQ action by programming the IRQ Alarm Enable Register (FCCU\_IRQ\_ALARM\_ENn).

### 55.9.9 Noncritical Fault Timeout Enable (FCCU\_NCF\_TOEn)

The FCCU\_NCF\_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective noncritical fault is enabled ( NCFEx and NCFTOEx are set). In case the respective timeout is disabled ( NCFTOEx is cleared) and the noncritical fault is enabled (NCFEx is set) the FCCU moves into the FAULT state if the related noncritical fault is asserted. The timer (preset with the timeout value defined by FCCU\_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the timeout the FCCU moves from the ALARM state to the FAULT state.

#### NOTE

These registers are writable only when the FCCU is in the CONFIG state.

| Noncritical Fault Timeout Enable (FCCU_NCF_TOEn) register (value of n) | Offset | NCFTOEx fields (value of x)     |                                   |

### 55.9.10 Noncritical Fault Timeout (FCCU\_NCF\_TO)

Defines the preset value of the timer for the recovery of enabled noncritical faults. Once FCCU enters Alarm state, following the assertion of a noncritical fault that is enabled (NCFEa and NCFTOEa are set), the timer starts the countdown.

If the fault is not recovered within the timeout period, the FCCU moves from the Alarm state to the Fault state. The alarm timeout value should be programmed to be less than FOSU\_COUNT, or resets may be generated by FOSU timeouts.

#### NOTE

This register is writable only when FCCU is in Configuration state.

Address: 0h base + B4h offset = B4h

| 0–31<br>TO | Noncritical Fault Timeout<br>Timeout = (TO) × T <sub>RC16MHz</sub> |

### 55.9.11 Configuration-State Timer Interval (FCCU\_CFG\_TO)

Writable only when FCCU is in Normal, Alarm, or Fault state (not in Configuration state). Not accessible while a Configuration-state timeout (OP14 operation) is in progress. Controls the maximum amount of time that FCCU can be in Configuration state.

#### NOTE

When a Configuration-state timeout occurs, FCCU changes the value of this register to its reset value.

## 55.9.12 IO Control (FCCU\_EINOUT)

The FCCU\_EINOUT register allows the following operations typically in NORMAL state:

- to control the EOUT[1] output level when the FCCU is configured in "Test1" or "Test0" fault output mode (FCCU\_CFG.FOM)
- to control the EOUT[0] output level when the FCCU is configured in "Test1" or "Test2" fault output mode (FCCU\_CFG.FOM)
- to observe the EOUT[1:0] signals in input mode

[Table 55-36](#) shows Bi-stable encoding.

**Table 55-36. Bi-stable encoding**

| Mode = FCCU_CFG.FOM | EOUT[0] | EOUT[1] |
|---------------------|---------|---------|
| Test1               | output  | output  |
| Test2               | output  | input   |
| Test0               | input   | output  |

**NOTE**

Due to the resynchronization stage of the EOUT interface, there is a latency of a few CLKSAFE cycles following a write/read operation of the FCCU\_EINOUT register.

**55.9.13 Status (FCCU\_STAT)**

The FCCU\_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine operates by the RC oscillator clock asynchronous with the system clock. The FCCU status read operation requires a safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the FCCU status (FCCU\_STAT register).

Address: 0h base + C0h offset = C0h

**55.9.14 NA Freeze Status (FCCU\_N2AF\_STATUS)**

The N2AF\_STATUS register contains a unique code to identify the "noncritical fault" source ( fccu\_ncf[x] ) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the N2AF\_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the N2AF\_STATUS register.

The SW application executes the N2AF\_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

**55.9.15 AF Freeze Status (FCCU\_A2FF\_STATUS)**

The A2FF\_STATUS register contains a unique code to identify the timeout trigger (noncritical fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF\_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the A2FF\_STATUS register.

The SW application executes the FCCU\_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).

All the freeze registers are cleared by this operation.

## 55.9.17 FA Freeze Status (FCCU\_F2A\_STATUS)

The F2AF\_STATUS register contains a unique code to identify the source of the noncritical fault (fccu\_ncf[x]) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the F2AF\_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU\_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU\_CTRL.OPS field).
3. Read the F2AF\_STATUS register.

The SW application executes the F2AF\_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU\_CTRL.OPR field.

## Register descriptions

- Wait for the completion of the operation (FCCU\_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

## 55.9.18 Noncritical Fault Fake (FCCU\_NCFF)

The FCCU\_NCFF register contains a unique code to set a noncritical fault in mutually exclusive mode by the external FAULT interface (signal setting). It allows the SW emulation of the noncritical faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The reaction following a fake noncritical fault cannot be masked. The FCCU\_NCFF is a write-only register with a set of codes corresponding to each noncritical fault injection.

**55.9.19 IRQ Status (FCCU\_IRQ\_STAT)**

The FCCU\_IRQ\_STAT register provides the FCCU interrupt status related to the following events:

- Configuration timeout error
- Alarm interrupt
- NMI interrupt

The configuration timeout interrupt is asserted if the CFG\_TO\_STAT bit of the FCCU\_IRQ\_STAT register is set and the CFG\_TO\_IEN bit of the FCCU\_IRQ\_EN register is also set. It is cleared when a 1 is written to the CFG\_TO\_STAT bit.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU\_IRQ\_STAT trace the status of the related interrupt lines.

55.9.20 IRQ Enable (FCCU\_IRQ\_EN)

The FCCU\_IRQ\_EN register defines the FCCU interrupt enable register related to the following event:

- Configuration timeout error

The configuration timeout interrupt is asserted if the CFG\_TO\_STAT bit of the FCCU\_IRQ\_STAT register is set and the CFG\_TO\_IEN bit of the FCCU\_IRQ\_EN register is also set.

| 23–31<br>TRANSKEY | Transient Configuration Lock<br><br>Writable only by code running in Supervisor mode. Temporarily locks and unlocks the configuration. Locking the configuration prevents FCCU from entering Configuration state.<br><br><b>NOTE:</b> You can write to this field when FCCU is in any state, but the lock will not go into effect until FCCU is in Normal state.<br><br>BCh: Unlock.<br><br>Any other value: Lock. |

### 55.9.23 Permanent Configuration Lock (FCCU\_PERMNT\_LOCK)

Writable only by code running in Supervisor mode. Permanently locks the configuration, which prevents FCCU from entering Configuration state until FCCU is reset.

Address: 0h base + F4h offset = F4h

### 55.9.24 Delta T (FCCU\_DELTA\_T)

The FCCU\_DELTA\_T register is used for programming the value of delta\_T constant, in microseconds.

#### NOTE

This register can be written only when the FCCU is in CONFIG state.

#### NOTE

Reserved bits should always be written as all 0's.

| 18–31<br>DELTA_T  | <p>Bistable Minimum Fault-Output (EOUT) Faulty Interval</p> <p>Applies only to Bistable fault-output mode (FOM). Controls the minimum amount of time (T<sub>min</sub>) that the fault-output (EOUT) timer runs according to this equation:</p> $T_{min} = 250 \mu s + DELTA\_T$ <p>The following values and meanings are for DELTA_T:</p> <p>00_0000_0000_0000: 0 <math>\mu</math>s</p> <p>00_0000_0000_0001: 1 <math>\mu</math>s</p> <p>...</p> <p>11_1111_1111_1110: 16,382 <math>\mu</math>s</p> <p>11_1111_1111_1111: 16,383 <math>\mu</math>s</p> <p><b>NOTE:</b> The durations shown for the DELTA_T values are for CLKSAFE clock signals running at exactly 16 MHz. However, the CLKSAFE signals are sourced from an internal chip clock signal (for example, IRC)—or an integer division of it (see the chip-specific FCCU information)—that has a trimmed frequency variation. Therefore, the DELTA_T durations may vary. See your chip's data sheet for the trimmed frequency variation (for example, <math>\delta F_{var}</math>).</p> |

## 55.9.25 IRQ Alarm Enable (FCCU\_IRQ\_ALARM\_ENn)

These registers enable the corresponding IRQ alarm.

| IRQ Alarm Enable<br>(FCCU_IRQ_ALARM_ENn) register<br>(value of n) | Offset | IRQENx fields (value of x)      |                                   |
|-------------------------------------------------------------------|--------|---------------------------------|-----------------------------------|
|                                                                   |        | Most significant (leftmost) bit | Least significant (rightmost) bit |
| 0                                                                 | 0FCh   | 31                              | 0                                 |
| 1                                                                 | 100h   | 63                              | 32                                |

**NOTE**

These registers can be written only when the FCCU is in CONFIG state.

|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>EOUTENx | <p>Noncritical Fault-State EOUT Signaling Enable x</p> <p>Writable only when FCCU is in Configuration state. Changed by FCCU to its reset value when a Configuration-state timeout occurs. Applies only when the EOUT signals are active (<a href="#">FCCU_SET_AFTER_RESET</a>). When FCCU is configured for Bistable fault-output mode (<a href="#">FOM</a>), controls whether EOUT signaling is enabled as a Fault-state reaction for the associated noncritical fault channel (x). (For other fault-output modes, EOUT signaling is always enabled, regardless of the value of this field.) When EOUT signaling is enabled for an enabled noncritical fault channel, a fault on that channel causes FCCU to indicate the Faulty condition on the EOUT[1:0] signals when FCCU enters Fault state.</p> <p>For all fault-output modes, also controls whether FCCU asserts the FIF signal when a fault on the associated noncritical fault channel (x) causes FCCU to enter Fault state.</p> <p><b>NOTE:</b> For all fault-output modes, you must set this field to enabled to ensure that FCCU asserts the FIF signal when FCCU enters Fault state as the result of a fault on the associated noncritical fault channel (x) so the FOSU module doesn't mistakenly generate a destructive chip reset.</p> <p>For the mapping of the <a href="#">EOUTENx</a> fields among registers, see the earlier table in this register description.</p> <p>0 (in Bistable fault-output mode): EOUT signaling disabled; FIF assertion disabled</p> <p>0 (in other fault-output modes): EOUT signaling enabled; FIF assertion disabled</p> <p>1 (in Bistable fault-output mode): EOUT signaling enabled; FIF assertion enabled</p> <p>1 (in other fault-output modes): EOUT signaling enabled; FIF assertion enabled</p> |

|-------|-------------|

**55.9.28 Configuration registers****55.9.28.1 Definition**

*Configuration registers* are registers that:

- Let you configure FCCU's Alarm-state timer interval, fault channels, and fault-output (EOUT) signals.
- You can write to only when the configuration is not locked and FCCU is in Configuration state (see [Put FCCU in Configuration or Normal state](#)).
- Save the values you write to them while FCCU is in Configuration state only after you manually put FCCU in Normal state. If FCCU automatically leaves Configuration state and enters Normal state because the configuration-timer interval (TO) expires (called a Configuration-state timeout), FCCU changes the value of the FCCU\_CFG register to its Configuration-state-timeout value and the value of each of the other configuration registers to its reset value. For information on the Configuration-state timeout value, see [FCCU\\_CFG register bit value sources \(N and C\) by event](#).

**55.9.28.2 The configuration registers**

The following registers are the configuration registers, listed in offset order from lowest to highest:

- [Configuration \(FCCU\\_CFG\)](#)
- [Noncritical Fault Configuration \(FCCU\\_NCF\\_CFG \$n\$ \)](#)
- [Noncritical Fault State Configuration \(FCCU\\_NCFS\\_CFG \$n\$ \)](#)
- [Noncritical Fault Enable \(FCCU\\_NCF\\_En\)](#)
- [Noncritical Fault Timeout Enable \(FCCU\\_NCF\\_TOEn\)](#)
- [Noncritical Fault Timeout \(FCCU\\_NCF\\_TO\)](#)
- [Delta T \(FCCU\\_DELTA\\_T\)](#)
- [IRQ Alarm Enable \(FCCU\\_IRQ\\_ALARM\\_EN \$n\$ \)](#)
- [NMI Enable \(FCCU\\_NMI\\_EN \$n\$ \)](#)
- [Noncritical Fault-State EOUT Signaling Enable \(FCCU\\_EOUT\\_SIG\\_EN \$n\$ \)](#)

## 55.9.29 FCCU\_CFG register bit value sources (N and C) by event

Certain events affect the bit values of the [Configuration \(FCCU\\_CFG\)](#) register; when one of these events occurs, the bit value is either unaffected, or FCCU changes it to one of the following:

- N: a chip-specific (or, for some chips, user-specified) value provided by the bit's associated NVMCFG signal
- C: a chip-specific value provided by the bit's associated constant inside the module

For each bit in the [Configuration \(FCCU\\_CFG\)](#) register, this table shows the associated NVMCFG signal, if any, and indicates the source of the bit value for the events that affect it. For specific values of *N* and *C* for each bit, see the chip-specific FCCU information.

| <a href="#">Configuration (FCCU_CFG)</a><br>register bit | NVMCFG signal | Bit value source for<br>an<br>FCCU reset | Bit value source for<br>a<br>configuration-state<br>timeout | Bit value source for<br>an<br>OP31 operation |

## 55.10 FCCU Output Supervision Unit

The FOSU provides a supervision of the primary fault notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after a fault is signaled.

The intention of the FOSU is to provide a secondary fault reaction path in most cases when the FCCU fails but not to needlessly propagate a fault which is already handled by the FCCU in a full chip reset. Only a failed primary fault reaction (that is, FCCU's failure) is a reason for the secondary reaction to take over (and generate a reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction for ALL FAULTS. It is a "static" input in the sense that it does not change after FCCU configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted, (i.e., a disabled fault). There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU. FOSU does not monitor FCCU for the case of faults occurring during CONFIG state.

The FOSU contains a timer with a duration of FOSU\_COUNT, driven by CLKSAFE. The timer is initialized and started on any captured, enabled fault. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FOSU does not check whether the reaction is the configured one for the faults which occurred):

- Functional reset
- IRQ (triggered by ALARM state)

- NMI
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still 'stuck' in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted after it ensures that the fault is enabled and the static "fccu program to do nothing" signal is deasserted. This is because FCCU uses settings after it exits CONFIG state, even if fault captured before the exit.

The FOSU's failure indication output is connected to a reset input of the system reset state machine and is treated like a power-on reset event. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

### NOTE

FOSU is triggered on assertion of enabled fault. In case the triggering fault is disabled, FOSU times-out without reaction.

**Figure 55-56. FOSU connections to the FCCU and system reset state machine**

It is important to remember that there will be no FCCU reaction to a fault while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU\_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then resets the MCU.

### NOTE

FCCU and FOSU timeout counter settings: The FCCU counter value should always be programmed less than the FOSU counter value, FOSU\_COUNT, or resets may be generated by an FOSU time-out. This ensures that the FOSU reacts only when the FCCU fails to react to any particular fault.

## 55.11 Use cases and limitations

### 55.11.1 Configuration guidelines

Follow these guidelines to configure FCCU:

- If you want FCCU to react to a fault on a noncritical fault channel:
  - Enable the channel ([NCFEx](#)).
  - Enable at least one type of Fault-state reaction for the channel: chip reset ([NCFSCx](#)), fault-output (EOUT) signaling ([EOUTENx](#)), or nonmaskable interrupt ([NMIENx](#)).
  - If you enable chip reset as the type of Fault-state reaction for the channel ([NCFSCx](#)), enable either Alarm state ([NCFTOEx](#)) or at least one other type of Fault-state reaction for the channel: fault-output (EOUT) signaling ([EOUTENx](#)) or nonmaskable interrupt ([NMIENx](#)).
  - If you enable Alarm state for the channel ([NCFTOEx](#)), enable the Alarm-state reaction ([IRQENx](#)).
  - If you enable Alarm state for the channel ([NCFTOEx](#)), make sure the Alarm-state timer interval ([TO](#)) is less than the FOSU module's timer interval; otherwise, FOSU generates a chip reset every time a fault occurs on the channel. The FOSU timer interval (FOSU\_COUNT) is chip-specific. See the chip-specific FCCU information.

### NOTE

If you enable a noncritical fault channel but disable all reactions for that channel, FCCU changes state if necessary

but doesn't perform any reaction because reactions are disabled. If you enable reactions for a noncritical fault channel but disable that channel, and FCCU is in Normal state when a fault occurs on the channel, FCCU doesn't enter Alarm or Fault state and therefore doesn't perform any reaction.

### 55.11.2 Recommendations to configure FCCU

1. After a reset cycle in which the FOSU, FCCU, and system are initialized (such as caused by power-up, RESET pin, FOSU reset, or STCU reset), the following steps could be followed to configure FCCU:
  - a. Check and clear any pending fault status
  - b. Verify FCCU is in NORMAL state, else repeat step(a) above
  - c. Configure FCCU
2. After a reset cycle in which the system is re-initialized but the FOSU and RCCU are not re-initialized, the following steps could be followed to reconfigure FCCU:
  - a. If active, wait for the Error out T\_min to expire
  - b. Check and clear fault status
  - c. Error pin moves to "non faulty" state, once fault status is cleared and T\_min expires
  - d. Verify FCCU is in NORMAL state, else repeat step(a) above
  - e. Read and verify value in FCCU\_NCF\_Ex
  - f. Reconfigure FCCU, if necessary

## Chapter 56

# Self-Test Control Unit (STCU2)

### 56.1 Chip-specific STCU information

The STCU controls the execution of built-in self-tests (BISTs) of the chip.

The STCU manages two primary types of BISTs:

- MBIST: memory (SRAM/ROM) BIST
- LBIST: logic BIST for digital logic

The STCU has two sets of conditions under which it applies a self-test sequence:

- Off-line condition: After the user stores self-test parameters in flash memory and a reset cycle is initiated by a power-up event, RESET pin assertion, or FOSU reset, the STCU loads the stored parameters, executes a self-test, and then resets the chip.
- On-line condition: After the user initiates one or more self-tests during normal chip operation, the STCU executes the self-tests and then resets the chip.

The STCU controls the clocking and the reset of the chip during a self-test.

#### NOTE

If both MBIST and LBIST are scheduled to be executed, then MBIST should be executed first. LBIST can be executed only after MBIST is completed.

#### 56.1.1 Supported BIST sequences

NXP has validated and therefore supports only particular STCU2 built-in self-test (BIST) sequences for this chip. For descriptions of the supported BIST sequences for this chip, see the Application Note titled *MPC5777C STCU Quick Start Guide* (document AN5288).

This chip does not have a default offline BIST sequence.

### 56.1.2 Configure or bypass STCU2 off-line self-tests

During reset, the STCU2 has a watchdog timer that can time out and delay exit from reset by at least ~8 ms. To prevent this delay, program DCF records either to configure and run or to bypass STCU2 off-line self-tests at startup.

After programming one set of DCF records either to run or bypass off-line self-tests, do not program subsequent DCF records to change the initial selection of run or bypass.

For information about configuring and running self-tests, see [Supported BIST sequences](#).

To bypass STCU2 off-line self-test operation:

1. Program a DCF record for the client STCU\_SKC (see [Table 5-6](#)) to write the Key1 and Key2 codes for off-line self-test. See [STCU2 SK Code Register \(STCU2\\_SKC\)](#) for details about the register.
2. Program a DCF record for the client STCU\_RUN (see [Table 5-6](#)) to write 1 to STCU2\_RUN[BYP]. See [STCU2 Run Register \(STCU2\\_RUN\)](#) for details about STCU2\_RUN[BYP].

### 56.1.3 STCU interfaces to other modules

The STCU interfaces with other modules on the chip, including:

- SSCM: For off-line self-tests, the STCU uses the SSCM DCF bus to load self-test parameters from DCF records in flash memory. After the reset that precedes the off-line self-test, this SSCM interface is able to write the configuration parameters and start the off-line self-test execution only one time.
- IPS bus (Peripheral Bridge):
  - For on-line self-tests, the CPU accesses STCU memory-mapped registers to initiate execution of the self-tests.
  - For both off-line and on-line self-tests, the CPU accesses STCU memory-mapped registers to check self-test results.
- FCCU: For off-line self-tests, the STCU can be configured through DCF records to classify a hardware fault as a critical fault (CF) or non-critical fault (NCF).

