| 01    | issue Service Request on Match B only           |
| 10    | issue Service Request on 2nd <sup>1</sup> Match |
| 11    | issue Service Request on both Matches           |

1. 2nd Match means the Match that happens after the 1st Match in time, either Match A or Match B.

**Table 35-348. TCAP and TSR signals - Transition Captures and Service Requests**

| value | TCAP                                                                                                                                                                                                                                                                                  | TSR                                                      |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|

| M2BT<br>(Match B Blocks Transitions)           | Match B blocks Transitions                                                             |
| T1BM1<br>(Transition A Blocks Match A)         | Transition A blocks Match A                                                            |
| T2BM1<br>(Transition B Blocks Match A)         | Transition B blocks Match A                                                            |
| T1ET2<br>(Transition A Enables Transition B)   | Transition B is initially blocked, and Transition A enables Transition B               |

1. The initial condition of M1EM2 prevails over M1BM2, while M1BM2 blocking prevails over M1EM2 enabling, so that Match B stays always blocked when both M1BM2 and M1EM2 are active. This combination is used in single-match modes (sm\_\*).
2. Blocking of one Match by the other is done through MRLEs.
3. Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B)

1. signals TSR, TCAP and TBM2 replace the signal DTM used in previous eTPU versions.
2. bm\_dt and sm\_dt are exceptions in the match blocking logic by transitions. See [Both Match Request Modes \(bm\\_st, bm\\_dt\)](#) and [Single Match Modes \(sm\\_st, sm\\_dt\)](#).
3. sm\_st\_e is an exception in the capture scheme. See [Single Match Enhanced Mode \(sm\\_st\\_e\)](#).

Figure 35-307. Channel Mode Logic and Event Flags

### 35.15.5.4.2 Channel Modes Overview

The predefined channel modes are divided, according to the way they treat transitions, in two basic modes:

- **Single Transition Modes** (mnemonic suffix **\_st**): in these modes the first transition (flagged in TDLA) issues a service request, and captures both time bases (selected by TBSA[1] and TBSB[1]) except on sm\_st\_e. The second transition (flagged in TDLB) does not issue a service request, but it captures time base selected by TBSB[1], except on sm\_st\_e.
- **Double Transition Modes** (mnemonic suffix **\_dt**): in these modes the second transition (flagged in TDLB) issues a service request, and each transition captures its own selected time base (Transition A and Transition B capture time bases selected by TBSA[1] and TBSB[1], respectively).

In predefined modes, Transition B is always (but not only) enabled by Transition A, so that transitions are always ordered: TDLA is set on the first transition and TDLB on the second. Unordered transitions are possible with user-defined mode, when UDCM bit T1ET2=0. Matches are generally not ordered, except on specific ordered match modes m2\_o\_st and m2\_o\_dt. Match capture(s) never overwrites a Transition capture, while Transition captures can always overwrite a Match capture, either in predefined or user-defined modes.

The following general rules apply to both predefined and user-defined modes:

- Blocking of one Match by the other, when it occurs, is done through MRLEs.
- Matches always block themselves by resetting their own MRLEs (Match A always blocks Match A, Match B always blocks Match B).

Predefined modes differ mostly by the way matches affects and are affected by other matches and transitions, as explained in next sections. However, some general rules on Match blocking apply:

- Match B is blocked by first transition (TDLA) in single transition modes, and by second transition (TDLB) in double transition modes.
- Both Matches are blocked by first transition in single transition modes.

#### Note

The rules above and in following sections may be overruled by the state of the channel latches if they are set/reset by microcode or if channel mode is changed. Care must be taken

to change channel modes, and is advisable to reset channel flags MRLA/B, TDLA/B and MRLEA/B before writing PDCM, or to UDCM when user-defined mode is selected.

#### 35.15.5.4.2.1 Either Match, Blocking Modes (em\_b\_st, em\_b\_dt)

In these modes the first match recognition that occurs blocks the other match recognition and generates a service request. They end up with one service request for two programmed match recognitions where only the first match recognition has an actual effect. If both match recognitions occur at the same time, both MRLA and MRLB are set, before the mutual blocking takes effect. The associated logic is shown in the following figure.

Figure 35-308. Either Match, Blocking Modes (em\_b\_st, em\_b\_dt)

### 35.15.5.4.2.2 Either Match, Non Blocking Modes (em\_nb\_st, em\_nb\_dt)

In these modes both match recognitions are independent and each of them generates service request. Each match recognition captures its related time base and does not block the other. The associated logic is shown in the following figure.

Figure 35-309. Either Match, Non Blocking Modes (em\_nb\_st, em\_nb\_dt)

### 35.15.5.4.2.3 Match B Request Modes (m2\_st, m2\_dt)

In these modes transitions are initially blocked, and are enabled by Match A. Match B recognition generates the match service request and disables Match A recognition. Each match recognition captures its own programmed timebase. In case of simultaneous match

recognition, both MRLA and MRLB are set, and OPACB register has priority over OPACA for selecting the pin action. The associated logic is shown in the following figure.

Figure 35-310. Match B Request Modes (m2\_st, m2\_dt)

#### 35.15.5.4.2.4 Both Match Request Modes (bm\_st, bm\_dt)

In these modes, match service request is generated only after both match recognitions occurred. By definition this is a non-blocking match mode: match recognitions do not block each other, implementing a last-served scheme. Unlike other double transition

modes, `bm_dt` blocks Match A with Transition B (not with Transition A), so that the second transition blocks both matches. The associated logic is shown in the following figure.

Figure 35-311. Both Match Request Modes (`bm_st`, `bm_dt`)

#### 35.15.5.4.2.5 Ordered Modes with Match B Request (`m2_o_st`, `m2_o_dt`)

These are ordered match modes on which Match A recognition must precede Match B recognition (ordered 1->2). Match A asserts MRLA and enables Match B and transitions. Match B asserts MRLB, generates a match service request, and blocks both transitions. The associated logic is shown in the following figure.

Figure 35-312. Ordered Modes with Match B Request (m2\_o\_st, m2\_o\_dt)

#### 35.15.5.4.2.6 Single Match Modes (sm\_st, sm\_dt)

Single match modes support single or double transition with single match recognition. MRLB is never set, and MRLEB has no effect. The associated logic is shown in the following figure.

Figure 35-313. Single Match Modes (sm\_st, sm\_dt)

#### 35.15.5.4.2.7 Single Match Enhanced Mode (sm\_st\_e)

This is an enhanced single transition and single capture mode, which provides non-filtered input captures in addition to the single capture, allowing one to measure the delay of the digital filter. In an output channel, it has the same functionality of sm\_st (captures both time bases at once due to a match recognition). The associated logic is shown in the following figure.

Figure 35-314. Single Match Enhanced Mode (sm\_st\_e)

### 35.15.5.4.3 Predefined Channel Modes on Input Signal Processing

When processing an input signal, the predefined channel modes can be classified in the following primary mode groups:

- Single Transition, Single Match: em\_b\_st, sm\_st, sm\_st\_e
- Single Transition, Double Match: em\_nb\_st, bm\_st, m2\_st, m2\_o\_st
- Double Transition, Single Match: em\_b\_dt, sm\_dt
- Double Transition, Double Match: em\_nb\_dt, bm\_dt, m2\_dt, m2\_o\_dt

In single transition modes, TDLA assertion may capture both time bases at once, while in double transition modes each transition captures its related time base in its related capture register.

Double transition is always ordered, i.e TDLB is enabled by TDLA and generates the service request.

The channel logic supports various input modes with combinations of single/double transition and single/double match, explained in the following subsections.

#### **35.15.5.4.3.1 Either Match, Blocking, Single Transition (em\_b\_st)**

On an input signal, this mode provides double timeout mechanism on a programmed transition edge with two timebases. The signal transition blocks both pending matches, indicating that no timeout condition occurred. The two match recognitions block each other, giving good separation in the entry table as to which match recognition caused the first timeout condition, and generating only one service request. Either match performs timebase captures which do not overwrite captures by transitions.

#### **35.15.5.4.3.2 Either Match, Blocking, Double Transition (em\_b\_dt)**

In double transition mode each transition is related to one match recognition. TDLA assertion captures its related timebase, blocks Match A and enables TDLB. TDLB assertion blocks Match B, captures its related timebase and generates a service request. Match recognitions block each other, so if there is a match timeout condition on TDLA, only one match service request is generated. This mode is good for qualifying two signal transitions by match timeout mechanisms, with one service request. Note that although TDLA assertion does not block Match B recognition, the value captured in CaptureA by TDLA assertion is not overwritten by this recognition. The second transition blocks Match B. Either match performs timebase captures which do not overwrite captures by transitions.

#### **35.15.5.4.3.3 Either Match, Non Blocking, Single Transition (em\_nb\_st)**

On an input signal, this is a double timeout mechanism of independent match recognitions of two different timebases. The match recognitions do not block each other, such that the microcode can check if one or two match recognitions occurred before their related signal transition. The signal transition detection (by IPACA) asserts TDLA, blocks both matches, captures both time bases and generates a transition service request, indicating that none of the two timeout conditions occurred. Any combination can be easily resolved by microcode (for example, signal transition after Match A and before Match B, or signal transition after both Match A and Match B).

Another possible use of this mode is allocating one match recognition for transition timeout and the other for another non-critical timed task, adding functionality to a single channel. Since the transition detection blocks both match recognitions, the match recognition of the other timed task is based on the fact that the comparator checks greater-equal conditions. It may be delayed if it occurs in the period between the signal transition detection (which blocks it) and the time TDLA is negated by microcode. If matches are enabled during the service, the same code can check if the match recognition of the timed task occurred in this period, by negating TDLA and writing to the CHAN register its own value (in order to update the MRLA flag in the branch logic).

#### **35.15.5.4.3.4 Either Match, Non Blocking, Double Transition (em\_nb\_dt)**

In this mode each transition is related to one match recognition, and the match recognitions are independent of each other. This mode can be used to give independent timeout conditions for the first and the second signal transition recognitions, and call service in any case of any timeout condition.

The first transition detection programmed in IPACA sets TDLA, captures its related timebase, blocks Match A recognition and enables TDLB assertion. The second transition detection programmed in IPACB sets TDLB, blocks Match B recognition, captures its related timebase and generates a service request. Any match recognition that occurs captures its related time base and generates a match service request, independent on the other match recognition.

#### **35.15.5.4.3.5 Match B Request, Single Transition (m2\_st)**

On an input signal, this mode provides an open window filter for a single signal transition. MRLA assertion opens the window, and enables transition detection on TDLA from this time on. MRLB assertion blocks Match A (by negating MRLEA), providing conditional window opening, because transitions are indirectly blocked. It also generates service request, but if it happens after Match A it does not block transitions, providing a non-blocking timeout mechanism for the estimated signal transition time (typically it indicates a missing transition, or mis-prediction of the transition time).

Transitions can be detected from the microcycle following MRLA assertion. The Transition A detection asserts TDLA, blocks both matches, captures both timebases and generates service request.

Using this mode, the channel can replace software open window filtering of qualified transitions with the channel hardware window. The window opening and timeout can be scheduled for any of the two time bases or combination of them. Typically, Match A will be used to open a prediction window, and Match B will be used as a timeout condition

which does not close the prediction window. This configuration improves noise immunity from early signal transitions, and reduces the probability for blocking late signal transitions due to timeout mis-prediction.

Using these conditions, the microcode can easily resolve the state:

- If TDLA and MRLA are asserted and MRLB negated, signal transition is in the expected range.
- If MRLA and MRLB are both asserted, and TDLA is asserted, the signal transition had a timeout condition due to Match B mis-prediction.
- If MRLB is asserted and TDLA negated, a timeout condition occurred, and the expected signal transition had not occurred yet.
- If MRLA is negated and MRLB is asserted, the conditional window did not open at all (for example: a time window is open only after a specific angle, otherwise it is not opened).

#### **35.15.5.4.3.6 Match B Request, Double Transition (m2\_dt)**

This mode is used as an open window filter for two signal transitions. In this case the Match A recognition opens the window (unless Match B recognition occurred first), and Match B recognition blocks Match A and generates a match service request. It is similar to m2\_st, but in this case, it is the second transition that blocks Match B. MRLB assertion is a global timeout condition for the two pulses. Like m2\_st, MRLB can conditionally eliminate the window from opening.

Using the TDLA, TDLB, MRLA and MRLB conditions, the microcode can easily resolve the state, in a similar manner as m2\_st, with additional information on the second transition (TDLB).

#### **35.15.5.4.3.7 Both Match Request, Single Transition (bm\_st)**

On an input signal, this is a double timeout mechanism on two different time bases. Both match recognitions must occur before the signal transition to generate a match timeout service request. Assertion of TDLA blocks both Match A and Match B recognitions, and captures both time bases, indicating there was no double timeout condition from both time bases.

Using the same timebase implements two timeout conditions, the first only sets its related MRL and the second generates a service request. Using these flags allows the microcode to check if one or both match recognitions precede the signal transition.

### 35.15.5.4.3.8 Both Match Request, Double Transition (bm\_dt)

In this mode the first transition detection does not block matches, since both match recognitions are required to generate a match service request. The second transition detection asserts TDLB, blocks Match A and Match B, captures its related timebase and generates transition service request. In this mode, a Match A recognition which occurs after the assertion of TDLA does not capture a new value in CaptureA, to preserve the actual signal transition time. Assertion of TDLA, however, always captures its related timebase.

This mode allows putting a double match timeout condition on the second transition. Typically, a pulse trailing edge timing can be checked against two time bases, to indicate if the pulse has not ended when both MRLA and MRLB are asserted. When a transition service request is generated by TDLB assertion, the state of MRLA and MRLB indicates which timeout condition occurred, if any.

### 35.15.5.4.3.9 Ordered Mode with Match B Request, Single Transition (m2\_o\_st)

On an input channel, this mode provides a closing window filter for a single signal transition. Match A assertion captures its programmed time base in CaptureA, opens the filter window (enables assertion of TDLA), and enables assertion of MRLB. Match B recognition captures its related timebase, closes the window (disables assertion of TDLA) and generates a service request. Due to Match A and Match B ordering, the window is opened for at least one microcycle. Match B recognition indicates a window timeout condition which blocks late signal transitions, outside the prediction window. Transition detection blocks both matches, indicating the transition occurred inside the estimated window. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. When TDLA is asserted inside the window range it disables both matches, captures both time bases and generates a transition service request.

Using this mode, the channel can replace software window filtering of qualified transitions with the channel hardware window. The window opening and closing time can be scheduled for any of the two time bases or a combination of them.

### 35.15.5.4.3.10 Ordered Mode with Match B Request, Double Transition (m2\_o\_dt)

In this mode the channel logic implements a window filter for two detected signal transitions. MRLA assertion captures its related timebase and enables the assertion of both TDLA and TDLB. MRLB assertion captures its related timebase and disables the assertion of both TDLA and TDLB. Transitions can be detected from the microcycle following MRLA assertion until the microcycle on which MRLB is asserted. The first

signal transition (following MRLA assertion) asserts TDLA, captures its related timebase and enables assertion of TDLB. The second signal transition detection asserts TDLB, blocks Match B, captures its related timebase and generates the service request.

If both signal transitions occur inside the scheduled window, Match B recognition is blocked. If one or both signal transitions do not occur inside the scheduled window, Match B recognition generates a match service request and blocks further transition detections. The microcode can resolve the state using MRLA, MRLB, TDLA and TDLB, which affect the entry point selection.

#### 35.15.5.4.3.11 Single Match Enhanced Mode (sm\_st\_e)

This is an enhanced single transition and single match channel mode which provides timing information of the digital filter delay.

The CaptureA register captures the timebase selected by TBSA due to transition detection specified by IPACA or match recognition, as in sm\_st mode. Initially, the CaptureB register continuously captures the unfiltered IPACB-selected signal transitions from the digital filter input, directly from the signal synchronizer. When an IPACA-qualified, filtered transition detection occurs, TDLA is set, MRLA assertion is blocked, and, in addition, captures into CaptureB are also blocked. On service, CaptureA and CaptureB (copied into ERTA and ERTB) holds the time of the qualified transition detection (ERTA), and the time of the last signal transition at the input of the digital filter (ERTB). Subtracting the time in ERTB from the time in ERTA provides the delay of the digital filter.

In a quiet environment, the two captures provide the accurate delay of the digital filter in granularity of two eTPU clocks. In a noisy environment, false transitions may be detected at the input of the digital filter due to the noise, and the delay measurement may be reduced, especially if IPACB selects both edge detection. The microcode can do sanity checks on this value to recognize noise effects (for example: calculated delay is less than the minimum delay of the digital filter).

#### Note

In Channel 0, if eTPU\_TBR\_TBCR\_ENG $n$ [AM]=01 (Angle Mode), the unfiltered input comes from TCRCLK input and the filtered input comes from the TCRCLK filter output. The edge is selected by IPACA/B, and is independent of the edge selection by eTPU\_TBR\_TBCR\_ENG $n$ [TCR2CTL].

### 35.15.5.4.3.12 Single Match, Single Transition (sm\_st)

In this mode the channel logic is functionally back-compatible to a TPU3 single action channel, but a match or transition detection captures at once both timebases. The mode recognizes a single transition with single match timeout. Either TDLA or MRLA generates service request and captures both timebases. Assertion of TDLA blocks future assertions of MRLA.

### 35.15.5.4.3.13 Single Match, Double Transition (sm\_dt)

In this mode, the first transition detection asserts TDLA, captures a timebase in CaptureA and enables TDLB. The second signal transition asserts TDLB, blocks Match A, captures a timebase in CaptureB and generates a service request.

Match A (before TDLB) captures into CaptureB the timebase selected by TBSA, in order not to overwrite the captured value of TDLA.

This mode is used for scheduling one timeout condition on two input signal transitions (pulse timeout).

## 35.15.5.4.4 Channel Modes on Output Signal Generation

Since channel logic can generate output signal transitions based on Matches, the channel can be viewed as working in the following primary mode groups for signal generation:

- Single Match: em\_b\_st, sm\_st, sm\_st\_e, em\_b\_dt, sm\_dt
- Double Match: em\_nb\_st, bm\_st, m2\_st, m2\_o\_st, em\_nb\_dt, bm\_dt, m2\_dt, m2\_o\_dt

The channel logic supports various match channel modes with single/double match, as explained in the following subsections.

### 35.15.5.4.4.1 Either Match, Blocking Modes (em\_b\_st, em\_b\_dt)

On an output signal these modes are useful when using two different time bases to set a required signal transition. The first match condition which is met sets a required pin action, captures both time bases, blocks any effects of the other recognition, and generates a service request. Because the first match recognition blocks the other, the microcode can get good separation in the function entry table as to which match caused the timeout first, and both time bases are captured, enabling the microcode to compare one timebase to the other at the moment of the match recognition. These modes can be used for:

- Scheduling a required pin action to the first match recognition of two different time bases.
- Canceling a programmed pin action scheduled on one time base by match on another timebase (as a consequence of [Table 35-353](#)). Microcode has to set the OPAC register of the canceling match to no-action and the OPAC register of the other match to the required pin action which may be blocked. If Match A is the canceling match, it blocks the pin action also in case of two matches at the same time, since it has priority in this case. If Match B is the canceling match, it does not block the pin action in case of two matches at the same time.

#### **35.15.5.4.4.2 Either Match, Non Blocking Modes (em\_nb\_st, em\_nb\_dt)**

On an output signal these modes are useful in combination with the ME bit set on the entry point, to define an interlaced operation. For example, each match recognition can set a pin action, and the second pin action is not sensitive to microcode latency (ME bit asserted). Example for usage is PWM interlaced function on which the latency is determined by the period and not the duty cycle.

Another possibility is using one match for pin actions and the other match for an unrelated timed task without pin action (double the functionality of a single channel).

#### **35.15.5.4.4.3 Match B Request Modes (m2\_st, m2\_dt)**

On an output signal, these modes can generate narrow pulses or do conditional pin actions. A conditional pin action means that the pin state is changed only if the match recognitions occurred in the correct order, since the Match B recognition which generates the service request also has priority over the pin action and blocks future Match A recognitions.

Setting OPACA to a desired pin action and OPACB to no-action, and using different time bases for Match A and Match B defines a conditional OPACA pin action which can be blocked by Match B recognition. For example, setting Match A on time and Match B on angle can limit the pin action to a maximum angle value.

When pulses are generated, the service is requested at the trailing edge of the pulse, after MRLB is asserted.

#### **35.15.5.4.4.4 Both Match Request Modes (bm\_st, bm\_dt)**

On an output signal, each match recognition can affect the pin state, and capture its programmed time base. This way the pin action can be programmed separately for both match recognitions. For example, both match recognitions can negate the signal, and

service request is generated after both conditions are met. This mechanism can set two conditions to do a required pin action, and the first recognition changes the signal, but service is called only after both conditions occur.

When using the same time base, these modes can generate narrow pulses in any required order. For example, in a PWM function, when duty cycle is below 50% the function can get service on the low time and program the pulse to the required duty cycle of the high time. When duty cycle is equal or above 50%, the function can get service on the high time and program a negative pulse with the width of the required low time. To switch between the two states the function can program once the same transition time to MatchA and Match B with a required pin action, and on the next service program double match for the new state.

Another usage is generating a required pin action on one programmed time and service request later on another time, after the second match recognition occurs, or capturing some timebase on one time and generating a required signal transition and service request later.

#### **35.15.5.4.4.5 Ordered Modes with Match B Request (m2\_o\_st, m2\_o\_dt)**

The order of the match recognitions imply that OPACA register programmed pin action always precede the OPACB register pin action. Setting OPACA to no-action, based on the greater-equal comparator, enables using Match A on one time base to delay the signal effect of Match B on the other time base. This method implements a conditional pulse extension or conditional delay on signal transition.

These modes can also be used for deferred pulse generation with microcode service request after its trailing edge (if Match A condition comes after Match B condition). Another option is having Match A recognition associated with output pin actions and Match B recognition for a timed microcode task which has to be scheduled at a programmed time which may be delayed by the Match A pin action.

#### **35.15.5.4.4.6 Single Match Modes (sm\_st, sm\_dt, sm\_st\_e)**

There is no difference between plain and enhanced Single Match modes on an output signal.

In this mode the channel logic is functionally back-compatible to a TPU3 single match output channel. Match A recognition generates service request and sets the pin state according to OPACA register. It captures at once the timebase selected by TBSA in CaptureA and the timebase selected by TBSB in CaptureB.

### 35.15.5.4.4.7 Match/Transition Pin Action Conflict Resolution

In output signals, matches and/or transitions automatically cause pin actions defined by the OPACA/B and/or IPACA/B channel control registers (see [Pin Control Registers](#)). Simultaneous matches/transitions may be associated with different, possibly contradictory, pin actions. These conflicts are resolved according to the table below.

If an OPACA/B=000 (no action) prevails over non-zero OPAC according to the table below, then if Match A/Transition A and Match B/Transition B occur simultaneously, no output pin action occurs, that is: a match on the action logic with OPAC=000 inhibits simultaneous actions of the other OPAC, if prevailing according to the following table. That also applies when output actions are caused by inputs (OPAC=1xx).

**Table 35-353. Simultaneous Match Pin Action Priority**

| Channel Mode        | Priority                                                       |
|---------------------|----------------------------------------------------------------|
| em_nb_st / em_nb_dt | OPACA                                                          |
| em_b_st / em_b_dt   | OPACA                                                          |
| bm_st / bm_dt       | OPACA                                                          |
| m2_st / m2_dt       | OPACB                                                          |
| m2_o_st / m2_o_dt   | in these modes there is no possibility of simultaneous matches |
| user-defined        | OPACB if M2BM1 = 1 and M1BM2 = 0, OPACA otherwise              |

### 35.15.5.4.5 Combining Input and Output Signals

The processing of input signal can be combined with output signal generation. A detected input transition can trigger an output signal edge, even without microcode intervention, by using OPAC options 1xx.

The channel set-up examples below show these two capabilities combined (see the figure below).

The **first example** implements a fast (no microcode intervention) short-circuit protection feedback mechanism for driving high-current output devices. The signal after the high-current driver feeds back to the channel input. The input signal is normally delayed from the output signal by the device turn-on delay. After the channel output turns on, the channel logic must check if the driver output (connected to the channel input) follows the driven value after the maximum device turn-on delay. If it does not, the driver output is probably shorted, and the channel output must be turned off immediately to avoid damaging the device.

Match A causes the output to be driven high (for simplicity the output and input signals are shown as positive logic). It also causes a transition A, because  $IPACA=100$  and the input is still low. Match B occurs after the expected driver delay, and causes a service request. If the output is shorted, a Transition B occurs on Match B because  $IPACB=100$ . This will cause the output to go low immediately, because  $OPACB=100$ .

In the **second example**, an output pulse is generated from an input transition without microcode intervention. Match A opens a window for transitions and also enables Match B. A rising edge on input sets output high. On Match B the window closes, and input signal is checked: if sampled high, the output resets; otherwise it stays high.

In the **third example**, a pulse is generated depending on the value sampled on the input signal at a predetermined time. Match A samples the input signal, causing a Transition. Low level on input sets output low, otherwise it stays high. Match B sets output high. In both cases a service request is issued (microcode intervention), at the beginning and at the end of the pulse (Match B), if required ( $SRI := 0$ ).

### Note

When  $IPAC = 1xx$ , a match event can cause simultaneously a Match recognition and a Transition detection. Depending on the Channel Mode, these Match and Transition may have conflicting effects on other Transition/Match blocking or enabling. In these cases, blocking always prevails over enabling, effective on the next microcycle.

## Example 1: Short-circuit protection feedback

IPACA := 100; OPACA := 001; MatchA := output activate time;  
 IPACB := 100; OPACB := 100; MatchB := MatchA + max. high-current driver turn-on delay;  
 PDCM := bm\_dt;

## Example 2: Pulse generation on windowed input transition

IPACA := 001; OPACA := 101; MatchA := window open time;  
 IPACB := 101; OPACB := 100; MatchB := window close time, input sampling;  
 PDCM := m2\_o\_dt;

## Example 3: Pulse generation on input sampling

IPACA := 100; OPACA := 100; MatchA := window open time, input sampling;  
 IPACB := 000; OPACB := 001; MatchB := window close time = MatchA + pulse width;  
 PDCM := em\_nb\_dt;

### 35.15.5.5 Channel Link

A channel can issue service requests to other channels through microcode, by assigning to the write-only microengine register LINK (refer to [LINK Register](#)) a value which specifies the target channel of the Link Service Request, as shown in the figure below.

Writing to the LINK register issues a link request to the target channel, setting its LSR flag. Each channel has its own LSR flag, which can be tested as a microcode branch condition (see [Conditional/unconditional branch](#)) and reset through the microcode field LSR (see [Clear Link Service Request](#)). The link branch condition samples, at the TST start, the value used to calculate the Entry Point.

Writing LINK with another channel target value in the same thread issues a Link Service Request to the new target, without negating the service request to the former one. This allows a channel to issue service requests to any number of channels, including itself. Neither LINK nor LSR microengine accesses are qualified by the CHAN register, i.e., they always access the serviced channel LINK and LSR, regardless of the value written in CHAN.

Channels can also receive link service requests from the Shared Subsystem Units (see [Shared Subsystems support](#)). These links are set by the interrupt signals from the shared subsystem and are level-sensitive, that is, they keep on requesting link service as long as the interrupt is active. Therefore, it is not enough to clear the link service request through the LSR instruction field: one must clear beforehand the respective shared subsystem unit interrupt source.

If microcode executes an instruction with field LSR=0 (clear Link Service Request), the link branch condition is cleared. However, the link service request itself is cleared only if no link from other channel was received by the serviced channel during the same thread<sup>30</sup>. Note that this applies only to links that come from the other engine or the same channel: if only Shared Subsystem link was received during the thread, the link service is also cleared with field LSR=0. If microengine clears LSR of its channel and, simultaneously, Link Service Request is issued to the current serviced channel, the branch condition is cleared but the link service request remains pending.

|                  |   |                       |                |   |   |   |   |
|------------------|---|-----------------------|----------------|---|---|---|---|
| 7                | 6 | 5                     | 4              | 3 | 2 | 1 | 0 |
| Engine Selection |   | Reserved <sup>1</sup> | Channel Number |   |   |   |   |

NOTES:  
<sup>1</sup> reserved bit must be written 0.

**Figure 35-316. Microengine LINK Register**

30. That can only happen if the link service request came from the other Engine, or from the serviced channel itself.

A channel can issue Link Service Requests to channels in any of two Engines, determined by the LINK register field Engine Selection (2 bits), as shown in the following table. In a Single Engine eTPU, Link is ignored when sent to the other engine, or engine 2.

**Table 35-354. LINK Engine Selection**

| Engine Selection | Description      |
|------------------|------------------|
| 00               | this Engine      |
| 01               | Engine 1         |
| 10 <sup>1</sup>  | Engine 2         |
| 11 <sup>1</sup>  | the other Engine |

1. ignored in Single Engine eTPU.

There is no explicit hardware mechanism to allow the thread to identify the link service request source, but it can be done by a software protocol using SDM parameters. All links are negated on reset.

### 35.15.5.6 Enhanced Digital Filter - EDF

The EDF eliminates passing of signal transitions which are caused by noise. Its purpose is to eliminate false transition service requests caused by noise pulses which are shorter than a programmed width.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The EDF has three modes of operations, selected by the CDFC field in [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#). These modes offer selections of trade-off between noise immunity and signal latency. CDFC also allows the filter to be bypassed. [Table 35-355](#) gives an example of minimum detected signal pulse and maximum filtered noise pulse in the three EDF operation modes. In Angle Mode, if AM=01, the EDF in channel 0 is replaced with the digital filter and synchronizer of the TCRCLK signal. In this mode, channel 0 works in combination with the Angle Counter logic, and their operation is fully synchronized.

Following subsections provide the functional description of the eTPU channel digital filter.

### 35.15.5.6.1 Two-Sample mode

In this mode the EDF works like the TPU2/3 digital filter. It uses the filter clock which is the eTPU clock divided by (2, 4, 8,..., 256) as a sampling clock. The filter clock is selected by the FPSCK field in [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#). The EDF compares two consecutive samples. If both samples have the same value, the input signal state is updated. Note that when the FPSCK field selects the eTPU clock divided by two, the EDF works like the TPU1 four-clock digital filter.