- If a subsequent off-line self-test detects a hardware fault that is classified as a NCF, the FCCU's default response is no reaction.
- If a subsequent off-line self-test detects a hardware fault that is classified as a CF, the FCCU responds to the CF by initiating a new reset cycle.

### NOTE

On this chip, the critical fault (CF) output of the STCU is connected to a non-critical fault (NCF) input of the FCCU. This input is programmed to issue a reset by default. The FCCU itself is not configured to receive "native" CF inputs.

## 56.1.4 On-line LBIST and MBIST clock configuration

Before running an on-line LBIST or MBIST, configure clocking as follows to ensure proper execution:

1. PLL0 is the global clock source: Set PLL0 dividers to generate 200 MHz at PLL0's output.
2. Configure PLL0's clock source to be the crystal oscillator (XOSC): Set SIU\_SYSDIV[PLL0SEL] to 0.
3. Select the non-FM PLL, PLL0, to drive the system clock: set SIU\_SYSDIV[SYSCLKSEL] to 11b.
4. Disable the Progressive Clock Switch feature: Set SIU\_SYSDIV[PCSEN] to 0.
5. Set the System Clock Divider to divide by 1: Set SIU\_SYSDIV[SYSCLKDIV] to 1xx.
6. Set the Peripheral Clock Select: Set SIU\_SYSDIV[PERCLKSEL] to 0.
7. Ensure the fm\_per\_clk divider is 2: Ensure SIU\_SYSDIV[FMPERDIV] is 00b.
8. Set the LFAST clock source to be the peripheral clock coming from PLL: Set SIU\_LFCLKCFG[LFCLKSEL] to 10b.
9. Set SIU\_SYSDIV[MCANSEL] to 1.
10. Set FlexCAN's CAN\_CTRL1[CLKSRC] to 1.
11. Set SWT\_A's SWT\_CR[CSL] to 0 and SWT\_B's SWT\_CR[CSL] to 0.

In addition, before executing an on-line MBIST, set the following clock divider values:

1. Set the eTPU clock divider to 2: Set SIU\_SYSDIV[ETPUDIV] to 0.
2. Set the TCK divider to 3: Set STCU2\_CFG[CLK\_CFG] to 010b.

In addition, before executing an on-line LBIST:

- Configure the shift speed clock for the applicable LBIST with a divider equal to or greater than 2: Set the applicable STCU2\_LB\_CTRL $n$ [SHS] field to a value of 001b or greater.

During an on-line LBIST, clock dividers are bypassed by default.

### 56.1.5 STCU2\_PLL\_CFG configuration of PLLDIG\_PLL0DV

When used, the STCU2's [PLL interface](#) enables the STCU2 module to control PLL0 during off-line self-test operations. In this case, the values programmed into the fields of the [STCU2 PLL Configuration Register \(STCU2\\_PLL\\_CFG\)](#) configure the corresponding fields of the [PLLDIG PLL0 Divider Register \(PLLDIG\\_PLL0DV\)](#).

The following table shows the correlation between STCU2\_PLL\_CFG fields and PLLDIG\_PLL0DV fields.

**Table 56-1. STCU2\_PLL\_CFG and PLLDIG\_PLL0DV field alignment**

| STCU2_PLL_CFG field    | PLLDIG_PLL0DV field    |
|------------------------|------------------------|
| <a href="#">PLLLDF</a> | <a href="#">MFD</a>    |
| <a href="#">PLLIDF</a> | <a href="#">PREDIV</a> |
| <a href="#">PLLODF</a> | <a href="#">RFDPHI</a> |

### 56.1.6 Wait time for writing to the on-line registers

On this chip, no additional wait time applies to writing the on-line registers.

### 56.1.7 On-line MBIST

After the STCU2 triggers the execution of an on-line MBIST, the user cannot perform any access until the MBIST ends.

At the end of the execution of an on-line MBIST, the STCU2 does not generate any reset automatically. The reason is that the software application must manage the consequences of write operations that the MBIST's execution performs.

After the execution of an on-line MBIST ends, the user must ensure that memory controllers are in the correct state.

- Reset the chip to clear the memory output.
- If any memory content is destroyed by an MBIST, reload the content after the MBIST.

It is recommended to enable MBIST interrupts only when executing MBISTs exclusively, not MBISTs combined with LBISTs. If an MBIST is combined with an LBIST in the same test run, the LBIST triggers a reset after the test execution, and the MBIST interrupt will be pending coming out of reset.

This chip implements 65 MBIST partitions.

**Table 56-2. MBIST partitions**

| MBIST partition | Memory                   |
|-----------------|--------------------------|
| MBIST0          | SRAM 1_4                 |
| MBIST1          | SRAM 1_3                 |
| MBIST2          | SRAM 1_2                 |
| MBIST3          | SRAM 1_1                 |
| MBIST4          | SRAM 2_4                 |
| MBIST5          | SRAM 2_3                 |
| MBIST6          | SRAM 2_2                 |
| MBIST7          | SRAM 2_1                 |
| MBIST8          | FEC FIFO RAM             |
| MBIST9          | FEC MIB RAM              |
| MBIST10         | DMA RAM 2                |
| MBIST11         | DMA RAM 1                |
| MBIST12         | eTPU N3 SCM RAM 2        |
| MBIST13         | eTPU N3 SCM RAM 1        |
| MBIST14         | eTPU S32D SCM RAM        |
| MBIST15         | eTPU N3 SPM RAM 3        |
| MBIST16         | eTPU N3 SPM RAM 2        |
| MBIST17         | eTPU N3 SPM RAM 1        |
| MBIST18         | eTPU S32D SPM RAM 2      |
| MBIST19         | eTPU S32D SPM RAM 1      |
| MBIST20         | CSE RAM                  |
| MBIST21         | Core1 cache data RAM 1_4 |

*Table continues on the next page...*

**Table 56-2. MBIST partitions (continued)**

| <b>MBIST partition</b> | <b>Memory</b>            |
|------------------------|--------------------------|
| MBIST22                | Core1 cache data RAM 1_3 |
| MBIST23                | Core1 cache data RAM 1_2 |
| MBIST24                | Core1 cache data RAM 1_1 |

### 56.1.8.1 Off-line LBIST

The chip supports off-line LBIST operation for all six LBIST partitions.

Summary of an off-line LBIST sequence:

1. The user stores off-line self-test parameters in a DCF record in flash memory. The self-test can include multiple LBIST partitions.
  - For off-line self-tests, LBIST execution on individual LBIST partitions occurs serially. The chip does not support LBIST execution on individual LBIST partitions in parallel.
  - An off-line LBIST can run with either the 16 MHz IRC or with PLL0.
  - For an off-line self-test, the STCU can enable and program PLL0 using STCU DCFs.
2. The user resets the chip by cycling power or asserting the RESET pin.
3. The STCU loads the stored off-line LBIST parameters from the DCF record via the SSCM interface.
4. The off-line LBIST executes and ends.
5. Hardware issues a functional reset. The STCU is not affected by this reset.
6. The user verifies the FCCU channels corresponding to STCU faults. If any fault is flagged, the detailed cause can be checked by reading STCU status registers.

### 56.1.8.2 On-line LBIST

The chip supports on-line LBIST operation on all six LBIST partitions.

#### NOTE

When LBIST execution begins, the embedded flash memory must be in an idle state; program or erase operations must not be active. See the [Functional Description](#) of the embedded flash memory for details about its states.

Summary of an on-line LBIST sequence:

1. The user initiates an on-line LBIST by programming STCU memory-mapped registers.
  - An on-line LBIST is able to test only one partition at a time.
  - An on-line LBIST can run with the functional operating frequencies. The maximum-frequency clock for the LBIST partition is derived from PLL0.
  - The user can initiate a sequence of more than one on-line LBIST. Multiple on-line LBISTs can execute serially, with each self-test run on an individual partition.
  - Program the LBRMSW register to generate a global functional reset after an on-line LBIST. Avoid using a dedicated reset due to random data injected by the LBIST Controller.
2. Hardware forces all LBIST partitions into a quiescent state.
3. The on-line LBIST executes and ends.
4. After the completion of the LBIST on-line self-test sequence, hardware issues a functional reset. The STCU is not affected by this reset.
5. The user verifies the FCCU channels corresponding to STCU faults. If any fault is flagged, the detailed cause can be checked by reading STCU status registers.

For on-line LBISTs, this chip does not support the following features:

- Interrupt generation after each LBIST on an individual partition
- Software abort during an on-line LBIST

#### NOTE

An abort does occur under these conditions:

- A reset cycle is triggered in the middle of a self-test execution.
- The reset source is not POR, RESET pin, FOSU, or the STCU itself.

A reset caused by POR, RESET pin, or FOSU does not cause an abort because it resets the STCU and causes it to run the self-test again. A reset caused by the STCU itself implies successful completion of the self-test procedure.

### **56.1.8.3 Diagnostic self-test: On-line LBIST from JTAG/Nexus interface**

A "diagnostic self-test" is an on-line LBIST that is invoked via the chip's JTAG/Nexus debug/development interface. Via the chip's JTAG pins, a JTAG tool can access the Nexus debug interface in the CPU and use it to configure the STCU without interfering with normal chip operation.

However, after the LBIST of a partition starts, the STCU takes control of the chip, putting all partitions that are not being tested in a quiescent state. The chip resets at the end of the LBIST.

### **56.1.8.4 Multiple serial LBISTs**

The chip allows serial execution of off-line and on-line LBISTs. For example, this sequence is valid:

1. The user programs a DCF record in the flash memory to perform an off-line LBIST.
2. A power-on reset (POR) occurs.
3. The STCU executes the off-line self-test.
4. A functional reset occurs.
5. The CPU boots. The user programs STCU registers using the CPU to execute an on-line LBIST. An on-line LBIST is initiated.
6. A functional reset occurs.
7. The CPU boots again. No off-line or on-line self-test is initiated.

### 56.1.8.5 LBIST execution and dual cores

On this dual-core chip, either core can program (schedule) execution of an LBIST. After the LBIST of a partition begins, both cores and all other logic not included in that partition are maintained in a reset state. Neither core can operate during the LBIST execution of any partition, regardless of which core initially configured the LBIST.

### 56.1.9 STCU register default values

The following table documents STCU register default values that are specific to this chip. For the default values of all other STCU registers, see [Register description](#).

#### NOTE

Some of these registers are DCF clients whose values are overwritten by the values in STCU2-specific DCF records in UTEST flash memory. If the user programs a value for one of these DCF records, the corresponding register reflects the user-programmed value.

**Table 56-4. STCU register default values**

| Register                                        | Default value |
|-------------------------------------------------|---------------|
| STCU2_CFG                                       | 0000_0000h    |
| STCU2_PLL_CFG                                   | 0000_0000h    |
| STCU2_WDG                                       | 0000_FFFFh    |
| STCU2_ERR_FM                                    | 0000_0000h    |
| STCU2_LBRMSW                                    | 0000_003Fh    |
| STCU2_LBUFM                                     | 0000_0000h    |
| STCU2_MBUFML, STCU2_MBUFMM, STCU2_MBUFMH        | 0000_0000h    |
| STCU2_LB_CTRL $_n$                              | 0000_0000h    |
| STCU2_LB_PCS $_n$                               | 0000_0000h    |
| STCU2_LB_MISREL $_n$ , STCU2_LB_MISREH $_n$     | FFFF_FFFFh    |
| STCU2_LB_MISRRL $_n$ , STCU2_LB_MISRRH $_n$     | 0000_0000h    |
| STCU2_LB_MISRELSW $_n$ , STCU2_LB_MISREHSW $_n$ | FFFF_FFFFh    |
| STCU2_LB_MISRRLSW $_n$ , STCU2_LB_MISRRHSW $_n$ | 0000_0000h    |
| STCU2_MB_CTRL $_n$                              | 0000_0000h    |

## 56.1.10 AUTOLOCK\_VALUE for register write access and DCF\_COMPLETION value for DCF write completion

Register write-access watchdog timer refers to two clock-cycle values related to the STCU2's write-access watchdog. The following table provides these values on this chip.

| Clock-cycle value | Number of STCU2 clock cycles |
|-------------------|------------------------------|
| AUTOLOCK_VALUE    | 1024                         |
| DCF_COMPLETION    | 16                           |

## 56.2 Introduction

The *STCU2 self-test control unit* is a hardware module that:

- Manages the execution of built-in self-tests (BISTs)
- Indicates whether each BIST passed

## 56.3 Main features

- Internal Peripheral System (IPS) interface for reading from and writing to the STCU2 registers during runtime (online) via the CPU
- SSCM Device Configuration Format (DCF) interface for writing to the STCU2 registers from nonvolatile memory during reset (offline) via the SSCM module (has priority over the IPS interface)
- Programmable scheduler for BIST execution
- LBIST concurrent/sequential execution
- MBIST concurrent/sequential execution
- Programmable LBIST delayed concurrent start
- Programmable internal clock prescaler to reduce internal and BIST TCK clocks
- Programmable PLL direct control during offline BIST sequence
- PLL Lock signal monitoring during BIST sequences
- Dedicated online MBIST interrupt source generation
- Programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence

- Fixed offline-initialization watchdog timer that specifies the maximum time allowed for offline initialization before indicating an initialization fault
- Fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them
- Fields that indicate the execution status of each:
  - Online MBIST
  - Offline MBIST
  - Online LBIST
  - Offline LBIST
- Fields that indicate the status of each type of online STCU2 internal error condition
- Fields that indicate the status of each type of offline STCU2 internal error condition
- Programmable fault mapping for each BIST for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the BIST fails to execute
- Programmable fault mapping for each STCU2 internal error condition for controlling the type of fault that STCU2 reports (recoverable or unrecoverable) when the condition occurs
- Signals for reporting recoverable and unrecoverable faults to the FCCU module
- Redundant recoverable and unrecoverable fault-generation logic to improve reliability
- FCCU recoverable and unrecoverable fault-injection mechanism
- LBIST MISRE register access to perform redundant check by software
- Offline BIST-sequence bypass capability
- Global register write-protection mechanism that requires two security key codes
- Global automatic power saving when a BIST sequence is completed, Bypass mode is selected, or a watchdog timer time-out is detected
- ITF/watchdog automatic clock wake-up mechanism when software unlocks the STCU2 registers for write access
- ITF/watchdog automatic power saving when the fixed register-write-access watchdog timer times out

# 56.4 Block diagram

This diagram shows the parts of STCU2:

This table describes the parts of STCU2:

| Part            | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Reg interface   | Provides access to: <ul style="list-style-type: none"><li>Registers</li><li>The security key logic</li><li>The Internal Peripheral System (IPS) interface</li><li>The SSCM Device Configuration Format (DCF) interface</li></ul>                                                                                                                                                                                                                                                                                                                                                      |
| Fault interface | Does the following: <ul style="list-style-type: none"><li>Collects the fault conditions caused by STCU2 internal error conditions and each BIST executed in a sequence.</li><li>Depending on the fault mapping for a given BIST, sets the global recoverable or unrecoverable status flag.</li><li>Manages the recoverable and unrecoverable fault lines to and from the FCCU module</li><li>Manages the set/clear injection mechanism provided by the FCCU module.</li></ul> <p>To improve the intrinsic reliability of this critical logic, the generation logic is duplicated.</p> |
| Clock interface | Manages the internal and the BIST TCK clock prescaler, the internal clock-gating power saving, and the wake-up clock feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Table continues on the next page...

| Part                                      | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WDG FSM (watchdog finite state machine)   | Provides the following: <ul style="list-style-type: none"> <li>• A programmable BIST-sequence-execution watchdog timer that specifies the maximum time allowed for the execution of a BIST sequence</li> <li>• A fixed offline-initialization watchdog timer that specifies the maximum time allowed for offline initialization before indicating an initialization fault</li> <li>• A fixed register-write-access watchdog timer that specifies the maximum amount of time that STCU2 allows you to write to its registers after you unlock them</li> </ul> |
| Master FSM (finite state machine)         | Coordinates and schedules all of the operations performed during a BIST sequence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Loader Shifter FSM (finite state machine) | Programs the BIST registers and reads back the data to be checked at the end of each test operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| LBIST interface                           | Provides the interface between the chip's LBIST engines and the STCU2 controllers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| MBIST interface                           | Provides the interface between the MBIST controller and the STCU2 controllers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## 56.5 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers
- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode only in the following scenario:

- The Self-Test sequence parameters are loaded before Off-Line Self-test is executed
- The IPS access on a specific register is allowed by software only when the bit STCU2\_CFG.WRP is cleared
- In all the other conditions the write operations are not supported and all the STCU2 registers can be only read. Only exceptions are the following read/write bits: STCU2\_CFG.WRP, STCU2\_ERR\_STAT.UFSF and STCU2\_ERR\_STAT.RFSF. See related register description for additional details

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when the STCU2\_CFG.WRP bit is set and the access is performed through software (IPS interface)
- Any write operation performed through software (IPS interface) on Read/On-Line\_Write/Off-Line registers
- Any write operation performed off-line on registers in which writing operation is allowed only in the On-Line Self-Test phase when STCU2\_CFG[WRP] = 1
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

### **NOTE**

See the chip-specific STCU2 information for the wait time necessary to write to the online registers.

## **56.6 BISTs and BIST partitions**

### **56.6.1 Definition: BIST**

A *built-in self-test (BIST)* is a test that the chip can execute to verify the functional integrity of a part of itself. The chip uses STCU2 and other on-chip hardware to execute a BIST.

## 56.6.2 Definition: BIST partition

A *built-in self-test (BIST) partition* is a part of a chip for which a BIST has been defined. The hardware that is included in a given BIST partition is chip-specific. For a list of the hardware included in each of the BIST partitions on this chip, see the chip-specific STCU2 information.

## 56.6.3 Example: BIST partitions on a chip

This is an example of a chip with six built-in self-test (BIST) partitions:

## 56.6.4 Types of BIST partitions

The STCU2 module on this chip supports the following type or types of built-in self-test (BIST) partitions:

| BIST partition type           | Description                 |
|-------------------------------|-----------------------------|
| Memory BIST (MBIST) partition | An SRAM or ROM block        |
| Logic BIST (LBIST) partition  | One or more digital modules |

## 56.7 BIST sequences

### 56.7.1 Definition: BIST sequence

A *built-in self-test (BIST) sequence* is a programmable series of one or more phases, each of which executes one or more individual BISTs.

## 56.7.2 STCU2 executes MBISTs before LBISTs

If a built-in self-test (BIST) sequence includes both MBISTs and LBISTs, STCU2 executes the MBISTs first.

## 56.7.3 Example: Single-phase BIST sequence

This is an example of a single-phase BIST sequence in which STCU2 executes only one BIST:

| Phase | BIST executed |
|-------|---------------|
| 0     | MBIST 16      |

## 56.7.4 Example: Multiphase BIST sequence

This is an example of a multiphase BIST sequence in which STCU2 executes more than one BIST in parallel in some phases:

| Phase | BISTs executed       |
|-------|----------------------|
| 0     | MBISTs 7, 38         |
| 1     | MBIST 23             |
| 2     | MBISTs 6, 16, 29, 23 |
| 3     | LBIST 12             |
| 4     | LBISTs 13, 8, 11     |
| 5     | LBISTs 19, 6         |

## 56.7.5 Types of BIST sequences

The STCU2 module on this chip supports these types of built-in self-test (BIST) sequences:

| BIST sequence type   | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Online BIST sequence | <p>A BIST sequence that STCU2 executes during runtime at the request of software. Application software configures and initiates execution of the BIST sequence by loading values into STCU2 registers.</p> <p>Use this type of BIST sequence when you want to test the chip hardware but need to minimize the system startup time. Also use it for failure diagnostics and quality control within a</p> |

*Table continues on the next page...*

| BIST sequence type    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | manufacturing environment. You can choose the most appropriate point during runtime at which to execute this type of BIST sequence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Offline BIST sequence | <p>A BIST sequence that STCU2 automatically executes during reset, either when power is first applied to the chip or when the chip resets STCU2. The chip's SSCM module configures and initiates execution of the BIST sequence by loading values into STCU2 registers from Device Configuration Format (DCF) records that are stored in the chip's UTEST flash memory.</p> <p>Use this type of BIST sequence when you want to test the chip hardware before runtime.</p> <p>The location of the DCF record area is chip-specific. The size of the DCF record area is sequence-specific. For the location of the DCF record area, see the chip-specific STCU2 information.</p> |

### 56.7.6 Supported BIST sequences

NXP has validated and therefore supports only specific built-in self-test (BIST) sequences for this chip. For a list of the supported BIST sequences, see the chip-specific STCU2 information.

### 56.7.7 Definition: Default offline BIST sequence

A *default offline built-in self-test (BIST) sequence* is an offline BIST sequence whose configuration NXP has programmed into the chip's Device Configuration Format (DCF) records that are stored in the chip's UTEST flash memory. To determine whether this chip has a default offline BIST sequence, see the chip-specific STCU2 information.

If this chip has a default offline BIST sequence and you choose to use it, or if it's the only one supported by NXP, there is no need to create additional DCF records for the offline BIST sequence.

## 56.8 Functional description

## 56.8.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the Self Test operations and the other State Machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

## 56.8.2 Reset management

Assertion of the STCU2 reset input signal initializes the STCU2 module status, forcing the Off-Line Self-Test condition and cleaning up all the registers and state machine of the module.

The reset signals generated by the STCU2 module at the end of the Self-Test execution phase depends on the Self-Test conditions and on the content of the LBRMSW register.

### 56.8.2.1 Off-Line reset generation

At the end of the Off-Line Self-Test execution the STCU2 raises the global functional reset.

### 56.8.2.2 On-Line reset generation

See the chip-specific STCU2 information for details about On-Line reset generation.

## 56.8.3 Built-in self-test scheduling

The STCU2 module has been designed to be very flexible allowing to program the parallel/serial execution of the MBIST or LBIST depending on the power/timing/coverage constraints. The limitation in the programming flexibility is described in [Design implementation information](#).

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU2\_CFG.PTR. The first LBIST is mapped on 00h, the second on 01h, and so on. The first MBIST is mapped to the address 10h, the second to 11h and so on.

The additional pointers are in the bitfield STCU2\_LB\_CTRL[X].PTR for LBIST[X] (where X is the selected LBIST) and STCU2\_MB\_CTRL[Y].PTR for MBIST (where Y is the selected MBIST) and have to be filled depending on the selected sequence of run. The additional bitfield STCU2\_LB\_CTRL.CSM and STCU2\_MB\_CTRL.CSM provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list setting the NIL pointer. For more details, see [STCU2 LBIST Control \(STCU2\\_LB\\_CTRL<sub>n</sub>\)](#) and [STCU2 MBIST Control Register \(STCU2\\_MB\\_CTRL<sub>n</sub>\)](#).

### NOTE

Program operation should ensure that no flash write/erase operations are ongoing when online LBIST is triggered. Otherwise, a flash segment may be corrupted.

## 56.8.4 PLL interface

The STCU2 module is able to directly control the PLL during the Off-Line Self-Test operations depending on the status of the STCU2\_RUN[MBPLEN] and STCU2\_RUN[LBPLEN].

When STCU2\_RUN[RUN] is set to start the Off-Line Self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed into the STCU2\_PLL\_CFG register.

When the STCU2\_RUN[MBPLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock signal. As soon as the lock happens, the STCU2 forces the clock to switch to the PLL output clock. This allows the MBIST to proceed at the PLL output frequency. At the end of the MBIST run the clock source is reverted to the original one.

Same behavior will be applied when STCU2\_RUN[LBPLEN] is active and LBIST is currently selected.

## 56.8.5 Interrupt interface

Interrupt source:

- Triggered by MBIST (enabled by programming STCU2\_RUNSW[MBIE] = 1)

As described in the [RUNSW](#) description, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential run in the same session, the number of interrupts generated is equivalent to the number of the sequential session providing in such a way a fine granularity with respect to the completed run.

The MBIFLG bit in the [STCU2 Interrupt Flag Register \(STCU2\\_INT\\_FLG\)](#) register flag interrupt conditions and allow the clearing of interrupt requests. Interrupt bits are cleared by writing the related flag bit to 1 to enable the next interrupt request.

## **56.8.6 FCCU interface**

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable fault and/or a Recoverable fault failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

## **56.8.7 Watchdogs**

The STCU2 implements three different watchdogs to ensure that operations are finished in time.

### **56.8.7.1 Initialization watchdog timer**

The STCU2 has two initialization operating modes: program the self-test sequence and run it (Safety mode) or bypass completely the self-test sequence setting STCU2\_RUN[BYP]. In case there are faults during the initialization phase preventing the selection of one of these two operating modes, a hard-coded watchdog time-out flags the wrong behavior.

### **56.8.7.2 Built-in self-test watchdog timer**

The LBIST and MBIST execution time has to be configured as described in [STCU2 Watchdog Granularity \(STCU2\\_WDG\)](#) to account for the overall execution time of the Self-Test sequence. In case the selected LBISTs or MBISTs are not yet completed during

the Off-line Self-Test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into STCU2\_ERR\_STAT.WDTO and STCU2\_MBEL/M/H or STCU2\_LBE registers while in case of On-Line Self-Test into STCU2\_ERR\_STAT.WDTOSW and STCU2\_MBELSW/MSW/HSW or STCU2\_LBESW.

In case of multiple sequential run in the same On-LineOff-Line session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

In all the cases, the STCU2 reset generation is managed in one of the modes described in [Reset management](#).

### 56.8.7.3 Register write-access watchdog timer

As explained in the STCU2\_SKC register description:

- A key mechanism protects STCU2 registers during the self-test configuration phase (both online/offline) by preventing any unwanted access.
- A hardware watchdog timer locks register-write access after a number of STCU2 clock cycles. To refresh the hardware watchdog timer before it times out, write only security key 2 to STCU2\_SKC.

AUTOLOCK\_VALUE is the number of STCU2 clock cycles after which the hardware watchdog timer locks register-write access. See the chip-specific STCU2 information for the value of AUTOLOCK\_VALUE.

#### NOTE

For write completion, each DCF record requires a number of STCU2 clock cycles equal to DCF\_COMPLETION. The maximum number of DCF records that can be executed before the watchdog timer must be refreshed is AUTOLOCK\_VALUE divided by DCF\_COMPLETION. See the chip-specific STCU2 information for the value of DCF\_COMPLETION.

The hardware watchdog timer is particularly useful in case STCU2\_CFG[WRP] is 0 during the software self-test configuration. In this case, the software application might enable write access to the STCU2 registers.

## 56.8.8 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without the CPU intervention after a reset trigger event initializes the STCU2. This bus interface has the priority over the IPS.

## 56.9 Register description

During Offline SELFTEST, once the STCU2 registers are configured they cannot be overridden.

During Online SELFTEST, once the STCU2 registers are configured they cannot be overridden via IPS till the selftest is complete.

The STCU2 registers are listed in this section.

**STCU2 memory map**

| Address offset (hex) | Register name                                         | Width (in bits) | Access | Reset value                 | Section/ page                |

## 56.9.1 STCU2 Run Register (STCU2\_RUN)

The STCU2\_RUN register defines the RUN bit to start the off-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 0h offset = 0h

**56.9.2 STCU2 Run Software Register (STCU2\_RUNSW)**

The STCU2\_RUNSW register defines the RUN bit to start the on-line self testing procedure.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU2\_CFG[WRP] = 0
- On-line Self-Test phase is active. The On-Line condition starts when the Off-Line is over. In this condition, system is alive and the SW can program the STCU2

Address: 0h base + 4h offset = 4h

### 56.9.3 STCU2 SK Code Register (STCU2\_SKC)

The STCU2\_SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers. In order to unlock the STCU2 access after:

**Register description**

- The STCU2 asynchronous reset
- The end of the STCU2 run

the software (IPS bus) or the SSCM interfaces have to apply the following sequence:

- write the key1 into the STCU2\_SKC register
- write the key2 into the STCU2\_SKC register

Depending on the off/on-line test step, the two keys will be different. Byte write operation is not allowed since the full key has to be recognized as one unit.

It should be noted that after the Self-Test sequence has been completed or the Bypass feature has been enabled (setting the bit BYP into the STCU2\_CFG), the SSCM interface is no longer available.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

In case the STCU2 register access lasts more cycles than the one defined into the Hard-coded WDG time-out, the STCU2 write access is locked and the WDG and Register ITF clocks are switched off. Also in this case, in order to enable again the write access to the STCU2 and the WDG and Register ITF clocks, it is required to apply again the sequence.

In case it is required to extend the STCU2 register access cycles before the Hard-coded WDG time-out expires, only the Key2 has to be applied. The effect of this write operation is to re-initialize the WDG time-out counter. In such a condition, Key1 has not to be applied otherwise a transfer error on the IPS bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

The STCU2\_SKC register is not readable. The value 00000000h is always returned in case of read operation.

Address: 0h base + 8h offset = 8h

**56.9.4 STCU2 Configuration Register (STCU2\_CFG)****NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_CFG register includes the global configuration of the STCU2 and can be updated both in the Off/On-Line Test steps.

The access to this register is described in the following figure. It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the on-line Self-Test case without restrictions
- When WRP = 1:
  - The only bit that can be written without any restriction is WRP.
  - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

MBIST can be run in three different test types according to how the STCU2\_CFG register bits 27 and 28 are set.

The following table describes the test algorithm and coverage of the different test types.

**Table 56-10. MBIST algorithm and coverage according to test type**

| MBIST Type | STCU2_CFG[PM OSEN] | STCU2_CFG[MB U] | MBIST Algorithm                                                         | Internal Nodes/ Circuits Additionally Covered by Test                           | Use Case                                                                                 | Test Cycle                        |
|------------|--------------------|-----------------|-------------------------------------------------------------------------|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|-----------------------------------|
| Full Test  | 1                  | 0               | Test memory using all built in algorithms. Open PMOS algorithm included | Address Decoder and Bitcell as well as resistive defects in the address decoder | Used by MCU production test. Recommended to use in the field for MBIST online self-test. | About 3 to 4x more than Auto Test |

*Table continues on the next page...*

**Table 56-10. MBIST algorithm and coverage according to test type (continued)**

| MBIST Type   | STCU2_CFG[PM OSEN] | STCU2_CFG[MB U] | MBIST Algorithm                                                           | Internal Nodes/<br>Circuits Additionally Covered by Test            | Use Case                                                                                              | Test Cycle                          |
|--------------|--------------------|-----------------|---------------------------------------------------------------------------|---------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-------------------------------------|
| Reduced Test | 0                  | 0               | Test memory using all built in algorithms except the open PMOS algorithm. | Address Decoder and Bitcell                                         | Recommended to use in the field for MBIST online self-test if the Full Test takes too long.           | About 10% less than Full Test       |
| Auto Test    | x                  | 1               | A smaller set of algorithms which target latent defect mechanisms.        | Latent defects such as NBTI of the PMOS transistors in the bitcells | Recommended to use for MBIST offline self-test as an optimum balance of test time vs. fault coverage. | About 3 to 4x faster than Full Test |

## 56.9.5 STCU2 PLL Configuration Register (STCU2\_PLL\_CFG)

## NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_PLL\_CFG register defines the parameters used to program the PLL only when the Off-line L/MBIST are performed and STCU2\_RUN[MBPLEN] = 1 or STCU2\_RUN[LBPLEN] = 1.

In the On-line condition, these bits are not effective. It is also possible to set the PLL during active On-line mode to prevent any potential functionality issue.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 10h offset = 10h

**56.9.6 STCU2 Watchdog Granularity (STCU2\_WDG)****NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_WDG register defines the time limit for LBIST and MBIST execution, providing a protection mechanism in case of deadlock or endless conditions during the self test procedure.

When the offline self test sequence is not run and the STCU2\_CFG[BYP] field is not set, bits 15..0 define the time-out before the STCU2\_ERR[WDTO] field is set and the STCU2 core clock is switched off.

In case offline/online self test sequence is run, the STCU2\_WDG value defines the time-out of the execution run.

The register fields are always readable. You can write to these fields when either of the following conditions is true:

- Offline self test phase is active
- Online self test phase is active and CFG[WRP] = 0

Address: 0h base + 14h offset = 14h

### 56.9.7 STCU2 Interrupt Flag Register (STCU2\_INT\_FLG)

The STCU2\_INT\_FLG register includes an MBIST interrupt pending bit. The bit is effective only during the On-Line Self-Test phase and is managed only when the related control bit in the STCU2\_RUNSW register (MBIE) is enabled.

Address: 0h base + 18h offset = 18h

56.9.8 STCU2 Error Register (STCU2\_ERR\_STAT)

The STCU2\_ERR\_STAT register includes the status flags related to the STCU2 internal fault conditions occurred during the configuration or the On/Off-Line self testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels.

The access to this register is described in the following figure and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

**56.9.9 STCU2 Error FM Register (STCU2\_ERR\_FM)****NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_ERR\_FM register defines the fault mapping of the STCU2 faults described into the register STCU2\_ERR\_STAT in terms of Unrecoverable or Recoverable Fault. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2\_CFG[WRP] = 0

Address: 0h base + 28h offset = 28h

## 56.9.12 STCU2 On-Line LBIST Status Register (STCU2\_LBSSW)

The STCU2\_LBSSW register includes the results corresponding to the execution of the selected On-Line LBIST.

The size of the register depends on the number of LBIST .

The content of this register is initialized to its reset value as soon as STCU2\_RUNSW[RUNSW] = 1.

Address: 0h base + 34h offset = 34h

**56.9.13 STCU2 On-Line LBIST End Flag Register (STCU2\_LBESW)**

The STCU2\_LBESW register includes the End Flag related to the execution of the selected On-Line LBIST.

The size of the register depends on the number of LBIST.

The content of this register is initialized to its reset value as soon as STCU2\_RUNSW[RUNSW] = 1.

Address: 0h base + 38h offset = 38h

**56.9.14 STCU2 On-Line LBIST Reset Management (STCU2\_LBRMSW)****NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_LBRMSW register defines the On-Line reset mapping for each LBIST. Global or specific functional reset can be programmed depending on the On-Line Self-Test requirements and top level integration architecture .

The size of the register depends on the number of LBIST .

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2\_CFG[WRP] = 0

**56.9.17 STCU2 Off-Line MBIST Status Medium Register (STCU2\_MBSM)**

The STCU2\_MBSM register includes the results corresponding to the execution of the selected Off-Line MBIST in the range NMCUT = 32-63.

The size of the register depends on the number of BISTed RAMs/ROMs .

## Register description

Address: 0h base + 48h offset = 48h

**56.9.18 STCU2 Off-Line MBIST Status High Register (STCU2\_MBSH)**

The STCU2\_MBSH register includes the results corresponding to the execution of the selected Off-Line MBIST in the range NMCUT = 64-95.

The size of the register depends on the number of BISTed RAMs/ROMs.

Address: 0h base + 4Ch offset = 4Ch

### 56.9.19 STCU2 Off-Line MBIST End Flag Low Register (STCU2\_MBEL)

The STCU2\_MBEL register includes the End Flag related to the execution of the selected Off-Line MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs.

**56.9.20 STCU2 Off-Line MBIST End Flag Medium Register (STCU2\_MBEM)**

The STCU2\_MBEM register includes the End Flag related to the execution of the selected Off-Line MBIST in the range NMCUT = 32-63.

The size of the register depends on the number of BISTed RAMs/ROMs.

Address: 0h base + 54h offset = 54h

56.9.21 STCU2 Off-Line MBIST End Flag High Register (STCU2\_MBEH)

The STCU2\_MBEH register includes the End Flag related to the execution of the selected Off-Line MBIST in the range NMCUT = 64..95.

The size of the register depends on the number of BISTed RAMs/ROMs.

Address: 0h base + 58h offset = 58h

STCU2\_MBEH field descriptions

| Field            | Description                                                                                                                 |

56.9.22 STCU2 On-Line MBIST Status Low Register (STCU2\_MBSLSW)

The STCU2\_MBSLSW register includes the results corresponding to the execution of the selected On-Line MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2\_RUNSW[RUNSW] = 1.

Address: 0h base + 5Ch offset = 5Ch

**56.9.23 STCU2 On-Line MBIST Status Medium Register (STCU2\_MBSMSW)**

The STCU2\_MBSMSW register includes the results corresponding to the execution of the selected On-Line MBIST in the range NMCUT = 32..63.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2\_RUNSW[RUNSW] = 1.

## Register description

**56.9.24 STCU2 On-Line MBIST Status High Register (STCU2\_MBSHSW)**

The STCU2\_MBSHSW register includes the results corresponding to the execution of the selected On-Line MBIST in the range NMCUT = 64..95.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2\_RUNSW[RUNSW] = 1.

Address: 0h base + 64h offset = 64h

56.9.25 STCU2 On-Line MBIST End Flag Low Register (STCU2\_MBELSW)

The STCU2\_MBELSW register includes the End Flag related to the execution of the selected On-Line MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2\_RUNSW[RUNSW] = 1.

Address: 0h base + 68h offset = 68h

**56.9.26 STCU2 On-Line MBIST End Flag Medium Register (STCU2\_MBEMSW)**

The STCU2\_MBEMSW register includes the End Flag related to the execution of the selected On-Line MBIST in the range NMCUT = 32-63.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2\_RUNSW[RUNSW] = 1.

56.9.27 STCU2 On-Line MBIST End Flag High Register (STCU2\_MBEHSW)

The STCU2\_MBEHSW register includes the End Flag related to the execution of the selected On-Line MBIST in the range NMCUT = 64-95.

The size of the register depends on the number of BISTed RAMs/ROMs.

The content of this register is initialized to its reset value as soon as STCU2\_RUNSW[RUNSW] = 1.

Address: 0h base + 70h offset = 70h

STCU2\_MBEHSW field descriptions

| Field            | Description                                                                                                                  |
|------------------|------------------------------------------------------------------------------------------------------------------------------|

## 56.9.28 STCU2 MBIST Unrecoverable FM Low Register (STCU2\_MBUFML)

### NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_MBUFML register defines the fault mapping, in terms of Unrecoverable or Recoverable fault, of the MBIST in the range NMCUT = 0-31.

The size of the register depends on the number of BISTed RAMs/ROMs.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2\_CFG[WRP] = 0

Address: 0h base + 74h offset = 74h

**56.9.31 STCU2 LBIST Control (STCU2\_LB\_CTRLn)****NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_LB\_CTRL register defines the control setting of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Offline self test phase is active
- Online self test phase is active and STCU2\_CFG[WRP] = 0

Address: 0h base + 100h offset + (64d × i), where i=0d to 5d

**STCU2\_LB\_CTRLn field descriptions (continued)**

| Field | Description                                           |
|-------|-------------------------------------------------------|
| 100   | controller waits 4 shift cycles for capture to finish |
| 101   | controller waits 5 shift cycles for capture to finish |
| 110   | controller waits 6 shift cycles for capture to finish |
| 111   | controller waits 7 shift cycles for capture to finish |

**56.9.32 STCU2 LBIST PC Stop Register (STCU2\_LB\_PCSn)****NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_LB\_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2\_CFG[WRP] = 0

Address: 0h base + 104h offset + (64d × i), where i=0d to 5d

**56.9.33 STCU2 Off-Line LBIST MISR Expected Low Register (STCU2\_LB\_MISRELn)****NOTE**

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_LB\_MISREL register defines the LSB part (31-0) of the Expected MISR of the Off-Line LBIST controller.

The size of the register depends on the number of MISR bits of the related LBIST.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 110h offset + (64d × i), where i=0d to 5d

## 56.9.34 STCU2 Off-Line LBIST MISR Expected High Register (STCU2\_LB\_MISREH<sub>n</sub>)

### NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_LB\_MISREH register defines the MSB part (63-32) of the Expected MISR of the Off-Line LBIST controller.