### 35.15.5.6.2 Three-Sample mode

In this mode, like in the TPU2/3 mode, the EDF uses the filter clock as a sampling clock. The EDF compares three consecutive samples. If all three samples have the same value, the input signal state is updated.

The Three-Sample mode gives more signal latency than the Two-Sample mode, but also better noise immunity and better ratio between minimum detected signal pulse to maximum filtered noise pulse. When a certain filter clock frequency is selected for Two-sample mode, double filter clock frequency can be selected to get better latency in Three-sample mode.

### 35.15.5.6.3 Continuous mode

In this mode the EDF compares all the values sampled at the rate of eTPU clock divided by two, between two consecutive filter clock pulses. If the signal is continuously stable for the entire digital filter clock period (i.e all the samples have the same signal value), the input signal state is updated.

This method gives the same latency and the same ratio between minimum detected signal pulse to maximum filtered noise pulse, as the Two-Sample mode, as long as there is no noise. Each sampled noise delays the signal transition detection by at least a whole digital filter clock period.

The Continuous mode gives the best noise immunity by comparing multiple samples of the noise. On the other hand, when a short noise pulse appears in the middle of the filter clock period at the same time of a real signal transition, the Continuous mode may reject a real signal transition and delay the response to the first filter clock period in which the signal is continuously stable. This may add to the latency and also to the minimum detected signal pulse in a noisy environment.

### 35.15.5.6.4 Bypass Mode

In bypass mode the signal that feeds the edge detection comes directly from the output of the synchronizer, not filtered. Bypass mode automatically makes the channel logic work in T2/T4 timing mode (see [Channel timing modes](#)).

### 35.15.5.6.5 Filter clock prescaler

Each channel configured as an input has an associated synchronizer followed by a digital filter connected to the signal that samples signal transitions. After reset, the digital filter filters out high and low pulse widths smaller than the period of two eTPU clocks with eTPU\_SCR\_ECR\_ENG $n$  field FCSS=0, or 1 eTPU clock with FCSS=1 (see [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#)), preventing these transitions from being input to the transition detect logic. For FPSCK=0 and FCSS=0, the synchronizer and digital filter are guaranteed to pass pulses that are as wide as or wider than four eTPU clocks, meaning a minimum period of 8 eTPU clocks. These figures are halved by setting FCSS=1. By changing the FPSCK field in [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#) the user can select a lower clock rate for the filter signal to define wider valid pulses and filter out wider noise pulses. The filter prescaler clock control is a division of the eTPU clock. To guarantee pulse detection by the digital filter, the pulse must cover at least the stated number of samples at the filter clock rate. For example, a two sample digital filter must sample two points in the pulse to detect it. The table below shows the minimum guaranteed detected pulse width and the maximum filtered noise pulse width. The table refers only to the digital filter operation. The external pulses may have to be wider (to ensure detection) or narrower (to ensure filtering) depending on the rise/fall delay differences in the MCU receivers and internal logic. Delays introduced by synchronizer, filter and edge detection logic are explained in [Input/Output Signal Delays](#).

The TCRCLK signal also has a synchronizer and a filter. The FCSS bit has no influence on the clock prescaler of the TCRCLK filter, which works like the channel filter with FCSS=0.

**Table 35-355. Pulse widths and delays**

| Filter control (FPSCK) |          | Filter clock period <sup>1</sup> | Min. width guaranteed detected / max. width filtered<br>(min. filter delay / max. filter delay) <sup>1</sup> |                                              |
|------------------------|----------|----------------------------------|--------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| FCSS = 0               | FCSS = 1 |                                  | Two-Sample or Continuous mode                                                                                | Three-Sample or Integrator <sup>2</sup> mode |
| not avail.             | 000      | 1                                | 2 / 1 (2 / 3)                                                                                                | 3 / 2 (3 / 4)                                |
| 000 <sup>3</sup>       | 001      | 2                                | 4 / 2 (3 / 3)                                                                                                | 6 / 4 (5 / 5)                                |

*Table continues on the next page...*

**Table 35-355. Pulse widths and delays (continued)**

| Filter control (FPSC) |            | Filter clock period <sup>1</sup> | Min. width guaranteed detected / max. width filtered<br>(min. filter delay / max. filter delay) <sup>1</sup> |                                              |
|-----------------------|------------|----------------------------------|--------------------------------------------------------------------------------------------------------------|----------------------------------------------|

| 001                   | 010        | 4                                | 8 / 4 (5 / 7)                                                                                                | 12 / 8 (9 / 11)                              |
| 010                   | 011        | 8                                | 16 / 8 (9 / 15)                                                                                              | 24 / 16 (17 / 23)                            |
| 011                   | 100        | 16                               | 32 / 16 (17 / 31)                                                                                            | 48 / 32 (33 / 47)                            |
| 100                   | 101        | 32                               | 64 / 32 (33 / 63)                                                                                            | 96 / 64 (65 / 95)                            |
| 101                   | 110        | 64                               | 128 / 64 (65 / 127)                                                                                          | 192 / 128 (129 / 191)                        |
| 110                   | 111        | 128                              | 256 / 128 (129 / 255)                                                                                        | 384 / 256 (257 / 383)                        |
| 111                   | not avail. | 256                              | 512 / 256 (257 / 511)                                                                                        | 768 / 512 (513 / 767)                        |

1. This table shows pulse widths and delays in number of periods of the eTPU clock.
2. Integrator mode is available for TCRCLK filtering only, see [TCRCLK digital filter](#).
3. These delays also apply to the TCRCLK filter when TCRCF selects eTPU clock/2 as filter clock.

### Note

The TCRCLK filter is clocked as if FCSS=0, always dividing eTPU clock /2 using FPSC, regardless of the FCSS field.

## 35.15.5.7 Channel timing modes

Channels can work on two different timing schemes, defining the period of channel clocking, tied to T2 and T4 microengine phases, as explained in subsections below. Microengine T2 and T4 phases are shown in [Microcycle and I/O timing](#).

### 35.15.5.7.1 T2 channel timing

In T2 timing mode the channel event state can only be updated every two eTPU clocks (see [Figure 35-346](#)). Pin state, TDLs, MRLs and Capture registers are updated on the microengine's T2 clock phase. MRLE clears also happen on T2, but MRLE setting occurs on T4, together with the Match register write by microcode (see [Write Channel Match and UDCM Registers](#)).

Channels work in T2 timing mode when either the T4DIS field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#) is 1 or all the following conditions are true:

- The TCR1CS field in [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#) is 0.
- The Enhanced Digital Filter is not configured as bypass (see [Enhanced Digital Filter - EDF](#)).
- The FCSS field in [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#) is 0 (see [Filter clock prescaler](#)).

### 35.15.5.7.2 T2/T4 channel timing

In T2/T4 timing mode the channel event state can be updated on any eTPU clock (see [Figure 35-347](#)). Pin state, TDLs, MRLs, MRLEs, and Capture registers are updated either on microengine's T2 or T4 clock phases. MRLE clears can happen on T2 or T4, but MRLE setting occurs on T4 only, together with the Match register write by microcode (see [Write Channel Match and UDCM Registers](#)).

Channels work in T2/T4 timing mode when the T4DIS field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#) is 0 and either one of the following conditions are true:

- The TCR1CS field in [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#) is 1.
- The Enhanced Digital Filter is configured as bypass (see [Enhanced Digital Filter - EDF](#)).
- The FCSS field in [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#) (see [Filter clock prescaler](#)).

T2/T4 timing mode demands special care on channel microcode that reprograms a match in a thread with matches enabled (entry point ME=1, see the “Entry Points” section). When the match register is written and the MRLA/B flag(s) is(are) cleared in the same instruction, a match can occur after MRLA/B is cleared, together with the set of respective MRLE. In this case, both MRL and MRLE will be set, and a match service request will occur if enabled. However, the match happened on the old match value, not on the new (reprogrammed) one. In order to prevent this ambiguity to the code that services the match, it is advisable to clear the MRLE (besides MRL) together with the

match reprogramming, avoiding the match on the old value to occur while the new match value is being written. The set of the MRLE due to match reprogramming prevails over the MRLE clear, thus allowing the new programmed match to occur in the future.

A similar case occurs when a match is blocked by a transition, the blocking TDL is cleared and the blocked match is reprogrammed at the same instruction: in T2/T4 timing mode: a match can occur on the old match value. The solution is the same as the case above, that is, clear the respective MRLE in the same instruction.

## 35.15.6 Time bases

Each eTPU engine has two Time Counter Registers, TCR1 and TCR2. They provide 24-bit time bases, shared by all 32 channels. Any channel can use both time bases to:

- Match channel's internal registers MatchA or MatchB;
- Capture time base value to channel's internal registers, CaptureA and/or CaptureB, when a match recognition or an Input transition detection occurs. For more information on channel events refer to [Enhanced Channels](#).

The TCR1 and TCR2 counters are accessible by the microcode for read and write operations. Its current value is used for getting the current time, and the captured values are used for channel relative time calculations of future events. When they are written at the same time they are incremented from any clock source, the written value prevails.

TCR1 with `eTPU_TBR_TBCR_ENGn[TCR1CS]=0` and TCR2 values are updated in T2 and read in T4 (see [Microcycle and I/O timing](#)). TCR1 can also work at full-speed eTPU clock, and so be updated on both T2 and T4, when `eTPU_TBR_TBCR_ENGn[TCR1CS]=1`. Both TCR1 and TCR2 values can be imported from or exported to the STAC bus. When their values are imported ( STAC Clients), these registers are written from the STAC bus and can only be read by microcode.

The TCR2 counters between the two Engines are out of phase by 1 eTPU clock, even when Time Bases are shared between them through STAC. It also applies to TCR1 counters if `eTPU_TBR_TBCR_ENGn[TCR1CS]=0`, but they can be in phase otherwise.

### 35.15.6.1 Timer Count Register 1 - TCR1

TCR1 can be used in the following modes:

- Internally Clocked Mode

## Functional description

- Externally Clocked Mode
- STAC Bus Client Mode

The host program can read TCR1 time base through [eTPU Engine 1 Time Base 1 \(TCR1\) Visibility Register \(eTPU\\_TBR\\_TB1R\\_ENG1\)](#) and [eTPU Engine 2 Time Base 1 \(TCR1\) Visibility Register \(eTPU\\_TBR\\_TB1R\\_ENG2\)](#).

The TCR1 bus runs through all the local engine channels. In channels which select TCR1 as MatchA and/or MatchB source, when its value is greater or equal to the programmed match value, a Match A and/or Match B event occurs on that channel. A recognized match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels see [Enhanced Channels](#).

### 35.15.6.1.1 Externally Clocked Mode

TCR1 can be driven externally by the TCRCLK input, after the digital filter. The TCR1 clock source is configured by the TCR1CTL bit, as shown in the following figure. For more information on clock source selection, see [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#).

Figure 35-317. TCR1 clock selection

### 35.15.6.1.2 Internally Clocked Mode

TCR1 can be driven by the eTPU clock or eTPU clock divided by 2, before the prescaler. TCR1CTL can also be used to freeze TCR1 clock independently of TCR2 (unlike GTBE).

### 35.15.6.1.3 TCR1 clock prescaling

Any clock source selected by TCR1CTL is prescaled by a factor of 1 to 256, selected by the TCR1P field in [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#). For more information on prescaler configuration see [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#). The TCR1 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR1P when the eTPU GTBE input is asserted. When TCR1 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR1P becomes effective. When TCR1 is written by microcode, the prescaler is reloaded with TCR1P and it becomes effective, if the eTPU GTBE input is asserted.

### 35.15.6.1.4 STAC Bus Client Mode

In this mode the TCR1 register is continuously updated from the STAC bus, and the clock selection and prescaling logic becomes ineffective. It is not writable by the microcode, and when read, it reflects the STAC bus imported value. The use of EAC is not allowed in client mode. This mode is configured through [eTPU Engine 1 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG2\)](#).

### 35.15.6.1.5 STAC Bus Server Mode

TCR1 bus can be exported to the STAC bus as a server, providing time information to other peripherals. This mode is configured through [eTPU Engine 1 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG2\)](#).

## 35.15.6.2 Timer Count Register 2 - TCR2

The TCR2 is a 24-bit counter which can be used in the following modes:

- Pin Transition Mode: Count the rise, fall or both transitions of TCRCLK signal.
- Angle Clock Mode: Count internal tooth angle in combination with the eTPU Angle Counter (EAC) hardware which implements an Angle PLL, and generates angle information to the channels. This mode is targeted for angle based applications.
- STAC (STAC) Bus Client Mode: TCR2 is driven by an external source (see [STAC Bus Client mode](#)).

- Gated Mode: Count with rate derived from the eTPU clock divided by eight. The TCRCLK signal is used to gate this count, enabling pulse accumulator operations.
- Internally Clocked Modes: TCR2 is driven by internal clock, with count rate of eTPU clock divided by eight.

All clock sources pass through a prescaler. In addition, the TCR2 count can be originated from the EAC which is a hardware angle clock and angle counter. Figure 35-318 shows the diagram for TCR2 clock control. When TCR2 is not driven by the EAC or STAC, the eTPU\_TBR\_TBCR\_ENGn[TCR2CTL] field selects the clock source, also allowing TCR2 to be frozen independently of TCR1 (see eTPU Engine 1 Time Base Configuration Register (eTPU\_TBR\_TBCR\_ENG1) and eTPU Engine 2 Time Base Configuration Register (eTPU\_TBR\_TBCR\_ENG2)). When in Angle Mode, TCR2CTL selects the TCRCLK edge sensitivity.

**Figure 35-318. TCR2 clock control**

The TCRCLK signal input is passed through a synchronizer and a programmable digital filter. In Angle Mode with AM=01, synchronizer and filter are also used in Channel 0, replacing its input synchronizer and filter, to get the same timing in the EAC and Channel 0. The TCRCLK synchronizer is an improved filter that provides best latency while maintaining proper noise filtering (see the field TCRCF in eTPU Engine 1 Time Base Configuration Register (eTPU\_TBR\_TBCR\_ENG1))

The TCR2 bus runs through all the local engine channels. It transitions on clock T2 (see Microcycle and I/O timing). In channels which select TCR2 as MatchA and/or MatchB source, TCR2 value is compared against MatchA and/or MatchB registers. A recognized

match event sets its related Match Recognition Latch 1 or 2, and according to the Predefined Channel Modes (PDCM) it may generate a channel service request. For details on eTPU channels see [Enhanced Channels](#).

The TCR2 counter is accessible by the microcode for read and write operations. Its current value is used for getting the current counter value (representing signal transitions, time or angle), and the captured values are used for channel relative count calculations of future events. The TCR2 value is readable to the host through [eTPU Engine 1 Time Base 2 \(TCR2\) Visibility Register \(eTPU\\_TBR\\_TB2R\\_ENG1\)](#) and [eTPU Engine 2 Time Base 2 \(TCR2\) Visibility Register \(eTPU\\_TBR\\_TB2R\\_ENG2\)](#). When the TCR2 bus value is imported from the STAC bus (STAC client mode), TCR2 is not writable by the microcode, and read access from the microcode or from the host reflect the imported TCR2 value.

### 35.15.6.2.1 TCR2 clock prescaling

Except in Angle Mode, any clock source selected by TCR2CTL is prescaled by a factor of 1 to 64, selected by `eTPU_TBR_TBCR_ENGn[TCR2P]`. For more information on prescaler configuration, see [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#). The TCR2 Prescaler resets when the eTPU GTBE input is negated. After reset, it starts counting up to TCR2P when the eTPU GTBE input is asserted. When TCR2 increments (the eTPU GTBE input = 1), the prescaler starts a new count and the new TCR2P becomes effective. When TCR2 is written by microcode, the prescaler is reloaded with TCR2P and it becomes effective, if the eTPU GTBE input is asserted.

The counter that divides the eTPU clock by 8 before the prescaler also resets when the eTPU GTBE input is negated, or when TCR2 is written by microcode.

In Angle Mode the TCR2 prescaler is not used to directly increment TCR2, but can be used, selected by programming `eTPU_TBR_TBCR_ENGn[ATGC]=1`, as a clock source for the EAC generation of the angle ticks which increments TCR2. In this case, the TCR2 prescaler input is eTPU clock/2, independently of TCR2CTL. See [Generating the angle ticks](#) for details.

### 35.15.6.2.2 TCR2 Gated mode

TCR2 Gated mode is selected in the `eTPU_TBR_TBCR_ENGn[TCR2CTL]` field. In this mode the TCRCLK signal enables or disables transfer of the eTPU clock divided by 8 to the TCR2 prescaler. By programming the prescaler, TCR2 can run at rates from eTPU clock divided by eight down to eTPU clock divided by 512, in steps of eight eTPU clock

divisions. For more information, see [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#).

### 35.15.6.2.3 TCR2 Signal Transition modes

These modes are selected when eTPU\_TBR\_TBCR\_ENG $n$ [TCR2CTL] is set to rise, fall or "rise-and-fall". In these modes the TCRCLK signal is the TCR2 clock source, and its maximum transition rate depends on the TCRCLK digital filter mode of operation. The TCRCLK digital filter can be programmed to use the eTPU clock divided by two, or use the same filter clock of the channels, controlled by eTPU\_TBR\_TBCR\_ENG $n$ [TCRCF]. It contains an up-down counter which operates as a digital integrator, optimizing signal latency in the selected mode and clock rate.

When eTPU clock divided by two is selected, the synchronizer and the digital filter are guaranteed to pass pulses that are wider than four eTPU clocks (two filter clocks). Otherwise the TCRCLK is filtered with the same filter clock as the channel input signals. For details on TCRCLK and channels digital filter control, see [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#), [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#), and [Enhanced Digital Filter - EDF](#).

### 35.15.6.2.4 STAC Bus Client mode

In this mode the TCR2 register is continuously updated from the STAC bus, and the clock selection and prescaling logic becomes ineffective. It is not write accessible for the microcode, and when read, it reflects the STAC bus imported value. The use of EAC is not allowed in client mode. This mode is configured through [eTPU Engine 1 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG2\)](#).

### 35.15.6.2.5 STAC Bus Server mode

When TCR2 bus is exported to the STAC bus as a server, it can provide either time or angle bus to other peripherals, according to its operation mode. This mode is configured through [eTPU Engine 1 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG2\)](#). To provide sequential update of the STAC clients, the Angle tick rate must not be faster than the STAC programmed update rate. This requirement puts a limitation on the angle clock count rate on high rate mode. In this case the Angle and Angle Fraction accumulator (see [Angle Tick Generator](#) and [Figure 35-324](#)) are advanced at rate of eTPU clock divided by eight. Therefore, the STAC update rate for the Angle Bus must not be slower than eight eTPU clocks.

### 35.15.6.2.6 TCR2 bus in Angle Clock mode

In this mode the TCR2 counter operates as part of the eTPU Angle Counter (EAC). The TCR2 bus value reflects this angle representation in which it counts Angle Ticks. Angle Mode is selected when `eTPU_TBR_TBCR_ENGn[AM]=1`.

Note that when TCR2 works in Angle Mode, it does not count directly from the TCR2 clock input which indicates tooth signal transition. Its Angle counter is controlled by the Count Control and High Rate logic (see [Count Control and High Rate Logic](#)), which provides the interpolated pin position, and handle cases of missing tooth, acceleration, de-acceleration and mechanical corrections.

The EAC uses the TCRCLK signal to get the tooth transition indications. The `eTPU_TBR_TBCR_ENGn[TCR2CTL]` field has to be set for the appropriate tooth edge detection rise, fall, "rise-and-fall" or none. TCR2 count clock comes from the EAC control and not directly from the physical tooth. This way the EAC control processes the signal transitions and handles missing teeth and flywheel mechanical corrections. Note that when TCR2CTL selects "none" for tooth edge selection, the TCR2 is not necessarily frozen, but can still be incremented by the EAC logic.

In Angle Mode, eTPU channel 0, 1 or 2 operation is combined with the EAC operation. When channel 0 is selected for EAC operation, the TCRCLK digital filter is used both by the EAC and by channel 0 to get full synchronization between the two logics.

The eTPU Angle Counter (EAC) logic runs continuously and updates the TCR2 Angle counter, eliminating the microcode latency in updating the TCR2 value.

### 35.15.6.3 STAC interface

Both time bases TCR1 and TCR2 can be shared between the Engines and with other blocks in the same MCU. Each one of both eTPU engines can drive their time bases to the STAC (Shared Time and Count) bus, acting as a server, while any other block can capture the value into its resources and behave like a client. For further reference about the STAC bus operation see [eTPU Engine 1 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG2\)](#).

The eTPU can export to the STAC bus or import from the STAC bus the following internal resources:

- TCR1: Can be exported to or imported from the STAC bus. TCR1 can only be imported from STAC bus when the engine is not in Angle Mode. When TCR1 is imported from the STAC bus, it becomes read-only for the microcode and reflects the imported values. For details, see [Timer Count Register 1 - TCR1](#).
- TCR2: Can be exported to or imported from the STAC bus. TCR2 can only be imported from the STAC bus when engine is not in Angle Mode. When TCR2 is imported from the STAC bus, it becomes read-only for the microcode, and reflects the imported values. When exported to the STAC bus, TCR2 can work in either Angle Mode or as a free running counter associated with the TCRCLK signal. For details, see [EAC - eTPU Angle Counter](#).

Proper configuration of the following bits is necessary to determine what can drive the STAC bus: eTPU\_TBR\_TBCR\_ENGn[AM] and eTPU\_TBR\_STAC\_ENGn[REN2, RSC2], according to the following table.

**Table 35-356. STAC bus and host read sources**

| AM<br>(eTPU_TBR_TBCR_ENGn) | REN2, RSC2<br>(eTPU_TBR_STAC_ENGn) | TCR2 bus source<br>(Host read of<br>eTPU_TBR_TB2R_ENGn) | STAC<br>bus driver |
|----------------------------|------------------------------------|---------------------------------------------------------|--------------------|
| 00                         | 0x (disabled)                      | TCR2/Time                                               | ×                  |
| 01, 10 or 11               | 0x (disabled)                      | TCR2/Angle                                              | ×                  |
| 00                         | 11 (Server)                        | TCR2/Time                                               | TCR2/Time          |
| 01, 10 or 11               | 11 (Server)                        | TCR2/Angle                                              | TCR2/Angle         |
| 01, 10 or 11               | 10 (Client)                        | not allowed <sup>1</sup>                                |                    |

1. STAC client configuration in Angle Mode is also not allowed for TCR1.

Note that Angle Mode is not available for STAC bus clients: configuring both at the same time brings unspecified results and must be avoided. When TCR2 is a stand-alone counter or a STAC Bus server, the same value that is driven to the internal TCR2 bus is also exported to the STAC bus (either Time Count or Angle).

STAC bus configuration is provided by the eTPU\_TBR\_STAC\_ENGn fields REN1/2 and RSC1/2. REN1/2 enable the STAC interface to interact with the resource (either TCR1 or TCR2 bus). RSC1/2 configure the resource (either TCR1 or TCR2 bus) as Server or Client.

Each time base / angle count resource from each engine receives a unique 4-bit hard-wired address that identifies it as a potential server. This address is used by the STAC Controller to coordinate which resource will drive the bus at a given STAC time-slot. For any time-slot there is a server driving the bus upon selection of the STAC Controller, and there may be a client linked to that server by the eTPU\_TBR\_STAC\_ENGn fields bits SRV1/2 on each Engine. When the server address on the Red Line STAC bus matches

the value in SRV1/2, the client will load the STAC information into the appropriate resource. For information on eTPU STAC Bus configuration, see [eTPU Engine 1 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG1\)](#) and [eTPU Engine 2 STAC Configuration Register \(eTPU\\_TBR\\_STAC\\_ENG2\)](#).

The eTPU does not include a STAC Controller module, which is instantiated once in the system integration.

### Note

Setting a timebase as client of itself is not allowed.

#### 35.15.6.4 GTBE - Global Time Base Enable

**GTBE** enables time bases in both engines, allowing them to be started synchronously. GTBE is divided in two block interface signals: the eTPU GTBE output and the eTPU GTBE input. GTBE bit sets the eTPU GTBE output, and the eTPU GTBE input enables time bases to start. The eTPU GTBE output signal can be used by MCU integration for synchronization between eTPU time bases and time bases from other modules. If **GTBE** must enable only the eTPU time bases, the eTPU GTBE output is simply connected to the eTPU GTBE input. These two cases are shown in the figure below. Synchronization logic can be as simple as an OR logic gate.

Once the eTPU GTBE input transitions to 1, the Engine 1 Time Bases start 1 eTPU clock earlier than Time Bases in Engine 2, except when TCRCLK is selected as clock source or TCR1 when eTPU\_TBR\_TBCR\_ENG $n$ [TCR1CS]=1. This happens independently of prescaler values as long as they are the same for both engines, because the prescalers also freeze when the eTPU GTBE input = 0. Microcode can always write to TCR1/2 registers, with either value of the eTPU GTBE input.

### NOTE

The timebase prescalers are reset when the GTBE input is negated.

**Figure 35-319. Time base synchronization**

### 35.15.6.5 TCRCLK digital filter

The TCRCLK signal has an improved integrating digital filter with a 2-bit up-down counter. The counter counts up to 3 when a high signal level is detected, or down to 0 when a low level is detected. The signal state is updated to one when the counter stops at 3, or zero when the counter stops at 0. The `eTPU_TBR_TBCR_ENGn[TCRCF]` field (see [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#)) determines whether the TCRCLK signal input (after a synchronizer) is filtered with the same filter clock as the channel input signals (see [Enhanced Digital Filter - EDF](#)) or uses the eTPU clock divided by 2, and also whether the TCRCLK digital filter works in integrator mode or the same two sample mode as the channel filters (see [Table 35-339](#)).

The TCRCLK filter delay and prescaling determines the minimum detectable TCRCLK pulse widths and, therefore, its maximum frequency, as shown in [Filter clock prescaler](#) and [Table 35-355](#). The TCRCLK signal delay from the module input to TCR1/TCR2 incrementing or detection in the EAC logic is explained in [Input/Output Signal Delays](#).

## 35.15.7 EAC - eTPU Angle Counter

### 35.15.7.1 General

The EAC logic contains a mechanism which follows the flywheel angle, based on the tooth rate. This hardware works in combination with the TCRCLK signal, the TCR2 counter and Channel 0, 1 or 2 (depending on the eTPU\_TBR\_TBCR\_ENG $n$ [AM] field) to generate angle information on the TCR2 bus which is passed to all the local engine channels. The EAC helps to implement a digital angle PLL (see [Figure 35-323](#)), which combines hardware with microcode processing at channel 0, 1 or 2. The angle measurement is based on history knowledge of the tooth period, for predicting the period of the next tooth. The tooth period is partitioned into a programmable number of **Angle Ticks**. The eTPU application will use the divider in the MAC/Divide unit to calculate an integer and a fraction part of the angle tick such that the full tooth period gets the correct programmed number of angle ticks with no accumulated error.

Each single tooth can be divided in angle ticks, up to 1024. In a 60 teeth flywheel, 128 Angle Ticks per tooth provide resolution of ~0.05 degrees per tick, which meets the accuracy requirement of 0.1 degrees in current automotive applications.

The measurement of one tooth in angle ticks is independent on engine RPM; it is the tooth period itself (and the corresponding tick period) that is re-calculated for each new tooth, based on the difference between the estimated tooth and the actual detection.

For these applications, one of the eTPU channels 0, 1 or 2 is dedicated to service the physical tooth detection. Channel 0 shares the same filtered input as the TCRCLK signal to get the same timing as the EAC. The TCRCLK edge detection is selected by the eTPU\_TBR\_TBCR\_ENG $n$ [TCR2CTL] field for the EAC, and by IPACA/B on channel 0, which must be set to detect the same edge(s). When channels 1 or 2 are selected to work with the EAC, IPACA/B is used to select the tooth signal edge detection for both the channel and the EAC, and the tooth signal that feeds the EAC is the same filtered input which feeds the channel.

Channel 0, 1 or 2 generates the signal transition service request, and can also be used for generation of a window filter on this transition, to qualify TCR2 clocks. For this purpose, the selected channel should be configured with double match window filtering mode (refer to [Channel Modes](#)). Depending on the channel mode set for the channel, Match A recognition opens the window, and Match B recognition may close it or leave it open. See [Angle Logic and Channel Modes](#) for details. Match B also generates a time-out service request. Its input signal transition comes from the tooth. The window can be defined by microcode to open at a predefined point inside the tooth period, and stay open for a desired percentage to the tooth period. The window can be measured in angle or time. This method improves the noise immunity by allowing transition detection only on an expected period, a feature which was software responsibility in previous TPU versions.

The EAC supports deceleration, acceleration, last tooth and missing tooth scenarios. The large range of angle ticks per tooth can be used to cover longer tick counts caused by one or more missing teeth, or to provide extra resolution for future application requirements. In case of a missing tooth, the EAC can be configured to insert a dummy tooth or to simply measure a longer tooth.

Figure 35-324 shows the block diagram of the Angle Counter system. TCR1 or TCR2 prescaler is used as a time base which measures the tooth period and is used for partitioning the period to angle ticks.

35.15.7.2 Angle Mode registers

In Angle Mode, the registers described below control eTPU angle operations. They are accessible only by microengine as source and destination registers in microinstructions. When eTPU is not in angle mode (eTPU\_TBR\_TBCR\_ENGn[AM] field is negated), all Angle Mode registers can be used as general purpose registers.

35.15.7.2.1 TPR - Tooth Program Register

TPR provides configuration for the Angle Counter circuit. In this register, the microcode can properly adjust the tooth count (controlling last tooth, missing teeth, dummy tooth insertion, halt until tooth detection) and the number of angle ticks per tooth (field TICKS). Note that this register is sampled into a temporary register in the EAC logic when the High Rate Mode is detected (see High Rate Mode (Acceleration) and TPR Buffering), which means that changes to this register may take effect only for the next tooth.

See Count Control and High Rate Logic and to Special Cases of Missing Teeth and Last Tooth until Handling False Tooth Detection for a detailed explanation about the use of this register. The figure below provides a detailed description of TPR register.

Several conflict issues on TPR writes are explained in Special TPR write cases.

Figure 35-320. TPR

LAST —Last Tooth Indication  
Asserted by microcode and negated when a tooth is detected or inserted via IPH.

Table continues on the next page...

1 = Last Tooth - reset TCR2 Counter at the end of the tooth tick count (after physical tooth or IPH=1) when MISSCNT=0.

0 = Not Last Tooth.

If the tooth is detected or inserted before the tooth tick count completes (going High Rate mode, see [High Rate Mode \(Acceleration\)](#)), LAST resets immediately, but TCR2 resets only when the tooth count completes and MISSCNT=0.

#### MISSCNT — Missing Tooth Counter

Decrement on each estimated tooth, stops at zero. Used for generation of up to 7 "Dummy Teeth" whenever it holds a non-zero value.

If the tooth is detected or inserted before the missing tooth tick count completes (going High Rate mode, see [High Rate Mode \(Acceleration\)](#)), MISSCNT resets immediately, but missing teeth count continues in High Rate mode (see [TPR Buffering](#)).

#### IPH — Insert Physical Tooth

This bit generates a dummy physical tooth which has the same effect as a real physical tooth, and resets itself subsequently. If EAC is in Halt mode, it switches back to Normal mode<sup>1</sup>. If EAC is in Normal Mode, it switches to High Rate Mode. If Angle Logic is frozen by HOLD=1 (see below), it returns to the state it was at the freezing moment.

1 = Insert dummy physical tooth.

0 = No Operation.

**Note:** IPH reads as 1 in the next microinstruction after it is asserted, negating subsequently. However, it can be set twice in two consecutive microinstructions to generate two teeth and make the EAC go from Halt to Normal to High Rate Mode.

#### HOLD — Force EAC Hold

This bit forces the EAC to halt its operation in a special EAC freeze mode until a new physical tooth (a real one or emulated with IPH=1) is detected. Assertion of this bit immediately freezes the EAC in the middle of the tooth period. When a new physical tooth is detected, the bit is automatically negated by the EAC. The HOLD bit can be used for synchronizing the EAC tooth count, in case that a false physical tooth is detected due to noise.

1 = Force EAC to halt until detection of a physical tooth.

0 = Normal Operation.

#### TICKS — Angle Ticks Number in the Current Tooth

This field defines the number of angle ticks in the current physical tooth. It partitions the tooth period to the required number of angle ticks. The actual number of angle ticks in a tooth is (TICKS+1).

**Note:** In High Rate mode (see [High Rate Mode \(Acceleration\)](#)), TPR writes are immediately effective only for bits IPH and HOLD. All other fields changes are "buffered" and become effective when EAC leaves High Rate mode. See also [Special TPR write cases](#).

**Note:** Bits LAST, IPH and HOLD must not be asserted all at once

1. Missing a physical tooth naturally causes EAC to get into Halt mode.

### 35.15.7.2.2 TCR2 - Timer Counter 2

In Angle Mode, TCR2 (see the following figure) counts angle ticks instead of time.

**Figure 35-321. TCR2 in Angle Mode**

This 24-bit free-running counter is used to generate an accumulated Angle Fraction value. It is updated by the Angle Tick Generator - refer to [Angle Tick Generator](#) for more details. Refer to [Count Control and High Rate Logic](#) for a detailed explanation about the use of this register in Angle Mode.

TCR2 provides continuous count of the angle in units of angle ticks. The Angle Tick Counter in TCR2 can be reset due to "Last Tooth" microcode indication. TCR2 Prescaling is disregarded in Angle Mode: physical tooth detection is done by EAC regardless of the value set in TCR2P.

### 35.15.7.2.3 TRR - Tick Rate Register

The exact period of the Angle Tick is programmed in the Tick Rate Register (see the figure below) by microcode. The TRR time unit depends on eTPU\_TBR\_TBCR\_ENG $n$ [ATGC] (see [Figure 35-324](#)):

- if ATGC=0, the TRR time unit is the period of TCR1 clocks taken as eTPU clocks divided by  $2 \cdot (\text{TCR1P} + 1)$ , even if TCR1CS=1 (see [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#)).
- if ATGC=1, the TRR time unit is given by the eTPU clock divided by  $2 \cdot (\text{TCR2P} + 1)$ , using the TCR2 prescaler fed by eTPU clock/2 (independently of TCR1CS).

See [Calculating the Angle Tick Period Integer and Fraction](#) for a complete description about the mechanism to calculate the value to be written into this register.

**Figure 35-322. TRR**

**INTEGER** — The integer part of TCR1/TCR2 clocks in one Angle Tick.

This number, decremented by one, works as a down-counter preload value. A value of **INTEGER=0** represents an integer of 32768. A new value written is reloaded into the counter (becoming effective) when a new tick starts or a tooth is detected or inserted via **IPH**.

**FRACTION** — Nine-bit fractional part of TCR1/TCR2 clocks in one angle tick.

The **FRACTION** value is accumulated in the **EAC Fraction Accumulator**, and whenever the result overflows (i.e., the accumulated fraction added up to an integer), the **Tick Prescaler** is halted for one **TRR** time unit.

Figure 35-323. EAC "PLL"

Figure 35-324. eTPU angle counter system

### 35.15.7.3 Acceleration and Deceleration

Acceleration and deceleration affect the new tooth period relative to the known period of the last tooth. Changes in tooth period may be extreme at very low engine RPM (such as cold start and warm start). The worst case of tooth period changes is caused during missing teeth, since there is more time for changes in angular velocity to be unnoticed by the EAC hardware. For example, on cold start (~20 RPM) there may be extreme acceleration: the ratio between a known tooth period before two missing teeth and the new tooth period after the missing teeth can be very high (up to a factor of 75). Acceleration and deceleration effects from tooth to tooth are less extreme as the engine climbs to high RPM.

In case of deceleration, the estimated tooth period ends before the actual tooth detection arrives. In this case, the EAC hardware waits at the end of the current tooth period, when it is said to be in **Halt mode**, until the real tooth indication is received, then continues with normal operation (**Normal mode**). See [Figure 35-323](#).

In case of acceleration, the actual tooth period is shorter than the estimated tooth period. As a result, a new physical tooth indication arrives before the end of the estimated tooth period. In this case the EAC closes the gap on **High Rate mode** by counting on eTPU clock divided by eight to the end of the tooth, advances to the next tooth, and switches back to normal operation mode. See [Figure 35-323](#).

The reason that the EAC does not jump directly to the next tooth is the need to provide sequential angle count throughout the whole tooth period, for channels or external STAC clients (if TCR2 is a STAC server) which compare angle in "equal" mode. These peripherals must get all the valid angle values in a sequential manner, to avoid missing angle matches.

TCR2 advancing from one tooth to another is a continuous count, and can be optionally reset at the end of the tooth. An estimated tooth is generated after the Tooth Tick Counter reaches the TICKS programmed value.

The EAC works continuously and switches automatically between Normal, Halt and High Rate modes. It relies on the microcode to calculate the estimated tooth period on every tooth, and to update the correct angle tick and tooth parameters in the EAC control registers. On high RPM, tooth period changes are reduced from tooth to tooth, and the EAC may follow the angle with good accuracy for several teeth without microcode intervention.

The EAC handles missing teeth by insertion of "dummy" teeth, or by enlarging the expected tooth period. It is a good practice to locate the flywheel missing teeth in non-critical angles, since a missing tooth may increase the angle measurement error (acceleration and deceleration is detected late).

### 35.15.7.4 Angle Tick Generator

The Angle Tick Generator is responsible for generating a programmed number of angle ticks in the tooth period. It generates the ticks in an average rate which ensures completion of the correct number of angle counts in the estimated period of the tooth, since the count of one tooth in angle ticks is independent on engine RPM. The main output of the Angle Tick Generator is the tick clock that feeds TCR2 in Angle Mode, as well as the internal Tooth Tick Counter (see [Figure 35-324](#)). The Tooth Tick Counter counts ticks within a tooth, from 0 up to TICKS, is controlled by the Angle Tick Generator logic and cannot be accessed by microcode. Refer to [Figure 35-325](#) for a generic presentation of the angle tick count and the measurement of a single tooth period.

#### 35.15.7.4.1 Calculating the Angle Tick Period Integer and Fraction

On each tooth the microcode has to update the exact period of a single angle tick used for counting the internal angle in the tooth. The period of an angle tick is determined by the EAC configuration, see [Generating the angle ticks](#) for details.

The microcode can use the eTPU MAC Divider unit (see [MAC and Divide Unit \(MDU\)](#)) to divide the tooth period by the number of angle ticks per tooth, which is stored in the TICKS field of TPR (refer to [Angle Mode registers](#)). This division yields the integer part of the angle tick period and the remainder. Dividing again the remainder shifted left nine positions, by the number of angle ticks per tooth translates the remainder to a 9-bit fraction. The microcode concatenates the 15-bit integer and the 9-bit fraction to a 24-bit value and writes it to TRR. The new rate is effective immediately after the next Angle Tick is generated by the Angle Tick Generator<sup>31</sup>.

For high RPM, note that shifting the tooth period value nine positions to the left prior to the first divide operation would calculate, in one operation, the integer and the fraction. For example: On 60 teeth flywheel running at 1000 RPM, tooth period is 1 msec. If TCR1/TCR2 counts @25 MHz, it counts 25,000 times in a tooth, which can be represented by 15 bits. Therefore the tooth period can be shifted nine positions to the left prior to divide operation, and be represented with 24 bits.

Using shift left nine positions and one divide operation would get the result in MACL register (in MDU) which holds the integer and nine bits of the fraction:

```
Angle_Tick_Rate {Integer[14:0], Fraction[8:0]} = (ToothPeriod <<9) / Ticks
TRR = Angle_Tick_Rate {Integer[14:0], Fraction[8:0]}
```

31. In High-rate mode, the tick keeps being updated at the rate of eTPU clock/8 until it goes back to Normal mode, when the new TRR value is used.

**NOTE**

In the pseudocode above, the tooth period (ToothPeriod) is not, in general, the value of estimated tooth time. It is obtained by microcode by subtracting TCR1 values between two teeth detections, converted to TCR2 periods if ATGC=1. Its comparison with the estimated tooth time indicates acceleration (if minor) or deceleration (if greater) to the microcode.

On low RPM the initial tooth period, measured in TCR1/TCR2 counts, may be too big to be shifted nine positions to the left. For lower RPM (for example 500 RPM) the tooth period cannot be represented by 15 bits, and shifting it nine positions to the left would lose the MSB. In this case, two divide operations are required as follows: first divide the Tooth Period by the number of TICKS - the integer is stored in MACL and remainder in MACH. MACL is saved in another register. MACH is shifted 9 positions to the left and divided again by TICKS. In parallel with the second divide, the register which saved the original MACL is shifted left 9 positions. After the divide MACL contains the 9 bits fraction and the other register contains the 15-bit integer, shifted left nine times. The logical OR of the two registers is written to the TRR:

```
Angle_Tick_Rate {Integer[14:0]} = (ToothPeriod) / Ticks
Remainder[9:0] = (ToothPeriod) mod Ticks
Angle_Tick_Rate {Fraction[8:0]} = (Remainder[9:0] << 9) / Ticks
TRR = Angle_Tick_Rate {Integer[14:0], Fraction[8:0]} = (Integer[14:0] << 9) | Fraction[8:0]
```

**Figure 35-325. Angle Ticks Generation**

### 35.15.7.4.2 Generating the angle ticks

The integer part of TRR is preloaded to a prescaler, which counts in time intervals as follows (see [Figure 35-324](#)):

- If  $\text{eTPU\_TBR\_TBCR\_ENGn[ATGC]}=0$ , one unit of TCR1 clock period (if  $\text{TCR1CS}=0$ ) or twice the TCR1 clock period (if  $\text{TCR1CS}=1$ )<sup>32</sup>, that is,  $\text{eTPU clock period} \times 2 \times (\text{TCR1P}+1)$  (independently of TCR1CS).
- If  $\text{ATGC}=1$ , two units of the eTPU clock period multiplied by the TCR2 prescaler factor, that is,  $\text{eTPU clock period} \times 2 \times (\text{TCR2P}+1)$ .

When the down counter reaches zero, it generates an angle tick pulse to the Angle Counter Logic and a Load pulse to the Fraction Accumulator. It is then preloaded with most updated TRR integer part. Due to the Load pulse, the 9-bit fraction is accumulated in a 9-bit Fraction Accumulator. If a fraction overflow condition occurs (the 9-bit adder asserts carry out), the accumulator saves the lower 9 bits of the addition result, which is the remaining fractional part. The carry out bit indicates an accumulated integer "one" which means that the angle tick is early by one input clock. It halts the prescaler operation for one input clock to compensate the accumulated error generated by the integer prescaler. As a result, the average angle tick period takes into account both the integer and the fraction parts. The accuracy depends on the bit count of the fraction. Using 9-bit fraction part while the width of the field TICKS in register TPR is 10 bits provides accuracy of two LSB on a full scale ( $\text{TICKS}=1023$ ) or one LSB on lower scale ( $\text{TICKS} \leq 511$ ).

When the Tick Prescaler gets High Rate mode indication from the Angle Counter Logic, it generates angle ticks at a rate of eTPU clock divided by eight. In this case it does not generate Load pulses to the Fraction Accumulator, ignores its "hold" input and preloads internally to a fixed period of eight eTPU clocks. When High Rate mode is entered, the prescaler is preloaded to a period of eight eTPU clocks before its first angle tick generation, ensuring separation of at least eight eTPU clocks between the last Normal mode angle tick and the first High Rate mode angle tick. The fraction accumulator resets when the tick count advances to the next tooth, or when TRR is written by the microcode.

### 35.15.7.5 Count Control and High Rate Logic

The Count Control and High Rate Logic controls TCR2 operation in Angle Mode, using the angle ticks generated by the Angle Tick Generator. Count Control logic is responsible for advancing, holding and resetting the TCR2 and Tooth Tick Counter in the proper timing, such that the TCR2 time base will reflect the correct estimated angle. This logic also includes the Tooth Program Register (TPR, see [Angle Mode registers](#) for more information).

---

32. The EAC logic overall runs at a rate of eTPU clock divided by 2, therefore the tick generator takes the halved TCR1 clock when  $\text{TCR1CS}=1$  and  $\text{ATGC}=0$ .

The Count Control and High Rate Logic handles deceleration, acceleration, missing teeth and last tooth. On High Rate (acceleration) it ensures that the angle bus scans all valid angle values in a rate which can be traced by the STAC bus. This operation enables external STAC clients (if TCR2 is a STAC server) or channels working in "equal-only" comparator mode to match the TCR2 exported angle information in "equal" mode, in an exact match.

Because the eTPU channels are capable of capturing either TCR1 or TCR2 due to signal transition, the microcode can get either the angle or time of the physical pin transition. Since the EAC channel (0, 1 or 2) is connected to the physical tooth, the microcode can get the EAC error in angle domain (tooth appears at the wrong angle) or time domain (physical tooth captured time into the EAC channel, relative to the estimated tooth time). Note that in angle mode, the transition detect logic of the channel 0, if selected as the EAC channel, is fed from the digital filter of the TCRCLK signal, and not from the channel 0 internal digital filter. This ensures synchronous operation of channel 0 and the EAC hardware.

Another feature of the eTPU channel, when working in Single Match And Single Transition Enhanced Mode (refer to [Single Match Enhanced Mode \(sm\\_st\\_e\)](#)), is capturing a single time base due to signal transition before and after the digital filter. This option allows subtracting the digital filter delay to get accurate signal transition timing on the channel. This way, the TCRCLK signal may be programmed with a slow and reliable digital filter, and get accurate time measurement of the digital filter delay.

To assert the end of the estimated tooth period the Count Control and High Rate logic compares the TICKS field in TPR (refer to [Angle Mode registers](#)) with the current value of the tooth tick counter. When the Tooth Tick value is greater or equal to TICKS, it determines the end of the estimated tooth period. On acceleration this event occurs during High Rate mode operation, after the arrival of a physical tooth. In deceleration, this event occurs during Normal Mode, before the arrival of a physical tooth. On constant angular velocity, this event appears together with the arrival of a physical tooth.

The following sections describe the operation of the Counter Control and High Rate logic.

#### 35.15.7.5.1 Normal Mode

In Normal mode the Counter Control logic advances TCR2 and the Tooth Tick counter as if the engine has a constant speed during the tooth period. It receives the angle ticks from the Angle Tick Generator in an average rate which is determined by the Tooth Rate Register (TRR). This is the reset mode.

When the Tooth Tick Counter is about to reach the last value effectively stored in TPR field TICKS plus one, the hardware detects the end of the estimated tooth period. If the physical tooth and the estimated tooth arrive at the same time the EAC stays in Normal mode, the Tooth Tick Counter is reset, and TCR2 is incremented (depending on TPR bits LAST and MISSCNT). If the physical tooth and the estimated tooth do not arrive at the same time, either acceleration or deceleration is detected, and the EAC switches to the proper mode. See the figure below for a detailed diagram of Normal Mode behavior.

The microcode which services the EAC channel physical tooth transition may update TRR according to various conditions to give the best estimation of the current tooth period, according to the previous tooth period and other engine parameters.

Figure 35-326. Normal Mode

### 35.15.7.5.2 Halt Mode (Deceleration)

In case of deceleration, the Tooth Tick Counter reaches the TICKS value before the arrival of the next tooth. The Count Control logic does not reset neither advances TCR2 and Tooth Tick Counters. The Count Control logic halts TCR2 and Tooth Tick Counters at the end of the tooth, waiting for the physical tooth to arrive.

When the physical tooth is detected the EAC switches back to Normal Mode and releases TCR2 to count the angle ticks of the new tooth, also resetting the Tooth Tick Counter. Only then TCR2 may wrap to 0, if TPR bit LAST is asserted. See the figure below for a detailed diagram of Halt Mode behavior.

The microcode service caused by the physical tooth determines the deceleration, calculates the new tooth period and Angle Tick period and updates TRR. This operation slows the angle tick rate generated by the Angle Tick Generator on-the-fly, to the rate required for the new tooth period.

Since the microcode service is initiated by the physical tooth edge, microcode latency may introduce a small angle error caused by using the TRR value of the previous tooth at the beginning of the current tooth. On high RPM, deceleration is relatively small but the microcode latency may take a significant percentage of the tooth period. On low RPM microcode service latency takes little percentage of the tooth period, but there may be cases of extreme acceleration and deceleration. The microcode latency can be calculated knowing TCR1 value during the service time, and TCR1 value captured in the EAC channel due to the physical tooth pin transition. The duration of the Halt mode is obtained using the estimated tooth time.

Figure 35-327. Halt Mode - Deceleration

### 35.15.7.5.3 High Rate Mode (Acceleration)

In case of acceleration, the next tooth arrives before the Tooth Tick Counter reaches the TICKS value. In this case the High Rate logic is responsible for closing the gap and advancing the tooth on the correct timing. The High Rate mode operates as follows:

- When the acceleration is detected (physical tooth arrives before the Tooth Tick Counter reaches the TICKS value), the Count Control and High Rate logic switches to High Rate mode in which both the Tooth Tick Counter and TCR2 count at rate of

eTPU clock divided by eight, until the Tooth Tick Counter reaches the current TICKS value. To ensure correct operation, the TICKS value is sampled in the logic at the beginning of the mode.

- At this point, which represents the estimated tooth edge, the logic resets the Tooth Tick Counter and advances TCR2 (or resets it if LAST is asserted and MISSCNT = 0).
- The control logic switches back to Normal Mode, using the most updated TRR value as input to the Angle Tick Generator. The logic samples the updated TICKS value for the tooth estimation, last tooth indication and number of missing teeth from TPR.

In High Rate mode the angle ticks are provided at high speed until the end of the current tooth. This operation is required to scan all the valid angle values of the current tooth, in a rate which is not too high for the STAC bus continuous update, but much higher than the rate dictated by TRR.

EAC channel microcode, which services the physical tooth transition detection, can start its service either before High Rate mode operation is complete (the Tooth Tick Counter has not reached the TICKS value) or after the EAC switched back to Normal mode. Any physical teeth received while the EAC is in High Rate Mode does not alter the immediate EAC state, but it is still detected by the EAC channel logic and can, therefore, alter future EAC behavior (for instance, closing the tooth detection window - see [Angle Logic and Channel Modes](#)).

At the beginning of High Rate mode operation, the TPR value is preloaded into a temporary register in the Counter Control Logic, used for scanning all the valid values to the end of the current tooth, with its appropriate LAST and MISSCNT attributes. While the EAC is in High Rate mode operation, the effect of microcode update of TPR fields LAST, MISSCNT and TICKS is delayed to the next estimated tooth, after the High Rate mode operation is complete (see [Special TPR write cases](#)). This is because the current physical tooth represents the next estimated tooth. If the microcode updates this field after High Rate mode operation is complete, the current physical tooth and estimated tooth are the same, and the effect is immediate. Either in High-Rate mode or not, the value read by microengine is the same written, even if not yet effective, until the EAC resets LAST and/or IPH, or decrements MISSCNT. Typically the microcode service may occur during the High Rate mode on extreme acceleration situation at low RPM. Therefore, the microcode operations are always related to the real physical tooth. From the above it can be seen that the microcode updates of the TICKS field in TPR affect the end time of the current physical tooth. For correct operation, this field should be updated before the Tooth Tick Counter has reached either the old or the new TICKS value.

During High Rate mode operation, TRR is ignored and the Angle Tick Generator uses eTPU clock divided by eight. Therefore, the TRR update by microcode will take effect only after the EAC switches back to Normal mode. If microcode service occurs after the Tooth Tick Counter has been reset, the EAC is already back in Normal mode, and some angle ticks may have been counted at the rate of the previous tooth. In this case the new TRR value will have immediate effect on the angle tick period, and the microcode should take into consideration the delay from the physical tooth to the estimated tooth in calculation of the next tooth period. See the figure below for a detailed diagram of High Rate Mode behavior.

An angle error may be introduced by the duration of the High Rate mode. Also, the scheduler latency may introduce a small accumulated error by using TRR value of the previous estimated tooth at the beginning of the current tooth. After the estimated tooth has advanced, the duration of the High Rate mode operation is the actual delay from the physical tooth edge to the estimated tooth edge. This delay can be obtained by comparing the estimated tooth time with the EAC channel capture register which captured TCR1 on the physical pin transition.

Figure 35-328. High Rate Mode - Acceleration

### 35.15.7.6 Special Cases of Missing Teeth and Last Tooth

The EAC handles cases of up to three missing teeth and the last tooth in the engine cycle. The following paragraphs describe these functions.

### 35.15.7.6.1 Handling the Last Tooth

The microcode can set the TCR2 counter to work in engine periods (wrap-around count) or continuous angle measurement.

For periodic operation, during the last engine cycle tooth the EAC microcode has to set the LAST flag in TPR. As a result, when the tooth period is ended, the Counter Control Logic generates a reset command to both the Tooth Tick Counter and TCR2 instead of an advance command. The operation resets the TCR2 based angle count, indicating a new period of the engine cycle. This implementation provides an engine cycle based periodic angle measurement.

### 35.15.7.6.2 Handling Missing Teeth

The EAC can handle up to three missing teeth in two ways:

- Count the angle ticks relative to the last physical tooth. The microcode should update the TPR TICKS field to the number of angle ticks included in two, three or four teeth, according to the flywheel type (one, two or three missing teeth). EAC hardware works in its regular manner.
- Insert a "dummy" tooth instead of the missing tooth, at the estimated point in time. After the "dummy" tooth, the Angle Tick Counter is incremented as if there was a physical tooth. A "dummy" tooth can be inserted only during Normal or High Rate operation modes. The microcode inserts "dummy" teeth by writing to the MISSCNT field in TPR.

In the first option the missing tooth is not counted on the angle measurement. For example, a flywheel with 59 physical teeth and one missing tooth can be considered as 58 identical teeth numbered (0-57) and tooth number 58 has a double number of angle TICKS. In this case a 720 degrees engine cycle has 118 teeth. TCR2 reflects the real angle, since it counts angle ticks continuously.

In the second option, the missing teeth are counted as "regular" teeth by automatic insertion of "dummy" teeth. The microcode has to write a non-zero value to the MISSCNT field in TPR. This field is a 3-bit down counter which affects the operation of the Counter Control logic.

For example, a flywheel with 59 physical teeth (0-58) and one missing tooth (59) can be considered as 60 teeth numbered (0-59), all having the same number of angle ticks. The microcode has to write "001" to the MISSCNT bits during the period of tooth number 58 to indicate that next tooth (59) is missing.

When the Tooth Tick Counter reaches the TICKS value, TCR2 is incremented as if a physical tooth has been detected. In addition, the MISSCNT value initializes a "dummy tooth counter" which is decremented to indicate the number of left "dummy teeth" which still need to be generated. Because a dummy tooth was counted, EAC does not enter Halt Mode and Tooth Tick Counter continues incrementing in the absence of a physical tooth detection.

In case of extreme acceleration on very low RPM (cold start) there can be a situation that the first physical tooth after one or two missing teeth appears even before the "dummy" tooth is generated. Due to the acceleration the EAC switches to High Rate mode in order to run through all the valid angle values, including the dummy teeth. When the Tooth Tick Counter reaches the TICKS value on High Rate mode, and the "dummy tooth" down counter is not zero, the generated "dummy tooth" advances to the next tooth and decrements the "dummy tooth" counter, but does not switch the EAC back to Normal mode. The last "dummy tooth" decrements the counter to zero, indicating that no more dummy teeth are to be inserted, and the next tooth is an estimated physical tooth. The EAC continues at High Rate mode until the Tooth Tick Counter reaches the TICKS value again, then advances to the next tooth while switching back to Normal mode. When in High Rate mode, the TPR register does not reflect the MISSCNT downcounting, see [TPR Buffering](#) for details.

MISSCNT can be rewritten before it reaches 0, allowing it to count more than 7 missing teeth, as long as no physical tooth arrives between the first MISSCNT write and the rewrite.

### 35.15.7.6.3 Combining Missing Teeth and Last Tooth

The Last Tooth indication takes effect when there are no more missing teeth to be generated, i.e the "dummy tooth" counter value is zero. If, for example, the microcode sets the missing teeth counter to "10" (two missing teeth) and sets the LAST flag, the first and the second dummy teeth will increment TCR2, and the third estimated tooth, which correlates with the physical tooth (the first of the next cycle), will reset TCR2, because LAST was set. This scheme enables the microcode to define one or more missing teeth to be replaced by "dummy tooth" insertion, and the end of the engine cycle in one service request. It is assumed that the two missing teeth must come together in the same engine cycle, and not split between two engine cycles (either the missing teeth are both last in an engine cycle or both not last, but not last in one engine cycle and first in the next).

Figure 35-329. Missing Teeth and Last Tooth Combination

### 35.15.7.7 Handling Mechanical Tooth Correction

The EAC can handle tooth edge detection errors caused by flywheel mechanical errors. The eTPU application can hold a vector of tooth mechanical errors with one entry per tooth. This error can be measured in angle ticks which are independent of engine RPM. The TRR can be updated to the fixed period of any tooth, including its mechanical error.

Because TCR2 counts continuously, without being reset, the mechanical correction is transparent. Though the tooth has its own programmed TICKS value, TCR2 simply counts angle ticks, disregarding the boundary between two adjacent teeth.

### 35.15.7.8 Handling Mis-detected Tooth

When a physical tooth signal is missed by the engine sensor, the EAC may get into Halt mode at the end of the estimated tooth period, expecting the physical arrival. In this case, a Match timeout event of EAC channel will call service which detects extreme deceleration. The microcode can assert the IPH bit in TPR, to force the detection of the missed physical tooth. It can also calculate the accumulated angle bus error, and fix the next estimated tooth period, to close the gap.

### 35.15.7.9 Handling False Tooth Detection

Most of the false tooth detection, caused by noises on the engine tooth sensor, can be eliminated by the window blanking filtering, timed by EAC channel match recognitions. The EAC also provides means of fixing false detection of an additional tooth which passed the window filter. When such an event occurs, the EAC switched to High Rate

mode (advancing to the next tooth) and when the next physical tooth arrives, an extreme acceleration is detected: the EAC sees the remaining portion of the current tooth period as another tooth period. The microcode can detect the situation when the acceleration is not realistic, or when immediately after the detection of this extreme acceleration, the following tooth indicates extreme deceleration back to the original RPM.

When the microcode detects such a case, the Tooth Counter has been advanced by mistake to the next tooth. The microcode can set the HOLD bit in the TPR, forcing the EAC to freeze and wait for the next physical tooth to close the gap. When the next physical tooth arrives, HOLD is automatically negated and the EAC proceeds from that point to the remaining portion of the tooth period, in the same mode it was when HOLD bit was asserted.

### 35.15.7.10 Angle Logic and Channel Modes

The TCRCLK transition detection is qualified by a signal that comes from channel 0 (see [Figure 35-324](#)) and depends on the particular mode (PDCM) programmed for that channel. This configures a window for TCRCLK detection for the angle logic which is the same (except on High Rate mode, see [High Rate Mode \(Acceleration\)](#)) used to set the TDLA flag on single transition modes, and TDLB on double transition modes (see signals TSE1, TSE2 in [Figure 35-307](#)). The same applies when channels 1 or 2 are used to control EAC (see signals TS1, TS2 in [Figure 35-307](#)). As a consequence, the window depends on the channel mode as follows:

- on all modes, the window closes upon a tooth edge detection: TDLA asserted on single transition modes, TDLB asserted on double transition modes.
- on mode m2\_st: the window opens on Match A (which enables Transition A) and does not close with Match B. If Match B comes before Match A, it blocks Match A and, hence, Transition A.
- on mode m2\_o\_st: the window opens on Match A (which enables Transition A) and closes on Match B. Match B is enabled by Match A, so it cannot come before.
- on all other Single Transition modes, the window is "always open", independently of matches.
- on mode m2\_dt: the window opens on Transition A, which is enabled by Match A. The window does not close with Match B, but if it comes before Match A the later gets blocked and, hence, blocks Transitions. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.

- on mode m2\_o\_dt: the window opens on Transition A, which is enabled by Match A. The window closes on Match B, which is enabled by Match A. Match A is also a condition for the window, so the microcode closes it by clearing MRLA.
- on all other Double Transition modes, the window opens on Transition A.