The size of the register depends on the number of MISR bits of the related LBIST.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Address: 0h base + 114h offset + (64d × i), where i=0d to 5d

## 56.9.37 STCU2 On-Line LBIST MISR Expected Low Register (STCU2\_LB\_MISRELSWn)

### NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_LB\_MISRELSW register defines the LSB part (31-0) of the Expected MISR of the On-Line LBIST controller.

The size of the register depends on the number of MISR bits of the related LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2\_CFG[WRP] = 0

Address: 0h base + 120h offset + (64d × i), where i=0d to 5d

## 56.9.41 STCU2 MBIST Control Register (STCU2\_MB\_CTRLn)

### NOTE

The reset value is chip-specific; see the chapter that describes how modules are configured and connected.

The STCU2\_MB\_CTRL register defines the control setting of MBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU2\_CFG[WRP] = 0

The offset of this register is a function of NMCUT .

Address: 0h base + 600h offset + (4d × i), where i=0d to 64d

**56.10 Use cases and limitations**

The STCU2 module is designed to give high flexibility during the on/off-line test. In the following are reported the programming operations that have to be performed to correctly use the functionality of this module considering the three typical usage cases:

- the Off-line Self Test Sequence after a reset trigger event
- the bypass mode of the Self Test Sequence after a reset trigger event
- the On-line Self-test Sequence

**56.10.1 Offline self-test sequence**

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and L/MBIST execution parameters stored into the NVM memory. The target is to cover the amount of physical defects in the digital logic and in the System RAMs/ROMs according to the System specifications. The sequence is the following:

- Unlock the Off-Line STCU2 access writing the Key1/Key2 sequence into the STCU2\_SKC register
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU2\_LBUFM register
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU2\_MBUFML/M/H registers
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU2\_ERR\_FM register
- Program the STCU2\_LB\_CTRL, STCU2\_LB\_PCS, STCU2\_MISREL/H registers of each LBIST to be executed.
- Program the STCU2\_MB\_CTRL registers of each NMCUT to be executed

- Program the STCU2\_WDG register to define the time budget assigned for the L/MBIST execution
- Program the STCU2\_CFG register to define: the core and LBIST/MBIST TCK clock prescaling factor setting the CLK\_CFG bits, the LB\_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase, the PMOSEN or MBU in order to define the algorithm to be used during MBIST run, and finally set the pointer to the first LBIST/NMCUT to be executed
- In case the PLL usage has been enabled, program the STCU2\_PLL\_CFG value in order to set the required system frequency
- Program the RUN bit into the STCU2\_RUN register to enable the Off-Line Self-Test execution and the L/MBPLEN bits to enable the PLL during L/MBIST execution according to STCU2\_PLL\_CFG register content
- Start the Off-Line Self-Test and, depending on PLL management and L/MBIST execution order, when PLL LOCK is high.
- Wait the WDGEOC run time execution specified into the STCU2\_WDG register.
- The STCU2 switches off the core clock at the end of the Self-Test run and releases the PLL control in case this feature has been enabled.
- The STCU2 resets the STCU2\_RUN[RUN] bit and the device exits from boot sequence. In case there are failures, the STCU2 flags these failures toward the FCCU.
- The software application reads the STCU2\_LBS flag register to check the failed LBIST when UF or RF conditions is/are detected.
- The software application reads the STCU2\_LBE flag register to check the LBIST still on-going when UF or RF is/are detected.
- The software application reads the STCU2\_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
- The software application reads the STCU2\_MBEL/M/H flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.
- The software application reads the bits INV, ENGE, WDTO, LOCKE of the STCU2\_ERR\_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.
- The software application reads for each device's LBIST, the STCU2\_LBMISREL/H and STCU2\_LBIST\_MISRRL/H registers to check the coherence with the STCU2\_LBS bits.

**NOTE**

The software application reads operations on the STCU2 and LBIST MISR registers after off-line self test execution has been successfully performed are just an additional reliability layer added to improve the already implemented Auto Self-Test feature included into STCU2.

**56.10.2 Online self test sequence**

The online self test sequence is the most commonly used STCU2 application mode. The IPS interface is used to program the STCU2 registers and to schedule LBIST and MBIST execution. Since online LBIST and MBIST operations clean-up the content of Digital Logic (LBIST) or RAM (MBIST) tested, activation of this mode must be approached with caution. The suggested sequence is the following:

1. Write the Key1/Key2 sequence to the SKC register to unlock online STCU2 access.
2. Ensure CFG[WRP]=0 to enable IPS bus access to the online self test registers.
3. If required, program the following registers to select the LBIST, MBIST and STCU2 internal fault reaction: LBUFM, MBUFML/M/H and ERR\_FM.

**NOTE**

The LBIST, MBIST and STCU2 internal fault reaction should have been already programmed during the offline self test sequence and so there should be no need to program again. However, in case they have not been programmed or there is the need of changing them for any reason, they can be overwritten.

4. Select the reset management options for online LBIST execution by programming the LBRMSW register.
5. The LB\_CTRL and LB\_PCS registers should have been already programmed during offline self test sequence and so they should not need to be programmed again. However, if they have not been programmed or there is the need of changing them for any reason, they can be overwritten. The registers LB\_MISRELSW/HSW have to be programmed according to the expected signature.
6. Overwrite/Program the MB\_CTRL registers of each NMCUT to be executed.
7. Overwrite/Program the WDG register to define the time budget assigned for the L/MBIST execution
8. Overwrite/Program the CFG register to define: the core and L/MBIST TCK clock prescaling factor setting the CLK\_CFG bits, the LB\_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase, the PMOSEN or MBU in order to

define the algorithm to be used during MBIST run, and finally set the pointer to the first LBIST/NMCUT to be executed.

9. Program the RUNSW[RUNSW] field to enable online self test execution; the L/MSWPLEN bits to enable the PLL lock signal monitor during L/MBIST execution and the MBIE to enable the related Interrupt requests.
10. Start the online self test and depending on PLL management and L/MBIST execution order, also when PLL LOCK is high.
11. Wait the WDGEOC run time execution specified into the WDG register
12. In case the MBIE have been enabled, an interrupt is generated at the end of all the MBIST execution. The software application has to manage these interrupt signals and clean-up the related flag (MBIFLG) into the INT\_FLG register.
13. The STCU2 switch-off the core clock at the end of the self test run
14. The functional reset activated is managed by the LBRMSW register (See step 4).
15. In case, at least one of the selected LBIST enables the Global functional reset, the STCU2 requests a functional reset which restarts the system while, when all the selected LBIST enables its own dedicated functional reset, only these local reset lines are applied and only the related LBIST partitions are cleaned-up.
16. The STCU2 resets the RUNSW[RUNSW] field. In both the reset cases and in case of fault/s, the STCU2 flags the failure toward the FCCU.
17. The software application reads the LBSSW flag register to check the failed LBIST when UF or RF conditions is/are detected.
18. The software application reads the LBESW flag register to check if the LBIST is still on-going when UF or RF is/are detected.
19. The software application reads the MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
20. The software application reads the MBELSW/MSW/HSW flag registers, depending on the number of memories, to check if the RAMs/ROMs Memory BIST is still on-going when UF or RF is/are detected.
21. The software application reads the bit INVPSW, ENGESW, WDTOSW, LOCKESW of the ERR\_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.
22. The software application reads for each device's LBIST, the LBMISRELSW/HSW and LBIST\_MISRRLSW/HSW registers to check the coherence with the LBS bits

### NOTE

1. A reset is necessary after running any kind of online self test.
2. The software application read operations on the STCU2 and LBIST MISR registers after successful online self test execution are an additional reliability layer to improve the auto-self-test feature included in the STCU2.

3. Flash memory must be in the idle state when BIST execution is started. Program and erase functionality must not be enabled when entering BIST execution.

### 56.10.3 Bypass USER Mode

In this case, the USER application parameters stored in FLASH and read by SSCM are written in order to skip the Self-Test procedure after a reset trigger event is applied. It might be useful in case the device is not configured for applications requiring improved reliability. The sequence is the following:

1. Unlock the STCU2 access writing the Off-Line Key1/Key2 sequence into the STCU2\_SKC register
2. Set the BYP bit in the STCU2\_RUN register

After BYP bit is set, the core clock is switched off, the Self-Test sequence is not applied and the system can wake up and start the user application.

### 56.10.4 Design implementation information

The following list reports the limitations related to the current implementation:

- Every NMCUT BIST can be run once during the OnlineOffline self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- Because software has full control of the system while applications are running during the online self-test, STCU2 is not allowed to take control of the PLL but can just monitor the lock signal to flag wrong unlock events.

## Chapter 57

# Cyclic Redundancy Check (CRC) Unit

### 57.1 Chip-specific CRC information

This chip has one instance of the CRC module. It supports three contexts:  $N = 3$ .

### 57.2 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

### 57.3 Main features

- Three contexts for the concurrent CRC computation are supported
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- Three hard-wired polynomials (CRC-8, CRC-32 ITU-T V.42, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

### 57.3.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 ITU-T V.42 (see note below)

#### NOTE

Although the CRC-32 ITU-T V.42 polynomial is used for CRC generation, the generation algorithm differs (MISR) from the one used by the IEEE 802.3 standard.

## 57.4 Block diagram

The top level diagram of the CRC module is given in the following figure. Refer to [Main features](#) for number of contexts in this module.

Figure 57-1. CRC top level diagram

## 57.5 External signal description

The CRC module does not generate any external signals.

### 57.5.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers

- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers
- Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are read/write accessible in each access mode:

- user
- supervisor

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC\_CFG and CRC\_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC\_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC\_CSTAT or CRC\_OUTP registers immediately following (next clock cycle) a write operation to the CRC\_CSTAT, CRC\_INP, or CRC\_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

## 57.6 CRC memory map and registers

**CRC memory map**

| Address offset (hex) | Register name                        | Width (in bits) | Access | Reset value                 | Section/page                |

| 28                   | Current Status Register (CRC_CSTAT3) | 32              | R/W    | FFFF_FFFFh                  | <a href="#">57.6.3/2678</a> |
| 2C                   | Output Register (CRC_OUTP3)          | 32              | R      | FFFF_FFFFh                  | <a href="#">57.6.4/2679</a> |

## 57.6.1 Configuration Register (CRC\_CFGn)

Access: User read/write.

Address: 0h base + 0h offset + (16d × i), where i=0d to 2d

|       |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |
|-------|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|
| Bit   | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |
| R     | 0 |   |   |   |   |   |   |   | 0 |   |    |    |    |    |    |    |
| W     |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |
| Reset | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0  | 0  | 0  | 0  | 0  | 0  |

|       |    |    |    |    |    |    |    |    |    |    |               |    |              |    |       |    |      |     |
|-------|----|----|----|----|----|----|----|----|----|----|---------------|----|--------------|----|-------|----|------|-----|
| Bit   | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26            | 27 | 28           | 29 | 30    | 31 |      |     |
| R     | 0  |    |    |    |    |    |    |    |    |    | SWAP_BYTEWISE |    | SWAP_BITWISE |    | POLYG |    | SWAP | INV |
| W     |    |    |    |    |    |    |    |    |    |    |               |    |              |    |       |    |      |     |
| Reset | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0             | 0  | *            | *  | 0     | 0  |      |     |

\* Notes:

- POLYG field: Reset value is a function of n in CRC\_CFGn. When n%2 = 0, reset value = 01b. When n%2 = 1, reset value = 00b. So CRC\_CFG1 POLYG reset value = 00b (Since 1%2=1).

## CRC\_CFGn field descriptions

| Field           | Description                                                                             |
|-----------------|-----------------------------------------------------------------------------------------|

**57.6.2 Input Register (CRC\_INPn)**

Access: User read/write.

**NOTE**

High level code must be written in a way to realize byte-, halfword- and word-wide writes on assembler code level. Any endianness problem faced can be corrected by appropriate configuration of CRC\_CFG[SWAP\_BYTEWISE] and CRC\_CFG[SWAP\_BITWISE].

## 57.7 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC\_INP).

The data stream is generally executed by *n* concurrent DMA data transfers (mem2mem) where *n* is less or equal to the number of contexts.

The standard generator polynomials are given in [Equation 2 on page 2679](#), [Equation 3 on page 2679](#), and [Equation 4 on page 2680](#) for the CRC computation of each context. Two separate registers are available: CRC\_INP for writing data and CRC\_CSTAT for retrieving the (accumulated up to now) CRC.

$$x^8 + x^4 + x^3 + x^2 + 1$$

**Equation 2. CRC8 VDA CAN**

$$x^{16} + x^{12} + x^5 + 1$$

**Equation 3. CRC-CCITT (x.25 protocol)**

$$x^{32}+x^{26}+x^{23}+x^{22}+x^{16}+x^{12}+x^{11}+x^{10}+x^8+x^7+x^5+x^4+x^2+x+1$$

### Equation 4. CRC-32 (ITU-T V.42 protocol)

**Figure 57-18. CRC-CCITT engine concept scheme**

The initial seed value of the CRC can be programmed by initializing the CRC\_CSTAT register. A diagram illustrating serial data loading of the CRC engine is shown in [Figure 57-18](#) for the CRC-CCITT. Note that, conceptually, the least-significant, or "right-most," bit shown in [Input Register \(CRC\\_INP<sub>n</sub>\)](#), is fed first into the engine. The actual implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the IPS bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (high bit for low bit or low bit for high bit) and/or bit inversion of the final CRC signature can be applied to CRC\_OUTP before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in [Figure 57-19](#).

Figure 57-19. CRC computation flow

## 57.8 Use cases

### 57.8.1 Programming example

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has  $n$  channels (greater than or equal to the number of contexts) configurable for the following types of data transfer—mem2mem, periph2mem, mem2periph—the following sequence, as shown in the following figure, is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context  $x$ , channel  $x$ ) by CPU
2. Payload transfer from the MEM to the CRC module (CRC\_INP register) after MSB-to-LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel  $x$ )
3. CRC signature copy from the CRC module (CRC\_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel  $x$ )

Figure 57-20. DMA-CRC transmission sequence

## 57.8.2 Register programming

- INV and/or SWAP (affecting the output only) can be applied to CRC-8, CRC-16, and CRC-32. Both can be applied together.

#### Use cases

- SWAP\_BITWISE (affecting the input only) can be applied for all polynomials if required by an application.
- SWAP\_BYTEWISE (affecting the input only) can be applied for CRC-16 and CRC-32 polynomials only.
- SWAP\_BITWISE has priority over SWAP\_BYTEWISE when both are applied together.
- When generating CRC-32 for the ITU-T V.42 standard the user needs to set SWAP\_BYTEWISE together with INV and SWAP.
- When generating CRC-16 the user needs to set SWAP\_BITWISE bit.

# Chapter 58

## Security Overview

### 58.1 Introduction

This chip has a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access.

### 58.2 Security features summary

The chip's security features include:

- Device censorship based on life cycle model
- Memory security:
  - Password protection for flash memory with PASS module
  - One-time-programmable (OTP) flash memory areas
  - Tamper detection including flash memory erase counter
  - MBIST functionality that can be enabled for execution during an STCU2 off-line condition to initialize RAMs (see the STCU2 chapter for details about MBIST execution in an STCU2 off-line condition)
  - BAM with software routines to initialize RAMs when not booting from internal flash memory
  - Security functions described in the *Secure Hardware Extension (SHE) Functional Specification Version 1.1*
- Monitoring of operating conditions
- Security watchdog
- Secure debug

## 58.3 Flash memory read, write, and erase protection

[Flash memory read protection scenarios](#) explains the supported options for read protection.

The C55FMC and PASS modules provide write and erase protection:

- The C55FMC\_LOCK $n$  registers provide one level of write and erase protection.
- The PASS\_LOCK $n$ \_PG $m$  registers provide a higher level of password-protected write and erase protection that supersedes C55FMC's protection by overwriting the values of the C55FMC\_LOCK $n$  registers.
- After bootup, during which the values of PASS\_LOCK $n$ \_PG $m$  registers are loaded from DCF records: Users can override these values temporarily, until the next reset, by programming them to different values, thereby also temporarily programming different values for the C55FMC\_LOCK $n$  registers.

For details about these registers, see the [Embedded Flash Memory \(C55FMC\)](#) and [Password and Device Security Module \(PASS\)](#) chapters.

# Chapter 59

## Cryptographic Services Engine (CSE)

### 59.1 Chip-specific CSE information

This chip has one instance of the CSE module. The module:

- executes the chip's secure boot process. See [Parallel secure boot](#) in the System Boot details.
- has exclusive access to the flash memory blocks mapped to the C55FMC\_LOCK1 register, PASS\_LOCK1\_PGn registers, and TDRn\_LOCK1 DCF client. See [C55FMC\\_LOCK1 register bit mapping](#). The system MPU is automatically configured to prevent other bus masters from interfering with CSE's access to the flash memory.

#### 59.1.1 CSE configuration and SECURE\_BOOT execution

The [UTEST Secure Boot Configurations DCF client](#) automatically configures aspects of CSE operation at startup.

See this DCF client's description for details about its factory-programmed value, which ensures that reset logic issues the SECURE\_BOOT command to CSE during reset.

#### 59.1.2 CSE Clk Freq

In the description of CSE\_CR[DIV], the mentioned *CSE Clk Freq* corresponds to the FM\_PER\_CLK frequency on this chip. See the Clocking chapter for more information about FM\_PER\_CLK.

### 59.1.3 CSE clock: minimum frequency

To ensure compliance with SHE specification performance requirements, the CSE clock source (FM\_PER\_CLK) must have a minimum frequency of 105 MHz.

### 59.1.4 CSE debug not supported

This chip has no debug capability for the CSE module. Descriptions of CSE debug features in this chapter do not apply.

### 59.1.5 CSE command-processing completion before Stop mode entry

To ensure proper CSE operation: Before setting SIU\_HLT1[CSE] to 1, ensure CSE\_SR[BSY] is 0.

## 59.2 Introduction

### 59.2.1 Overview

The Cryptographic Services Engine (CSE) is a peripheral module that implements the security functions described in the *Secure Hardware Extension (SHE) Functional Specification Version 1.1*.

The CSE design includes a host interface with a set of memory mapped registers that are used by the CPU to issue commands and a system bus interface that allows the CSE to directly access system memory. Two dedicated blocks of system flash memory are used by the CSE for secure key storage.

### 59.2.2 Features

The CSE has the following features:

- Secure storage for cryptographic keys
- AES-128 encryption and decryption
- AES-128 CMAC authentication

- True random number generation
- Secure boot mode
- System bus master interface

### 59.2.3 Modes of operation

The CSE supports operation in Normal and Debug modes of operation. The use of the cryptographic keys stored by the CSE is controlled based on the activation of the CPU debug port and the successful completion of the secure boot process.

The CSE has a low-power mode that disables the clock to all logic except the host interface. Register accesses are supported in this mode, but commands are not processed.

### 59.2.4 Block diagram

The CSE design includes a command processor, host interface, system bus interface, local memory, AES logic, and True Random Number Generator (TRNG) as shown below.

**Figure 59-1. CSE block diagram**

## 59.3 External signal description

The CSE has no external interface signals.

## 59.4 Memory Map and Register Definition

The CSE programming model has ten 32-bit registers. The programming model can only be accessed using 32-bit (word) accesses. References using a different size are invalid. The CSE memory map is shown in the table below.