### 35.15.7.11 Restarting angle logic

It is not recommended to change the eTPU\_TBR\_TBCR\_ENGn[AM] field while GTBE=1. However, if the angle logic must be restarted without interfering with the timebase count running on TCR1, the procedure below must be followed:

1. Program eTPU\_TBR\_TBCR\_ENGn[AM]=00 and TCR2CTL=111 at once. That prevents TCR2 from incrementing while the angle logic is disabled. The angle logic state machine resets to Normal mode and the tick prescaler to the initial count with AM=00, but not the microengine registers TPR and TRR.
2. Start a thread to reconfigure the EAC. The thread must set the EAC controlling channel (0, 1 or 2) flags in a state, depending on the channel mode, that lets the channel tooth detection window open (see [Angle Logic and Channel Modes](#)). It can optionally write TCR2 with an angle preset value equivalent to the first tooth expected after restart. The thread must also set TPR bit HOLD=1. The TPR bit IPH must be 0.
3. After the thread is finished, program eTPU\_TBR\_TBCR\_ENGn[AM]=01, 10 or 11, and TCR2CTL according to the desired tooth edge selection if AM=01.

The first tooth detected after this procedure restarts the TCR2 counting, unfreezing the Angle Mode logic into normal mode.

### 35.15.7.12 Special TPR write cases

This section describes how simultaneous modification of TPR fields are resolved, and how the effect of TPR writes depend on the EAC mode.

#### 35.15.7.12.1 TPR Buffering

In High Rate mode (see [High Rate Mode \(Acceleration\)](#)), TPR writes are immediately effective only for bits IPH and HOLD. Writes to all other fields are "buffered" and become effective when EAC leaves High Rate mode. However, if TPR is written a

second time right after IPH is asserted in Normal mode, this second write behaves as if EAC is still in Normal mode. Only in the next microcycle (after execution of a nop, for instance) the TPR writes are buffered, acknowledging High Rate mode.

MISSCNT and LAST can be written any value during High Rate mode, and the value that prevails for the next tooth is the one sampled when EAC goes back to Normal mode (or the value written in Normal or Halt mode thereafter). If MISSCNT and/or LAST are not zero when High Rate mode begins, they are sampled into the internal EAC logic and are effective while High Rate lasts (missing teeth count continues, and TCR2 is reset at the end of High Rate if LAST=1). However, their values in TPR are reset when High Rate mode starts. After that and until the end of High Rate mode, the value read by microcode is the same written. This behavior prevents read-modify-writes to TPR from unwillingly rewriting LAST or MISSCNT.

### **35.15.7.12.2 IPH and LAST**

If both IPH and LAST are asserted in the same microinstruction with HOLD=0, the EAC acts as if LAST was set first and then IPH right after, so that:

- in Normal mode, it goes to High Rate with LAST=1;
- in Halt mode, it goes to Normal Mode resetting LAST (and TCR2);
- in High Rate mode, IPH is ignored and LAST becomes effective in the next tooth (physical or inserted) after it goes back to Normal mode.

### **35.15.7.12.3 IPH and TICKS**

Because of different results depending on the EAC mode at the time of TPR write, it is not advisable to write 1 to IPH and change TICKS at the same microinstruction. A consistent behavior is obtained if IPH is written first and TICKS on the second microinstruction after (for instance with a nop between them), making the new TICKS value valid for the next tooth regardless of the mode.

The mode-dependent behavior is (assuming HOLD=0):

- in Normal mode, the new TICKS value becomes valid before EAC goes High Rate due to the IPH;
- in Halt mode, the EAC goes to Normal mode, and new TICKS is valid for the next tooth;
- in High Rate mode, the new TICKS value is effective when EAC leaves High Rate mode, and IPH is ignored;

### 35.15.7.12.4 IPH and MISSCNT

If both IPH and MISSCNT are written non-zero values with HOLD=0:

- in Normal mode, at the next microcycle the EAC goes to High Rate mode, the MISSCNT field in TPR goes to 0, and the missing teeth are counted in High Rate mode.
- in Halt mode, the EAC goes to Normal mode for one microcycle and then, yet another microcycle later, goes to High Rate mode, counting the missing teeth. The TPR fields IPH and MISSCNT are zeroed on the transition from Normal to High Rate mode.
- in High Rate mode, IPH is ignored (resetting at the next microcycle) and MISSCNT is buffered (see [TPR Buffering](#)).

### 35.15.7.12.5 IPH and HOLD

If IPH and HOLD are asserted at once, IPH cancels the HOLD and both reset. The EAC is not frozen, regardless of the EAC mode (High Rate, Normal or Halt).

### 35.15.7.12.6 LAST and HOLD

If LAST and HOLD are written 1 at once, LAST asserts and EAC is frozen. Afterwards, when a physical tooth is detected or IPH is asserted, the EAC is unfrozen in the same state it was before, and LAST is kept asserted.

## 35.15.8 Microengine

Each eTPU engine has a microengine that fetches, decodes and executes microinstructions. The Microengine only works when there are service requests to be attended, otherwise it turns to idle state, controlled by Hardware Scheduler (see [Scheduler](#)).

Microcode is stored in Shared Code Memory (SCM) that is 32-bit wide. Microengine can access SCM using a different bus from the one used to access code memory, so that code and data can be accessed at the same time (Harvard Architecture).

Some of eTPU functionality can only be made through the microengine, like configuring channels and interrupting host. Microengine gives eTPU a high degree of flexibility, since any desired treatment for channel's events can be implemented; however, that

flexibility comes at the cost of channel service's latency. Latency is worsened when channels from a same eTPU engine contend for microengine service. In the figure below, a block diagram of microengine architecture is shown.

Follows a summary of Microengine features:

- P, DIOB, A, B, C, D, SR, RAR, LINK, CHAN, MACL, MACH, ERTA, ERTB, TCR1, TCR2, TPR, TRR registers are accessible by microcode.
- 24-bit ALU and Post-ALU shifter performs basic arithmetic and logical operations described in [ALU and Post-ALU Shifter](#).
- MDU (MAC/Divide Unit) performs integer MAC, multiply and divide operations.
- Fixed Microinstruction Size of 32bits.
- Fixed-length instruction execution (2 eTPU clocks)
- Static superscalar operation

Figure 35-330. Microengine Block Diagram

### 35.15.8.1 Registers

eTPU microengine accesses a total of 18 registers. Fourteen of them are special purpose (registers A, B, C and D are for general use). Special purpose registers except CHAN and LINK can also be used as general use if the operation that use their contents are not performed. Register description is intended to just introduce their functionalities and not to provide detailed explanation of it since it will be described in [Microinstruction Set](#). Registers less than 24 bits in size are right-justified.

None of the registers have guaranteed reset values. However, some are initialized just before the thread starts (see [Time Slot Transition](#)).

#### 35.15.8.1.1 P Register

P register is the only one that is 32-bit wide. It can be used as source and destination for arithmetic/logical operation, and as source and destination for SDM read/write operations.

For P source/destination possibilities in ALU/MDU microoperations, see [Selecting sources and destination](#).

When P is used as SDM read/write operations source or destination there are only 3 possibilities of access: all 32 bits, lower 24 bits and upper 8 bits. SDM operations are explained in detail in [SDM Microoperations](#).

P is automatically loaded with one parameter before the thread starts (parameter preload). For more information see [Entry Point format](#) and [Time Slot Transition](#).

Upper 8 bits of P register can be used as application state, since these bits can be tested as branch conditions. P[31:24] is also used in dispatch microoperation (see [Dispatch Microoperation](#)), and bit pairs P[29:28], P[27:26], P[25:24] can be directly copied into Channel flags 1 and 0 using field FLC. Together with Entry Table Condition Encoding, it provides fast state resolution without code execution.

#### 35.15.8.1.2 DIOB Register

DIOB is an abbreviation for Data Input/Output Buffer. DIOB is 24-bit wide and can be used as source and destination for arithmetic/logical operations as well as SDM data source and destination. DIOB only can be accessed as 24 bits, both in arithmetic/logical and SDM read/write operations. When using DIOB to perform an SDM access, only lower 24 bits of SDM will be accessible (SDM upper 8 bits always remains unchanged).

DIOB can also be used as SDM addressing register, when DIOB contents is used as absolute SDM address (14-bit wide). In this case DIOB can also be pre-decremented or post-incremented (see [Indirect Addressing Mode](#)).

DIOB is automatically loaded with one parameter before the thread starts (parameter preload). For more information see [Entry Point format](#) and [Time Slot Transition](#).

### 35.15.8.1.3 ERTA and ERTB Registers

ERTA/B registers are 24-bit wide and can be used as source or destination in arithmetic/logical operations. ERTA/B are the only source for channel's match registers write (see [Write Channel Match and UDCM Registers](#)). ERTA can also be the source for UDCM write.

When a thread starts to be executed, ERTA and ERTB are loaded with a copy of CaptureA and CaptureB registers respectively. ERTA/B can be used to receive a copy of MatchA and MatchB registers. ERTA/B are the only destination of MatchA/B read operation (see [Special T4ABS Source Operation: Read Match Registers](#)).

ERTA and ERTB also receive a copy of CaptureA and CaptureB registers when CHAN register is written (see [CHAN Register](#)). For more information about Capture and Match registers see [MatchA and MatchB Registers](#) and [CaptureA and CaptureB Registers](#).

### 35.15.8.1.4 SR register - Shift Register

SR is a 24-bit wide register that can be used as source and destination register for arithmetic/logical operations. SR can shift right its contents by 1 bit at time and, at the same time, receive in its bit 23 the lost bit of a shift-right operation in post-ALU shifter ([ALU and Post-ALU Shifter](#)), allowing SR to be used to perform 48-bit shift right (see [Shift Operations](#)).

### 35.15.8.1.5 MACH and MACL Registers

Both MACH and MACL are 24-bit registers, part of MAC/Divide unit (see [MAC and Divide Unit \(MDU\)](#)). They can be used as source and destination in most arithmetic/logic operations. When multiply or divide operations are used (multiply-accumulate included), MACH and MACL have special purpose and some restrictions apply, see [MAC and Divide Unit \(MDU\)](#) for more information.

### 35.15.8.1.6 LINK Register

Link Register is an 8-bit wide register and can be used only as destination in arithmetic operations. LINK is a write-only command register, which precludes its use as a source register for ALU operations. When LINK register is written, it issues a service request for the channel number and eTPU engine equal to the number written in LINK register (see [Functions and threads](#) and [Channel Link](#) for information about Link Service Request).

### 35.15.8.1.7 RAR Register

RAR is a 14-bit register and can be used as source and destination in arithmetic operations. RAR also receives the contents of PC register when a subroutine call is executed. The contents of RAR register is loaded into PC when a return from subroutine is executed. RAR is loaded with value 0x3FFF during TST. For more information about subroutine call and return see [Branch Operations](#) and [Return from subroutine](#) respectively.

### 35.15.8.1.8 CHAN Register

CHAN is a 5-bit register that can be used as source and destination in arithmetic operations. The contents of CHAN register affects the execution of many channel-related microinstructions, because its number indicates the **selected channel**. CHAN register must not be used to store temporary values in arithmetic operations. For more details, refer to [Channel Selection Register - CHAN](#).

### 35.15.8.1.9 Counter Registers: TCR1, TCR2, TPR and TRR

All these registers are 24-bit wide except TPR, which is a 16-bit register. They can be read or written in arithmetic/logical operations, and have special-purpose uses for time base and angle mode operations. For more information about those registers see [Time bases](#) and [EAC - eTPU Angle Counter](#).

### 35.15.8.1.10 General Purpose Registers: A, B, C and D

A, B, C and D are 24-bit general purpose registers, which can be used to store intermediate values and do not have other specific uses with any eTPU feature.

## 35.15.8.2 ALU and Post-ALU Shifter

The ALU executes 24-bit arithmetic and logical operations. ALU's output goes directly to a 1-bit shifter, called post-ALU shifter, so it is possible, for example, to add and shift using only one microinstruction.

In some microinstruction formats, it is not possible to specify the operation executed by ALU. In these cases ALU will always perform addition.

In formats which have the field ALUOP for ALU operation selection, all of them can be performed, including add/subtract using C (carry) flag as ALU's carry-in, bitwise AND/OR/NOT/XOR, and shift/rotate of 2, 4, 8 and 16 bits. See [ALU/MDU Operation Selection](#).

Subtraction, inversion, increment and decrement can be performed by combinations of source inversion and setting ALU's carry-in to 1.

ALU always performs 24-bit operations on its inputs, called **A-source** and **B-source**, and outputs a 24-bit result. 8-, and 16-bit inputs are zero padded to 24 bits. Likewise, ALU 24-bit output is always truncated to the destination register size.

### 35.15.8.2.1 ALU flags

Four flags - Carry, Negative, Overflow, Zero - described below, are related to ALU and post-ALU shift operations. Operation size and shifting affect flags generation logic. Operation size determines the result boundary to be used for flags generation. Operation size is determined by size of sources and destination (see [Flags Sampling Control](#)). For more information about flag generation, see [Flags Sampling Control](#). ALU flags can be used as branch condition (see [Conditional/unconditional branch](#)) or conditional ALU/MDU operation (see [Conditional ALU/MDU Operation Execution](#)).

Field CCS/CCSV in microinstructions can force **no update** of all flags. Not all flags are updated in all ALU operations: Overflow is updated only on addition and absolute value operations, Carry flag is updated in most ALU operations, and only Zero and Negative are updated in all ALU operations.

ALU flags are never updated when microinstruction starts an MDU operation, regardless of CCS/CCSV, but are updated normally afterwards, on ALU operations that are executed in parallel with an ongoing MDU operation (MDU has its own flags).

#### Note

Operation size can be smaller than destination register. For example:  $0xFFFF + 0x0001$  (both 16-bit sources) stores  $0x10000$  in a 24-bit register and sets Zero and Carry flags because operation size is 16 bits.

#### 35.15.8.2.1.1 Carry flag (C)

In an unsigned addition without shifting, Carry flag is the ALU carry from bit 7 to 8, 15 to 16, or 23 to 24 on 8-, 16- and 24-bit operation sizes respectively. In an unsigned subtraction without shifting, Carry Flag represent the sign of ALU's result considering operation size (Carry Flag equal to 1 means a negative result).

Carry flag definition is operation-dependent. The Carry flag in add/subtraction with Post-ALU shift is defined in [Table 35-362](#). Find the definitions for other operations in the following sections.

### 35.15.8.2.1.2 Negative flag (N)

Negative flag indicates the sign of result based on the operation size, regardless of the operation performed, as shown in the following table.

**Table 35-358. Negative (N) flag behavior**

| Operation size | Value                   |
|----------------|-------------------------|
| 8 bits         | $N = \text{result}[7]$  |
| 16 bits        | $N = \text{result}[15]$ |
| 24 bits        | $N = \text{result}[23]$ |

### Note

The N flag may not reflect the sign of the value actually written into the destination register, if it does not have the same size of the operation (see [Flags Sampling Control](#)). This is always the case for registers RAR (14 bits) and CHAN (5 bits).

### 35.15.8.2.1.3 Overflow (V)

Overflow is updated only on addition (with or without carry) and absolute value operations. In signed operations, overflow flag indicates that the result of arithmetic operation (add or subtraction) can not be represented by a word of the size of the operation. Overflow flag behavior for addition is defined in the following table. Overflow flag for Absolute operation is explained in [Absolute Value operation](#). V Flag is calculated using ALU adder output (i.e., it is not affected by 1-bit shift/rotate operations).

**Table 35-359. Overflow flag on addition - V**

| Op. size | Value <sup>1</sup>                                                                                                |
|----------|-------------------------------------------------------------------------------------------------------------------|
| 8 bits   | $(AS[7] \& BS[7] \& !\text{alu\_adder\_output}[7]) \vee (!AS[7] \& !BS[7] \& \text{alu\_adder\_output}[7])$       |
| 16 bits  | $(AS[15] \& BS[15] \& !\text{alu\_adder\_output}[15]) \vee (!AS[15] \& !BS[15] \& \text{alu\_adder\_output}[15])$ |
| 24 bits  | $(AS[23] \& BS[23] \& !\text{alu\_adder\_output}[23]) \vee (!AS[23] \& !BS[23] \& \text{alu\_adder\_output}[23])$ |

1. BS is taken after any inversion by the BINV field, but not added to the carry bit (CIN field)

**NOTE**

For V-flag definition on the absolute operation, see “Absolute Value Operation”.

**35.15.8.2.1.4 Zero flag (Z)**

Zero flag equal to 1 indicates that the result from the ALU, limited to the operation size, is zero, regardless of the operation performed, whether the result is written, or where it is written. It depends on the operation size, as shown in the following table.

**Table 35-360. Zero flag - Z**

| Operation size | Value                                   |
|----------------|-----------------------------------------|
| 8 bits         | $Z = (\text{result}[7:0] == 0x00)$      |
| 16 bits        | $Z = (\text{result}[15:0] == 0x0000)$   |
| 24 bits        | $Z = (\text{result}[23:0] == 0x000000)$ |

**35.15.8.2.2 ALU ADD operation with and without shifting**

ADD operation is selected by ALUOP or ALUOPI fields and when none of them is available in a microinstruction format<sup>33</sup>. Optionally, result can be shifted or rotated right by 1 bit, which is selected by SHF, ALUOP or ALUOPI fields. See [Microinstruction Set](#) for more details. The following table describes how CIN and BINV fields change ADD operation behavior.

**Table 35-361. Types of ADD operations**

| BINV | CIN | Operation (adder output) |
|------|-----|--------------------------|
| 1    | 1   | $AS + BS$                |
| 1    | 0   | $AS + BS + 1$            |
| 0    | 0   | $AS - BS$                |
| 0    | 1   | $AS - BS - 1$            |

ALU adder output can be 1-bit shifted or 1-bit rotated right as follows:

Shift right:

```
if BINV==1
    result [23:0] = adder_output [24:1]
else
    result [23:0] = adder_output [24:1] xor 0x800000
endif
```

Shift left:

33. ALU operations only occur on formats where a destination field is found (T2ABD/T2D).

## Functional description

```
result[23:1] = adder_output[22:0]
result[0]     = 0
```

### Rotate right:

```
case (opsize/CCSV)
8-bit:
    result[6:0] = adder_output[7:1]
    result[7]   = adder_output[0]
    result[23:8] = adder_output[23:8]
16-bit:
    result[14:0] = adder_output[15:1]
    result[15]   = adder_output[0]
    result[23:16] = adder_output[23:16]
24-bit:
    result[22:0] = adder_output[23:1]
    result[23]   = adder_output[0]
```

### Note

Only for the Post-ALU rotate right, the operation size is determined by the field CCSV (see [Flags Sampling Control](#)). For example: if CCSV=00, T4ABS=P (24-bits), T4BBS=A (24 bits), T2ABD=B (24 bits), and ALUOP="Add ROR", then B gets A+P with bits 7:0 rotated, even though the operation size is 24 bits.

The following table describes Carry flag behavior.

**Table 35-362. Carry flag update on ADD operation**

| BINV <sup>1</sup>                                                                            | Op. size | shift/rotate | Value                              |
|----------------------------------------------------------------------------------------------|----------|--------------|------------------------------------|
| 1                                                                                            | 8 bits   | none         | adder carry from bit 7 to bit 8    |
| 1                                                                                            | 16 bits  | none         | adder carry from bit 15 to bit 16  |
| 1                                                                                            | 24 bits  | none         | alu_adder_output[24]               |
| 0                                                                                            | 8 bits   | none         | !adder carry from bit 7 to bit 8   |
| 0                                                                                            | 16 bits  | none         | !adder carry from bit 15 to bit 16 |
| 0                                                                                            | 24 bits  | none         | !alu_adder_output[24]              |
| 0 or 1                                                                                       | 8 bits   | shift left   | alu_adder_output[7]                |
| 0 or 1                                                                                       | 16 bits  | shift left   | alu_adder_output[15]               |
| 0 or 1                                                                                       | 24 bits  | shift left   | alu_adder_output[23]               |
| 0 or 1                                                                                       | x        | shift right  | alu_adder_output[0]                |
| 1                                                                                            | 8 bits   | rotate right | adder carry from bit 7 to bit 8    |
| 1                                                                                            | 16 bits  | rotate right | adder carry from bit 15 to bit 16  |
| 1                                                                                            | 24 bits  | rotate right | alu_adder_output[24]               |
| 0                                                                                            | 8 bits   | rotate right | !adder carry from bit 7 to bit 8   |
| 0                                                                                            | 16 bits  | rotate right | !adder carry from bit 15 to bit 16 |
| 0                                                                                            | 24 bits  | rotate right | !alu_adder_output[24]              |
| except on max-constant generation (see <a href="#">Max Const Generation With T4BBS=111</a> ) |          |              |                                    |

1. BINV has no effect on carry-out when used to code max constant (see [Max Const Generation With T4BBS=111](#)).

Flags N and Z on shift are updated according to the result after shift. Flag V with shift is updated according to the ADD operation only, the same way as without shift.

### 35.15.8.2.3 ADC Operation

ADC operation is selected by the ALUOP field. CIN field is ignored when this operation is selected. The following table describes how BINV change ADC operation behavior.

**Table 35-363. Types of ADC operations**

| BINV | CIN | Operation        |
|------|-----|------------------|
| 1    | x   | AS + BS + C flag |
| 0    | x   | AS - BS - C flag |

Flags behave exactly the same way as for ADD operation without shift/rotate.

### 35.15.8.2.4 Bitwise Operations

Bitwise AND, OR and XOR are selected by ALUOP field. On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V Flags are never updated on these operations. The following table describes AND, OR and XOR bitwise operations.

**Table 35-364. Types of Bitwise Operations**

| ALUOP | BINV | Operation  |
|-------|------|------------|
| 10000 | 1    | AS   BS    |
| 10000 | 0    | AS   (~BS) |
| 10001 | 1    | AS ^ BS    |
| 10001 | 0    | AS ^ (~BS) |
| 10010 | 1    | AS & BS    |
| 10010 | 0    | AS & (~BS) |

### 35.15.8.2.5 Set Bit / Clear Bit Operations

These operations set or clear the AS bit determined by BS[4:0]. If the bit number resolves to a value greater than 23, no bit is set or cleared (i.e., result is equal to AS). On these operations CIN field is ignored and BINV field inverts (bitwise NOT) BS. C and V flags are never updated for set/clear bit operations. These operations **override** B-Source size to 8 bits.

set bit (BINV = 1):

## Functional description

```
result = AS | (1 << BS)
```

clear bit (BINV = 1):

```
result = AS & ~(1 << BS)
```

set bit (BINV = 0):

```
result = AS | (1 << (31 - BS))
```

clear bit (BINV = 0):

```
result = AS & ~(1 << (31 - BS))
```

### 35.15.8.2.6 Exchange Bit

Exchange the AS bit determined by BS with C flag. If the bit number resolves to a value greater than 23, no exchange is performed (i.e., result is equal to AS and C flag is not updated). This operation **overrides** BS size to 8 bits. On this operation, CIN field is ignored and BINV field inverts (bitwise NOT) BS. V flag is never updated on exchange bit operation. C flag is always updated, regardless of CCSV, unless BS > 23.

Exchange Bit (BINV=1):

```
if BS <= 23
begin
    temp_C_flag = AS[BS]
    if C_flag == 1
        result = AS | (1 << BS)
    else
        result = AS & ~(1 << BS)
    C_flag = temp_C_flag
end
```

Exchange Bit (BINV = 0):

```
if (31 - BS) <= 23
begin
    temp_C_flag = AS[31 - BS]
    if C_flag == 1
        result = AS | (1 << (31 - BS))
    else
        result = AS & ~(1 << (31 - BS))
    C_flag = temp_C_flag
end
```

### 35.15.8.2.7 Multibit shift/rotate operations

These operations shift or rotate AS by 2, 4, 8 or 16 bits. Size of shift/rotate is determined by BS[1:0]. The following table describes the number of shifted/rotated bits depending on BS[1:0] value.

**Table 35-365. Number of shifted/rotated bits for each BS[1:0] value**

| BS[1:0] | Bits shifted/rotated |
|---------|----------------------|
| 0       | 2                    |
| 1       | 4                    |
| 2       | 8                    |
| 3       | 16                   |

Shift right is a logical operation (i.e., zeros are inserted on left). Multibit shift and rotate operations **overrides** BS size to 8 bits. The shifts and rotate operate on 24 bits, independently of the operation size.

V flag is never updated for multibit shift or rotate operations. Carry flag behavior is described in the following table. CIN is ignored in these operations, but BINV is effective.

**Table 35-366. Carry flag value on multibit shift/rotate operations**

| ALUOP                | BS[1:0] | C flag value <sup>1</sup> |
|----------------------|---------|---------------------------|
| 11001 (shift left)   | 0       | AS[22]                    |
| 11001 (shift left)   | 1       | AS[20]                    |
| 11001 (shift left)   | 2       | AS[16]                    |
| 11001 (shift left)   | 3       | AS[8]                     |
| 11010 (shift right)  | 0       | AS[1]                     |
| 11010 (shift right)  | 1       | AS[3]                     |
| 11010 (shift right)  | 2       | AS[7]                     |
| 11010 (shift right)  | 3       | AS[15]                    |
| 11011 (rotate right) | 0       | AS[2]                     |
| 11011 (rotate right) | 1       | AS[4]                     |
| 11011 (rotate right) | 2       | AS[8]                     |
| 11011 (rotate right) | 3       | AS[16]                    |

1. CCS/CCSV can disable flag update on multibit shift/rotate, but the specified flag size in CCSV is ignored for the C flag.

### 35.15.8.2.8 Absolute Value operation

Absolute Value operation is selected by ALUOP field. On this operation, AS is interpreted as a signed number and its absolute value is the result. V and N flags are updated with the result signal determined by the operation size. AS bit 23 after size override and sign extension (if any, see [A-Source Size Override](#)), regardless of A-source register size, is used to check the operand signal and is copied to C-flag. Note that if AS is 8-bit or 16-bit, its sign is taken into account and copied to C only if sign-extension is performed. The following table summarizes flag updating for Absolute Value operation.

This operation is independent of B-source. Instruction fields T4BBS, BINV and CINV are ignored in this operation. The Absolute Value operation size is the minor between A-source size and Destination size.

**Table 35-367. ALU flags in Absolute Value operation**

| operation size | V, N <sup>1</sup> | C      | Z                     |
|----------------|-------------------|--------|-----------------------|
| 8              | alu_output[[7]    | AS[23] | alu_output[7:0] == 0  |
| 16             | alu_output[15]    |        | alu_output[15:0] == 0 |
| 23             | alu_output[23]    |        | alu_output[23:0] == 0 |

1. V, N can be 1 on 8- and 16-bit Absolute Value, because the operand sign is always taken from bit 23. V, N can also be 1 in 23-bit Absolute Value (or 8-bit and 16-bit with sign extension), if the operand is 0x800000 (0x80, 0x8000).

### 35.15.8.3 MAC and Divide Unit (MDU)

MDU is an autonomous resource in the microengine which can carry out sequential multiply, multiply-accumulate, fractional multiplication and divide operations, selected through the microinstruction fields ALUOP or ALUOPI. The unit supports signed and unsigned multiply and fractional multiplication of any combination of 8, 16 or 24 bit operands <sup>34</sup>, and also signed and unsigned 24-bit multiply-accumulate. Divide operation is unsigned, and both operands are always 24-bit wide.

Depending on the size of operands and the type of operation, MDU can take more than one microcycle to execute the operation, but microengine continues to execute microinstructions in parallel. When the microcode issues an END command, any MDU executing operation terminate immediately and is left incomplete. When selecting an operation that uses MDU, the result is always placed in MACH and MACL registers, and the register selected as destination does not have its value changed ([Selecting sources and destination](#)). During calculations, MACH and MACL holds temporary values and should not be written, otherwise the result is unspecified. One must not start an MDU operation while MDU is already busy: the result is unspecified for both the ongoing operation and the started one.

MDU Operations update its own set of 5 flags, described in [MDU Flags](#). MDU operations never update C, N, V and Z flags. CIN and BINV microinstruction fields affect MDU operations according to the following table.

**Table 35-368. CIN and BINV with MDU Operations**

| B-source operand | BINV | CIN | Op. Performed |
|------------------|------|-----|---------------|
| signed           | 1    | 1   | AS mdu_op BS  |

*Table continues on the next page...*

34. There is no distinct selection of 24-bit fractional multiplication, for it works exactly as a 24-bit ordinary multiplication.

**Table 35-368. CIN and BINV with MDU Operations (continued)**

| B-source operand      | BINV | CIN | Op. Performed    |
|-----------------------|------|-----|------------------|
|                       | 0    | 0   | AS mdu_op (-BS)  |
|                       | 1    | 0   | reserved         |
|                       | 0    | 1   | reserved         |
| unsigned <sup>1</sup> | 1    | 1   | AS mdu_op BS     |
|                       | 1    | 0   | AS mdu_op (BS+1) |
|                       | 0    | x   | reserved         |

1. includes the B-source (unsigned) in fmults (signed) operations.

### 35.15.8.3.1 Multiply and Multiply-Accumulate Operation Length

MDU needs 2 sources, A source and B source, to perform an operation. The time needed to perform a multiply or multiply-accumulate is:

- on 24-bit x 8 bit multiplies: 2 microcycles (one start-MDU plus one execution microcycle)
- on 24-bit x 16 bit multiplies: 3 microcycles (one start-MDU plus two execution microcycles)
- on 24 bit x 24 bit multiplies/macs: 4 microcycles (one start-MDU plus three execution microcycles)

An internal pipeline in MDU allows multiply-accumulate (or even non-fractional multiply) operations to start one microinstruction before a multiplication or multiply-accumulate (signed or unsigned) has been completed (e.g., one can start one multiply or multiply-accumulate once every three microinstructions). However, by doing that it is not possible to read the result in MACH and MACL (although the MDU flags can be tested), so this is intended to be used in a multiply-accumulate sequence. It is also allowed to mix different sizes in multiply/mac sequences.

Multiply-accumulate operations are similar to multiply operations, except that the contents of MACH and MACL registers are added to the multiplication result.

When multiply or multiply accumulate operations finish, MACL and MACH hold the least and the most significant 24-bit words, respectively.

### 35.15.8.3.2 Divide Operation Length

The divide operation is always unsigned. The division completes in 13 microcycles, meaning that after the start divide microinstruction, one has to wait for 12 microcycles and then read the result and the remainder in MACH and MACL registers. During the 12 execution microcycles, microengine can execute microinstructions unrelated to the MDU.