**CSE memory map**

| Address offset (hex) | Register name                     | Width (in bits) | Access | Reset value                 | Section/page                |
|----------------------|-----------------------------------|-----------------|--------|-----------------------------|-----------------------------|

The TRNG clock is the module clock divided by a programmable ratio:<br>$\text{TRNG Clk Freq} = \text{CSE Clk Freq} / (2 * (\text{DIV} + 1))$ The divide ratio must be set such that the TRNG clock frequency is between 500 kHz and 2MHz.<br>0x00 divide by 2<br>0x01 divide by 4<br>0x02 divide by 6<br>...<br>0xFE divide by 510<br>0xFF divide by 512 |
| 24–25<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                             |
| 26<br>KBS         | Key Bank Select. Selects which set of application keys are visible for commands. See <a href="#">Table 59-13</a> .<br>0 Select KEY_1-KEY_10<br>1 Select KEY_11-KEY_20                                                                                                                                                                                                                                                               |
| 27<br>SFE         | Security Flag Extension. When the SFE bit is set, the CSE recognizes the VERIFY_ONLY security flag during LOAD_KEY processing; otherwise, it is ignored. The SFE bit has no effect on the enforcement of the VERIFY_ONLY security flag once a key is loaded.<br>0 Security Flag Extension disabled.<br>1 Security Flag Extension enabled.                                                                                           |
| 28<br>MDIS        | Module Disable. When the MDIS bit is set, the CSE is put into a low-power mode that disables the clock to all of the CSE logic except for the host interface. The MDIS bit should not be set during command processing (CSE_SR[BSY] = 1). The current command should be canceled and processing stopped (CSE_SR[BSY] = 0) before setting the MDIS bit.<br>0 Normal mode<br>1 Low-power mode                                         |
| 29<br>SUS         | Suspend Command Processing. When the SUS bit is set, the CSE suspends processing of the current command until the SUS bit is cleared. The current execution status of the command processor is reflected by the CSE_SR[EX] flag.<br>0 Enable processing of commands.<br>1 Suspend command processing.                                                                                                                               |
| 30<br>DRE         | DMA Request Enable. When the DRE bit is set, the DMA request is asserted when command processing is completed.<br><b>NOTE:</b> DMA is not implemented on this chip.<br>0 DMA request not enabled.<br>1 DMA request enabled.                                                                                                                                                                                                         |
| 31<br>CIE         | Command Complete Interrupt Enable. When the CIE bit is set, an interrupt request is generated and the CSE_IR[CIF] flag is set when command processing is completed.<br>0 Command Complete Interrupt disabled.<br>1 Command Complete Interrupt enabled.                                                                                                                                                                              |

## 59.4.2 CSE Status Register (CSE\_SR)

The CSE\_SR contains flags indicating the status of the CSE. Reading CSE\_SR[24:31] is the same as the SHE GET\_STATUS command.

Address: 0h base + 4h offset = 4h

| Field | Description                           |
|-------|---------------------------------------|
|       | 0x12 TRNG error                       |
|       | 0x13 CSE flash block error            |
|       | 0x14 Internal command processor error |
|       | 0x15 Length error                     |

**59.4.5 CSE Command Register (CSE\_CMD)**

Commands are issued by first loading the appropriate parameter registers (CSE\_Px) and then writing a command code to the command register (CSE\_CMD). Reads of the CSE\_CMD register have no effect on the operation of the CSE. See [Command processing](#) for a description of command processing and [CSE commands](#) for a description of each command.

**59.5 CSE functional description**

The CSE implements a comprehensive set of cryptographic functions as described in the *SHE Functional Specification*, including secure key storage, AES encryption, secure boot, AES CMAC authentication, and random number generation.

## 59.5.1 Host interface

The host interface includes all of the CSE memory mapped registers (see the memory map and register section).

The Control Register (CSE\_CR) is used to set configuration options and control operation of the CSE. If the CSE\_CR[CIE] bit is set, an interrupt request is generated after the CSE finishes processing each command. The interrupt is cleared by writing a 1 to the CSE\_IR[CIF] bit. When the CSE\_CR[SUS] bit is set, the CSE suspends processing of the current command and does not respond to new commands including the CANCEL command.

Command processing is resumed by clearing the CSE\_CR[SUS] bit. The CSE cannot respond immediately to changes in the CSE\_CR[SUS] bit, so the CSE\_SR[EX] flag indicates the current status of the CSE command processor. The CSE\_SR[EX] flag is set when the CSE command processor is running and is cleared when the CSE is idle or has suspended processing. The CSE\_CR[MDIS] bit puts the CSE into a low-power mode. In low-power mode, registers can be accessed but commands are not processed. Before setting the CSE\_CR[MDIS] bit or entering any device low-power modes, application software should cancel any pending command and wait for the CSE\_SR[BSY] bit to be cleared. The CSE\_CR[SFE] bit enables loading of the VERIFY\_ONLY flag during the LOAD\_KEY command. The CSE\_CR[KBS] bit selects which key bank (KEY\_1–KEY\_10 or KEY\_11–KEY\_20) is active.

The Status Register (CSE\_SR) contains a set of nine status flags. Reading CSE\_SR[24:31] is equivalent to the SHE GET\_STATUS command. The CSE\_SR[BSY] bit indicates when the CSE is processing a command. The flag is cleared when processing is completed. Polling the CSE\_SR[BSY] bit is an alternative to interrupt-driven operation. The CSE\_SR[SB], CSE\_SR[BIN], CSE\_SR[BFN] and CSE\_SR[BOK] bits reflect the secure boot status (see [Secure boot](#)). The CSE\_SR[RIN] bit is set when the PRNG is initialized with a seed value generated by the TRNG. The CSE\_SR[EDB] is set if an external debugger is connected. The CSE\_SR[IDB] flag is set when internal debugging has been enabled with the DEBUG\_CHAL and DEBUG\_AUTH commands. The CSE\_SR is a read-only register and can be read at any time.

The Error Code Register (CSE\_ECR) contains the error code from the last completed command. The CSE\_ECR is set to 0 if no error occurred while processing the command. The CSE\_ECR is a read-only register.

## 59.5.2 Command processing

CSE functions are accessed through a set of commands that are listed in [CSE commands](#). Commands are issued by first loading the appropriate parameter registers (CSE\_Px) and then writing a command code to the command register (CSE\_CMD). CSE\_CMD register reads have no effect on the operation of the CSE.

Command inputs and outputs that are 32 bits or less in size are stored directly into a parameter register. Inputs and outputs that are larger than 32 bits are kept in system memory and the address of the data (pointer) is loaded into the parameter register. All data must be aligned on a 32-bit (word) boundary. The two least significant bits of an address are ignored. All data is stored in big-endian format with the most significant byte of the data block stored in the lowest address.

The first command issued to the CSE after reset must be either SECURE\_BOOT or INIT\_CSE. In some device boot modes, system boot logic or BAM code will issue the SECURE\_BOOT command, which initializes the CSE and starts the SHE secure boot protocol (see [Secure boot](#)). For details about how and when the SECURE\_BOOT command is issued on this chip, see the chip-specific CSE information. For the other boot modes, application software must issue the INIT\_CSE command before issuing other CSE commands. The INIT\_CSE command can only be issued one time after reset and only in boot modes that do not issue the SECURE\_BOOT command. Application software cannot issue the SECURE\_BOOT command.

The CSE can only process one command at a time. Commands take a number of clock cycles to complete, so one of the following must be used to determine when the output data is valid and the next command can be issued:

- The CSE\_SR[BSY] flag
- The interrupt request

Parameter registers cannot be modified while the CSE is processing a command. Command processing can be suspended and resumed using the CSE\_CR[SUS] bit (see [Host interface](#)). If the CSE\_CMD register is written while a command is being processed, processing is aborted and an error is generated with CSE\_ECR[EC] = 0x0B. The CANCEL command can be used to abort processing of a command without generating an error. The CSE\_ECR is updated and the CSE\_SR[BSY] bit is cleared upon completion of command processing (see [Error handling](#)).

### 59.5.3 Secure storage

The CSE provides secure, nonvolatile storage for cryptographic keys as described in the *SHE Functional Specification*. The keys are stored in 25 memory slots, with one ROM slot, 23 nonvolatile slots, and one RAM slot as shown in [Table 59-13](#). The first four slots have a dedicated use; the other slots are available for application specific keys. The CSE extends the SHE specification by providing 10 extra application key slots (KEY\_11–KEY\_20) which are enabled by setting the CSE\_CR[KBS] bit. The BOOT\_MAC slot is loaded with a MAC value used by the secure boot process. All other slots are used for encryption or message authentication keys. The SECRET\_KEY slot is programmed with a random value during device fabrication. All CSE encryption and message authentication commands specify a key by its Key ID.

**Table 59-13. Memory slots**

| Slot name      | KBS | Key ID  | Type        |
|----------------|-----|---------|-------------|
| SECRET_KEY     | x   | 0x0     | ROM         |
| MASTER_ECU_KEY | x   | 0x1     | nonvolatile |
| BOOT_MAC_KEY   | x   | 0x2     | nonvolatile |
| BOOT_MAC       | x   | 0x3     | nonvolatile |
| KEY_1–KEY_10   | 0   | 0x4–0xD | nonvolatile |
| KEY_11–KEY_20  | 1   | 0x4–0xD | nonvolatile |
| RAM_KEY        | x   | 0xE     | RAM         |

In addition to the 25 memory slots, the CSE holds a 120-bit read-only unique identification number (UID) that is programmed during device fabrication. The UID is used in the memory update procedure and is available for application-specific uses.

Each memory slot holds a 128-bit value, 6 security flags, and a 28-bit counter. See the *SHE Functional Specification* for the required structure needed for the LOAD\_KEY command. The security flags are defined in [Table 59-14](#). The 28-bit counter must be advanced each time a new key is loaded. The counter value is zero for an empty memory slot.

**Table 59-14. Memory slot security flags**

| Flag name   | Description                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| VERIFY_ONLY | If set, the memory slot key cannot be used by the GENERATE_MAC command, only by the VERIFY_MAC command. This bit has no effect if KEY_USAGE = 0. |
| WRITE_PROT  | If set, the memory slot cannot be updated.                                                                                                       |
| BOOT_PROT   | If set, the memory slot is disabled if CSE_SR[BOK] = 0 or CSE_SR[BFN] = 0.                                                                       |
| DEBUG_PROT  | If set, the memory slot is disabled if CSE_SR[EDB] = 1.                                                                                          |
| KEY_USAGE   | If set, the memory slot holds a MAC key; otherwise, it holds an encryption key.                                                                  |
| WILDCARD    | If set, the memory slot cannot be updated with the wildcard UID.                                                                                 |

The memory slot security flags for a specified key are checked against the associated bits in the CSE\_SR during command processing as described in the SHE specification. If the memory slot is disabled due to security flag settings, a key not available error (EC = 0x03) is returned by the command. The VERIFY\_ONLY security flag is a CSE-specific feature that is not defined in the SHE specification. If the CSE\_CR[SFE] bit is set when the LOAD\_KEY command is executed, the security flag field (FID) in the M2 message is extended by one bit with the VERIFY\_ONLY flag and the adjacent zero fill field is reduced to 94 bits. The CSE\_CR[SFE] bit has no effect on the enforcement of the VERIFY\_ONLY flag for commands issued after the LOAD\_KEY.

A key is loaded into a memory slot using the LOAD\_KEY command which implements the SHE memory update protocol. An empty key slot can only be used as the authorization key to update itself (KeyID = AuthID). In this case, the authorization key has a value of 0. The BOOT\_PROT and DEBUG\_PROT security flags are not enforced for the LOAD\_KEY command except when the RAM\_KEY slot is loaded. In that case, the BOOT\_PROT and DEBUG\_PROT flags of the AuthID slot are applied. Additionally, when loading the RAM\_KEY slot, the counter and security flag fields in the M2 message must be zero.

The LOAD\_PLAIN\_KEY command can be used to load a key into the RAM\_KEY slot. The EXPORT\_RAM\_KEY command can then be used to export the key in an encrypted form compatible with the LOAD\_KEY command for storage outside the CSE. The BOOT\_PROT and DEBUG\_PROT security flags of the MASTER\_ECU\_KEY are enforced for the EXPORT\_RAM\_KEY command.

Two dedicated blocks in the system flash memory are used to implement the secure storage feature. These blocks are not program visible and only the CSE can read, erase, and program these blocks. The CSE reads and writes to the system flash memory via the system bus master interface during the SECURE\_BOOT, INIT\_CSE, DEBUG\_AUTH, and LOAD\_KEY commands. During execution of these commands, the system MPU (if present) must be configured to allow the CSE access to the system flash memory and other bus masters must be programmed properly to avoid interfering with the CSE.

## 59.5.4 Encryption and decryption

The CSE supports AES-128 encryption and decryption in ECB and CBC modes of operation. The key is selected from one of the memory slots, which must be enabled for the operation. A plaintext key can be loaded into the RAM\_KEY slot using the LOAD\_PLAIN\_KEY command for keys that are not stored in a nonvolatile memory slot.

### 59.5.5 Message authentication

The CSE uses the AES-128 CMAC algorithm for message authentication. The key for the CMAC operation is selected from one of the memory slots which must be enabled for the operation. A plaintext key can be loaded into the RAM\_KEY slot using the LOAD\_PLAIN\_KEY command for keys that are not stored in a nonvolatile memory slot. The VERIFY\_MAC command supports comparison of a calculated MAC with an input MAC value.

### 59.5.6 Secure boot

The CSE implements the SHE secure boot protocol. In some device boot modes, the BAM or system boot logic issues the SECURE\_BOOT command to the CSE, which starts the secure boot process. For details about how and when the SECURE\_BOOT command is issued on this chip, see the chip-specific CSE information.

The first step in the process is for the CSE to download the command processor firmware and memory slot data from the CSE flash memory blocks into local memory. If the BOOT\_MAC\_KEY slot is empty, the CSE\_SR[SB] flag is cleared and the process is finished. Otherwise, the CSE\_SR[SB] flag is set and CSE calculates the MAC over the specified bootloader code. If the BOOT\_MAC slot is empty, the calculated MAC is loaded into the BOOT\_MAC slot, the CSE\_SR[BIN] and CSE\_SR[BFN] flags are set, and the process is finished. Otherwise, the calculated MAC value is compared to the value in the BOOT\_MAC slot. If the values match, the CSE\_SR[BOK] bit is set; otherwise, the CSE\_SR[BFN] bit is set. If the CSE\_SR[BOK] flag is set, the user boot code can issue the BOOK\_OK command which sets the CSE\_SR[BFN] bit. The memory slots that have the BOOT\_PROT flag set are enabled when both the CSE\_SR[BFN] and CSE\_SR[BOK] flags are set.

The SECURE\_BOOT command can run either before the user boot code is executed or in parallel with the user boot code. If the parallel mode is used, the user boot code must suspend command processing (set CSE\_CR[SUS] to 1) while performing any operations—such as configuring the flash controller—that may interfere with the CSE accessing flash memory. A device-specific bit selects whether to run the SECURE\_BOOT command before or in parallel with the user boot code. For details about this bit, see the chip-specific CSE information.

The CSE implements an internal timer that is started when the SECURE\_BOOT command is issued. The initial value of the timer is set to 0x00F4\_2400 (16,000,000 CSE system clocks). If the timer expires before the SECURE\_BOOT command completes, any application code intended to be blocked by the SECURE\_BOOT process will instead see the non-completed SECURE\_BOOT status of CSE\_SR[BSY]=1 and

CSE\_SR[BOK]=0. In the event of a SECURE\_BOOT timeout, the CSE will continue executing the SECURE\_BOOT command until completion, until suspended, or until receiving the CANCEL command from the application code. There is no error code associated with a SECURE\_BOOT timeout.

### 59.5.7 Random number generation

The CSE has both a Pseudo Random Number Generator (PRNG) and a True Random Number Generator (TRNG).

The PRNG has a 128-bit state variable and uses AES in output feedback mode to generate pseudo random values. A key derived from the SECRET\_KEY is used for the PRNG. The RND command updates the state of the PRNG and returns the 128-bit random value. The EXTEND\_SEED command can be used to add entropy to the PRNG state. The PRNG state is initialized after each reset with the INIT\_RNG command, which uses the TRNG to generate a 128-bit seed value for the PRNG. The CSE\_SR[RIN] flag is set when the PRNG is initialized.

The INIT\_RNG and TRNG\_RND commands use the TRNG to generate truly random values. The TRNG hardware runs off of a slower clock derived from the system clock. The CSE\_CR[DIV] field needs to be configured for these commands such that the TRNG clock is between 500 kHz and 2 MHz. Random values generated by the TRNG are checked with a statistical test to verify proper operation of the TRNG. If the test fails, a TRNG error (EC = 0x12) is returned. Due to the statistical nature of this test, there is a very small probability ( $< 10^{-9}$ ) that a properly operating TRNG will return an error. If an TRNG error is returned, the command can be issued again.

### 59.5.8 Error handling

When the CSE command processor encounters an error condition, it stops processing and returns an error code as described in [Table 59-15](#). The CSE\_SR[BSY] and CSE\_SR[EX] bits are cleared with interrupt requests generated the same as if the command had completed successfully. In most cases, error conditions are detected before data processing begins and no output values are written. Intermediate or invalid output data is never written to the parameter registers or system memory. However, it is possible for outputs to system memory to be partially written when an error occurs. The CSE does not zero out this partially written data.

**Table 59-15. Error code summary**

| Error code | Error description                  | Error conditions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x00       | No error                           | 1. Command successfully executed with no errors encountered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 0x02       | Command sequence error             | <ol style="list-style-type: none"> <li>1. Command issued (except for CANCEL) before the SECURE_BOOT or INIT_CSE command.</li> <li>2. **Table 59-15. Error code summary (continued)**

| Error code | Error description                | Error conditions                                                                                                                                                       |
|------------|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x11       | Invalid command                  | 1. Value written to CSE_CMD register is out of range.                                                                                                                  |
| 0x12       | TRNG error                       | 1. One or more statistical tests run on the TRNG output failed (see <a href="#">Generate Random Number</a> ).                                                          |
| 0x13       | CSE flash memory block error     | 1. Error reading, programming, or erasing one of the CSE flash memory blocks.<br>2. UID or SECRET_KEY required but not available.                                      |
| 0x14       | Internal command processor error | 1. An internal error condition was encountered while executing the command.                                                                                            |
| 0x15       | Length error                     | 1. MAC length for VERIFY_MAC command is greater than 128.<br>2. Message length for GENERATE_MAC, VERIFY_MAC, or MP_COMPRESS command is greater than 0x7FFFFFFF (4 GB). |

## 59.6 CSE commands

This section describes the set of CSE commands. Commands are issued by first loading the appropriate parameter registers (CSE\_Px) and then writing a command code to the command register (CSE\_CMD) as described in [Command processing](#). The first command issued to the CSE after reset must be INIT\_CSE for device boot modes that do not support secure boot. Command inputs and outputs that are 32 bits or less in size are stored directly in a parameter register. Inputs and outputs that are larger than 32 bits are kept in system memory and the address of the data (pointer) is loaded into the parameter register. The data direction indication in the tables below refers to the command parameter value which may be stored in memory.

### 59.6.1 Encrypt ECB

The ENC\_ECB command performs AES-128 encryption in ECB mode on n 128-bit blocks of data with the parameters specified in the table below.

**Table 59-16. ENC\_ECB command**

| Register | Value                | Data direction |
|----------|----------------------|----------------|
| CSE_CMD  | 0x01                 | —              |
| CSE_P1   | Key ID               | Input          |
| CSE_P2   | Number of blocks (n) | Input          |

*Table continues on the next page...*

**Table 59-16. ENC\_ECB command (continued)**

| Register | Value                          | Data direction |
|----------|--------------------------------|----------------|
| CSE_P3   | First plaintext block address  | Input          |
| CSE_P4   | First ciphertext block address | Output         |

## 59.6.2 Encrypt CBC

The ENC\_CBC command performs AES-128 encryption on  $n$  128-bit blocks of data in CBC mode with the parameters specified in the table below. The number of blocks parameter is a 32-bit value.

**Table 59-17. ENC\_CBC command**

| Register | Value                          | Data direction |
|----------|--------------------------------|----------------|
| CSE_CMD  | 0x02                           | —              |
| CSE_P1   | Key ID                         | Input          |
| CSE_P2   | IV address                     | Input          |
| CSE_P3   | Number of blocks ( $n$ )       | Input          |
| CSE_P4   | First plaintext block address  | Input          |
| CSE_P5   | First ciphertext block address | Output         |

## 59.6.3 Decrypt ECB

The DEC\_ECB command performs AES-128 ECB decryption on  $n$  128-bit blocks of data with the parameters specified in the table below.

**Table 59-18. DEC\_ECB command**

| Register | Value                          | Data direction |
|----------|--------------------------------|----------------|
| CSE_CMD  | 0x03                           | —              |
| CSE_P1   | Key ID                         | Input          |
| CSE_P2   | Number of blocks ( $n$ )       | Input          |
| CSE_P3   | First ciphertext block address | Input          |
| CSE_P4   | First plaintext block address  | Output         |

## 59.6.4 Decrypt CBC

The DEC\_CBC command performs AES-128 decryption in CBC mode on  $n$  128-bit blocks of data with the parameters specified in the table below. The number of blocks parameter is a 32-bit value.

**Table 59-19. DEC\_CBC command**

| Register | Value                          | Data direction |
|----------|--------------------------------|----------------|
| CSE_CMD  | 0x04                           | —              |
| CSE_P1   | Key ID                         | Input          |
| CSE_P2   | IV address                     | Input          |
| CSE_P3   | Number of blocks ( $n$ )       | Input          |
| CSE_P4   | First ciphertext block address | Input          |
| CSE_P5   | First plaintext block address  | Output         |

## 59.6.5 Generate MAC

The GENERATE\_MAC command calculates the MAC of a given message with the parameters specified in the table below. The AES CMAC algorithm is used to calculate a 128-bit MAC output. The message length input is a 64-bit value that specifies the length of the message in bits. A length error (EC = 0x15) is returned if the message length is greater than 0x7fffffff (4 GB).

**Table 59-20. GENERATE\_MAC command**

| Register | Value                         | Data direction |
|----------|-------------------------------|----------------|
| CSE_CMD  | 0x05                          | —              |
| CSE_P1   | Key ID                        | Input          |
| CSE_P2   | Message length (bits) address | Input          |
| CSE_P3   | Message start address         | Input          |
| CSE_P4   | MAC address                   | Output         |

## 59.6.6 Verify MAC

The VERIFY\_MAC command verifies the MAC of a given message with the parameters specified in [Table 59-21](#). The AES CMAC algorithm is used to calculate a 128-bit MAC that is truncated according to the MAC length parameter, which specifies the number of most significant bits in the MAC to compare. A MAC length value of 0 indicates that all 128 bits are compared; a value greater than 128 returns a length error (EC = 0x15). The

message length input is a 64-bit value that specifies the length of the message in bits. A length error (EC = 0x15) is returned if the message length is greater than 0x7fffffff (4 GB). If the input MAC matches the MAC calculated over the message, the CSE\_P5 register is set to 0; otherwise, it is set to 1.

**Table 59-21. VERIFY\_MAC command**

| Register | Value                                     | Data direction    |
|----------|-------------------------------------------|-------------------|
| CSE_CMD  | 0x06                                      | —                 |
| CSE_P1   | Key ID                                    | Input             |
| CSE_P2   | Message length (bits) address             | Input             |
| CSE_P3   | Message start address                     | Input             |
| CSE_P4   | MAC address                               | Input             |
| CSE_P5   | MAC length (bits)/<br>Verification status | Input /<br>Output |

### 59.6.7 Load Key

The LOAD\_KEY command updates a memory slot using parameters specified in [Table 59-22](#) according to the SHE memory slot update protocol (see [Secure storage](#)). The 128-bit M1 message contains the UID, Key ID, and Authentication Key ID. The 256-bit M2 message contains the new security flags, the counter, and the key value all encrypted using a derived key generated from the Authentication Key. The 128-bit M3 message is a MAC generated over messages M1 and M2. The 256-bit M4 message is the concatenation of the UID, Key ID, Authorization Key ID, and the encrypted counter value. The 128-bit M5 message is the MAC calculated over message M4.

The derived keys used to generate messages M2, M3, M4, and M5 deviate from the SHE memory slot update protocol when updating the second bank of user keys (KEY\_11–KEY\_20). During the generation of M2 and M4, K1 and K3 shall be derived using a constant equal to KEY\_UPDATE\_ENC\_C + 0x00800000\_00000000\_00000000\_00000000. Similarly, during generation of M3 and M5, K2 and K4 shall be derived using a constant equal to KEY\_UPDATE\_MAC\_C + 0x00800000\_00000000\_00000000\_00000000. This is intended to prevent aliasing between the two banks of user keys.

**Table 59-22. LOAD\_KEY command**

| Register | Value      | Data direction |
|----------|------------|----------------|
| CSE_CMD  | 0x07       | —              |
| CSE_P1   | M1 address | Input          |

*Table continues on the next page...*

**Table 59-22. LOAD\_KEY command (continued)**

| Register | Value      | Data direction |
|----------|------------|----------------|
| CSE_P2   | M2 address | Input          |
| CSE_P3   | M3 address | Input          |
| CSE_P4   | M4 address | Output         |
| CSE_P5   | M5 address | Output         |

### 59.6.8 Load Plain Key

The LOAD\_PLAIN\_KEY command updates the RAM key memory slot with a 128-bit plaintext key with the parameter shown in the table below.

**Table 59-23. LOAD\_PLAIN\_KEY command**

| Register | Value       | Data direction |
|----------|-------------|----------------|
| CSE_CMD  | 0x08        | —              |
| CSE_P1   | Key address | Input          |

### 59.6.9 Export RAM Key

The EXPORT\_RAM\_KEY command exports the RAM key data with the parameters in the table below. Only keys loaded with the LOAD\_PLAIN\_KEY command may be exported. The output messages are compatible with the messages used for LOAD\_KEY (see [Load Key](#) for details).

**Table 59-24. EXPORT\_RAM\_KEY command**

| Register | Value      | Data direction |
|----------|------------|----------------|
| CSE_CMD  | 0x09       | —              |
| CSE_P1   | M1 address | Output         |
| CSE_P2   | M2 address | Output         |
| CSE_P3   | M3 address | Output         |
| CSE_P4   | M4 address | Output         |
| CSE_P5   | M5 address | Output         |

## 59.6.10 Initialize RNG

The INIT\_RNG command initializes the internal PRNG state with a seed value generated by the TRNG and sets the CSE\_SR[RIN] flag. It takes 2048 TRNG clock cycles to generate a seed value. The CSE\_CR[DIV] field must be properly configured before this command is executed (see register descriptions for further information). There is a very small probability that this command may return a TRNG error (EC = 0x12) even when the TRNG is operating properly (see [Random number generation](#)). The INIT\_RNG command must be called after each reset before the RND command is issued. The command has no parameters as shown the table below.

**Table 59-25. INIT\_RNG command**

| Register | Value | Data direction |
|----------|-------|----------------|
| CSE_CMD  | 0x0A  | —              |

## 59.6.11 Extend PRNG Seed

The EXTEND\_SEED command extends the state of the PRNG using a 128-bit entropy input value. The current PRNG state and the input data are compressed into a new PRNG state value. This command is issued with the parameter shown in the table below.

**Table 59-26. EXTEND\_SEED command**

| Register | Value                 | Data direction |
|----------|-----------------------|----------------|
| CSE_CMD  | 0x0B                  | —              |
| CSE_P1   | Entropy value address | Input          |

## 59.6.12 Generate Random Number

The RND command generates a 128-bit random value and updates the state of the internal PRNG. The PRNG state must be initialized after reset using the INIT\_RNG command before this command can be issued. This command is issued with the parameter shown in the table below

**Table 59-27. RND command**

| Register | Value                | Data direction |
|----------|----------------------|----------------|
| CSE_CMD  | 0x0C                 | —              |
| CSE_P1   | Random value address | Output         |

### 59.6.13 Secure Boot

The SECURE\_BOOT command loads the command processor firmware and memory slot data from the CSE flash memory blocks, and then it executes the SHE secure boot protocol using the parameters shown in [Table 59-28](#) (see [Secure boot](#) for details). The bootloader size is a 32-bit value. The CSE firmware version is loaded into CSE\_P3 register.

The SECURE\_BOOT command is issued during the boot processes by the system boot logic. For details about how and when the SECURE\_BOOT command is issued on this chip, see the chip-specific CSE information.

**Table 59-28. SECURE\_BOOT command**

| Register | Value                    | Data direction |
|----------|--------------------------|----------------|
| CSE_CMD  | 0x0D                     | —              |
| CSE_P1   | Bootloader size (bytes)  | Input          |
| CSE_P2   | Bootloader start address | Input          |
| CSE_P3   | Firmware version         | Output         |

### 59.6.14 Boot Failure

The BOOT\_FAILURE command sets the CSE\_SR[BFN] flag and clears the CSE\_SR[BOK] flag to disable use of memory slots that have the BOOT\_PROT flag set. This command is issued with no parameters as shown in the table below.

**Table 59-29. BOOT\_FAILURE command**

| Register | Value | Data direction |
|----------|-------|----------------|
| CSE_CMD  | 0x0E  | —              |

### 59.6.15 Boot OK

The BOOT\_OK command sets the CSE\_SR[BFN] flag and leaves the CSE\_SR[BOK] flag set to confirm successful completion of the secure boot processes. This enables the use of memory slots that have the BOOT\_PROT flag set if they are not disabled for some other reason. This command is issued with no parameters as shown in the table below.

**Table 59-30. BOOT\_OK command**

| Register | Value | Data direction |
|----------|-------|----------------|
| CSE_CMD  | 0x0F  | —              |

### 59.6.16 Get ID

The GET\_ID command returns the UID, CSE\_SR[24:31], and a 128-bit MAC calculated over the concatenation of a 128-bit input challenge value, UID, and CSE\_SR[24:31]. The MASTER\_ECU\_KEY is used for the MAC calculation. A value of 0 is returned for the MAC if the MASTER\_ECU\_KEY slot is empty. The UID output is a 128-bit value with the 8 least significant bits set to 0. This command is issued with the parameters shown in the table below.

**Table 59-31. GET\_ID command**

| Register | Value               | Data direction |
|----------|---------------------|----------------|
| CSE_CMD  | 0x10                | —              |
| CSE_P1   | Challenge address   | Input          |
| CSE_P2   | UID output address  | Output         |
| CSE_P3   | CSE_SR[24:31] value | Output         |
| CSE_P4   | MAC address         | Output         |

### 59.6.17 Cancel

The CANCEL command aborts processing of the current command and clears the CSE\_SR[BSY] flag. This command is issued with no parameters as shown in the table below.

**Table 59-32. CANCEL command**

| Register | Value | Data direction |
|----------|-------|----------------|
| CSE_CMD  | 0x11  | —              |

## 59.6.18 Debug Challenge

The `DEBUG_CHAL` command generates a 128-bit random challenge output value that is used in conjunction with the `DEBUG_AUTH` command. The PRNG state must be initialized after reset using the `INIT_RNG` command before this command can be issued. This command is issued with the parameter shown in the table below.

**Table 59-33. `DEBUG_CHAL` command**

| Register | Value             | Data direction |
|----------|-------------------|----------------|
| CSE_CMD  | 0x12              | —              |
| CSE_P1   | Challenge address | Output         |

## 59.6.19 Debug Authorization

The `DEBUG_AUTH` command erases all user keys and sets the `CSE_SR[IDB]` flag which enables internal debugging if the 128-bit authorization input value is valid and no memory slots are write protected. The authorization input is generated using the `DEBUG_CHAL` command output and the UID as described in the *SHE Functional Specification*. If the `DEBUG_CHAL` command is not issued before the `DEBUG_AUTH` command, a command sequence error (`EC = 0x02`) is returned. However, other commands may be issued between the `DEBUG_CHAL` and `DEBUG_AUTH` commands. This command is issued with the parameter shown in the table below.

**Table 59-34. `DEBUG_AUTH` command**

| Register | Value                 | Data direction |
|----------|-----------------------|----------------|
| CSE_CMD  | 0x13                  | —              |
| CSE_P1   | Authorization address | Input          |

## 59.6.20 Generate TRNG Random Number

The `TRNG_RND` command generates a 128-bit random output value using the TRNG. It takes 2048 TRNG clock cycles to generate a random value. The `CSE_CR[DIV]` field must be properly configured before this command is executed (see the register descriptions section for further information). This command takes much longer to execute than the `RND` command that should normally be used to generate random values. There is a very small probability that this command may return a TRNG error (`EC = 0x12`) even when the TRNG is operating properly (see [Random number generation](#)). This command is issued with the parameter shown in the table below.

**Table 59-35. TRNG\_RND Command**

| Register | Value                | Data direction |
|----------|----------------------|----------------|
| CSE_CMD  | 0x14                 | —              |
| CSE_P1   | Random value address | Output         |

### 59.6.21 Initialize CSE

The INIT\_CSE command loads the command processor firmware and memory slot data from the CSE flash memory blocks into local memory. It does not execute the secure boot protocol. The CSE firmware version is loaded into the CSE\_P1 register as shown in the table below. This command must be issued before any other command when secure boot is not enabled.

**Table 59-36. INIT\_CSE Command**

| Register | Value            | Data direction |
|----------|------------------|----------------|
| CSE_CMD  | 0x15             | —              |
| CSE_P1   | Firmware version | Output         |

### 59.6.22 Miyaguchi-Preneel (MP) Compression

The MP\_COMPRESS command is a one-way compression function used to derive a 128-bit output from a given message with the parameters specified in [Table 59-37](#). The AES ECB algorithm is used to derive the 128-bit output as described in the SHE specification. The message length input is a 64-bit value which specifies the length of the message in bits. A length error (EC=0x15) is returned if the message length is greater than 0x7fffffff (4GB).

**Table 59-37. MP\_COMPRESS Command**

| Register | Value                         | Data direction |
|----------|-------------------------------|----------------|
| CSE_CMD  | 0x016                         |                |
| CSE_P1   | Message length (bits) address | Input          |
| CSE_P2   | Message start address         | Input          |
| CSE_P3   | Output address                | Output         |

# Chapter 60

## Password and Device Security Module (PASS)

### 60.1 Chip-specific PASS information

This chip has one instance of the PASS module. PASS implements password-based read and write protection for flash memory blocks.

This chip implements four protection regions.

#### 60.1.1 Accesses to unimplemented PASS registers

On this chip, accesses to unimplemented PASS registers generate bus aborts.

#### 60.1.2 PASS\_LOCKm\_PGn register bit mapping

Each password group defined in the DCF records is associated with a set of four PASS\_LOCKm\_PGn registers. Each implemented bit in these registers maps to a specific memory block.

**NOTE**

These registers are initialized via DCF records, so the reset values depend on user settings.

##### 60.1.2.1 PASS\_LOCK0\_PGn register bit mapping

The flash memory blocks mapped to the [Password Group n - Lock 0 Status Register \(PASS\\_LOCK0\\_PGn\)](#) bits, and the corresponding PASS protection regions, are as follows.

|   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

Table continues on the next page...

| Protection Region                  | Flash Memory Block Name                | Register Field |          |
|------------------------------------|----------------------------------------|----------------|----------|
|                                    |                                        | TSLOCK         | Reserved |
| PASS Read Lock Protection Region 0 | UTest NVM Block Space 16 KB            | LOWLOCK[13:0]  |          |
|                                    | —                                      |                |          |
|                                    | —                                      |                |          |
|                                    | —                                      |                |          |
|                                    | —                                      |                |          |
|                                    | —                                      |                |          |
|                                    | —                                      |                |          |
|                                    | —                                      |                |          |

### 60.1.2.2 PASS\_LOCK1\_PG $n$ register bit mapping

The flash memory blocks mapped to the [Password Group  \$n\$  - Lock 1 Status Register \(PASS\\_LOCK1\\_PG \$n\$ \)](#) bits, and the corresponding PASS protection region, are as follows.

#### NOTE

This register cannot be used to manage the blocks mapped to the register's implemented bits because the CSE module has exclusive access to these blocks. The bits' value is 1 to reflect

the corresponding blocks' locked state, and the bits cannot be written to change that state.

### 60.1.2.3 PASS\_LOCK2\_PGn register bit mapping

The flash memory blocks mapped to the Password Group  $n$  - Lock 2 Status Register (PASS\_LOCK2\_PG $n$ ) bits, and the corresponding PASS protection region, are as follows.

\_\_\_\_\_

[illegible]

#### 60.1.2.4 PASS\_LOCK3\_PGn register bit mapping

The flash memory blocks mapped to the Password Group  $n$  - Lock 3 Status Register (PASS\_LOCK3\_PG $n$ ) bits, and the corresponding PASS protection region, are as follows.

Reserved bits read as 0.

|   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
|---|---|---|---|---|---|---|---|---|---|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|

[illegible]

### 60.1.3 PASS chip select (client select)

On this chip, the chip select (client select) for the PASS module is CS[3].

For details about CS[3], see the DCF Records chapter.

#### 60.1.4 Flash memory read protection scenarios

The following table summarizes the scenarios of read lock (RL) region protection on this chip. For more information, see [Flash Memory Read Protection](#).

### Table 60-1. Flash memory read protection truth table

| Inputs                     |                       |                 |            | Outputs                      |                                                        |
|----------------------------|-----------------------|-----------------|------------|------------------------------|--------------------------------------------------------|
| Life Cycle                 | Censorship DCF client | Debug Interface | LOCK3[RLx] | Read Protected RL[0] (UTest) | Read Protected RL[3:1] (other regions) <sup>1, 2</sup> |
| Customer Delivery          | Don't care            | Don't care      | Don't care | Readable                     | Readable                                               |
| OEM Production or In Field | 0x55AA                | Don't care      | Don't care | Readable                     | Readable                                               |
|                            | Any other value       | Blocked         | Don't care | Readable                     | Readable                                               |
|                            |                       | Enabled         | Locked     | Read Blocked <sup>34</sup>   | Read Blocked <sup>3, 4</sup>                           |

*Table continues on the next page...*

**Table 60-1. Flash memory read protection truth table (continued)**

| Inputs           |                       |                 |            | Outputs                      |                                                        |
|------------------|-----------------------|-----------------|------------|------------------------------|--------------------------------------------------------|
| Life Cycle       | Censorship DCF client | Debug Interface | LOCK3[RLx] | Read Protected RL[0] (UTest) | Read Protected RL[3:1] (other regions) <sup>1, 2</sup> |
|                  |                       |                 | Unlocked   | Readable                     | Readable                                               |
| Failure Analysis | 0x55AA                | Don't care      | Don't care | Readable                     | Readable                                               |
|                  | Any other value       | Don't care      | Locked     | Readable                     | Read Blocked                                           |
|                  |                       |                 | Unlocked   | Readable                     | Readable                                               |

1. When Life Cycle is other than In Field: If the BAM cannot find a valid RCHW because the corresponding regions are Read Blocked, the boot mode is switched to serial.
2. After the Life Cycle state OEM Production, the UTest space reserved for passwords is protected by the flash memory interface instead of PASS. PASS has no effect on the space.
3. Flash memory is readable if the JTAG password is used to break the censorship scheme.
4. When Life Cycle is In Field, the BAM will not switch to serial boot mode. Instead, it will keep searching for a valid RCHW until SWT requests a reset.

## 60.1.5 Debug Interface Access

Whether the Debug Interface Access is enabled or blocked depends on multiple input conditions. The following table shows the the Debug Interface Access scenarios on this chip.

**Table 60-2. Debug Interface Access truth table**

| Life Cycle                    | Production Disable | Censorship DCF client | Debug Enable LOCK3[DBL] bit | JTAG Password | Debug Interface Access status |
|-------------------------------|--------------------|-----------------------|-----------------------------|---------------|-------------------------------|
| Customer Delivery             | Don't care         | Don't care            | Don't care                  | Don't care    | Enabled                       |
| OEM Production                | Don't care         | 0x55AA                | Don't care                  | Don't care    | Enabled                       |
|                               |                    | Any other value       | Unlocked (DBL = 0)          | Don't care    | Enabled                       |
|                               |                    |                       | Locked (DBL = 1)            | Matched       | Enabled                       |
|                               |                    |                       |                             | Not Matched   | Blocked                       |
| In Field                      | Off                | 0x55AA                | Don't care                  | Don't care    | Enabled                       |
|                               |                    | Any other value       | Unlocked (DBL = 0)          | Don't care    | Enabled                       |
|                               |                    |                       | Locked (DBL = 1)            | Matched       | Enabled                       |
|                               |                    |                       |                             | Not Matched   | Blocked                       |
|                               |                    |                       |                             | Not Matched   | Blocked                       |
|                               | On                 | Don't care            | Don't care                  | Don't care    | Blocked                       |
| Failure Analysis <sup>1</sup> | Don't care         | 0x55AA                | Don't care                  | Don't care    | Enabled                       |
|                               |                    | Any other value       | Unlocked (DBL = 0)          | Don't care    | Enabled                       |
|                               |                    |                       | Locked (DBL = 1)            | Matched       | Enabled                       |
|                               |                    |                       |                             | Not Matched   | Blocked                       |

1. When advancing the Life Cycle to FA, program the Censorship DCF client with 0x55AA to enable the Debug Interface Access for Freescale.