### 35.15.8.3.3 Signed Multiplication (mults)

MDU signed multiplication is defined as follows:

```
(signed) MACH,MACL = (signed) AS * (signed) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is set if result is negative.

### 35.15.8.3.4 Unsigned Multiplication (multu)

MDU unsigned multiplication is defined as follows:

```
(unsigned) MACH|MACL = (unsigned) AS * (unsigned) BS
```

MC and MV flags are reset. MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

### 35.15.8.3.5 Signed Multiply-Accumulate (macs)

MDU signed multiply-accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (signed) AS * (signed) BS
```

MC is not altered.

MV is set if result can not be represented by a 48-bit signed number. MACS never resets MV flag: it is left as is if no overflow occurs, or set it otherwise. This allows checking the overflow flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < -247) || ({MACH,MACL} += AS * BS > 247 - 1))
    MV = 1
```

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

### 35.15.8.3.6 Unsigned Multiply-Accumulate (macu)

MDU Unsigned Multiply-Accumulate is defined as follows:

```
(signed/unsigned) {MACH,MACL} += (unsigned) AS * (unsigned) BS
```

MC is set if result can not be represented by a 48-bit unsigned non-negative number. MACU never resets MC flag: MC flag is left as is if no carry occurs, or set otherwise. This allows checking the carry flag only once at the end of a series of multiply-accumulate operations in a scalar product calculation.

```
if (({MACH,MACL} += AS * BS < 0) || ({MACH,MACL} += AS * BS > 248 - 1))
    MC = 1
```

MV is not altered.

MZ is set if result is 0, resets otherwise. MN is a copy of the most significant bit of result.

Note that only 24-bit multiply-accumulate is available.

### 35.15.8.3.7 Signed Fractional Multiplication (fmults)

MDU Signed Fractional Multiplication takes the B-Source as an **unsigned** 8- or 16-bit<sup>35</sup> fraction between 0 and  $(2^8 - 1)/2^8$  (inclusive) for the 8-bit operation, or between 0 and  $(2^{16}-1)/2^{16}$  (inclusive) for the 16-bit operation. Only A-Source is taken as a signed number. The value of B-Source is considered the unsigned numerator of a fraction with denominator  $2^8$  or  $2^{16}$  for the 8- and 16-bit operations, respectively.

The integer part of the result is stored in MACH, and the fractional part in MACL. The result is signed, so that the concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations. To calculate the unsigned numerator of the fractional part (with denominator  $2^{24}$ ) of the result, one must take the absolute value of MACL considering the signal of the result (not MACL alone), i.e.: if flag MN=1, invert MACL and add 1.

MDU flags are updated in the same way as in the Signed Multiplication.

### 35.15.8.3.8 Unsigned Fractional Multiplication (fmultu)

MDU Unsigned Fractional Multiplication takes both A-Source and B-Source as unsigned operands. B-Source is taken as an 8- or 16-bit<sup>36</sup> fraction between 0 and  $(2^8 - 1)/2^8$  (inclusive) for the 8-bit operation, or between 0 and  $(2^{16}-1)/2^{16}$  (inclusive) for the 16-bit operation. The value of B-Source is considered the numerator of a fraction with denominator  $2^8$  or  $2^{16}$  for the 8- and 16-bit operations, respectively.

35. 24-bit fractional signed/unsigned multiplication is equivalent to mults/multu.

36. 24-bit fractional signed/unsigned multiplication is equivalent to mults/multu.

The integer part of the result is stored in MACH, and the fractional part in MACL. The fractional part in MACL is the numerator of a fraction with denominator  $2^{24}$ . The concatenation of MACH and MACL form a 48-bit fixed point number with a 24-bit integer part, both for 8- and 16-bit operations.

MDU flags are updated in the same way as in the Unsigned Multiplication.

### **35.15.8.3.9 Unsigned Divide (div)**

At the end of a divide operation MACL holds the result of the division, taking A-source as numerator and B-source as denominator, while MACH holds the remainder. If a divide by 0 is executed, MACL holds the maximum unsigned number (0xFFFFFFFF) as result and flag MV is set to indicate division by 0 (otherwise reset). The contents of MACH become indetermined.

MC flag is always reset.

MZ flag is set if MACL equals 0, and reset otherwise.

MN receives a copy of MACH bit 23 (msb from the remainder).

Note that signed division is not available.

### **35.15.8.3.10 MDU Flags**

MDU has its own flags to indicate the result and status of an MDU operation. They are: MC, MZ, MV, MN and MB. All MDU flags are updated with the final result at the end of the operation, and do not change until the next operation finishes. Therefore it is possible to start a new MDU operation and test the flags of the previous one in parallel, except for mult/mac with 8-bit operand (takes only 1 microcycle).

#### **35.15.8.3.10.1 MDU Negative Flag - MN**

MN flag is always a copy of MACH bit 23 at the end of the operation, either in signed or unsigned ones. Note that MACH holds the rest of a division operation, which is always unsigned.

#### **35.15.8.3.10.2 MDU Carry Flag - MC**

MDU carry flag indicates if the result cannot be represented by a 48-bit number, in Signed and Unsigned Multiply Accumulates. It is reset in the other operations.

### 35.15.8.3.10.3 MDU Zero Flag - MZ

In multiply and multiply-accumulate operations, MDU zero flag is asserted if MACH and MACL are equal to zero at the end of an operation. In divide operations, zero flag is asserted if MACL (result) is equal to 0.

### 35.15.8.3.10.4 MDU Overflow Flag - MV

In multiply operations, MV flag is negated and keeps negated in the end, because the result of a multiplication can always fit in a 48-bit result (MACH and MACL concatenated). In a multiply-accumulate operation, MV is asserted if the result size is wider than 48 bits. MV flag work in both signed and unsigned operations.

In divide operations it is only asserted if a divide-by-zero operation was executed.

### 35.15.8.3.10.5 MDU Busy Flag (MB)

MB tests as true at the next microinstruction after the MDU start operation, and as false at the last microcycle of any MDU operation execution.

## 35.15.8.4 Branch conditions

Microengine allows conditional branch. There are five sets of flags that can be tested in a conditional branch: ALU flags, MDU flags, P flags, Channel flags, and Semaphore flag (flag SMLCK).

When a thread starts to be executed, the values in MDU and ALU flags are not initialized. ALU flags are described in [ALU flags](#), MDU flags are described in [MDU Flags](#). MDU and ALU flags are updated during execution of microinstructions.

P flags are actually the upper byte of P register, which optionally can work as user defined flags (see [P Register](#)).

Channel flags Flags0, Flag1, MRLA, MRLB, TDLA, TDLB, PSS, PRSS and PSTO are obtained from the selected channel (value in CHAN register), while channel flags, LSR, FM[0] and FM[1] are selected by the serviced channel, regardless of the CHAN value<sup>37</sup>.

Flags TDLA/B, MRLA/B, LSR, FM and PSS, are sampled at the beginning of a thread. Flag PSS does not change during its execution while CHAN register is not written. When a write in CHAN register is performed, all flags except LSR and FM are updated according to the channel specified by CHAN value. Flags MRLA/B and TDLA/B are reset when their respective latches in channel are cleared by microcode.

---

37. Serviced channel does not change during execution of a thread, and it is the channel that requested a service (initial value of CHAN register when a thread starts).

**Table 35-369. Channel flags as branch condition**

| Flag  | Description                                | Service or selected channel                                                                                                                                                                                                                     |
|-------|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Flag0 | State Resolution flag                      | reflects the selected channel (CHAN)                                                                                                                                                                                                            |
| Flag1 | State Resolution flag                      | reflects the selected channel (CHAN)                                                                                                                                                                                                            |
| MRLA  | Match A Recognition Latch                  | these flags reflect the selected channel (CHAN)see <a href="#">MRLA/B - Match Recognition Latches</a> and <a href="#">TDLA/B - Transition Detect Latches</a> for more information.                                                              |
| MRLB  | Match B Recognition Latch                  |                                                                                                                                                                                                                                                 |
| TDLA  | Transition A Detection Latch               |                                                                                                                                                                                                                                                 |
| TDLB  | Transition B Detection Latch               |                                                                                                                                                                                                                                                 |
| LSR   | Link Service Request                       | reflects the serviced channel.                                                                                                                                                                                                                  |
| PRSS  | Input Pin state sampled at service request | reflects the selected channel (CHAN). Does not change if CHAN is not changed.                                                                                                                                                                   |
| PSS   | Sampled Input Pin State                    | reflects the selected channel (CHAN). Does not change if CHAN is not changed (see <a href="#">Pin Control Registers</a> ).                                                                                                                      |
| PSTI  | Current Input Pin State.                   | reflects the selected channel (CHAN). Changes any time.                                                                                                                                                                                         |
| PSTO  | Current Output Pin State                   | reflects the selected channel (CHAN). Changes any time.                                                                                                                                                                                         |
| FM    | Function Mode Bits                         | reflects the Function Mode for serviced channel (see <a href="#">eTPU Channel n Status Control Register for Engine 1</a> (eTPU_CCCR_CnSCR_ENG1) and <a href="#">eTPU Channel n Status Control Register for Engine 2</a> (eTPU_CCCR_CnSCR_ENG2)) |

Semaphore condition SMLCK always indicates if a semaphore is locked for the Engine, resolving as false before any lock attempt. For each trial, the SMLCK flag is updated. The SMLCK value set in one thread is not meaningful to the other. After a free, the SMLCK condition tests as false until a new lock attempt on the same thread.

Branch conditions are selected through instruction fields BCC and BCF (see [Conditional/unconditional branch](#)).

### 35.15.9 Microinstruction Set

Each microinstruction can execute up to 3 microoperations in parallel. Microinstructions are grouped into formats, and there are four types of microoperations:

- ALU/MDU Operations
- SDM Operations
- Channel Configuration/Control Operations
- Flow Control Operations

Each microinstruction format is defined by a set of microinstruction fields, which determine the operations, each belonging to one of the groups above (there may be several in one group). Complete microinstruction formats are shown in [Microinstruction formats](#).

Parallelism conflicts may arise when two operations are executed in the same microinstruction. These situations are explained in [Microinstruction Parallelism Issues](#).

### 35.15.9.1 SDM Microoperations

The access to SDM is made by providing an address and a register to perform a data transfer, except semaphore operations, which are also classified in the SDM group. Only P and DIOB registers can exchange data with SDM. Microengine always addresses SDM in 32-bit boundaries, for 8, 24, or 32 bit wide data.

Direction is determined by the field RW in all addressing modes: RW=0 selects read and RW=1 selects write.

#### 35.15.9.1.1 SDM Addressing Modes

There are 4 addressing modes in eTPU:

- Absolute
- Selected Channel Relative
- Indirect
- Engine Relative

The addressing modes Absolute and Selected Channel Relative use immediate bits to form the physical address of SDM, which is identified in microinstruction as a field called AID. AID field can be 3-, 7-, or 8-bit wide depending on the addressing mode.

##### 35.15.9.1.1.1 Absolute Addressing Mode

In Absolute addressing mode, the address range is 256 parameters, addressed by field AID, which in this mode is 8-bit wide. These parameters are located in SDM addresses from 0 to 255.

```
physical_address = AID[7:0]
```

### 35.15.9.1.1.2 Selected Channel Relative Addressing Mode

In Selected Channel Relative addressing mode, only the first 8 (with 3-bit AID) or 128 (with 7-bit AID) parameters of the selected channel are accessible, depending on the microinstruction format. Physical address is calculated using the channel parameter base address that is specified in the CPBA field of [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#). AID field is added to channel parameter base address to compose the physical address. The address equation is:

```
physical_address = selected_channel_parameter_base_address + AID[6:0], or
physical_address = selected_channel_parameter_base_address + AID[2:0]
```

### 35.15.9.1.1.3 Indirect Addressing Mode

In Indirect Addressing mode the physical address is taken from DIOB register. Only DIOB bits 14 to 2 are relevant. Since the SDM word address is shifted two bits up in DIOB, its contents hold the same parameter address value used by Host. The address equation for SDM access is:

```
physical_address = DIOB[13:2], or
physical_address = (truncated to 12 bits) (DIOB / 4)
```

Indirect addressing mode is used to access the Shared Subsystem Area when `eTPU_CCCR_CxCR_ENGn[SSMAE]=1` and DIOB addresses the 16 Kbytes just above the SDM range (DIOB bit 14 = 1). See [Shared Subsystems support](#) for more details. If `SSMAE=0`, accesses with DIOB bit 14 = 1 hit the same SDM addresses as with bit 14 = 0, providing full backwards compatibility with respect to DIOB contents.

Indirect addressing mode can have post-increment or pre-decrement on DIOB, allowing stack operations. See [DIOB stack operation](#) for more information.

### 35.15.9.1.1.4 Engine Relative Addressing Mode

In Engine Relative Addressing mode the physical address is the concatenation of the `eTPU_SCR_ECR_ENGn[ERBA]` field (see [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#)) with the 7-bit AID instruction field. This allows the same function microcode, when running on distinct engines, to access different address spaces, global to the engine only.

The SDM physical word address in Engine Relative Addressing mode is calculated as follows:

```
physical address = (eTPU_SCR_ECR_ENGn[ERBA] << 7) + AID[6:0]
```

### 35.15.9.1.2 SDM source/destination registers

When performing an SDM operation, only DIOB or P can be used as data source or destination. P is 32-bit wide, and DIOB is 24-bit wide. Microinstruction field P/D (1 bit) is used to choose between P and DIOB as data the source or destination. When the P/D field is not available in microinstructions that support SDM access, the source/destination is P.

**Table 35-370. SDM source/destination Register Selection**

| P/D | Meaning     |
|-----|-------------|
| 0   | P access    |
| 1   | DIOB access |

### 35.15.9.1.3 SDM Operation Size

When using DIOB register to perform SDM data transfers, the operation size is always 24-bit wide (lower 24 bits of SDM). When using P register, the operation size can be 8-, 24- or 32-bit wide, which is controlled by microcode RSIZ field (2 bits). RSIZ meaning is shown in the following table.

**Table 35-371. SDM P access Size**

| RSIZ | P access                                                              | DIOB access             |
|------|-----------------------------------------------------------------------|-------------------------|
| 00   | full 32-bit access (i.e. P[31:0]=SDM[addr] [31:0])                    | RESERVED                |
| 01   | only upper 8 bits are transferred (i.e. P[31:24] = SDM[addr] [31:24]) | RESERVED                |
| 10   | only lower 24 bits are transferred (i.e. P[23:0] = SDM[addr] [23:0])  | DIOB = SDM[addr] [23:0] |
| 11   | RESERVED                                                              | RESERVED                |

RSIZ is not available in all microinstructions that support SDM access. In microinstructions where RSIZ field is not available, SDM access will be 24 bits by default.

When performing a Zero SDM write operation (see [Zero SDM Operation](#)), RSIZ defines the size of operation regardless of the P/D field ([SDM source/destination registers](#)).

### 35.15.9.1.4 SDM access direction

RW field defines the direction of the access in the SDM. The access direction is summarized in the following table.

**Table 35-372. SDM access direction**

| R/W | Meaning                                      |
|-----|----------------------------------------------|
| 0   | read SDM parameter into P or DIOB registers  |
| 1   | write SDM parameter from P or DIOB registers |

### 35.15.9.1.5 Zero SDM Operation

Zero SDM operation is controlled by microcode field ZRO (1bit). When ZRO field is 0, the data portion written in SDM or in P/DIOB (SDM read) registers will always be 0x0. When performing a Zero SDM write operation, the RSIZ is relevant regardless of the P/D field (usually RSIZ is meaningful only for P/D = 0), which means that zero SDM write operation can be performed with 32, 24 or 8 bits according to SDM operation size. These conditions are summarized in the following table.

**Table 35-373. Zero SDM Operation**

| ZRO | RW | P/D | Meaning                                                                                       |
|-----|----|-----|-----------------------------------------------------------------------------------------------|
| 0   | 0  | 0   | Clear P register. Size is determined by RSIZ field. See <a href="#">SDM Operation Size</a>    |
| 0   | 0  | 1   | Clear DIOB (all 24 bits), independently of RSIZ                                               |
| 0   | 1  | x   | Clear SDM parameter. Size is determined by RSIZ field. See <a href="#">SDM Operation Size</a> |
| 1   | RW | P/D | Regular SDM operation                                                                         |

### Note

When field STC is present, STC=11 also disables Zero SDM operation (see [Table 35-374](#)). The conflicts with DIOB operations (see [DIOB stack operation](#)) and ALU operations are resolved like a normal SDM operation (see [Table 35-415](#)).

Zero SDM read operations do check memory errors on the read data, however discarded. Zero SDM write operations normally update the ECC of the written data.

### 35.15.9.1.6 DIOB stack operation

SDM Indirect Addressing Mode (see [Indirect Addressing Mode](#)) is used if STC field (2 bits) exists in the microinstruction, controlling automatic increment/decrement of DIOB register, as shown in the following table, thus allowing stack operations. DIOB is incremented and decremented in word addresses, only from bits 15 downto 2, i.e.: the bits 23 to 16 and 1 to 0 are left untouched by STC pre-decrement and post-increment.

**Table 35-374. DIOB Post-Increment / Pre-Decrement - STC**

| STC | Meaning                                |
|-----|----------------------------------------|
| 00  | Post-Increment of DIOB                 |
| 01  | Pre-Decrement of DIOB                  |
| 10  | No Increment/Decrement (normal access) |
| 11  | No SDM Access <sup>1</sup>             |

1. Also disables Zero SDM operation.

### 35.15.9.1.7 Semaphore Operations

Semaphore lock and free operations are available through eTPU microcode. For more information about semaphores see [Hardware Semaphores](#). There are 2 microinstruction fields that control semaphore operations: FL (1 bit) and SMPR (2 bits). Serviced channel sees 4 semaphores, selected by field SMPR.

**Table 35-375. Semaphore Operations Fields**

| Field | Meaning                                   |
|-------|-------------------------------------------|
| FL    | 0 = free semaphore,<br>1 = lock semaphore |
| SMPR  | semaphore number selector                 |

When freeing a semaphore, the field SMPR has no meaning. This is because only one semaphore can be locked at a time by each engine, so when freeing a semaphore it is not necessary to specify its number.

#### Note

If microcode tries to lock a semaphore already locked for the same Engine, the semaphore continues locked for the Engine and the SMLCK branch condition resolves as true.

### 35.15.9.2 ALU/MDU Operations

ALU/MDU microoperations mostly comprises two sources, one destination and one operation. The operation is generally selected through fields ALUOP, ALUOPI or SHF. In formats where there is no operation selection field (ALUOP, ALUOPI or SHF), the operation performed is always addition; however, it is possible to perform subtraction, increment or decrement using fields BINV (see [B-Source Inversion](#)) and CIN (see [Carry-in Control](#)).

### 35.15.9.2.1 Source and Destination Register Set Selection

Microcode field T4ABS allows selection of a source from either one of two register sets, shown in [Table 35-379](#). The same applies to T2ABD, used for ALU destination selection with other two register sets, as shown in [Table 35-380](#). Microinstruction fields ABSE and ABDE control the register set selection for source and destination, respectively, when available at the format. In formats without ABSE/ABDE, the field T4BBS determines the register sets used by T2ABD and T4ABS, as shown in [Microinstructions without fields ABSE and ABDE](#).

#### 35.15.9.2.1.1 Microinstructions With Fields ABSE and ABDE

In microinstructions where ABSE and ABDE fields are available (1 bit each), ABSE controls register set selection for T4ABS and ABDE controls register set selection for T2ABD. The following table shows the meaning of values for ABSE and ABDE fields.

**Table 35-376. Register Set Selection by ABSE or ABDE**

| ABSE or ABDE | Register Set Selected |
|--------------|-----------------------|
| 0            | second                |
| 1            | first                 |

#### 35.15.9.2.1.2 Microinstructions without fields ABSE and ABDE

When ABSE and ABDE are not available in a microinstruction format, register set is selected by T4BBS field. The following table explains how to select a register set either for T4ABS and T2ABD.

**Table 35-377. Register set selection by T4BBS without ABSE and ABDE**

| T4BBS             | Register set for T2ABD | Register set for T4ABS |
|-------------------|------------------------|------------------------|
| 0xx               | first                  | first                  |
| 100               | second                 | second                 |
| 101               | second                 | first                  |
| 110               | first                  | second                 |
| 111               | first                  | first                  |
| none <sup>1</sup> | first                  | first                  |

1. Refers to operations with immediate data as B-source, without ABSE and ABDE.

### 35.15.9.2.2 Selecting sources and destination

All ALU/MDU operations need 2 sources (called AS and BS) and 1 destination (called AD), except for some of those that use immediate data (see [Operations With Immediate Data](#)). Fields T4ABS (4 bits), ABSE (1 bit), T4BBS (3 bits) select sources, while T2ABD (4 bits) and ABDE (1 bit) select the destination. When MDU is used (multiply/divide), T2ABD destination selection is ignored and results are stored in MACH and MACL (see [MAC and Divide Unit \(MDU\)](#)). ABSE and ABDE are not available in some microinstruction formats that support ALU/MDU operations. However, in all formats where ABSE is available, ABDE is also available and vice-versa. The existence of ABSE/ABDE fields changes the meaning of T4BBS field, as shown in the table below. On instructions with immediate data, it is used as B-source (see [Operations With Immediate Data](#)).

All sources and destinations have a size associated to it, and these sizes are used to select flag sample position (see [Flags Sampling Control](#)). Sizes can be 8, 16 or 24 bits. Registers that are not exactly of one of these sizes are treated as the immediately upper size (e.g., CHAN[4:0] is an 8-bit source). See [Flags Sampling Control](#) for more information.

Some parallelism issues arise when selecting P, DIOB, ERTA or ERTB as destination registers, since they can be modified by other microoperations in the same microinstruction (see [Microinstruction Parallelism Issues](#) for details).

**Table 35-378. B source selection - T4BBS**

| T4BBS | Meaning in microinstruction formats with ABSE/ABDE                                         | Meaning in microinstruction formats without ABSE/ABDE <sup>1</sup> |
|-------|--------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| 000   |                                                                                            | BS[23:0] = P[23:0]                                                 |
| 001   |                                                                                            | BS[23:0] = A[23:0]                                                 |
| 010   |                                                                                            | BS[23:0] = SR[23:0]                                                |
| 011   |                                                                                            | BS[23:0] = DIOB[23:0]                                              |
| 100   | reserved                                                                                   | BS = 0                                                             |
| 101   | reserved                                                                                   | BS = 0                                                             |
| 110   | reserved                                                                                   | BS = 0                                                             |
| 111   | BS=0, or Max const., if CIN=0 and BINV=0 (see <a href="#">Generating "max" constant</a> ). |                                                                    |

1. T4BBS also selects A-source and destination register set in this case, according to [Table 1](#).

T4ABS selects one source from 2 register sets, shown in the following table. ABSE and T4BBS control which set T4ABS field uses to select the source. For more information about how to select a register set for T4ABS and T2ABD see [Source and Destination Register Set Selection](#). All sources are zero-filled to 24 bits, unless sign-extension is specified (see [A-Source Size Override](#)).

**Table 35-379. A source selection - T4ABS**

| T4ABS | First register set    |      | Second register set                  |      |
|-------|-----------------------|------|--------------------------------------|------|
|       | Selected register     | Size | Selected Register                    | Size |
| 0000  | AS[7:0]=P[7:0]        | 8    | AS[7:0]=0                            | 8    |
| 0001  | AS[7:0]=P[15:8]       | 8    | AS[23:0]=C[23:0]                     | 24   |
| 0010  | AS[7:0]=P[31:24]      | 8    | AS[15:0] = TPR[15:0]                 | 16   |
| 0011  | AS[23:0] = ERTB[23:0] | 24   | AS[23:0] = B[23:0]                   | 24   |
| 0100  | AS[23:0] = D[23:0]    | 24   | AS[23:0] = TRR[23:0]                 | 24   |
| 0101  | AS[15:0] = P[15:0]    | 16   | AS[7:0] = 0, read_match <sup>1</sup> | 8    |
| 0110  | AS[15:0] = P[31:16]   | 16   | AS[13:0] = RAR[13:0]                 | 16   |
| 0111  | AS[7:0] = P[23:16]    | 8    | AS[23:0] = MACH[23:0]                | 24   |
| 1000  | AS[23:0] = P[23:0]    | 24   | AS[23:0] = MACL[23:0]                | 24   |
| 1001  | AS[23:0] = A[23:0]    | 24   | AS[4:0]=CHAN[4:0]                    | 8    |
| 1010  | AS[23:0] = SR[23:0]   | 24   | AS[14 :2] = CHAN_BASE <sup>2</sup>   | 16   |
| 1011  | AS[23:0] = DIOB[23:0] | 24   | AS[13:0] = ENGINE_BASE <sup>3</sup>  | 16   |
| 1100  | AS[23:0] = TCR1[23:0] | 24   | Reserved                             | -    |
| 1101  | AS[23:0] = TCR2[23:0] | 24   | Reserved                             | -    |
| 1110  | AS[23:0] = ERTA[23:0] | 24   | Reserved                             | -    |
| 1111  | AS[23:0] = 0          | 24   | Reserved                             | -    |

1. T4ABS=0101 with second register set also reads MatchA/B registers into ERTA/B (see [Special T4ABS Source Operation: Read Match Registers](#)).
2. CHAN\_BASE is the selected channel's base SDM address in channel relative address mode (see [CHAN\\_BASE as a source](#)).
3. ENGINE\_BASE is the eTPU\_SCR\_ECR\_ENGn[ERBA] field shifted left 9 positions.

T2ABD selects the destination from 1 of 2 register sets, shown in the following table. ABDE and T4BBS control which set T2ABD field uses to select the destination.

**Table 35-380. Destination selection - T2ABD**

| T2ABD | First register set                 |      | Second register set   |      |
|-------|------------------------------------|------|-----------------------|------|
|       | Selected register                  | Size | Selected Register     | Size |
| 0000  | A[23:0] = AD[23:0]                 | 24   | C[23:0] = AD[23:0]    | 24   |
| 0001  | SR[23:0] = AD[23:0]                | 24   | LINK[7:0] = AD[7:0]   | 8    |
| 0010  | ERTA[23:0] = AD[23:0] <sup>1</sup> | 24   | TPR[15:0] = AD[15:0]  | 16   |
| 0011  | ERTB[23:0] = AD[23:0] <sup>2</sup> | 24   | B[23:0] = AD[23:0]    | 24   |
| 0100  | DIOB[23:0] = AD[23:0]              | 24   | CHAN[4:0] = AD[4:0]   | 8    |
| 0101  | P[15:0] = AD[15:0]                 | 16   | D[23:0] = AD[23:0]    | 24   |
| 0110  | P[31:16] = AD[15:0]                | 16   | RAR[12:0] = AD[12:0]  | 16   |
| 0111  | P[23:0] = AD[23:0]                 | 24   | MACH[23:0] = AD[23:0] | 24   |
| 1000  | TCR1[23:0] = AD[23:0]              | 24   | MACL[23:0] = AD[23:0] | 24   |
| 1001  | TCR2[23:0] = AD[23:0]              | 24   | Reserved              | -    |
| 1010  | P[31:24] = AD[7:0]                 | 8    | Reserved              | -    |

Table continues on the next page...

**Table 35-380. Destination selection - T2ABD (continued)**

| T2ABD | First register set                   |      | Second register set |      |
|-------|--------------------------------------|------|---------------------|------|
|       | Selected register                    | Size | Selected Register   | Size |
| 1011  | P[23:16] = AD[7:0]                   | 8    | Reserved            | -    |
| 1100  | P[15:8] = AD[7:0]                    | 8    | Reserved            | -    |
| 1101  | P[7:0] = AD[7:0]                     | 8    | Reserved            | -    |
| 1110  | TRR[23:0] = AD[23:0]                 | 24   | Reserved            | -    |
| 1111  | no destination selected <sup>3</sup> | 24   | Reserved            | -    |

1. T2ABD=0010 with first register set also writes to MatchA or UDCM registers of the selected channel if field ERWA=0 (see [Write Channel Match and UDCM Registers](#)).
2. T2ABD=0011 with first register set also writes to MatchB register of the selected channel if field ERWB=0.
3. if no destination is selected, ALU flags are updated, although the result is lost.

### 35.15.9.2.2.1 Max Const Generation With T4BBS=111

When T4BBS = 111, BINV = 0, and CIN = 0, the value assigned to BS will be 0x800000, and not 0x0 as expected. See [Generating "max" constant](#) for detailed explanation about this.

### 35.15.9.2.2.2 Special T4ABS Source Operation: Read Match Registers

When T4ABS = 0101 and the source for T4ABS is selected from the second register set, the constant 0x00 is used as AS (8-bit size) and the following register transfer is performed in parallel as well: match registers of the selected channel (value in CHAN register) are copied to ERTA/ERTB registers, where ERTA receives the value of MatchA register and ERTB receives the value of MatchB register (see [ER - Event Registers](#)). Note that ALU destination can still be chosen by T2ABD in parallel. When ERTA or ERTB is selected by T2ABD, a parallelism issue arises (see [ALU Operations and Read Match Registers](#)).

### 35.15.9.2.2.3 CHAN\_BASE as a source

Each channel has a parameter base address in SDM, which is configured in the CPBA field of [eTPU Channel n Configuration Register for Engine 1](#) (eTPU\_CCCR\_CnCR\_ENG1) and [eTPU Channel n Configuration Register for Engine 2](#) (eTPU\_CCCR\_CnCR\_ENG2). CHAN\_BASE, which represents a parameter address (CPBA\*2), can be used as A-source using T4ABS=1010 when T4ABS selects a source from the second register set. In this case, CHAN\_BASE is loaded into AS[13:2] to form the byte address (AS[23:14]=0, AS[1:0]=0). For example, in Indirect addressing mode, where the destination register is DIOB, CHAN\_BASE is loaded into DIOB[13:2], which is the parameter address, and DIOB[13:0] represents the byte address. CHAN\_BASE is the base address of the selected channel (given by CHAN register).

### 35.15.9.2.3 Flags Sampling Control

This section explains how the flags Z (zero), C (carry), N (negative) and V (overflow) are updated in an ALU operation. When there are post-ALU shift operations, the ALU Carry Out is not directly sampled in Carry flag, but passed to the post-ALU shifter (see [Shift Operations](#)). Since the size of source operands in ALU operations is variable, flags can be sampled as an operation of 8, 16 or 24 bits wide. The operation size selection is automatic, based on defined sizes of sources and destination, using the equation:

```
operation_size = minor(size_of(destination), greater(size_of(A-Source),
size_of(B-Source)))
```

Operation size can also be shown with the following table:

**Table 35-381. Operation Size Determination**

| A Source      | B Source     | Destination | Operation Size |
|---------------|--------------|-------------|----------------|
| x             | x            | 8 bits      | 8 bits         |
| 8 bits        | 8 bits       | x           | 8 bits         |
| 16 or 24 bits | x            | 16 bits     | 16 bits        |
| 16 bits       | 8 or 16 bits | 24 bits     | 16 bits        |
| 8 or 16 bits  | 16 bits      | 24 bits     | 16 bits        |
| 24 bits       | x            | 24 bits     | 24 bits        |
| x             | 24 bits      | 24 bits     | 24 bits        |

#### Note

Whenever BS = (constant) 0, its size is considered 8 bits, and all 24 bits in B-bus are set to 0. Therefore, all operations with BS = (constant) 0 have their size determined by AS and Destination only.

CCS field (1 bit) controls whether flags will be updated or not ([Table 35-383](#)). When CCS bit exists in a microinstruction, the operation size will be used to sample flags. In some microinstructions CCS field is replaced by CCSV (2 bits, [Table 35-382](#)). Flag sampling according to CCSV can be set as defined by the operation size, or fixed as 8 or 16 bit operations.

#### Note

For the post-ALU rotate right operation, CCSV also determines the rotate size: whether 8-bit, 16-bit, or determined by the operation size.

**Table 35-382. Flag Sampling Using CCSV field**

| CCSV | Meaning                                   |
|------|-------------------------------------------|
| 00   | sample flags as an 8 bit operation        |
| 01   | sample flags as a 16 bit operation        |
| 10   | sample flags as defined by operation size |
| 11   | do not sample flags                       |

**Table 35-383. Flag Sampling Using CCS field**

| CCS | Meaning                                   |
|-----|-------------------------------------------|
| 0   | sample flags as defined by operation size |
| 1   | do not sample flags                       |

When neither CCS nor CCSV are present in the microinstruction, flags are not sampled. CCS and CCSV do not affect the Carry update on Exchange Bit operation (see [Exchange Bit](#)), but does control the N and Z flags.

### 35.15.9.2.4 B-Source Inversion

The data selected as second source (T4BBS) can be inverted (bitwise boolean NOT) before operation. This is controlled by microinstruction field BINV (1 bit, in the following table). A zero value for BINV activates B-source inversion.

**Table 35-384. B-Source Inversion - BINV**

| BINV | Meaning                      |
|------|------------------------------|
| 0    | invert B-source <sup>1</sup> |
| 1    | keep B-source bus unchanged  |

1. Except on max-constant selection, see [Generating "max" constant](#) .

BINV also selects between *adc* or *sbc* enhanced ALU operation, using inverted C flag as carry-in besides BS inversion for *sbc* . Note that BINV does not invert carry in fixed-carry operations (see [Table 35-385](#)).

When BINV = 0, T4BBS = 111 and CIN = 0, the value assigned to BS is 0x800000, instead of 0x0. See [Generating "max" constant](#) for more details.

### 35.15.9.2.5 Carry-in Control

CIN field (1 bit, [Table 35-385](#)) controls the carry-in for addition/subtraction operations. Functionality of CIN field depends on the arithmetic operation selected by ALUOP. When ALUOP is not available in microinstruction, the operation selected is *add*. For carry-in control in MDU operations, see the following table.

**Table 35-385. ALU Carry-In Control**

| operation                                         | CIN=0                            | CIN=1              |
|---------------------------------------------------|----------------------------------|--------------------|
| <i>add</i> (addition)                             | carry-in used is 1 <sup>1</sup>  | carry-in used is 0 |
| <i>adc</i> (addition with carry) <sup>2</sup>     | carry-in used is C flag          |                    |
| <i>sbc</i> (subtraction with borrow) <sup>3</sup> | carry-in used is inverted C flag |                    |

1. Except on max-constant selection, see [Generating "max" constant](#).

2. Selected by ALUOP=11000 and BINV=1

3. Selected by ALUOP=11000 and BINV=0

#### 35.15.9.2.5.1 Generating "max" constant

When T4BBS = 111, CIN = 0 and BINV = 0, BS is assigned to 0x800000 (called "max constant") instead of 0x000000. This is an exception for CIN and BINV fields: when "max constant" is selected, the carry in is 0 and B-source ("max constant" itself) is not inverted, neither the carry out.

"Max constant" is the value which, added to a time base value minus 1, gives the farthest wrapped time base value that satisfies a channel greater-equal comparison. See [Enhanced Channels](#) for more info.

### 35.15.9.2.6 Shift Operations

There are three types of shift operations: ALU, post-ALU and Shift Register. ALU shift operations are covered in [ALU/MDU Operation Selection](#). Post-ALU and Shift Register are covered in the following sections.

#### 35.15.9.2.6.1 Shift Register Operations

SR can be used as a general purpose register and it can easily shift-right its contents, combined or not to post-ALU shift operations. If field SRC (1 bit) in microcode is 0, SR will shift its contents 1 bit to the right according to the algorithmic description below. SR shifting operation depends also on SHF or ALUOP fields. ALUOP and SHF never exist both on the same microinstruction format.

**Table 35-386. Shift Register Control - SRC**

| SRC | Meaning              |
|-----|----------------------|
| 0   | shift right SR 1 bit |
| 1   | no shift             |

**SR Operation:**

```

SR[22:0] = SR[23:1];
if SHF == "01" or ALUOP == "10110" then
    SR[23] = ALU_OUT[0];
else
    SR[23] = 0;
endif;

```

**35.15.9.2.6.2 Post-ALU shift operations**

Post-ALU shift can be selected by SHF field (2 bits) or by some specific ALUOP field values. SHF and ALUOP fields are never both available in the same microinstruction format. When selecting post-ALU shift operation using ALUOP field, ALU will always add the sources before shifting the result.

**Table 35-387. Post-ALU shift operation**

| Post ALU operation   | SHF <sup>1</sup> | ALUOP                  |
|----------------------|------------------|------------------------|
| shift left (1 bit)   | 00               | 10101                  |
| shift right (1 bit)  | 01               | 10110                  |
| rotate right (1 bit) | 10               | 10111                  |
| no shift/rotate      | 11               | any other <sup>2</sup> |

1. ALU performs AS+BS before shift/rotate for all SHF values.
2. Some ALUOP combinations perform shift/rotate, but not using the Post-ALU Shifter (see [Table 1](#))

Carry flag is only updated when CCS or CCSV fields allow it (see [Flags Sampling Control](#)). Algorithmic descriptions of post-ALU shift operations are presented in [ALU ADD operation with and without shifting](#).

**35.15.9.2.7 Conditional ALU/MDU Operation Execution**

The 3-bit field AS/CE allows conditional execution of arithmetic operation, as shown in the following table. The same field can also be used for overriding the size of A-Source (see [A-Source Size Override](#)).

**Table 35-388. ALU/MDU Conditional Execution**

| AS/CE | Meaning                                                                       |
|-------|-------------------------------------------------------------------------------|
| 000   | used for A-Source size override (see <a href="#">A-Source Size Override</a> ) |

*Table continues on the next page...*

**Table 35-388. ALU/MDU Conditional Execution (continued)**

| AS/CE | Meaning                                  |
|-------|------------------------------------------|
| 001   |                                          |
| 010   | execute if C = 1                         |
| 011   | execute if C = 0                         |
| 100   | execute if Z = 1                         |
| 101   | execute if Z = 0                         |
| 110   | execute if N = 1                         |
| 111   | execute unconditionally/no size override |

Other operations not related to ALU/MDU in the same microinstruction are not affected by the AS/CE field.

If a conditional operation is selected, there is no A-Source size override; similarly, when size override for A-Source is selected, the ALU/MDU operation executes unconditionally.

When a conditional ALU/MDU operation is not executed:

- the destination register is not updated. If the destination is CHAN, no actions associated with CHAN assignment occur (see [Channel Selection Register - CHAN](#)).
- the ALU and MDU flags are not updated.
- MDU does not start any operation, i.e., MACH and MACL are not updated.
- SR does not shift.
- T4ABS-selected read-match does not occur.

### 35.15.9.2.8 A-Source Size Override

Some values of the AS/CE field are used for A-Source Size Override, as shown in the following table.

**Table 35-389. A-Source Size Override**

| AS/CE | Meaning                                                                                       |
|-------|-----------------------------------------------------------------------------------------------|
| 000   | A-source size override to 8 bits                                                              |
| 001   | A-source size override to 16 bits                                                             |
| 010   | used for conditional execution (see <a href="#">Conditional ALU/MDU Operation Execution</a> ) |
| 011   |                                                                                               |
| 100   |                                                                                               |
| 101   |                                                                                               |
|       |                                                                                               |

*Table continues on the next page...*

**Table 35-389. A-Source Size Override (continued)**

| AS/CE | Meaning                                  |
|-------|------------------------------------------|
| 110   |                                          |
| 111   | execute unconditionally/no size override |

Register size override zero-pads an overridden source to 24-bits (if no sign extension is performed, see [A-source Sign Extension](#)) and affects operation size calculation. When register source is wider than size override, most significant bits of selected register are not used as A source (zeros are used instead). When size override is wider than selected register, register value is padded to zeros.

When size override is used with MDU operations, it affects only the operand values, but not the operation size: MDU operation size is fully determined by the operation definition (fields ALUOP, ALUOPI).

**Table 35-390. AS/CE field A source size override functionality**

| Size Override | Size of Selected Register | AS Value <sup>1</sup> |
|---------------|---------------------------|-----------------------|
| 8 bits        | 8 bits                    | reg[7:0]              |
| 8-bits        | 16 bits                   | reg[7:0]              |
| 8bits         | 24 bits                   | reg[7:0]              |
| 16 bits       | 8 bits                    | reg[15:0]             |
| 16 bits       | 16 bits                   | reg[15:0]             |
| 16 bits       | 24 bits                   | reg[15:0]             |

1. All values are zero-padded to 24 bits

### 35.15.9.2.9 A-source Sign Extension

The SEXT microinstruction field forces sign extension of A source according to the size of A operand, either overridden or not by AS/CE field, according to the following table. The sign is taken from the size-overridden value, not the original one.

**Table 35-391. A source Sign Extension**

| SEXT | Meaning                                           |
|------|---------------------------------------------------|
| 0    | extends sign of A source from its size to 24-bits |
| 1    | does not extend sign of A source                  |

A-source sign is not extended in microinstructions without SEXT field, even if AS/CE field is present.

### 35.15.9.2.10 ALU/MDU Operation Selection

When field ALUOP is available in microinstruction, enhanced ALU operations shown in the following table can be performed, otherwise addition is performed. The ALU operations are defined in [ALU and Post-ALU Shifter](#). The MDU operations are defined in [MAC and Divide Unit \(MDU\)](#).

**Table 35-392. ALU Operation Selection - ALUOP**

| ALUOP | Operation                           | Comment                                                                                            |
|-------|-------------------------------------|----------------------------------------------------------------------------------------------------|
| 00000 | AS mults BS[7:0]                    | signed multiplication                                                                              |
| 00001 | AS multu BS[7:0]                    | unsigned multiplication                                                                            |

1. Addition/Subtraction is selected by field BINV (see [B-Source Inversion](#))

2. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.
3. In setb and clrb operations, the register that drives A source is not changed, unless selected as destination of the operation.

### 35.15.9.2.11 Operations With Immediate Data

Immediate data can be used with some specific microinstruction formats. eTPU microcode allows 8-, 16- or 24-bit immediate data. Immediate data is loaded as B-source, so T4BBS field is not available. When using 24-bit immediate, an add is performed with A-source = 0 and flags are not updated. ALU operations are available with 8-bit immediate, although the field that selects ALU operation in this case is ALUOPI.

#### 35.15.9.2.11.1 24-bit Immediate Destination

When using 24-bit immediate data, the destination register is selected by T2D field (2 bits), according to the following table.

**Table 35-393. 24-bit Immediate Destination - T2D**

| T2D | Target Register |
|-----|-----------------|
| 00  | P[23:0]         |
| 01  | A               |
| 10  | SR              |
| 11  | DIOB            |

#### 35.15.9.2.11.2 Enhanced ALU Operations With Immediate Data

Enhanced operations with immediate data, selected by ALUOPI (5 bits) are allowed only with an 8 bit immediate operand (see the following table).

**Table 35-394. ALU Operation Selection With Immediate Data - ALUOPI**

| ALUOPI | Operation                                         | Comment                            |

### 35.15.9.3 Channel Control and Configuration Microoperations

Channel Control and Configuration fields set configuration values in the channel logic of the channel selected by the CHAN register, except fields LSR and CIRC.

#### 35.15.9.3.1 Channel flags operations

Each channel has two associated hardware flags, called Channel Flag 0 and Channel Flag 1. Microcode field FLC (3 bits) allows them to be set or cleared, as shown in the following table. These flags can be tested by microcode as a branch condition, and may also influence in the Entry Point taken, allowing fast state decoding. For more details, see [Entry Points](#).

**Table 35-395. P flags operation - FLC**

| FLC | Meaning                        |
|-----|--------------------------------|
| 000 | Clear flag0                    |
| 001 | Set flag0                      |
| 010 | Clear flag1                    |
| 011 | Set flag1                      |
| 100 | Copy flag1:flag0 from P[25:24] |
| 101 | Copy flag1:flag0 from P[27:26] |
| 110 | Copy flag1:flag0 from P[29:28] |
| 111 | No operation                   |

#### 35.15.9.3.2 Comparator and Time Base Selection

TBSA and TBSB fields (4-bit wide each) are used to configure the type of the comparator and the time bases used for match or capture (see the following tables). TBSA can also be used to control the Output Buffer Enable signal (See [Pin Control Registers](#)).

**Table 35-396. Time Base Selection A - TBSA**

| TBSA[3] = 0 | TBSA bit               | 2                    | 1                 | 0                  |
|-------------|------------------------|----------------------|-------------------|--------------------|
|             | bitfield               | Comparator selection | Capture selection | Match TB selection |
|             | 0                      | greater or equal     | TCR1              | TCR1               |
|             | 1                      | equal-only           | TCR2              | TCR2               |
| TBSA[3] = 1 | action                 | 2                    | 1                 | 0                  |
|             | set OBE=1 <sup>1</sup> | 0                    | 0                 | 0                  |

*Table continues on the next page...*

**Table 35-396. Time Base Selection A - TBSA (continued)**

|  |                        |                  |   |   |
|--|------------------------|------------------|---|---|
|  | set OBE=0 <sup>1</sup> | 0                | 0 | 1 |
|  | do nothing             | 1                | 1 | 1 |
|  | reserved               | all other values |   |   |

1. Output Buffer Enable is not available on this chip.

**Table 35-397. Time Base Selection B - TBSB**

|             | TBSB bit   | 2                    | 1                 | 0                  |
|-------------|------------|----------------------|-------------------|--------------------|
| TBSB[3] = 0 | bitfield   | Comparator selection | Capture selection | Match TB selection |
|             | 0          | greater or equal     | TCR1              | TCR1               |
|             | 1          | equal-only           | TCR2              | TCR2               |
|             |            |                      |                   |                    |
| TBSB[3] = 1 | action     | 2                    | 1                 | 0                  |
|             | do nothing | 1                    | 1                 | 1                  |
|             | reserved   | all other values     |                   |                    |

### 35.15.9.3.3 Transition Detection and Pin Action Control

IPACA/B and OPACA/B fields are used to configure transition detection sensitivity (for the channel input signal) or output pin action control (for the channel output signal), as defined in the table below. IPACA and IPACB have the same format, where IPACA is related to Match A and first transition detection, and IPACB to Match B and second transition detection. The same applies in analogue way to OPACA and OPACB.

For the output signal, configuring OPAC registers does not change the current signal state, but defines the action to be done when a match or transition detection occurs. See [Match Recognition](#) and [Channel Modes on Output Signal Generation](#) for more information.

IPACA/B=1xx also enables assertion of MRLA/B during Time Slot Transition. See [Match Recognition](#).

**Table 35-398. Input and Output Pin Action Control - IPACA/B and OPACA/B**

| value | IPAC meaning                                  | OPAC meaning                                 |
|-------|-----------------------------------------------|----------------------------------------------|
| 000   | Do not detect transitions                     | Do not change output signal                  |
| 001   | Detect rising edge only                       | Match <sup>1</sup> sets output signal high   |
| 010   | Detect falling edge only                      | Match <sup>1</sup> sets output signal low    |
| 011   | Detect both edges                             | Match <sup>1</sup> toggles output signal     |
| 100   | Detect input signal = 0 on Match <sup>1</sup> | Transition detection sets output signal low  |
| 101   | Detect input signal = 1 on Match <sup>1</sup> | Transition detection sets output signal high |

*Table continues on the next page...*

**Table 35-398. Input and Output Pin Action Control - IPACA/B and OPACA/B (continued)**

| value | IPAC meaning       | OPAC meaning                               |
|-------|--------------------|--------------------------------------------|
| 110   | reserved           | Transition detection toggles output signal |
| 111   | do not change IPAC | do not change OPAC                         |

1. Match A is used for IPACA/OPACA, and Match B for IPACB/OPACB.

### 35.15.9.3.4 Immediate Pin State Control

It is possible to change output signal state immediately by using PSC (2 bits) and PSCS (1 bit) fields.

**Table 35-399. Immediate Pin State Control - PSC and PSCS**

| PSC | PSCS | Meaning                                                                                             |
|-----|------|-----------------------------------------------------------------------------------------------------|
| 00  | 0    | set signal as specified by OPACA (see <a href="#">Transition Detection and Pin Action Control</a> ) |
| 00  | 1    | set signal as specified by OPACB (see <a href="#">Transition Detection and Pin Action Control</a> ) |
| 01  | x    | set signal high                                                                                     |
| 10  | x    | set signal low                                                                                      |
| 11  | x    | don't change signal state                                                                           |

### 35.15.9.3.5 Write Channel Match and UDCM Registers

Match registers can have their values changed using ERWA and ERWB fields (1 bit each). They also set their respective MRLE register (see [Match Recognition](#)).

ERWA can also be used to program the UDCM register (see [UDCM - User Defined Channel Mode](#)). The field CMW selects where the contents of ERTA is copied when ERWA is active (see the following table).

**Table 35-400. Write MatchA/B - ERWA/B**

| Field | CMW | Value | Action                                                                       |
|-------|-----|-------|------------------------------------------------------------------------------|
| ERWA  | 1   | 0     | write ERTA value in MatchA. Enable matches for MatchA register (MRLEA=1)     |
|       | 0   | 0     | write ERTA value into UDCM                                                   |
|       | 1   | 1     | don't change UDCM, MatchA and MRLEA                                          |
|       | 0   | 1     | reserved                                                                     |
| ERWB  | 1   | 0     | write ERTB value in MatchB. Enable matches for MatchB register (set MRLEB=1) |
|       | 1   | 1     | don't change MatchB and MRLEB                                                |
|       | 0   |       |                                                                              |
|       | 0   | 0     | reserved                                                                     |

If ERTA or ERTB is a destination of an ALU operation and, at the same time, the respective ERWA/B field is active, the new ERTA value is the one written into the MatchA/B register or the UDCM register.

### 35.15.9.3.6 Clear Transition/Match Event Registers

Flags MRLA, MRLB, TDLA and TDLB (see [ER - Event Registers](#)) indicate the state of matches and transitions detected in the selected channel, and it is possible to clear those flags using the microcode fields MRLA, MRLB (1 bit each) and TDL (1 or 2 bits, depending on the format). The flags cleared by these microcode fields are the actual channel flags, and also the ones sampled into the branch logic.

TDL can be one or two bits wide, depending on the microinstruction format (see [Microinstruction formats](#)). Two-bit TDL allows independent clearing of TDLA and/or TDLB. [Table 35-402](#) defines the two-bit TDL field.

**Table 35-401. Clear Transition/Match Event Registers - MRLA/B, TDL**

| Field       | Meaning                                         |
|-------------|-------------------------------------------------|
| MRLA        | 0 = clear MRLA event register, 1 = don't change |
| MRLB        | 0 = clear MRLB event register, 1 = don't change |
| TDL (1 bit) | 0 = clear TDLA and TDLB flags, 1 = don't change |

**Table 35-402. Independent TDLA/B clear - two-bit TDL**

| value | Meaning                   |
|-------|---------------------------|
| 0 0   | clear TDLA                |
| 0 1   | clear TDLB                |
| 1 0   | clear both TDLA and TDLB  |
| 1 1   | do not clear TDLA or TDLB |

### 35.15.9.3.7 Disable Matches

Microcode field MRLE (1 bit) allows disabling matches on channel selected by CHAN register, for both MatchA and MatchB registers, by clearing their respective MRLE bits. Matches can be enabled for each Match register using ERWA and ERWB fields (see [Write Channel Match and UDCM Registers](#)).

**Table 35-403. Disable Matches - MRLE**

| MRLE | Meaning                                 |
|------|-----------------------------------------|
| 0    | Disable matches for Match A and Match B |
| 1    | don't change match enabling             |

Some instruction formats have a two-bit MRLE field (see [Microinstruction formats](#)) which allows independent disabling of Matches 1 and 2, as shown in the following table.

**Table 35-404. Two-bit MRLE**

| MRLE | Meaning                                      |
|------|----------------------------------------------|
| 0 0  | Disable Match A (clear MRLEA)                |
| 0 1  | Disable both Matches (clear MRLEA and MRLEB) |
| 1 0  | Disable Match B (clear MRLEB)                |
| 1 1  | nop                                          |

### 35.15.9.3.8 Disable Match and Transition Service Requests

Microcode field MTD (2 bits) disables match and transition service requests for the selected channel. MTD does not disable Link Service Request and Host Service Request. MTD sets or resets register SRI (for more details see [SRI - Match/Transition Service Request Inhibit Latch](#)) and TCCEA (see [TCCEA - Transition Continuous Capture Enable](#)) .

**Table 35-405. Disable Match and Transition Service Request - MTD**

| MTD | Action on SRI                                              | Action on TCCEA                                                   |
|-----|------------------------------------------------------------|-------------------------------------------------------------------|
| 00  | SRI = 0: enable service requests for match and transition  | TCCEA = 0: disable transition captures <sup>1</sup> when TDLA = 1 |
| 01  | SRI = 1: disable service requests for match and transition |                                                                   |
| 10  | SRI = 1: disable service requests for match and transition | TCCEA = 1: enable transition captures <sup>2</sup> when TDLA = 1  |
| 11  | don't change                                               |                                                                   |

1. Disables only captures on transition events specified by IPACA.

2. Enables only captures into CaptureA register, on transition events specified by IPACA.

### 35.15.9.3.9 Predefined Channel Modes

Microcode PDCM field (4 bits) defines the channel mode (see [Channel Modes](#)).

PDCM coding is shown in the table below. Note that PDCM bit 0 selects between Single Transition (PDCM[0]=0) and Double Transition (PDCM[0]=1) predefined modes.

PDCM is also used to select the user-defined channel mode, defined by the channel register UDCM (see [UDCM - User Defined Channel Mode](#)).

**Table 35-406. Predefined Channel Modes**

| PDCM | Channel mode |
|------|--------------|
| 0000 | em_b_st      |

*Table continues on the next page...*

**Table 35-406. Predefined Channel Modes (continued)**

| PDCM        | Channel mode                     |
|-------------|----------------------------------|
| 0001        | em_b_dt                          |
| 0010        | em_nb_st                         |
| 0011        | em_nb_dt                         |
| 0100        | m2_st                            |
| 0101        | m2_dt                            |
| 0110        | bm_st                            |
| 0111        | bm_dt                            |
| 1000        | m2_o_st                          |
| 1001        | m2_o_dt                          |
| <b>1010</b> | <b>user-defined channel mode</b> |
| 1011        | reserved                         |
| 1100        | sm_st                            |
| 1101        | sm_dt                            |
| 1110        | sm_st_e                          |
| 1111        | keep current channel mode        |

### 35.15.9.3.10 Channel Interrupt and Data Transfer Requests

Microcode can issue Interrupt Requests, Data Transfer Requests and Global Exception through CIRC field. For more information see [Interrupts and data transfer requests](#).

**Table 35-407. Channel and Data Transfer Requests - CIRC**

| CIRC | Meaning                                                            |
|------|--------------------------------------------------------------------|
| 000  | Channel Interrupt Request from selected channel                    |
| 001  | Data Transfer Request from selected channel                        |
| 010  | Channel Interrupt and Data Transfer requests from selected channel |
| 011  | Channel Interrupt and Data Transfer requests from serviced channel |
| 100  | Channel Interrupt Request from service channel                     |
| 101  | Data Transfer Request from service channel                         |
| 110  | Global Exception                                                   |
| 111  | don't request interrupt                                            |

### 35.15.9.3.11 Clear Link Service Request

Microcode LSR field (1 bit) is used to clear the Link Service Request flag of the serviced channel (may not be the one selected by CHAN). The LSR branch condition is always cleared, but not the Link Service Request, if another channel link was received by the serviced channel during the executing thread. See [Channel Link](#) for more information.

**Table 35-408. Link Service Request Negation Control - LSR**

| LSR | Meaning                               |
|-----|---------------------------------------|
| 0   | clear Link Service Request (flag LSR) |
| 1   | don't change                          |

### 35.15.9.4 Flow Control Microoperations

eTPU has *jump* and *call* microoperations to change microcode flow. Besides, eTPU has *dispatch jump* and *dispatch call* that can be used to implement a jump table. In *call* (or *dispatch call*) microoperation, the return address is saved in RAR register. If nested sub-routine calls are necessary, return address values have to be saved in a stack, usually implemented with DIOB register.

Flow Control microoperations are also provided to repeat a given microinstruction, to finish the current thread execution, and to halt the microengine.

#### 35.15.9.4.1 Ending Current Thread - END

Microcode END field (1 bit) finishes current thread and allows other channels to be serviced. If END field is 0, the current instruction is completed and the thread is finished. END = 1 has no effect, and the next microinstruction is executed Any MDU operation (see [MAC and Divide Unit \(MDU\)](#)) that could be still pending when the thread is finished is left incomplete. END also releases any semaphore locked by the Engine.

#### 35.15.9.4.2 Branch Operations

Branch operations can be **jump** or **call**. The target address of *jump* or *call* microoperations is always immediate and absolute. Branch microoperation is affected by FLS field (refer to [Flush Pipeline](#)).

##### 35.15.9.4.2.1 Selecting Jump or Call Microoperations

The only difference between *jump* and *call* microoperations is that when a *call* is executed the value of PC or PC+1 (depending on flush, see [Flush Pipeline](#)) is saved in RAR register. The microcode field J/C (1 bit) selects whether *jump* or a *call* is executed, according to the following table.

**Table 35-409. Jump / Call Selection - J/C**

| J/C | Meaning |
|-----|---------|
| 0   | jump    |
| 1   | call    |

### 35.15.9.4.2.2 Branch Target Address

Microcode BAF field (14 bits) indicates the absolute address of a *jump/call target*.

### 35.15.9.4.2.3 Conditional/unconditional branch

*Jump* and *call* can be conditional or unconditional, depending on the BCC (6 bits) and BCF (1 bit) fields, as shown in [Table 35-410](#) and [Table 35-411](#). BCF determines whether branch is taken when condition specified by BCC is true or false. When a branch condition uses the channel flags, the channel context is related to the channel number written in CHAN register.

**Table 35-410. Branch Condition Inversion - BCF**

| BCF | Meaning                                        |
|-----|------------------------------------------------|
| 0   | branch if condition determined by BCC is false |
| 1   | branch if condition determined by BCC is true  |

**Table 35-411. Branch Condition Selection - BCC**

| BCC    | Meaning           | BCC    | Meaning                                                       |
|--------|-------------------|--------|---------------------------------------------------------------|
| 001110 | Flag 0            | 001111 | Flag 1                                                        |
| 100000 | V ALU flag        | 110000 | PSS channel flag                                              |
| 100001 | N ALU flag        | 110001 | PRSS channel flag                                             |
| 100010 | C ALU flag        | 110010 | "Less Than" ALU flag combination (signed) <sup>1</sup>        |
| 100011 | Z ALU flag        | 110011 | "Lower or Equal" ALU flag combination (unsigned) <sup>2</sup> |
| 100100 | MV MDU flag       | 110100 | P[24]                                                         |
| 100101 | MN MDU flag       | 110101 | P[25]                                                         |
| 100110 | MC MDU flag       | 110110 | P[26]                                                         |
| 100111 | MZ MDU flag       | 110111 | P[27]                                                         |
| 101000 | TDLA channel flag | 111000 | P[28]                                                         |
| 101001 | TDLB channel flag | 111001 | P[29]                                                         |
| 101010 | MRLA channel flag | 111010 | P[30]                                                         |
| 101011 | MRLB channel flag | 111011 | P[31]                                                         |
| 101100 | LSR channel flag  | 111100 | PSTO channel flag                                             |
| 101101 | MB flag MDU flag  | 111101 | PSTI channel flag                                             |

Table continues on the next page...

**Table 35-411. Branch Condition Selection - BCC (continued)**

| BCC                       | Meaning            | BCC    | Meaning              |
|---------------------------|--------------------|--------|----------------------|
| 101110                    | FM[1] channel flag | 111110 | SMLCK semaphore flag |
| 101111                    | FM[0] channel flag | 111111 | false                |
| all other values reserved |                    |        |                      |

1. "less than" is a signed comparison, equal to the xor between ALU flags V and N; e.g.,  $0 < 0xFFFFFFFF$  tests as false ( $0 < -1$ ).
2. "lower equal" is an unsigned comparison, equal to Z or C; e.g.,  $0 < 0xFFFFFFFF$  tests as true.

### 35.15.9.4.3 Dispatch Microoperation

Dispatch microoperation is an unconditional branch where the target address is always  $PC+P[31:24]$  (unsigned). Dispatch is affected by FLS field (refer to [Flush Pipeline](#)). Dispatch microoperation is defined by R/D field (2 bits, see the following table). Field R/D can also be used to define return from sub-routine (see [Return from subroutine](#)).

**Table 35-412. Return and Dispatch - R/D**

| R/D | Meaning                                                              |
|-----|----------------------------------------------------------------------|
| 00  | return from subroutine (see <a href="#">Return from subroutine</a> ) |
| 01  | dispatch jump                                                        |
| 10  | dispatch call                                                        |
| 11  | don't change microinstruction flow                                   |

### 35.15.9.4.4 Return from subroutine

When a subroutine *call* or a *dispatch call* microoperation is executed, the return address is saved in RAR register. To return from a subroutine a microoperation is available to load the contents of RAR register back to the PC. Fields R/D (2 bits) or RTN (1 bit, see the table below) can be used to return from subroutine. For R/D field, see [Table 35-412](#).

Return from subroutine microoperation is affected by FLS (see [Flush Pipeline](#)) when field R/D is used. Return execution through RTN always flushes the pipeline.

**Table 35-413. Return from subroutine - RTN**

| RTN | Meaning                    |
|-----|----------------------------|
| 0   | Return with pipeline flush |
| 1   | Do not return              |

### 35.15.9.4.5 Flush Pipeline

When a branch, dispatch or subroutine return microoperation is executed, the next microinstruction can be executed unconditionally before the flow change takes effect, since microengine has a three-stage pipeline. Executing the next microinstruction after a branch maximizes execution performance. This feature is controlled by field FLS (1 bit, see the table below). When FLS=0 the pipeline is flushed, so the next microinstruction placed after a branch is decoded as NOP if the branch is taken. If FLS=1, the microinstruction placed after the branch is executed, either if the branch is taken or not, as shown in the figure below.

Flush also controls which value is stored in RAR in a call: in case of no flush, it is the address of the branch/dispatch instruction + 2, even if RAR is the ALU destination of the instruction after the call; in case of a flush, it is the address of the instruction following branch/dispatch.

If a branch with no flush is followed by another branch with no flush, the instructions are executed in the following order:

1. first branch
2. second branch
3. first branch's destination instruction
4. second branch's destination instruction, and the flow proceeds normally from then on

The destination of the first branch must not be another flow changing instruction (branch, return or dispatch). Similar flows apply when returns or dispatches are used instead of branches. This scheme can be used to implement quick table look-ups with a dispatch replacing the first branch, for instance.

**Table 35-414. Flush Pipeline - FLS**

| FLS | Meaning                                                                                     |
|-----|---------------------------------------------------------------------------------------------|
| 0   | flush pipeline when jump / call / dispatch jump / dispatch call / return is executed        |
| 1   | do not flush pipeline when jump / call / dispatch jump / dispatch call / return is executed |

Figure 35-331. Flush Pipeline

### 35.15.9.4.6 HALT microinstruction

HALT is a microinstruction provided to implement software breakpoints (see [Software breakpoints](#)). Note that HALT is coded as a microinstruction format, not a field (see [Microinstruction formats](#)). The execution of this instruction puts the microengine in halt state. For more information about the implications of microengine halt state, see [Microengine Halt State](#). HALT is valid only if software breakpoints are enabled at the Debug interface. If software breakpoints are not enabled, HALT executes as a NOP and is treated as an Illegal Instruction (see [Illegal instructions](#)).

### 35.15.9.4.7 NOP microinstruction

There is not a unique microinstruction with an assigned opcode to do No Operation. NOP microinstruction is achieved through any of the formats shown on [Microinstruction formats](#) where the user can assign to each individual field the corresponding value for "No Operation". However, to prevent future impacts of instruction changes on object code compatibility, the instruction value 0x4FFFFFFF should always be used for NOP.

## 35.15.9.5 Illegal instructions

An instruction is considered illegal if any reserved field value is used, including when the fields marked rsv in the instruction formats (see [Microinstruction formats](#)) are assigned value 0. A HALT instruction is exceptionally considered illegal when executed with software breakpoints disabled (see [HALT microinstruction](#)). Global Exception may be issued up to two microcycles after instruction fetch. The execution results of an illegal instruction on the microengine, channel logic or host interface are unspecified, except for the HALT case.

If the microengine decodes an illegal instruction, the following actions are taken:

- A Global Exception is issued.
- The ILF1/2 flags in [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) are set to indicate this occurrence to the Host.
- A breakpoint occurs, if NDEDI is present and configured to do so (see the NDEDI details for more information).

### **35.15.9.6 Microinstruction Parallelism Issues**

This section clarifies parallelism issues that arise when two non-commutative microoperations appear in the same microinstruction.

#### **35.15.9.6.1 ALU Operations and Read Match Registers**

ALU operations have only one destination register, but there is one case where source selection determines destination: read Match register in ERTA and ERTB registers. In this case if ALU destination is ERTA or ERTB a conflict arises. The ALU destination value overwrites the value read from the match registers.

#### **35.15.9.6.2 ALU and SDM Operations**

P and DIOB registers can be selected as destination by both ALU and SDM (read) microoperations in the same microinstruction. Since P and DIOB update from SDM data happens after P and DIOB update for ALU/MDU microoperations, the data read from SDM remains in P or DIOB after an operation when one of them is specified as destination for both ALU and SDM microoperations. In this case, the value loaded into P or DIOB is the one read from SDM. However, the ALU operation is executed and its flags are updated accordingly.

When P or DIOB is destination of an SDM read and also an ALU source at the same microinstruction, the value before the read is used for the ALU operation.

If DIOB is the ALU destination and P is loaded from SDM or vice-versa, no conflict occurs, and the result is the same as if operations occurred separately.

All the above also applies to Zero SDM operations.

When using P or DIOB as destination for ALU operations and also as source for a SDM write operation, the data written in SDM is the one calculated by ALU, which means it is possible to calculate a value and write it in an SDM address using only one microinstruction.

The old value of DIOB or the old value minus 4 (pre-decrement) is always used when DIOB is selected as address (indirect address mode), no matter if DIOB is selected as destination of either the SDM or ALU. For the value loaded into DIOB, refer to the following table.

**Table 35-415. DIOB load from SDM and ALU**

| DIOB selected as<br>SDM read destination? | DIOB selected as<br>ALU destination? | DIOB load value                                                |
|-------------------------------------------|--------------------------------------|----------------------------------------------------------------|
| no                                        | no                                   | DIOB,<br>--DIOB (pre-decrement),<br>or DIOB++ (post-increment) |
| yes                                       | no                                   | SDM read data<br>(post-inc and pre-dec ignored)                |
| yes                                       | yes                                  | SDM read data<br>(post-inc, pre-dec and ALU result ignored)    |
| no                                        | yes                                  | ALU result<br>(post-inc and pre-dec ignored)                   |

When CHAN is the destination of an ALU operation in parallel with a channel-relative SDM access, the CHAN value used to calculate the address is the one before the ALU operation.

### 35.15.9.6.3 ERTA/B as ALU destination and ERWA/B

The value in ERTA and ERTB registers can be written in match registers of the selected channel by using fields ERWA and ERWB ([Write Channel Match and UDCM Registers](#)). If, at the same microinstruction, ERTA or ERTB is destination of an ALU/MDU microoperation, the value written in Match registers is the ALU/MDU result.

The same applies to UDCM when ERTA is the destination of an ALU operation and instruction fields ERWA and CMW are active .

If an ALU operation occurs in parallel with ERWA/B but ERTA/B are not the destination of an ALU/MDU operation, then UDCM and MatchA/B receives the ERTA/B value.

#### 35.15.9.6.4 ERWA/B and MRLE

ERWA/B automatically sets the MRLEA/B channel latch, respectively (see [Write Channel Match and UDCM Registers](#)). Microinstruction fields ERWA/B independently sets MRLEA/B channel flags, regardless of MRLE.

#### 35.15.9.6.5 CHAN assignment, Read Match and ERWA/B

When CHAN is a destination of an ALU operation it causes a read of the CaptureA/B register values into ERTA/B. The Capture registers loaded into ERTA/B are selected by the new CHAN value. The value of the CaptureA/B registers overwrites any read-match commanded simultaneously.

If CHAN assignment happens with an ERWA/B operation in the same instruction, the updated Match register(s) belong to the new selected channel.

#### 35.15.9.6.6 Read Match and ERWA/B

If a read match operation is executed with ERWA/B in the same microinstruction, the MatchA/B registers receive the old values of ERTA/B, and the ERTA/B registers receive the old MatchA/B values simultaneously, i.e.: ERTA/B and MatchA/B swap their values.

If ERTA/B is the destination of an ALU operation at the same instruction, MatchA/B gets the ALU result (see [ERTA/B as ALU destination and ERWA/B](#)), but the ERTA/B not being written still receives the old MatchA/B values.

#### Note

Read match, ERWA/B and CHAN assignment can be active at the same instruction. Combining rules [CHAN assignment, Read Match and ERWA/B](#) and [Read Match and ERWA/B](#), the result is: ERTA/B receives the CaptureA/B values of the new CHAN value, and MatchA/B of the new channel receives the old ERTA/B value(s).

#### 35.15.9.6.7 Stack accesses and ALU operations

Post-increment is ignored in a stack operation (field STC) if DIOB is loaded from SDM: DIOB keeps the value read from SDM. Pre-decrement is ignored in a stack operation (field STC) if DIOB is destination of an ALU operation, for DIOB load value, but not for DIOB as address. Post-increment/pre-decrement remains valid in all other situations. These rules can be summarized in the following equivalent C code, and in [Table 35-415](#).

```
DIOB = *DIOB[15:2];    // read without posinc/predec
*DIOB[15:2] = DIOB;    // write without posinc/predec
```

```

DIOB = * (--DIOB[15:2]); // read with predec
DIOB = *DIOB[15:2];      // read with posinc (ignored)
* (--DIOB[15:2]) = DIOB; // write with predec
*DIOB[15:2]++ = DIOB;    // write with posinc (value written is before
increment)

```

### 35.15.9.6.8 SRC and ALU/MDU operations

If operation SRC is active (field SRC = 0) and register SR is selected as destination of an ALU operation, the value of the ALU operation prevails over the shifted value.

The value of SR used as source in the ALU/MDU operation is the one before the shift.

### 35.15.9.6.9 Semaphore lock/free and SMLCK branch condition

When the SMLCK branch condition is tested at the same microinstruction of a semaphore lock or free, the condition is evaluated after the semaphore action (either free or lock) is taken.

### 35.15.9.6.10 Dispatch and SDM Read

When the most significant byte of P is read from SDM (read 8 msb bits or 32 bits) and a dispatch instruction is executed simultaneously, the dispatch target address is calculated upon the P value before the read.

### 35.15.9.6.11 CHAN Assignment, PSC/PSCS, and clear MRLEA/B, MRLA/B, TDLA/B

When clear MRLEs, MRLA/B or TDLs is done and a CHAN assignment is done at the same time, the flag selected by the old CHAN value is cleared in the channel, but the branch conditions receive the state of the flags selected by the new CHAN.

When a pin action is commanded through PCS/PSCS and a CHAN assignment is done simultaneously, the output signal affected is selected with the old CHAN value.

## 35.15.9.7 Microinstruction formats

| format | 31    | 30 | 29 | 28         | 27   | 26       | 25   | 24   | 23    | 22   | 21  | 20  | 19         | 18   | 17  | 16   | 15  | 14  | 13   | 12  | 11  | 10   | 9       | 8          | 7         | 6   | 5   | 4         | 3   | 2    | 1            | 0                        |        |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |      |     |     |
|--------|-------|----|----|------------|------|----------|------|------|-------|------|-----|-----|------------|------|-----|------|-----|-----|------|-----|-----|------|---------|------------|-----------|-----|-----|-----------|-----|------|--------------|--------------------------|--------|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----|-----|------|-----| All bits marked "rsvd" are reserved, and must be coded as 1.

### 35.15.10 Shared Subsystems support

Shared Subsystems support allows eTPU to control other modules, either independently or sharing control with the host. A notable example of shared subsystem is the Reaction Module (see the Reaction Module chapter for details), which is connected to the eTPU as shown in the figure below. The host CPU accesses the Reaction Module through the eTPU, which can also access the same registers.

When the SSMAE field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) or [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#) is 1, the eTPU channel's threads can control shared subsystems by accessing their registers, which are mapped onto the higher 16 Kbytes of the microcode data address space (byte addresses/DIOB values 0x4000 to 0x7FFF, equivalent to parameters 0x1000 to 0x1FFF), as shown in [Figure 35-334](#). The shared subsystem registers are accessible by microcode only with the indirect address mode (see [SDM Addressing Modes](#)).

When the SSMAE field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) or [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#) is 0, the channel's threads can access only the SDM, mirrored throughout the whole DIOB address range.

The same Shared Subsystem register address space is accessible by the host through the Shared Subsystem Area within the eTPU memory map (see [Figure 35-334](#) and [Memory map](#)), allowing shared control and/or supervision between the host and the eTPU. The arbitration mechanism between host and eTPU accesses is the same used for SDM accesses (see [SDM arbitration](#)). The CDC (see [Coherent Dual-parameter Controller \(CDC\)](#)) cannot be used for coherent transfers between SDM and the Shared Subsystem Area, or within the Shared Subsystem Area itself.

#### Note

The detailed register map within the Shared Subsystem Area depends on the subsystem module.

Bus errors coming from the Shared Subsystem cause a Global Exception and are flagged by the MCR[SSAERR] bit on microengine accesses only. In the case of host access, the bus error only propagates to the slave bus, which also issues a bus error.

A Shared Subsystem may be divided into submodules or channels, hereafter called **Shared Subsystem Units** (or **Shared Units** for short), which can be individually controlled by an eTPU function (see [Functions and threads](#))

A Shared Unit is logically linked with an eTPU channel through the eTPU\_SSIR\_ETPUSSSIR<sub>n</sub> configuration<sup>38</sup>. There is one eTPU\_SSIR\_ETPUSSSIR register for each Shared Unit to configure its interface with the eTPU (see [eTPU Shared](#)

[Subsystem n Integration Register \(eTPU\\_SSIR\\_ETPUSSSIR<sub>n</sub>\)](#)). The Shared Unit uses the Link Service Request (LSR) mechanism to request service to the eTPU. The Link Service Request is targeted to the channel/engine configured in [LENG](#) and [LCHAN](#). The function assigned to this channel must be written to service the Shared Unit. The Shared Unit link service request may have the same source as an interrupt to the host.

### Note

Shared Unit link service requests are level-sensitive to the eTPU. If it comes from an interrupt source, the link service request stays asserted as long as the interrupt is asserted and enabled, so the interrupt request must be cleared before the clear of the LSR flag in the link service request thread.

[LENG](#) can also be used by the host to disable Link Service Requests to the eTPU. The eTPU microcode can only disable LSRs from the Shared Unit through configuration specific to the Shared Unit itself.

Note that more than one Shared Unit can generate LSRs to the same eTPU channel, in which case the LSR source can be determined by microcode through the Shared Unit status register(s). An eTPU channel configured as a Shared Unit LSR target can also receive Link Service Requests from other eTPU channels or Shared Units. The same LSR service and flag behavior found in links between eTPU channels applies to Shared Unit links (see [Channel Link](#)).

The table below summarizes the mapping of Reaction Module resources into Shared Subsystem Support.

---

38. However, in the case of Reaction Module, the eTPU\_SSIR\_ETPUSSSIR<sub>n</sub> configuration does not determine which eTPU channel output enables the Reaction Channel modulation; this is defined in the Reaction Module configuration.

### 35.15.11 Development support features

Following sections describe several features available to support development. Most debug features are accessible through a separate debug bus, and are not available through registers in the standard eTPU memory map. The details of the access to this interface are MCU-dependent (see Debug Interface chapter). The microengines can also be put in halt state by a device-level debug request.

#### NOTE

The behavior of the debug support logic is not specified in the event of a non-correctable memory error on either SCM or SDM (see [Memory error support](#)).

#### 35.15.11.1 Nexus Class 3 Support

NDEDI is an IP block designed to support Nexus functionality for the eTPU. It provides a Nexus class 3 or class 1 debug interface, depending on the MCU (see Configuration section). Nexus is a development support external interface defined by the **IEEE standard ISTO 5001-1999**. More details about it can be found in the NDEDI details.

Some of the next subsections describe debug features provided by the eTPU microengine debug support combined with the NDEDI block.

#### 35.15.11.2 Microengine Halt State

Halt is a microengine state where it suspends execution during a thread, or does not start executing a scheduled thread from idle state. While Idle State is entered from END execution without any other scheduled thread, microengine enters Halt State by any of the following events:

- execution of the HALT microinstruction (software breakpoint).

- external halt request through the Debug Interface (includes Nexus breakpoint request via EVTI input pin - see [Nexus Class 3 Support](#)).
- the other Engine enters halt state and they are configured to halt simultaneously (bit HTWIN is asserted via Nexus Interface).
- System level device debug request assertion and NDEDI register NDEDIETPUx\_DC field CBI=1. If same register's field CBT=1, microengine halts at the next time-slot boundary, if CBT=0 it halts immediately. As a particular case, microengines come halted out of reset if device debug request is asserted, since CBI reset value is 1. Microengine does not execute out of reset, either in halt (device debug request asserted) or idle state (device debug request negated), but halt enables several other features (see below).
- occurrence of any of the hardware breakpoint conditions. See [Hardware breakpoints](#) for details.
- execution of a single-step microinstruction: microengine returns to halt state after executing a single microinstruction while in halt state. See [Single-step Execution](#) and [Forced microinstruction execution](#) for details.

When microengine enters halt state, it automatically triggers the following actions:

- suspends input signal sampling and filters (respective Engine channels only), if NDEDI\_ENGINEx\_DC[PINS] = 1 at the Debug Interface.
- releases the SDM arbitration for Host or CDC accesses, no matter if microengine was halted in the middle of a dual parameter (back-to-back) access.
- stops TCR1/2 clocks of the respective Engine, if signal ndedi\_stop\_tcr is asserted at the Debug Interface.
- if the other Engine is also in halt state or stopped, allows turning the [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) VIS bit to 1.

If all halt conditions are cleared when VIS=1, microengine(s) keep on halt state until VIS=0, when it automatically exits halt state, except on single-step (see [Single-step Execution](#)), so that single-step execution is ignored while VIS=1.

MDU continues executing until it finishes any ongoing operation even if microengine is in halt state, except when the halted instruction is an END.

There are two kinds of halt state, depending on the previous microengine state when halted:

1. **halt\_idle**, if the engine was not executing a thread when halted; the engine cannot leave **halt\_idle** to fetch instructions, so one cannot single-step or follow a program flow; it can, however, execute forced instructions (see [Forced microinstruction execution](#)).
2. **halt\_exec**, if the engine was executing a thread when halted. The engine can single-step and continue a program flow from **halt\_exec**.

When microengine exits halt state, any dependable action is suspended and, if exiting **halt\_exec**, the instruction pointed by the PC is fetched, while the instruction already fetched before halt is executed. Note that both the PC and the prefetched instructions can be modified during halt state, with a forced execution of a branch instruction (see [Forced microinstruction execution](#)).

### 35.15.11.3 Hardware breakpoints

Microengine can enter halt state through a command from the Debug Interface, configuring a hardware breakpoint. Hardware breakpoints can halt the microengine on specific conditions, listed below. These conditions depend on NDEDI configuration (see the NDEDI details for more information).

- CHAN register assignment (only by microcode, not by time slot transition).
- SDM read and/or write to a given address and/or write data. The breakpoint is always qualified by the SDM address, but the following variations are allowed:
  - break on write only, read only, or read-and-write.
  - break on higher-byte write data value, lower 24-bit write value, full word (32-bit) write value, or regardless of data. Break on read data is not supported.
- PC (program counter) value.
- Beginning of a thread with a Host Service Request pending.
- Beginning of a thread with a Link Service Request pending.
- Beginning of a thread with a Match Service Request pending.
- Beginning of a thread with a Transition Service Request pending.
- End of a thread.
- Illegal instruction execution.

All these conditions can also be qualified by the value of the CHAN register.

## NOTE

Data breakpoints are not supported on Shared Subsystem Area accesses (see [Shared Subsystems support](#)).

Hardware breakpoints halt the microengine before the halted instruction is executed, except on data breakpoints. Data breakpoints allow the instruction that performs the data access to be executed before the microengine is halted.

## Note

Data breakpoints in eTPU versions before eTPU2 halt the breakpoint instruction before its execution in all cases, including data breakpoints.

On any of these conditions, halt of one microengine does not depend on the halt of the other, unless the other engine is configured to do so, via Nexus Interface. Occurrence of any of these conditions halts the microengine, i.e., the conditions are logically ORed together, and they can be individually enabled.

While in halt state, the microengine can also execute any forced microinstruction not in the normal program flow (see [Forced microinstruction execution](#)) or, if in halt\_exec, in single-step (see [Single-step Execution](#)).

There are situations when requests for stopping an engine, breakpoint and service can occur simultaneously. Breakpoint requests always prevails over a stop request ([eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) or [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#) bit MDIS=1 or device debug request=1). When the eTPU is idle: stop request prevails over Service Request if there is not a hardware breakpoint request; a hardware breakpoint request leads to debug mode immediately if there is no Service Request, and after TST if there is Service Request (regardless of stop requests). The rules above are summarized in the the following table, showing the destination state of the microengine in each situation.

**Table 35-417. Breakpoint, stop and service requests resolution from idle**

| Breakpoint request | MDIS | Service request | Final state      |
|--------------------|------|-----------------|------------------|
| no                 | 0    | 0               | Idle             |
| no                 | 1    | 0               | Stop             |
| no                 | 0    | 1               | TST              |
| no                 | 1    | 1               | Stop             |
| Yes                | 0    | 0               | Halt_idle        |
| Yes                | 1    | 0               | Halt_idle        |
| Yes                | 0    | 1               | TST <sup>1</sup> |
| Yes                | 1    | 1               | TST <sup>1</sup> |

1. Breaks after TST, if signal `ndedi_sync_break` is still asserted.

When a thread is ending, it goes to Idle or TST only if there is neither a hardware breakpoint request nor a request to stop ([eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) or [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#) bit MDIS=1 or device debug request=1). When thread is ending and there are simultaneous hardware breakpoint and stop (MDIS=1 or device debug request=1) requests, hardware breakpoint prevails and the engine enters Debug mode (Halt\_idle state).

If the engine entered Debug mode after a thread finished (Halt\_idle state) and a "go" command comes from the debug interface, the engine state machine goes to Idle and the rules above apply. It means that if a "go" is issued in Halt\_idle state with MDIS=1, the engine goes to Idle for one microcycle and then stops (if MDIS or device debug request keeps asserted and there is no other breakpoint request).

### **Note**

Hardware breakpoint requests are ignored for the first microinstruction executed when microengine leaves halt.

## **35.15.11.4 Hardware Watchpoints**

Debug Interface allows watchpoints on the same conditions available for hardware breakpoints (see [Hardware breakpoints](#)).

### **Note**

Data breakpoints are not supported on Shared Subsystem Area accesses (see [Shared Subsystems support](#)).

## **35.15.11.5 Software breakpoints**

A software breakpoint occurs when microengine executes a HALT microinstruction. Any number of software breakpoints can be set in code, usually replacing an active microinstruction.

Like any other microinstruction, HALT increments the PC and pre-fetches the next instruction. So, before the halt state is suspended, if the original program flow must be followed, the original instruction at the HALT address must be executed, regardless if the software breakpoint is removed (replacing HALT by the original microinstruction) or not. Follows the procedure to resume execution from a software breakpoint:

1. restore the original instruction in SCM (replace HALT).
2. force a jump with flush to the original instruction (see [Forced microinstruction execution](#)).
3. if the software breakpoint must be kept: single-step and replace the original instruction with a HALT.
4. let the flow continue, issuing a GO command (leaving halt state).

Special care must be taken if HALT is followed by another HALT, and the second HALT is removed when microengine was halted by the first one. In this case, replacing the second HALT with the original microinstruction is not enough to remove the second breakpoint, because the second HALT was already prefetched and would be executed anyway when halt was suspended. The debugger must also do a forced execution of unconditional branch with flush to the original microinstruction address. That will clear the pipeline, replacing the prefetched instruction with a NOP, and load PC with the address of the removed breakpoint. So, when halt state is suspended, the original microinstruction will be fetched while NOP is executed, and program flow continues normally from then on.

### Note

A HALT instruction placed after a no-flushing branch, dispatch or return may be a problem from the debugger application standpoint: after the HALT is executed, the eTPU debug interface informs the address of the branch/dispatch/return destination, and the debugger application has no direct way to identify which HALT instruction was executed, if multiple HALTs lead to the same address. This can be solved if the debug support block (NDEDI) has a register holding the address of the last instruction executed, otherwise one should forbid non-flushed HALT instructions. See the NDEDI details.

Software breakpoint setting and removal is possible only with SCM RAM implementations or ROM implementations with SCM RAM emulation (see [SCM Emulation](#)). There is only one way of inserting software breakpoints into SCM RAM: programming VIS=1 in [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#), and then accessing SCM as an ordinary RAM from the slave bus. This can be done only if both Engines are halted or stopped.

### 35.15.11.6 Single-step Execution

When microengine is already in halt\_exec state, it can run the next microinstruction in the normal program flow and get back to halt state. PC is incremented, or assigned the BAF value in a branch with satisfied condition. Note that the executed instruction was already prefetched in the instruction pipeline, and a new microinstruction is fetched during its execution. The prefetched instruction may be cleared during halt state by the forced execution of a branch with flush (see [Forced microinstruction execution](#)), making single-step execute a NOP instead of the next instruction in the program flow.

Single-step execution is controlled by the debug interface, and is a feature available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details).

The single-step execution of a NOP instruction can be useful to control input signal sampling and filtering, if NDEDI\_ENGINEx\_DC[PINS] = 1 at the Debug Interface (see NDEDI details). Single-step does not happen if VIS=1.

### 35.15.11.7 Forced microinstruction execution

When microengine is already in halt state (either halt\_idle or halt\_exec), it can run forced microinstructions through the debug interface. This feature is available from Nexus if eTPU is connected to the NDEDI block (see NDEDI details). The microinstruction, specified by the user, is not fetched from SCM and comes directly from the debug interface. MDU start commands issued by forced instructions are executed, and the MDU runs the operation until the end, independently of the halt state. The microinstruction field END is ignored.

During forced execution of any instruction except Branches, Returns and Dispatches, the PC does not change, and the prefetched instruction in the pipeline is bypassed, but not discarded. When halt state is suspended, the prefetched instruction is executed and the instruction pointed by the PC is prefetched in parallel (two-stage pipeline).

Forced execution of a Branch, Dispatch or Return loads the PC with the BAF field (if branch condition is satisfied), PC+P or RAR, respectively. If branch condition is not satisfied, PC value stays unaltered. The flush control (field FLS) also works, so that a successful forced branch with flush replaces the prefetched instruction with a NOP. So, to clear the instruction pipeline during halt, all one has to do is an unconditional branch to the desired address with flush. HALT instructions must not be executed as forced.

Forced operations that depend on the serviced channel are unspecified when executed in halt\_idle and must be avoided.

## Note

Forced instructions must not be commanded when [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) field VIS=1.

### 35.15.11.8 Microengine Register Access

eTPU provides no direct access to microengine and channel registers from the slave bus or any other interface. However, these registers can be read and written in halt state by executing forced microinstructions (see [Forced microinstruction execution](#)). Immediate data microinstructions may be used to set register values. Some registers are not selectable for immediate data destination, so intermediary register(s) - notably P - may have to be used to carry the desired new value to the target register in two or more microinstructions. Usually the previous values of intermediary register(s) must be previously saved and restored after the whole operation.

Similar procedures apply for register reads: their contents must be dumped to SDM, where they can be read from the slave bus.

### 35.15.11.9 Microengine Flag Access

Microengine halt state allows reading the branch conditions flags through forced microinstructions or, more easily, through the NDEDI register NDEDI\_ENGINEx\_CFSR (see the NDEDI details). Flag conditions set by the user are seen by microengine for the next microinstruction execution. The flag set options are limited by the possibilities of forced microinstruction execution.

If the eTPU runs (not single-stepping) after exiting the halted state, the conditions modified during halt may remain only for the first microcycle after the halted state. After the first microcycle, branch conditions are altered only according to their regular update scheme.

### 35.15.11.10 Microengine Stall

Microengine can get into a stall state, attending a request from a debug interface signal assertion. The reason for a Stall request from NDEDI (or from any other debug support block) should be a temporary lack of resources, for instance queue full. During stall the microengine suspends execution, but all the other Engine logic continues operating: time

bases, angle logic, channel logic, input sampling and filters. Stall differs from Halt, not enabling any of the debug features that Halt enables (see [Microengine Halt State](#)). It also does not break an atomic microengine access, unlike halt.

The Microengine can be stalled when idle and from the moment TST ends, before executing the first thread microinstruction, until just before the last thread microinstruction is executed. Stall requests are ignored in any other occasions.

Microengines in a dual engine system can be independently stalled. If a forced end is issued when microengine is in stall coming from execution, the END is executed only when the microengine resumes execution from stall.

### 35.15.12 SCM Emulation

If SCM is implemented as ROM, an external RAM may be used to replace it, allowing code patching and software breakpoint setting for debugging purposes. SCM ROM replacement by Emulation RAM is MCU-dependent. The SCM may even be divided into a ROM part and a RAM part. In this case, both microengines can run code from both ROM and Emulation RAM. It is possible to make one Engine run code from RAM and the other from ROM, by using different Entry Tables. The SCM visibility conditions also apply to Emulation RAM.

All SCM implementations, either RAM, ROM or Emulation RAM, are external to the eTPU block. eTPU provides a signal to enable the switching between external SCM banks. The conditions for this switching are:

1. Both Engines stopped.
2. VIS bit = 0.

Note that these conditions also stop the clocks of the SCM interface and MISC logic.

### 35.15.13 Safety features

This section describes embedded safety features: MISC and memory error support.

The Multiple Input Signature Calculator - MISC - is an SCM test feature accessible through [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) and [eTPU MISC Compare Register \(eTPU\\_SCR\\_MISCCMPR\)](#). MISC allows SCM test "on the fly", i.e., while eTPU is running, with no impact on eTPU functionality or performance.

Memory Error support features comprises SCM and SDM error detection, correction, report, and soft error.

### 35.15.13.1 SCM Test - Multiple Input Signature Calculator

The Multiple Input Signature Calculator (MISC) comprises special hardware that sequentially reads all SCM positions and calculates, in parallel, a 32-bit signature from a 32-input CRC signature calculator with the following polynomial:

$$1 + x^1 + x^2 + x^{22} + x^{31}$$

A complete description of the signature calculation procedure can be found in [MISC Algorithm](#).

Once started by the Host the MISC runs continuously, restarting after the completion of each cycle, when it sets [SCMMISC](#). The average time for a MISC calculation can be measured by checking SCMMISC state at regular intervals, incrementing a counter and clearing SCMMISC if it is set.

MISC accesses to the SCM array are executed if none of the engines is accessing the SCM, to avoid degradation of the microengine performance: it happens while no channel is being serviced. An ongoing MISC operation can be aborted by writing 0 to SCMMISEN.

The Host must load [eTPU MISC Compare Register \(eTPU\\_SCR\\_MISCCMPR\)](#) with the expected value to be found at the end of the MISC cycle, and then start the signature calculation by programming field SCMMISEN=1 in [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#). MISC zeroes the signature accumulator and starts reading SCM data and calculating the signature. After last SCM position is read, MISC compares the value in signature accumulator against the value in eTPU\_SCR\_MISCCMPR: if there is a mismatch MISC stops, a Global Exception is issued and [SCMMISF](#) assumes value 1. If no mismatch is found, MISC repeats the procedure automatically. When signature is being calculated, SCM address starts at the last SCM address and counts down to 0. The conditions for executing a MISC operation are (see also [Table 35-335](#)):

- Both microengines in idle state (no channel is being serviced) or stopped, in any combination (e.g., engine 1 idle with engine 2 stopped).
- [VIS](#) =0.
- [SCMMISEN](#) =1.

Note that MISC can run regardless of SCM implementation type (RAM or ROM).

If SCMMISEN=0 or VIS=1, the MISC logic stays at its initial state, with address counter pointing to the last SCM position and accumulator reset.

MISC can also be used to perform single-bit error fixes in the SCM. For more details, see [Error fixing](#).

### 35.15.13.2 Memory error support

Error Correction Code (ECC) support for SDM and SCM provides guaranteed single bit error correction and double bit error detection. Error detection and correction is performed on read accesses and on write accesses less than 32-bit wide to the SCM.

SDM ECC is calculated per byte, 5 bits wide each, totalling 20 ECC bits for each 32-bit word. That allows the ECC to be updated without a read-modify-write operation on writes of any size.

Error is not checked on bytes not selected on SDM read accesses, either by the Host, CDC or microengine. For instance, the most significant byte is not checked for errors on a microengine 24-bit read access.

Error detection also works for host accesses to the PSE area (see [Parameter Sign Extension area](#)). In this case, error is not detected in the most significant byte (bits 31:24). Also, because of sign extension, error is always detected on the bits 23:16, regardless if they are selected, whenever the most significant byte is read.

SCM ECC is 7 bits wide, comprising the whole 32-bit word. Read-modify-write is automatically made when 16-bit or 8-bit wide writes are made into the SCM in a host access. SCM errors are also detected on Entry Table accesses during TST (see [Time Slot Transition](#)) and on MISC accesses, which are considered microengine accesses with regards to interrupt generation and error reporting.