When the Life Cycle is Customer Delivery, the Debug Interface Access is fully enabled regardless of any boundary conditions.

When the Life Cycle is OEM Production, In Field, or Failure Analysis, the Debug Interface Access depends on the Censorship DCF client settings, the 256-bit JTAG Password entered via JTAG mechanism, and the LOCK3[DBL] bit.

For the Life Cycle of In Field, the Debug Interface is further conditioned by the Production Disable feature. If the Production Disable feature is enabled when the Life Cycle is In Field, the Debug Interface Access may be permanently blocked because Production Disable overrides all other debug controls. The preceding table emphasizes this scenario by shading the set of conditions and the result in grey.

### 60.1.6 Duration of Debug Interface Access via JTAG password

[JTAG Password Challenge](#) explains the method for enabling Debug Interface Access by writing the [JTAG\\_PASSWORD register](#) via an external tool. Debug Interface Access granted by a password match remains enabled until the next "destructive" reset. On this chip, a "destructive" reset is any of the following:

- POR
- A reset caused by:
  - LVD or HVD event
  - Temperature threshold detection event
  - RESET pin
  - STCU2 self test
  - FOSU timeout

### 60.1.7 Production Disable enablement

The enablement of the Production Disable feature is done via a DCF client that is not accessible by software and that is automatically loaded during the reset phase of the device. For more information, see [Production disable](#).

#### CAUTION

Be careful when configuring the Production Disable feature because enabling Production Disable might permanently block the Debug Interface Access.

### 60.1.8 PASS\_LCSTAT[LIFE] value source

On this chip, the SSCM is the "external" module from which PASS\_LCSTAT[LIFE] derives its reset value. The value of PASS\_LCSTAT[LIFE] directly reflects the value of SSCM\_LCSTAT[LC].

## 60.2 Introduction

### 60.2.1 Overview

The Password and device security (PASS) module shown in the following figure, receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 60-1. PASS module block diagram

### 60.2.2 Features

The PASS includes these distinctive features:

- Life Cycle status
- Password comparison
- JTAG password comparison
- Production Disable control
- Flash read, write, and erase control

### 60.2.3 Modes of operation

The PASS operates identically in all system modes.

## 60.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers and DCF clients in the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in flash UTEST region.

The following table shows the memory map for the PASS. Note that all addresses are offsets; the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual.

#### NOTE

Non-implemented registers generate bus aborts if enabled.

The following registers are available in the PASS. These bit fields are chip-specific and user should refer to PASS chip-specific chapter to see the flash memory regions to which they apply the shaded bits are reserved for future use. For future compatibility, only write '0' to these bits; they always read '0'.

**PASS memory map**

| Address offset (hex) | Register name                            | Width (in bits) | Access | Reset value                 | Section/ page               |
|----------------------|------------------------------------------|-----------------|--------|-----------------------------|-----------------------------|
| 0                    | Life Cycle Status Register (PASS_LCSTAT) | 32              | R      | <a href="#">See section</a> | <a href="#">60.3.1/2725</a> |
| 8                    | Challenge Selector Register (PASS_CHSEL) | 32              | R/W    | 0000_0000h                  | <a href="#">60.3.2/2726</a> |
| 10                   | Challenge Status Register (PASS_CSTAT)   | 32              | R      | 0000_0000h                  | <a href="#">60.3.3/2727</a> |

*Table continues on the next page...*

**PASS memory map (continued)**

| Address offset (hex) | Register name                                              | Width (in bits) | Access                | Reset value                 | Section/ page               |
|----------------------|------------------------------------------------------------|-----------------|-----------------------|-----------------------------|-----------------------------|
| 20                   | Challenge Input Register (PASS_CIN0)                       | 32              | W<br>(always reads 0) | 0000_0000h                  | <a href="#">60.3.4/2727</a> |
| 24                   | Challenge Input Register (PASS_CIN1)                       | 32              | W<br>(always reads 0) | 0000_0000h                  | <a href="#">60.3.4/2727</a> |
| 28                   | Challenge Input Register (PASS_CIN2)                       | 32              | W<br>(always reads 0) | 0000_0000h                  | <a href="#">60.3.4/2727</a> |
| 2C                   | Challenge Input Register (PASS_CIN3)                       | 32              | W<br>(always reads 0) | 0000_0000h                  | <a href="#">60.3.4/2727</a> |

**60.3.1 Life Cycle Status Register (PASS\_LCSTAT)**

The Life Cycle Status Register reflects the production status and DCF Censorship client status of the device. It is possible to mature the device (move the device life cycle forward), but never to revert the life cycle to an earlier state.

The reset value of the LCSTAT register LIFE field derives from an external life cycle management module (like SSCM). It is a 3-bit life cycle. This register simply displays the life cycle input from external blocks.

Address: 0h base + 0h offset = 0h

**60.3.2 Challenge Selector Register (PASS\_CHSEL)**

This register determines which password group is challenged via the Challenge Input Register.

When the Master Only (MO) bit of the PASS\_LOCK3\_PGn register is set, only the master that unlocked access to the passgroup settings will be able to access these registers. The CMST field of the Challenge Status Register will reflect the locking master. When the Master Only (MO) bit of the PASS\_LOCK3\_PGn register is not set, the passgroup settings can be accessed by any master.

When a master writes this register, its ID sets the CMST field of the Challenge Status register.

Address: 0h base + 8h offset = 8h

| 28–31<br>CMST    | ID of the master which has last written the CHSEL register                              |

**60.3.4 Challenge Input Register (PASS\_CINn)**

This register is used to provide the Challenge word *n* for a password group as selected by the Challenge Selector Register.

After programming the Challenge Selector Register, the password challenge needs to be written with eight 32-bit writes from CIN0 to CIN7 in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written, the password is compared. The write access only completes after the comparison has been

executed. In case of a successful password comparison, the PASS module stores the ID of the master which has written CIN0 to CIN7 in the PASS\_LOCK3\_PGn register of the selected password group, as well as clears the PGL bit of that register.

All accesses to these registers need to be made by the bus master that wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison fails.

Address: 0h base + 20h offset + (4d × i), where i=0d to 7d

PASS\_CINn field descriptions

| Field        | Description                                                                |
|--------------|----------------------------------------------------------------------------|
| 0–31<br>PW32 | 32 bits of the 256-bit password challenge. Only 32-bit writes may be used. |

60.3.5 Password Group n - Lock 0 Status Register (PASS\_LOCK0\_PGn)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register becomes writable. For additional details of the LOCK bits, refer to the Flash memory description.

The LOCK bits do not come into effect before the life cycle has matured to *OEM Production* or older.

LOCK0\_PGn register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', indicating that a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes to this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

## Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 100h offset + (16d × i), where i=0d to 3d

\* Notes:

- MIDLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- LOWLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- TSLOCK field: If no DCF records have been written to change the TS bit state, the bit will reset to '1'.

## PASS\_LOCK0\_PGn field descriptions

| Field            | Description                                                                                                                                                                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>TSLOCK      | UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable). These bit fields are chip-specific and user should refer to PASS chip-specific chapter to see the flash memory regions to which they apply. |
| 1<br>Reserved    | This field is reserved.                                                                                                                                                                                                                                                                       |
| 2–15<br>LOWLOCK  | Low Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. These bit fields are chip-specific and user should refer to PASS chip-specific chapter to see the flash memory regions to which they apply.                |
| 16–31<br>MIDLOCK | Mid Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. These bit fields are chip-specific and user should refer to PASS chip-specific chapter to see the flash memory regions to which they apply.                |

60.3.6 Password Group *n* - Lock 1 Status Register (PASS\_LOCK1\_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable . For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK1\_PG*n* register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset . The default value before any DCF record is written is '1', which indicates a block is locked. If no DCF records have been written to change the lock state, the bits will reset to '1'.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group to prevent permanent and irreversible locking of Flash blocks.

CAUTION

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 104h offset + (16d × i), where i=0d to 3d

- HIGHLOCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.

### PASS\_LOCK1\_PG<sub>n</sub> field descriptions

| Field             | Description                                                                                                                                                                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                         |
| 16–31<br>HIGHLOCK | High Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. These bit fields are chip-specific and user should refer to PASS chip-specific chapter to see the flash memory regions to which they apply. |

## 60.3.7 Password Group *n* - Lock 2 Status Register (PASS\_LOCK2\_PG<sub>n</sub>)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits do not come into effect before the life cycle is matured to OEM Production or older.

### NOTE

Lock registers can only be accessed with 32-bit operations.

LOCK2\_PG<sub>n</sub> register functions are as shown in this section.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

### Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Address: 0h base + 108h offset + (16d × i), where i=0d to 3d

- \* Notes:
- L\_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit resets to '1'.

PASS\_LOCK2\_PGn field descriptions

| Field            | Description                                                                                                                                                                                                                                                                               |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>L_256LCK | Lower 256KByte Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase. These bit fields are chip-specific and user should refer to PASS chip-specific chapter to see the flash memory regions to which they apply. |

60.3.8 Password Group n - Lock 3 Status Register (PASS\_LOCK3\_PGn)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the register becomes writable.

The LOCK bits do not come into effect before the life cycle matures to OEM Production or older.

LOCK3\_PGn register functions are as shown in this section.

NOTE

Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTEST Flash block and copied over during functional reset except for DBL and RLx bits. DBL and RLx bits are updated on a destructive reset. The default value before any DCF record is written is '1', which indicates a block is locked.

During the Customer Delivery life cycle, the user must program a valid password or a DCF record that writes this register to unprotect the UTEST for each password group in order to prevent permanent and irreversible locking of Flash blocks.

## Warning

Failure to program valid passwords or DCF records for all password groups before the life cycle matures to OEM Production renders the part unusable. However, additional DCF Records can be written to UTEST to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible. However, unless the life cycle is OEM Production or older, the Flash blocks are always unlocked, regardless of the values in the password groups.

Once a censored device enters the Failure Analysis life cycle, read protection is active regardless whether the system is in debug mode or not. It is still possible to unlock Flash regions with the correct passwords, however. Flash Utest region controlled by LOCK3[0] is read unlocked in Failure Analysis life cycle.

## NOTE

Do not toggle DBL and RLx bits with the same write command. Use one instruction to program the DBL bit and a separate instruction to toggle the RLx bits.

\* Notes:

- U\_256LCK field: For each implemented bit of this field, if no DCF records have been written to change the lock state, the bit will reset to '1'.
- RL0 field: If no DCF records have been written to change the RL0 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- RL1 field: If no DCF records have been written to change the RL1 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.

## Memory map and register definition

- **RL2 field:** If no DCF records have been written to change the RL2 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- **RL3 field:** If no DCF records have been written to change the RL3 bit lock state, the bit will reset to a logic 1. This Flash block region is always readable if the life cycle is Customer Delivery or earlier. To determine if this region is readable for Life Cycle states later than Customer Delivery, consult the Flash Memory Read Protection Truth Table.
- **Reserved field:** The reset value is chip-specific. See the chip-specific PASS information
- **MO field:** If no DCF records have been written to change the MO bit lock state, the bit will reset to '1'.
- **DBL field:** If no DCF records have been written to change the DBL bit lock state, the bit will reset to '1'.
- **PGL field:** Reset value depends on life cycle. If life cycle is Customer Delivery or earlier, the value will be 0, otherwise 1.

### PASS\_LOCK3\_PGn field descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## 60.4 DCF clients

The following table shows the DCF clients for the PASS.

Where a DCF client is listed, the reset value of that register may automatically be pre-loaded during reset based on the data stored in DCF Records in Flash UTEST region.

The address of the DCF client is local to the PASS module and must be qualified with the appropriate Client Select (CS[14:0]) for the PASS module, as defined in the DCF Record Section of the Reference Manual or in DCF sheet attached to this document.

**Table 60-36. PASS DCF clients**

| Offset                    | Register           | Access | Reset Value | DCF Client Address (ADDR[14:0]) | Section            |
|---------------------------|--------------------|--------|-------------|---------------------------------|--------------------|
| <b>Censorship</b>         |                    |        |             |                                 |                    |

## 60.4.1 Censorship

Censorship is a DCF client that is *not* accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region.

## 60.4.2 Production Disable

Production Disable is a DCF client that is not accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the Flash UTEST region. The Production disable DCF client defines the Debug Disable aspects of the Production Disable feature.

The DCF client implements 1 bit with a default value of '0'. The DCF client can only be written once and writes from subsequent DCF records are ignored.

For more information on Production disable, see [Production disable](#)

DCF Client Address: 0x00C0 Production Disable

Access: DCF Record Write Once Only

|       | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 |

**Figure 60-34. Production Disable DCF client**

**Table 60-37. Production Disable DCF Client field descriptions**

| Field | Description                                                                                                                                                                      |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0-30  | This bit is reserved and always has the value 0.                                                                                                                                 |
| 31    | Debug disable.                                                                                                                                                                   |
| DD    | '0' = Debug Interface is Enabled and Disabled using Censorship, JTAG password and PASS_LOCK3[DBL] bit (see chip-specific PASS information).<br>'1' = Debug Interface is disabled |

### 60.4.2.1 Debug Disable (DD)

Debug Disable is an optional feature that, once the life cycle is In Field overrides all other debug controls and disables the debug interface. The Debug Disable feature has a higher priority than Censorship, JTAG password and the PASS LOCK3[DBL] bit.

## 60.5 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

### 60.5.1 Valid password

Each password should have at least one 1 and one 0. Other than all 0's and all 1's, all passwords are valid. If user sets all 0's or all 1's as password, then password check will always fail.

### 60.5.2 Censorship

Censorship is the overall control that enables and disables two independent security features: Debug Interface access and flash memory read protection.

The Debug Interface access is controlled by the CNS and LIFE bits of the LCSTAT register ([Life Cycle Status Register \(PASS\\_LCSTAT\)](#)) according to the Debug Interface Access truth table. The flash memory read protection is also controlled by the CNS and LIFE bits of the LCSTAT register according to the Flash memory read protection truth table.

The CNS bit is set or cleared by executing a DCF record that writes to the Censorship DCF client (See [Censorship](#)). The LIFE bits of the LCSTAT register are controlled by the SSCM using user programmed values from specific locations in the UTEST flash.

### 60.5.3 Debug Interface Access

The debug interface is fully enabled in Customer Delivery life cycle. But from OEM Production life cycle, it can be blocked using censorship and unlocked by either entering a 256 bits password via JTAG or by software clearing the DBL bit the PASS\_LOCK3 registers (See [Password Group \*n\* - Lock 3 Status Register \(PASS\\_LOCK3\\_PG\*n\*\)](#)). Both these debug enabling options are further conditioned by life cycle and Production Disable.

The debug interface enable truth table for this chip is shown in the device specific PASS section of this chapter.

### 60.5.3.1 JTAG Password Challenge

To enable the Debug Interface Access, the JTAG password challenge register in the JTAGC, needs to be written by an external tool. If that password matches the JTAG password stored in UTEST flash, Debug Interface Access is enabled until the next destructive reset.

### 60.5.4 Flash Memory Read Protection

Flash Memory Read Protection is a security feature that can selectively make regions of the flash memory unreadable. Any attempt to read a region of flash that is read protected results in the read access terminating with a transfer error. This is consistent for all bus masters including debug bus masters.

The assertion of flash memory region read protection is controlled by Life Cycle, Censorship and whether the Debug Interface access is enabled or blocked. The Flash memory read protection truth table describes the combination of conditions that drive Flash Memory Read Protection.

The intention of the feature is to protect the contents of the flash from being read. The flash memory is readable in normal operation, allowing the application to run, but read protection becomes enabled when DBL bit is cleared 0(debug interface is enabled).

The flash memory is also read protected when the life cycle status is Failure Analysis. This life cycle is used for a module field failure, where the device is returned for failure analysis. This protection prevents the contents of the flash memory from being read.

The flash memory is divided into a number of Regions (3 to 5 depending on the device). The assignment of the regions is defined in the device reference manual.

#### NOTE

When read protection is enabled all reads ( instruction fetches and data reads) are disabled and any code execution is no more possible from flash.

The memory read protection truth table for this chip is shown in the device specific PASS information.

## 60.5.5 Flash Memory Write and Erase Protection

This section describes write and erase permissions for flash memory. From power ON till system configuration and monitor block is done with system initialization, all regions of flash memory are in locked state. After power ON, System Configuration and monitor block scans flash memory for valid DCF records. These DCF records carry program and erase protection settings for flash memory regions. System Configuration and monitor block finds the settings and load them into PASS configuration via the DCF path. Once system configuration and monitor block is done with system initialization, the new configuration loaded into PASS come into force and unlocks different regions of flash for program and erase.

To enable write and erase access of a particular region of flash memory, add corresponding DCF records in the flash memory once chip comes out of reset. User can also change the settings by providing valid password to the PASS module, and by modifying the settings of following registers bits fields:

- PASS\_LOCK0\_PGn[MIDLOCK]
- PASS\_LOCK0\_PGn[LOWLOCK]
- PASS\_LOCK1\_PGn[HIGHLOCK]
- PASS\_LOCK2\_PGn[L\_256LCK]
- PASS\_LOCK3\_PGn[U\_256LCK]

See chip-specific PASS information for mapping of the above mentioned bits fields.

In the PASS module there is no individual access protection for 'write' or 'erase' access types, but has combined 'write' and 'erase' accesses.

### NOTE

This feature is controlled by the LC of the device and will become active from OEM LC on.

## 60.5.6 Production Disable

### 60.5.6.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to function completely normally without any constraints, except the Debug interface is disabled.

### 60.5.6.2 Enabling

The feature is enabled via the Production Disable DCF client in the PASS module. Bit 0 enables the Debug Interface Disable. See [Production Disable](#) for details.

This information can be written by adding a DCF Record to the DCF record list in Flash UTEST. The DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

If no DCF Record writes to this client, the default state of this feature is disabled. If, for a particular application, there is no intention of ever using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000\_0000. This is not essential, but ensures the feature can not be enabled accidentally.

## 60.6 Initialization/application information

### 60.6.1 Reset

The reset state of each individual bit is shown within the Register Description section. However, many bits receive their values based on DCF records stored in the UTEST Flash memory block.

### 60.6.2 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTEST Flash, apart from the available space for DCF records. It is possible to set and clear them multiple times.

**Table 60-38. CS/ADDR Values for Lock Registers**

| Register   | DCF Command Word          |
|------------|---------------------------|
| PW Group 0 |                           |
| Lock0      | 0xxxxx <sup>1</sup> _0100 |
| Lock1      | 0xxxxx <sup>1</sup> _0104 |
| Lock2      | 0xxxxx <sup>1</sup> _0108 |
| Lock3      | 0xxxxx <sup>1</sup> _010C |
| PW Group 1 |                           |
| Lock0      | 0xxxxx <sup>1</sup> _0110 |

*Table continues on the next page...*

**Table 60-38. CS/ADDR Values for Lock Registers (continued)**

| Register   | DCF Command Word          |
|------------|---------------------------|
| Lock1      | 0xxxxx <sup>1</sup> _0114 |
| Lock2      | 0xxxxx <sup>1</sup> _0118 |
| Lock3      | 0xxxxx <sup>1</sup> _011C |
| PW Group 2 |                           |
| Lock0      | 0xxxxx <sup>1</sup> _0120 |
| Lock1      | 0xxxxx <sup>1</sup> _0124 |
| Lock2      | 0xxxxx <sup>1</sup> _0128 |
| Lock3      | 0xxxxx <sup>1</sup> _012C |
| PW Group3  |                           |
| Lock0      | 0xxxxx <sup>1</sup> _0130 |
| Lock1      | 0xxxxx <sup>1</sup> _0134 |
| Lock2      | 0xxxxx <sup>1</sup> _0138 |
| Lock3      | 0xxxxx <sup>1</sup> _013C |

1. Value depends on the DCF Client Select assigned to the PASS module in the device. See chip specific PASS information for the Client Select assignment

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF and other fields to 0, the DCF record has to be added as shown in [Table 60-39](#).

**Table 60-39. Setting some bits in the MIDLOCK field**

| ADDR offset | DATA        | Description                              |
|-------------|-------------|------------------------------------------|
| 0x00        | 0x05AA_55AF | Start Record                             |
| 0x04        | 0x0000_0000 |                                          |
| 0x08        | 0x0000_00FF | PW Group 1, Lock0<br>Set MIDLOCK to 0xFF |
| 0x0C        | 0xxxxx_0110 |                                          |

# Chapter 61

## Tamper Detection Module (TDM)

### 61.1 Chip-specific TDM information

This chip has one instance of the TDM. The TDM and its associated DCF clients enable the user to:

- Select a flash memory block for tamper detection protection by assigning the block to a Tamper Detection Region (TDR)
- Override a block's tamper detection protection under certain circumstances
- Disable the override of a block's tamper detection protection
- Configure a flash memory block as One Time Programmable (OTP), meaning the block can be written only once

#### CAUTION

Specifying flash memory blocks to be monitored by the TDM and configuring flash memory blocks as OTP is done by defining DCF records. Use caution when assigning flash memory blocks to TDRs or configuring blocks as OTP. Some DCF records can be written only one time. Many DCF records can be written more than once, but the setting defined in each write is irreversible. For details about TDM-related DCF records and DCF clients, see [DCF clients](#). For additional information, see the chip-level [Device Configuration Format \(DCF\) Records](#) details.

#### 61.1.1 Disabling the override of tamper detection

The [Tamper Region Override \(TO\) DCF client](#) allows the user to override tamper detection protection. The override cancels tamper detection protection for all blocks in a TDR and is irreversible.

The [Software Tamper Region Override Disable \(STO\\_DIS\) DCF client](#) allows the user to disable the override option permanently.

To optimize security on this chip, disable the Tamper Region Override option permanently by using the Software Tamper Region Override Disable DCF client.

## 61.1.2 TDR<sub>n</sub>\_LOCK<sub>m</sub> DCF client bit mapping

The TDR<sub>n</sub>\_LOCK<sub>m</sub> DCF clients provide a means to select flash memory blocks for inclusion in a TDR. Specific memory blocks map to particular bits in TDR<sub>n</sub>\_LOCK<sub>m</sub> clients.

### 61.1.2.1 TDR<sub>n</sub>\_LOCK0 DCF client bit mapping

The flash memory blocks mapped to the [Tamper Region Assignment DCF client \(TDR<sub>n</sub>\\_LOCK0\)](#) bits are as follows.

|                                        | 0        | 1        | 2        | 3        | 4               | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15              | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |
|----------------------------------------|----------|----------|----------|----------|-----------------|---|---|---|---|---|----|----|----|----|----|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Register Field                         | Reserved | Reserved | Reserved | Reserved | LOWTDRAGN[11:0] |   |   |   |   |   |    |    |    |    |    | MIDTDRAGN[15:0] |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| Flash Memory Block Name                | —        | —        | —        | —        | —               | — | — | — | — | — | —  | —  | —  | —  | —  | —               | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  | —  |
| 64 KB EEPROM Data Block1 - Partition 1 |          |          |          |          |                 |   |   |   |   |   |    |    |    |    |    |                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 64 KB EEPROM Data Block0 - Partition 0 |          |          |          |          |                 |   |   |   |   |   |    |    |    |    |    |                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 64 KB EEPROM Data Block1 - Partition 3 |          |          |          |          |                 |   |   |   |   |   |    |    |    |    |    |                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
| 64 KB EEPROM Data Block0 - Partition 2 |          |          |          |          |                 |   |   |   |   |   |    |    |    |    |    |                 |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

61.1.2.2 TDRn\_LOCK1 DCF client bit mapping

The flash memory blocks mapped to the [Tamper Region Assignment DCF client \(TDRn\\_LOCK1\)](#) bits are as follows.

NOTE

Because the CSE module has exclusive access to these flash memory blocks, this DCF client and the associated DCF records are ignored.

|                         |          | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15               | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31                                  |                                     |

### 61.1.3 OTPEN<sub>n</sub> DCF client bit mapping

The OTPEN<sub>n</sub> DCF clients provide a means to configure flash memory blocks to be One Time Programmable (OTP). Specific memory blocks map to particular bits in OTPEN<sub>n</sub> clients.

#### 61.1.3.1 OTPEN<sub>0</sub> DCF client bit mapping

The flash memory blocks mapped to the [One Time Programmable Enable \(OTPEN<sub>0</sub>\) DCF client](#) bits are as follows.

|                                        | 0        | 1        | 2        | 3        | 4              | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15             | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 |

#### 61.1.3.2 OTPEN<sub>1</sub> DCF client bit mapping

The flash memory blocks mapped to the [One Time Programmable Enable \(OTPEN<sub>1</sub>\) DCF client](#) bits are as follows.

#### NOTE

When the value of a bit in this DCF client reflects that the corresponding flash block is one-time programmable (OTP),

Chip-specific TDM information

the OTP status applies to the block even though the CSE module has exclusive access to the block.

## 61.2 Overview

The Tamper Detection Module provides a type of flash memory erase protection mechanism that requires software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prohibit* an erase operation on any block within a TDR—it requires a record to be written before the operation can execute. Collectively, the records are referred to as a “diary”. At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

The following figure shows the block diagram of the TDM and its interface to other system components.

**Figure 61-1. Tamper Detection Module block diagram**

Security information is passed to the TDM by the SSCM module via the DCF bus. Among the data are:

- OTP (One Time Programmable) settings for each of the flash blocks
- Base address for the diary in the flash
- Block assignments for the TDRs
- Tamper region override information
- Software tamper region disable

The TDM module controls the flash blocks for erase operations and sets them as OTP.

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are already erased can be programmed. Over-programming is not possible.

### NOTE

The pass module provides the control for erase operation for each flash block as well as for each region of flash memory, and the PASS settings have priority over the settings of TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a means to verify whether the block is part of any TDRs. The memory map registers interface provides a means to the user to read information of the TDM registers.

## 61.3 Features

The Tamper Detection Module supports these distinctive features:

- Erase counter (diary) for each TDR to record up to 256 write attempts on the flash blocks
  - The diary is divided into 6 parts (TDRs), each consisting of 256 64-bit records.
  - The diary block should be assigned as OTP region in flash.
  - The diary area can store any type of relevant information.
- Tamper Detection Region Block Assignment
  - Any flash block can be assigned to any TDR and be controlled.
- 32-bit Erase Lock DCF clients for each flash memory TDR defined.
- 32-bit OTP Enable DCF clients to disable the erase operation for an entire flash block
- Override TDR via DCF records<sup>1</sup>
  - Allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation.
- Memory mapped registers interface for reading via software of specific registers.

## 61.4 External signal description

There are no external signals driving or being driven by the TDM.

---

1. The Tamper Region Override DCF record is a "write one only" DCF record. If an override is applied to a TDR it is permanent and cannot be reversed.

## 61.5 DCF clients

TDM-related DCF records perform the following functions:

- Establish a permanent diary base address
- Define Tamper Detect Regions (TDRs) to monitor on-chip flash memory program/erase activity
- Permanently disable one or more Tamper Regions
- Permanently disable ability for software to permanently override one or more TDRs
- Configure flash memory as One Time Programmable (OTP) on a per-block basis

The following table gives an overview on the TDM DCF clients implemented.

**Table 61-1. DCF clients**

| DCF Client Name                         | Description                                                                                                                                                                                                                | Strategy                      |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| Diary Base Address                      | Stores the base address of the tamper detection diary                                                                                                                                                                      | write once, write 1 to 0 only |
| Tamper Region Override                  | Stores information of which TDR is to be overridden                                                                                                                                                                        | write 0 to 1 only             |
| Software Tamper Region Override Disable | Stores information to disable the software mechanism to override the TDR                                                                                                                                                   | write once, write 0 to 1 only |
| OTPEN[nb] (OTP Enable)                  | Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory                                                               | write 0 to 1 only             |
| TDR[n]_LOCK[m] Region Assignment        | Stores information of which flash block is assigned to a TDR. <ul style="list-style-type: none"> <li>• n specifies a TDR</li> <li>• m specifies the flash blocks as per the LOCK registers of the flash memory.</li> </ul> | write 0 to 1 only             |

### 61.5.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. The following diagram depicts this client.

**CAUTION**

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

**Table 61-2. Diary Base Address (DBA) DCF client field description**

| Field       | Description                                                                                                                                                                                                                           |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>DBA | Diary Base Address. This field holds the base address of the diary. This information is then used to verify if the diary being programmed matches any TDR region.<br><br><b>NOTE:</b> Diary Base Address must be on a 16 KB boundary. |

## 61.5.2 Tamper Region Override (TO) DCF client

This DCF client holds override information for each TDR. The following figure shows the diagram for this register.

**CAUTION**

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the override of a TDR permanent.

**Table 61-3. Tamper Region Override (TO) DCF client field descriptions**

| Field                 | Description                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–25<br>Reserved      | This field is reserved and should be written with all zeroes when programming the TOE fields.                                                                                                                                                                                                                                                                        |
| 26–31<br>TOE5 to TOE0 | TDR Override Enable. Each TOE <sub>n</sub> field, where <i>n</i> represents the TDRs, holds information of the Override Enable status for each TDR.<br><div> 0 Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written.<br/> 1 Diary override. The blocks assigned to this TDR can be erased WITHOUT writing to the diary. </div> |

### 61.5.3 Software Tamper Region Override Disable (STO\_DIS) DCF client

This DCF client holds information to disable the software mechanism to override the tamper detect regions.

#### CAUTION

This write-once DCF client can be written only one time. After one DCF record has written to this client, all subsequent writes are ignored.

DCF Client Address: 0x0002

Access: DCF write

|         |   |   |   |   |   |   |   |   |   |   |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

Any attempt to override TDR <sub>n</sub> by loading a service key value in STO_KEY <sub>n</sub> register is ignored. |

### 61.5.4 One Time Programmable Enable (OTPEN0) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK0 register of the flash memory. The following diagram depicts this client.

#### CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

DCF Client Address: 0x0008

Access: DCF write

|         |   |   |   |   |                |   |   |   |   |   |    |    |    |    |    |    |                |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

61.5.5 One Time Programmable Enable (OTPEN1) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK1 register of the flash memory. The following diagram depicts the client.

CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

Table 61-6. One Time Programmable Enable (OTPEN1) DCF client field descriptions

| Field              | Description                                                                                                                                                                                                                                                                                                                                                                                  |

### 61.5.7 One Time Programmable Enable (OTPEN3) DCF client

This DCF client holds OTP information for particular blocks of flash memory. This DCF client mirrors the LOCK3 register of the flash memory. The following diagram depicts the client.

**CAUTION**

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the OTP assignment of a flash memory block irreversible.

**Table 61-8. One Time Programmable Enable (OTPEN3) DCF client field descriptions**

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                          |

The same mapping also applies to control similar functions in the flash memory module.<br>0 Corresponding flash blocks are not assigned as OTP<br>1 Corresponding flash blocks are assigned as OTP |

### 61.5.8 Tamper Region Assignment DCF client (TDRn\_LOCK0)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR ( $n$  varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK0 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK0 register in the flash memory. The following diagram depicts the TDRn\_LOCK0 DCF client.

#### CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address:  $0x0014 + ((n \times 4) + 0)$ 

Access: DCF write

### 61.5.10 Tamper Region Assignment DCF client (TDRn\_LOCK2)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR (*n* varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK2 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK2 register in the flash memory. The following diagram depicts the TDRn\_LOCK2 DCF client.

#### CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

**Table 61-11. Tamper Region Assignment DCF client (TDRn\_LOCK2)**

### 61.5.11 Tamper Region Assignment DCF client (TDRn\_LOCK3)

This DCF client holds the assignment information of flash memory blocks to a specific TDR. Each flash memory block can be assigned to any TDR ( $n$  varies from 0 to 5). This DCF client holds the assignment information for only those blocks specified in the LOCK3 register in the flash memory. For that reason, the layout of this DCF client mirrors the LOCK3 register in the flash memory. The following diagram depicts the TDRn\_LOCK3 DCF client.

#### CAUTION

This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 are ignored, making the assignment of a flash memory block to a TDR irreversible unless the entire TDR is overridden.

DCF Client Address:  $0x0014 + ((n \times 4) + 3)$

Access: DCF write

**61.6.1 TDR Status Register (TDM\_TDRSR)**

This register contains the current status, i.e., locked or unlocked, of each tamper region, i.e., TDR.

- If a tamper region is locked, the blocks assigned to that tamper region cannot be erased.
- If a region is unlocked, the blocks within the tamper region can be erased.

The register contains a status bit for each TDR. Status is determined as follows:

1. The default status for each TDR is '1', which indicates that the erase operation is disabled for all flash blocks associated with the TDR.
2. The status bit for a TDR is set to '0' (indicating that the erase operation for all flash blocks associated with the TDR is enabled) if either a successful programming operation to the TDR diary region has been performed or the TDR Override bit for that TDR is set.

**NOTE**

- TDRSR is a read-only register and writes have no effect on it. Write operations result in a transfer error.
- If the reset value for this register is determined by a DCF record, it will be noted in the chip-specific information at the beginning of this chapter. Otherwise, the reset value is as shown.

Address: 0h base + 0h offset = 0h

**TDM\_TDRSR field descriptions**

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**61.6.2 Last Flash Programmed Address Register (TDM\_LFPAR)**

This register holds information of the address of the last successful programming operation provided from the flash memory to the TDM. Writes to this register are ignored and will generate a transfer error.

Address: 0h base + 4h offset = 4h

## 61.7 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

### 61.7.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the diary is defined by a DCF Record.

The diary is divided into 6 parts where each part consists of  $256 \times 64$ -bit records, to record up to 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of  $4 \times 32$ -bit internal hardware registers that are initialized by DCF records that define the tamper region. These registers mirror exactly the LOCK registers bits from the flash module.

Each TDR $n$ \_LOCK $m$  register is loaded at boot time by the SSCM, which defines if the associated flash block is Locked for Erase in a particular TDR:

- '1' means the flash block is locked for erase
- '0' means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensures that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double-word program operation, the flash module indicates to the TDM the address of the programmed double word. The TDM determines whether the programmed data was written to the correct TDR diary location and then unlocks the

blocks for erase operation for the corresponding TDR. The TDM ensures that this erase operation on unlocked blocks is allowed until the completion of the erase sequence or until next destructive reset.

When attempting to update the TDM diary and erase flash blocks, set MCR[PECIE] in the Embedded Flash Memory registers to enable interrupt notification for program and erase operations. Then clear MCR[PECIE] to service the interrupt after each program or erase operation. This sequence must be executed before attempting to update the TDM diary, and then again before attempting to erase the unlocked flash blocks.

### NOTE

All blocks associated to a TDR where an erase operation is allowed can be erased all together.

The data programmed in the diary location is flexible, and may include count information or other important customer information.

### NOTE

There is no restriction on the type or format of data that can be programmed in the diary, so software must verify whether the diary is full. If a TDR's diary area is full, the tamper detect mechanism can be disabled for that TDR by creating a Tamper Region Override (TO) DCF record with the TDR's corresponding TDR Override Enable (TOE) bit set to '1'. This allows erase operations to be performed to the TDR without any diary entry.

The setting from “override tamper region lock” DCF record ([Diary](#)) has priority over the settings in the TDR<sub>n</sub>\_LOCK0 – 3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDR<sub>n</sub>\_LOCK<sub>m</sub> bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, if a block is locked by the PASS\_LOCK<sub>x</sub>\_PG<sub>n</sub> registers or by TDR<sub>n</sub>\_LOCK<sub>m</sub>, the block is locked for erase.

### NOTE

The settings in the Tamper Region Override Register have priority over the TDR<sub>n</sub>\_LOCK<sub>m</sub> registers. The PASS module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via the TDM, but the same blocks are programmed to be locked for erase operation in PASS, the blocks end up being locked for erase operation.

Attempts to erase the flash without first writing the diary will be ignored by the flash. The contents in the flash block will remain unchanged and MCR[PEG] will be asserted, indicating the operation was successful and the contents of the block are properly protected from the erase operation.

### 61.7.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is defined by a group of 4 x 32-bit DCF records and clients, with each containing bits that map to specific blocks in a flash region. These mappings mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as  $TDR_n\_LOCK_m$  where  $n$  is the number of a tamper region, that is, 0- 5 and  $m$  varies from 0-3 as flash contains four Lock registers.

In these DCF records:

- '1' means that the corresponding flash block is assigned to this TDR
- '0' means that the corresponding flash block is not assigned to this TDR (Default)

DCF clients are not visible to software. They can not be read nor written. They can only be initialized by DCF record within the UTest flash block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that correspond to these clients.

#### NOTE

No flash block should be assigned to more than one TDR. Each block should correspond to a single TDR. For example, if a single block is assigned to TDR0 and TDR1, then even if the Diary is programmed for both TDR0 and TDR1, this flash block will never be unlocked for erase operation.

### 61.7.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 2 KB, and the minimum size of any programming operation is 8 bytes to honor OTP restrictions. Therefore, each diary can hold a maximum of 256 64-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core.

**NOTE**

To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once and the default bit state is 1.

The DCF clients can not be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

### 61.7.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes. Therefore, each diary region limits the erases of the assigned blocks to 256 erases.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once and the default bit state is '1'.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 2 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 16 KB boundary. Therefore the least significant 14 bits of the base address must all be '0'.

The Base address of the diary is represented by:

Diary\_Base\_Address = 0bxxxx\_xxxx\_xxxx\_xxxx\_xx00\_0000\_0000\_0000

The base address of each TDR is shown below:

- TDR0 = Diary\_Base\_Address + 0b00\_0000\_0000\_0000

- $\text{TDR1} = \text{Diary\_Base\_Address} + 0b00\_1000\_0000\_0000$
- $\text{TDR2} = \text{Diary\_Base\_Address} + 0b01\_0000\_0000\_0000$
- $\text{TDR3} = \text{Diary\_Base\_Address} + 0b01\_1000\_0000\_0000$
- $\text{TDR4} = \text{Diary\_Base\_Address} + 0b10\_0000\_0000\_0000$
- $\text{TDR5} = \text{Diary\_Base\_Address} + 0b10\_1000\_0000\_0000$
- End of the diary =  $\text{Diary\_Base\_Address} + 0b11\_0000\_0000\_0000$

### 61.7.5 TDR lock status

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. The default state of these bits is 1, which is defined as "TDR Erase Blocked". See [TDR Status Register \(TDM\\_TDRSR\)](#) for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. See [TDR Status Register \(TDM\\_TDRSR\)](#). The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. See [Last Flash Programmed Address Register \(TDM\\_LFPAR\)](#).

### 61.7.6 TDR override

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to '0' in each 64 bit double word within the 2 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits, one for each TDR. See the device configuration information at the beginning of this chapter for TDM DCF client details.

The Diary Override bits are by default set to '0'; which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to '1'. Writes to '0' are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to '1'. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

The application can also override the diary by loading a service key to the `STO_KEYn` program-visible register, where *n* denotes the tamper detect region. By loading the value `0x55AA5A5A` into `STO_KEYn` register, the corresponding tamper detect region is overridden. This software override mechanism is disabled if the `STO_DISn` field of the `STO_DIS` DCF Client is set.

## 61.7.7 One time programmable (OTP)

### 61.7.7.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and only 64-bit double words that are already erased (that is, flash content is `0xFFFF_FFFF_FFFF_FFFF`) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next functional reset.