#### 35.15.13.2.1 Error detection disabling

The error detection logic in SDM and SCM can be disabled by setting the [eTPU Memory Error Control Register \(eTPU\\_MESR\\_MECCR\)](#) bits DEDD and CEDD, respectively. The disabled state turns ineffective any action due to error detection, including error correction. Note that error detection is always enabled out of reset.

#### 35.15.13.2.2 Memory error flags

SDM single (correctable) and non-correctable bit errors are flagged in [eTPU Memory Error Status Register \(eTPU\\_MESR\\_MESR\)](#) fields DCERR and DNCERR, respectively.

SCM correctable and non-correctable errors are flagged in the eTPU\_MESR\_MESR fields CCERR and CNCERR, respectively.

Double bit errors are guaranteed to be flagged, while three or more simultaneous bit errors in an SDM byte or SCM word are not. An error flagged as non-correctable can be in two or more bits.

Overflow flags DCOVR and CCOVR indicate, for SDM and SCM respectively, when a correctable error occurs when DCERR, CCERR are already asserted. Similarly, overflow flags DNCOVR/CNCOVR assert when a non-correctable error occurs when DNCERR/CNCERR are asserted already.

### 35.15.13.2.3 Memory error reports

The address, syndrome and data of a non-correctable SDM access can be sampled into [eTPU Data Error Report Address Register \(eTPU\\_MESR\\_DERAR\)](#), [eTPU Data Error Report Syndrome Register \(eTPU\\_MESR\\_DERSR\)](#), and [eTPU Data Error Report Data Register \(eTPU\\_MESR\\_DERDR\)](#), respectively. eTPU\_MESR\_DERAR also captures the SDM read access originator, whether the host, CDC, or specific eTPU channel service.

Similarly, non-correctable SCM accesses address, syndrome and data are stored in [eTPU Code Error Report Address Register \(eTPU\\_MESR\\_CERAR\)](#), [eTPU Code Error Report Syndrome Register \(eTPU\\_MESR\\_CERSR\)](#), and [eTPU Code Error Report Data Register \(eTPU\\_MESR\\_CERDR\)](#), respectively. eTPU\_MESR\_CERAR also captures the SCM read access originator, whether the host, MISC, or specific eTPU channel service. The occurrence of a non-correctable error overwrites the report register values from a correctable error, either on SDM (DCERR=1) or SCM (CCERR=1).

The last address, syndrome and data of a correctable SDM access can also be sampled into eTPU\_MESR\_DERAR, eTPU\_MESR\_DERSR, and eTPU\_MESR\_DERDR, but only if [DNCERR](#) is 0. That prevents access address, syndrome and data from a correctable error to overwrite the same information from a non-correctable access.

Similarly, the last address, syndrome and data from a correctable SCM access are stored in eTPU\_MESR\_CERAR, eTPU\_MESR\_CERSR, and eTPU\_MESR\_CERDR only if [CNCERR](#) is 0.

For either SDM or SCM, a new correctable error overwrites the report registers' values from an earlier correctable error, but report values from a non-correctable error are not overwritten, as long as bit DNCERR/CNCERR is asserted, neither by a new correctable error nor by a non-correctable one.

The sampling of SDM and SCM error report registers can be disabled through the eTPU\_MESR\_MECR fields DRDIS and CRDIS, respectively. When DRDIS (CRDIS) is asserted, the update of the SDM (SCM) error report registers is disabled, but not of

eTPU\_MESR\_MESR fields DCERR, DNCERR (CCERR, CNCERR). DRDIS, CRDIS must be set before reading the respective report registers to assure their coherent reading, preventing them to be updated between reads.

#### 35.15.13.2.4 Error detection and wait-states

Microengine SDM accesses do not take any wait-state due to ECC support. Host SDM read accesses take two wait-states minimum<sup>39</sup> in MCUs with SDM ECC support, regardless if an error was detected or not, if the SDM error detection is enabled ([eTPU Memory Error Control Register \(eTPU\\_MESR\\_MECR\)](#) field DEDD=0). Host SDM read accesses take a minimum of one wait-state if the SDM error detection is disabled (eTPU\_MESR\_MECR[DEDD]=1). Host SDM write accesses take one wait-state minimum, regardless of ECC support presence or enabling.

Host SCM read accesses have two wait-states<sup>39</sup>, regardless if an error was detected or not. Writes from the host to the SCM take one wait-state on 32-bit accesses, and one additional wait-state (two wait-states total<sup>39</sup> on 16-bit and 8-bit wide accesses. Those figures are not affected by the SCM error detection disabling (eTPU\_MESR\_MECR[CEDD]).

#### 35.15.13.2.5 Memory error interrupts

For **microengine accesses**, the Global Exception interrupt asserts whenever a non-correctable error is detected, either on SCM or SDM (see [Interrupts and data transfer requests](#)). These errors are flagged by [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) fields SCMERR and SDMERR, respectively. Single bit errors are corrected and activate the Memory Error Correction Interrupt if it is enabled (see [Interrupt types and sources](#)), but do not generate Global Exceptions.

For **host accesses** a bus error is issued whenever a non-correctable error is detected, either on SCM or SDM (but not through the CDC) and it also generates a Global Exception. Single bit errors are corrected (if the error correction feature is available) and do not cause bus transfer errors, but assert the Memory Error Correction Interrupt if it is enabled (see [Interrupt types and sources](#)).

#### 35.15.13.2.6 Effect of errors on microcode execution

Correctable errors, either on SCM or SDM, do not affect microcode execution if detection/correction is enabled.

The executing thread is affected by a non-correctable SDM error as follows:

39. One wait-state more, compared with eTPU versions before eTPU2 and previous eTPU2 without ECC support

- If **DTEND** = 1: on SDM errors due to a read operation, if the instruction is not also an END, the following instruction automatically executes an END, and its operations may be executed, totally or partially. On SDM errors during the TST preload, the thread automatically ends on the first instruction, if the error occurs on a preload parameter selected by the entry point bit PP (see Entry Point Format section.) The first instruction may be executed totally or partially. Data read into P or DIOB may be corrupted in either case.
- If **DTEND** = 0: the TST or thread continues the execution flow normally. Data read into P or DIOB may be corrupted in either case.

The executing thread is affected by a non-correctable SCM error as follows:

- If **CTEND** = 1: on SCM errors, the corrupted instruction is not executed, instead replaced by a simple END. Due to instruction prefetching, an error may be detected and yet not affect the thread execution. However, an error detected in a prefetched instruction may cause error report and global or memory error interrupts, even if not executed. If a non-correctable error occurs on the entry table read during TST (see Time Slot Transition section), the first instruction in the thread is replaced with a simple END, a global exception is issued and the reports and flags are normally updated.
- If **CTEND** = 0: the execution flow continues normally, and the results depend on the particular instruction corruption.

**Table 35-418. Error support summary if CEDD = DEDD = 0**

| Action                            |            | SCM                                                           |                                                    | SDM              |                                              |
|-----------------------------------|------------|---------------------------------------------------------------|----------------------------------------------------|------------------|----------------------------------------------|
|                                   |            | single bit error                                              | double bit error                                   | single bit error | double bit error                             |
| Memory Error Correction Interrupt |            | Asserts                                                       | Not asserted                                       | Asserts          | Not asserted                                 |
| Global Exception                  |            | Not asserted                                                  | Asserts                                            | Not asserted     | Asserts                                      |

Table continues on the next page...

**Table 35-418. Error support summary if CEDD = DEDD = 0 (continued)**

| Action                      |            | SCM              |                  | SDM                                                          |                  |
|-----------------------------|------------|------------------|------------------|--------------------------------------------------------------|------------------|
|                             |            | single bit error | double bit error | single bit error                                             | double bit error |
| Data Error Report Registers | DNCERR = 0 | Not related      |                  | Updates eTPU_MESR_DERAR, eTPU_MESR_DESR, eTPU_MESR_DERDR     |                  |
|                             | DNCERR = 1 |                  |                  | eTPU_MESR_DERAR, eTPU_MESR_DESR, eTPU_MESR_DERDR not updated |                  |

1. The thread executes correctly if the error is detected on an instruction fetched but not executed.
2. The erroneous instruction is not executed at all, and replaced by a simple END.
3. The instruction following the erroneous read may be executed totally or partially.

### 35.15.13.2.7 Error Correction Code (ECC) and syndrome definition

SDM ECC is composed of 5 Hsiao code<sup>40</sup> bits for each data byte. SCM ECC is composed of 7 Hsiao code bits for each 32-bit word.

Table 35-419 shows the encoding of the SDM syndrome and global parity fields as they read on eTPU Data Error Report Syndrome Register (eTPU\_MESR\_DESR). There is one syndrome and one global parity for each byte in an SDM word, numbered SYND0 to SYND3 from the least to the most significant.

**Table 35-419. SDM syndrome definition**

| SYNDn<br>(hex) | Result                 | SYNDn<br>(hex) | Result                        |
|----------------|------------------------|----------------|-------------------------------|
| 0E             | error on data bit 8n+7 | 10             | error on <b>code</b> bit 8n+4 |
| 15             | error on data bit 8n+6 | 08             | error on <b>code</b> bit 8n+3 |
| 07             | error on data bit 8n+5 | 04             | error on <b>code</b> bit 8n+2 |
| 1A             | error on data bit 8n+4 | 02             | error on <b>code</b> bit 8n+1 |
| 19             | error on data bit 8n+3 | 01             | error on <b>code</b> bit 8n   |
| 13             | error on data bit 8n+2 |                |                               |
| 16             | error on data bit 8n+1 | 00             | no error                      |
| 1C             | error on data bit 8n   | any other      | non-correctable error         |

The following table shows the definition of the SCM syndrome field as it reads on eTPU Code Error Report Syndrome Register (eTPU\_MESR\_CERSR).

40. Hsiao, M.Y.; A Class of Optimal Minimum Odd-weight-column SEC-DED Codes; IBM Journal of Research and Development [http://ieeexplore.ieee.org/xpl/freeabs\\_all.jsp?arnumber=5391627](http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?arnumber=5391627)

Table 35-420. SCM syndrome definition

| SYND<br>(hex) | Result                     | SYND<br>(hex) | Result               | SYND<br>(hex) | Result                |
|---------------|----------------------------|---------------|----------------------|---------------|-----------------------|
| 40            | error on <b>code</b> bit 6 | 58            | error on data bit 25 | 46            | error on data bit 11  |
| 20            | error on <b>code</b> bit 5 | 0B            | error on data bit 24 | 4A            | error on data bit 10  |
| 10            | error on <b>code</b> bit 4 | 54            | error on data bit 23 | 52            | error on data bit 9   |
| 08            | error on <b>code</b> bit 3 | 15            | error on data bit 22 | 62            | error on data bit 8   |
| 04            | error on <b>code</b> bit 2 | 16            | error on data bit 21 | 13            | error on data bit 7   |
| 02            | error on <b>code</b> bit 1 | 34            | error on data bit 20 | 29            | error on data bit 6   |
| 01            | error on <b>code</b> bit 0 | 25            | error on data bit 19 | 31            | error on data bit 5   |
|               |                            | 26            | error on data bit 18 | 43            | error on data bit 4   |
| 49            | error on data bit 31       | 64            | error on data bit 17 | 45            | error on data bit 3   |
| 0D            | error on data bit 30       | 2C            | error on data bit 16 | 19            | error on data bit 2   |
| 0E            | error on data bit 29       | 1A            | error on data bit 15 | 51            | error on data bit 1   |
| 38            | error on data bit 28       | 23            | error on data bit 14 | 61            | error on data bit 0   |
| 4C            | error on data bit 27       | 2A            | error on data bit 13 | 00            | no error              |
| 1C            | error on data bit 26       | 32            | error on data bit 12 | any other     | non-correctable error |

### 35.15.13.2.8 Error injection

Errors can be injected into the SDM read data path through [eTPU Data Error Injection Address Register \(eTPU\\_MESR\\_DEIAR\)](#), [eTPU Data Error Injection Data Pattern Register \(eTPU\\_MESR\\_DEIDPR\)](#) and [eTPU Data Error Injection Parity Pattern Register \(eTPU\\_MESR\\_DEIPPR\)](#). They define bit flips on accesses at the specific address specified in eTPU\_MESR\_DEIAR.

SDM error injection is enabled independently for host and microengine accesses by the [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) fields HDEIE and MDEIE, respectively. The user must program eTPU\_MESR\_DEIAR, eTPU\_MESR\_DEIDPR, and eTPU\_MESR\_DEIPPR with HDEIE=MDEIE=0, and only then enable error injection by setting HDEIE=1 and/or MDEIE=1 to avoid races (see [eTPU Memory Error Status Register \(eTPU\\_MESR\\_MESR\)](#)).

Similarly, SCM errors can be injected into the SCM read data path through [eTPU Code Error Injection Address Register \(eTPU\\_MESR\\_CEIAR\)](#), [eTPU Code Error Injection Data Pattern Register \(eTPU\\_MESR\\_CEIDPR\)](#) and [eTPU Code Error Injection Parity Pattern Register \(eTPU\\_MESR\\_CEIPPR\)](#), enabled by the [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) field CEIE. Errors are injected on host accesses to the address specified in eTPU\_MESR\_CEIAR when **VIS** =1, or on microengine and MISC accesses when **VIS**=0 .

### 35.15.13.2.9 Error fixing

Single bit **soft errors** can be fixed by rewriting the right value, as corrected by the ECC logic, into the same address of the erroneous data. eTPU provides means to perform such fixes safely, coherently and concurrently with the normal operation.

**SDM fixes** can be done using the CDC (see [Coherent Dual-parameter Controller \(CDC\)](#)), limited to the lower 8 Kbytes of SDM. The Host application simply has to program a transfer with both origin and destination positions pointing to the address of the data to be fixed. Because the PBBASE field has an address granularity of 8 bytes, a word adjacent to the one to be fixed must also be rewritten. The CDC transfer is atomic, therefore the fix is done coherently and does not interfere with the application code or data flows.

**SCM fixes** can be done by programming [eTPU Code Error Fix Register \(eTPU\\_MESR\\_CEFR\)](#) (see [eTPU Code Error Report Syndrome Register \(eTPU\\_MESR\\_CERSR\)](#)). The fixes are performed by the MISC logic, which must be enabled (see [SCM Test - Multiple Input Signature Calculator](#)). The modes available, selected by [CFIXM](#), are:

- **Automatic Fix Mode (CFIXM=11)**: the MISC logic automatically rewrites the contents of an address whenever it finds a correctable error; the CFIXM field keeps its value if a fix is made.

## 35.15.14 Performance monitoring features

### 35.15.14.1 Idle Counter

The Idle Counters [eTPU Idle Register for Engine 1 \(eTPU\\_ER\\_IDLER\\_ENG1\)](#) and [eTPU Idle Register for Engine 2 \(eTPU\\_ER\\_IDLER\\_ENG2\)](#) continuously count microcycles in which the microengine is not busy with channel service. They can be used to measure the microengine utilization by rating the count measured during a period of time to the number of microcycles contained in the period. The Idle Counters do not count microcycles when the engine is stopped, or is in TST or halt states.

### 35.15.14.2 Latency Monitor

eTPU implements Latency Monitors to measure the time taken to service a request. Each Latency Monitor provides:

- The measure of the greatest latency found during actual thread executions, accessed from [eTPU Latency Monitor Measure Register for Engine 1](#) (`eTPU_LMR_LMnMR_ENG1`) and [eTPU Latency Monitor Measure Register for Engine 2](#) (`eTPU_LMR_LMnMR_ENG2`).
- A comparison between the measured latency and a threshold, determined through [eTPU Latency Monitor Measure Register for Engine 2](#) (`eTPU_LMR_LMnMR_ENG2`) and [eTPU Latency Monitor Configuration Register for Engine 2](#) (`eTPU_LMR_LMnCR_ENG2`).

Each Latency Monitor works independently in one of the following modes, selected with the LMM field in [eTPU Latency Monitor Configuration Register for Engine 1](#) (`eTPU_LMR_LMnCR_ENG1`) and [eTPU Latency Monitor Configuration Register for Engine 2](#) (`eTPU_LMR_LMnCR_ENG2`) :

- **Disabled mode:** no latency measures or actions are taken.
- **Channel mode:** monitors the latency of an individual channel.
- **Priority mode:** monitors the combined latency of all channels in a given priority level - High, Medium or Low (see [Scheduler](#)).

Channel and Priority modes are detailed in the subsections below. The following applies to both modes:

- After each latency measurement, the value measured is compared with the LATENCY value in [eTPU Latency Monitor Measure Register for Engine 1](#) (`eTPU_LMR_LMnMR_ENG1`) and [eTPU Latency Monitor Measure Register for Engine 2](#) (`eTPU_LMR_LMnMR_ENG2`). If the new measured value is greater, it replaces the old value in [eTPU Latency Monitor Measure Register for Engine 1](#) (`eTPU_LMR_LMnMR_ENG1`) and [eTPU Latency Monitor Measure Register for Engine 2](#) (`eTPU_LMR_LMnMR_ENG2`).
- After each latency measurement, the value measured is compared with the MAXLAT value in [eTPU Latency Monitor Configuration Register for Engine 1](#) (`eTPU_LMR_LMnCR_ENG1`) and [eTPU Latency Monitor Configuration Register for Engine 2](#) (`eTPU_LMR_LMnCR_ENG2`), and if the new measured value is greater:

- A Global Exception is issued.
- The [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) flag LTO1 (engine 1) or LTO2 (engine 2) is set, independently of the LATENCY value in [eTPU Latency Monitor Measure Register for Engine 1 \(eTPU\\_LMR\\_LMnMR\\_ENG1\)](#) and [eTPU Latency Monitor Measure Register for Engine 2 \(eTPU\\_LMR\\_LMnMR\\_ENG2\)](#).

**NOTE**

The LATENCY value is updated even if MAXLAT=0.

**NOTE**

MAXLAT=0 just inhibits the assertion of the LTO1/2 flag and Global Exception due to the respective Latency Monitor. Other Latency Monitor instances with non-zero MAXLAT value may assert LTO1/2 and Global Exception.

**35.15.14.2.1 Channel mode**

When the Latency Monitor operates in Channel mode:

- Only the channel selected by the MONCHAN field in [eTPU Latency Monitor Configuration Register for Engine 1 \(eTPU\\_LMR\\_LMnCR\\_ENG1\)](#) and [eTPU Latency Monitor Configuration Register for Engine 2 \(eTPU\\_LMR\\_LMnCR\\_ENG2\)](#) is monitored.
- Any combination of Host Service Requests (HSR), Channel Service Requests and Link Service Requests can be selected for monitoring, based on the SRSEL field in [eTPU Latency Monitor Configuration Register for Engine 1 \(eTPU\\_LMR\\_LMnCR\\_ENG1\)](#) and [eTPU Latency Monitor Configuration Register for Engine 2 \(eTPU\\_LMR\\_LMnCR\\_ENG2\)](#).
- The latency is counted in microcycles, from the moment the logic OR of all the service requests selected by SRSEL asserts to the moment this logic OR negates.
- The latency count is interrupted when the channel is disabled, either by programming the CPR field in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#) to 0, or by a watchdog timeout. Latency is counted until the channel is disabled and is not discarded; a new count can start from zero when the channel is re-enabled.

**NOTE**

If a selected service request type or a combination of them continues asserted during and after its service thread execution,

its latency counter will keep on running; this can happen, for instance, if either matches can service requests (e.g. channel modes `em_st/em_dt`), one match happens before the other is serviced, and only one of them is cleared. The Latency Monitor can, in cases like this, yield pessimistic measurements.

### NOTE

The Latency Monitor in channel mode must be disabled before the channel it monitors is disabled.

#### 35.15.14.2.2 Priority mode

When the Latency Monitor operates in Priority mode:

- Only the combination of channels assigned with the priority selected by the `SRSEL` field in [eTPU Latency Monitor Configuration Register for Engine 1](#) (`eTPU_LMR_LMnCR_ENG1`) and [eTPU Latency Monitor Configuration Register for Engine 2](#) (`eTPU_LMR_LMnCR_ENG2`) is monitored.
- The latency is measured in microcycles, starting from either of these two events, whichever happens first:
  - The logic OR of service requests of the selected priority transitions from 0 to 1 at a moment when all their grants are at state negated.
  - The grants of the selected priority are cleared by the scheduler at the end of the thread, and any of the service requests at the same priority is still active soon after the thread ends.
- The latency is measured until the grants of the selected priority are cleared by the scheduler, after the measurement started.

### Note

A Latency Monitor in priority mode must be disabled before any of the channels in the selected priority is disabled, or any disabled channel is assigned with the selected priority.

### 35.15.14.3 Watchdog Monitor Operation

The watchdog mechanism can also be used to monitor, without interfering with the application execution, whether the execution time of any individual thread or a sequence of threads reaches a given limit. This can be achieved by asserting the WMO field in [eTPU Watchdog Timer Register for Engine 1 \(eTPU\\_ER\\_WDTR\\_ENG1\)](#) and [eTPU Watchdog Timer Register for Engine 2 \(eTPU\\_ER\\_WDTR\\_ENG2\)](#).

## 35.16 Initialization/application information

### 35.16.1 Configuration sequence

After initial power-on reset the eTPU remains in an idle state<sup>41</sup>, requiring initialization of several registers before any function can begin execution. Also, if the SCM is implemented in RAM, it should be initialized with the eTPU application code prior to configuring the eTPU. Configuration procedures are summarized as follows:

- If SCM is implemented as RAM, load the eTPU application code (see [SCM access](#)).
- Initialize SDM (optional if no ECC support available)
- Initialize the SCM MISC logic (optional, see [SCM Test - Multiple Input Signature Calculator](#)).
- Initialize Watchdog and Latency Monitors (optional).
- Initialize [eTPU Engine 1 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG1\)](#) and [eTPU Engine 2 Time Base Configuration Register \(eTPU\\_TBR\\_TBCR\\_ENG2\)](#) to set up:
  - TCR1 and TCR2 prescalers and clock sources.
  - Select digital filtering mode.
  - TCRCLK signal filter control.
  - Angle mode operation (if necessary).
- Initialize [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#) to set up:

---

41. Except when device debug request is asserted on power-on reset: in this case, the microengines wake-up in halt state.

- Entry table base.
- Filter prescaler clock control.
- Initialize eTPU Engine 1 STAC Configuration Register (eTPU\_TBR\_STAC\_ENG1) and eTPU Engine 2 STAC Configuration Register (eTPU\_TBR\_STAC\_ENG2) if you need to set up TCR1/2 resource Client/Server operation.
- Write to eTPU Channel n Configuration Register for Engine 1 (eTPU\_CCCR\_CnCR\_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU\_CCCR\_CnCR\_ENG2) to choose the Function to be performed by each channel, and its parameter base address.
- Write to eTPU Channel n Status Control Register for Engine 1 (eTPU\_CCCR\_CnSCR\_ENG1) and eTPU Channel n Status Control Register for Engine 2 (eTPU\_CCCR\_CnSCR\_ENG2) to choose among the possible variations within the function flow (FM bits).
- Write to SDM for parameter initialization of each configured channel.
- Write to eTPU Watchdog Timer Register for Engine 1 (eTPU\_ER\_WDTR\_ENG1) and eTPU Watchdog Timer Register for Engine 2 (eTPU\_ER\_WDTR\_ENG2) if you need to enable and set up the Watchdog(s) mode and timeout.
- Write to eTPU Channel n Host Service Request Register for Engine 1 (eTPU\_CCCR\_CnHSRR\_ENG1) and eTPU Channel n Host Service Request Register for Engine 2 (eTPU\_CCCR\_CnHSRR\_ENG2) to initialize the active channels.
- Write to eTPU Channel Interrupt Enable Register for Engine 1 (eTPU\_GCR\_CIER\_ENG1) and eTPU Channel Interrupt Enable Register for Engine 2 (eTPU\_GCR\_CIER\_ENG2) if interrupts are to be enabled from the appropriate channels. Likewise for Data Transfer Requests (eTPU Channel Data Transfer Request Enable Register for Engine 1 (eTPU\_GCR\_CDTRER\_ENG1) and eTPU Channel Data Transfer Request Enable Register for Engine 2 (eTPU\_GCR\_CDTRER\_ENG2)). This can also be done through eTPU Channel n Configuration Register for Engine 1 (eTPU\_CCCR\_CnCR\_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU\_CCCR\_CnCR\_ENG2).
- Write to eTPU Channel n Configuration Register for Engine 1 (eTPU\_CCCR\_CnCR\_ENG1) and eTPU Channel n Configuration Register for Engine 2 (eTPU\_CCCR\_CnCR\_ENG2) to enable each channel by assigning it a high, middle, or low priority (CPR field).<sup>41</sup>

- Monitor [eTPU Channel n Host Service Request Register for Engine 1 \(eTPU\\_CCCR\\_CnHSRR\\_ENG1\)](#) and [eTPU Channel n Host Service Request Register for Engine 2 \(eTPU\\_CCCR\\_CnHSRR\\_ENG2\)](#) for completion of initialization.
- Write [GTBE](#) =1 to start TCR1/TCR2 time base counting at same time in both Engines (may be done before or never, depending on the particular application and use of Red Line bus).

See [Initialization Code Example](#).

## 35.16.2 Reset options

### 35.16.2.1 Hardware reset

Hardware reset is achieved by assertion of device synchronous reset. Both Engines and common logic is reset, and even the System Configuration and Global Channel registers assume their reset values.

#### Note

All eTPU input clocks must pulse during reset so that both engines are reset, even if they are in Module Disable or Stop mode.

### 35.16.2.2 Software reset

eTPU has no software reset. To abort infinite microcode loops, the Force END mechanism must be used (see field FEND in [eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#)).

## 35.16.3 Multiple parameter coherency methods

Follows a description of two methods for coherent transfer of multiple parameters between Host and eTPU. Both methods involve the use of two parameter areas: the Transfer Parameter Area (hereafter called TPA), which is the SDM area directly accessed by the Host for reads and writes, and the Permanent Parameter Area (hereafter called

PPA), which are the SDM positions where channel parameters are normally accessed by the Function microcode. Note that parameters in either TPA or PPA do not have to be in sequential addresses. TPAs and PPAs allocation are completely defined by the application, and there may be any number of them, independently of the channels.

The methods described here are not the only solutions for the coherent transfer problem, and both can coexist in eTPU and even used in combination. Also note that for transfers of a pair of parameters, the Coherent Dual-parameter Controller is faster and have less impact on both eTPU and Host performance. That said, the methods are:

- **Transfer Service:** a microengine thread transfers, upon Host Service Request, data from/to a TPA to/from a PPA. Coherency is guaranteed by the fact that a thread is atomic with respect to other threads in the same Engine, and so are its transfers. If parameters in PPA are shared by both Engines, hardware semaphores have to be used to access them.
- **Mailbox:** for Host to eTPU transfers, the microcode checks a flag, set by the host, indicating the existence of new parameter data in the TPA. It can, then, either access TPA data directly or copy it to the PPA. For eTPU to Host transfers, when microcode changes PPA, it copies them to the TPA and flags updated TPA data to Host, possibly using an Interrupt or a Data Transfer Request. The Mailbox flag is reset when data is copied: by the eTPU microcode, when it transfers TPA to PPA (possibly followed by an Interrupt); by the Host, when it reads data from the TPA. This indicates that TPA is free for another transfer.

Transfer Service has the advantage of separating the task of data transfer from the functional service thread that accesses the parameters, with less impact to the latter. Compared to the Mailbox method, however, it has bigger average latency, because the Transfer Service thread has to contend for a time slot to execute. This latency can be minimized if Transfer Service thread is assigned to a separate channel with higher priority, but even so it does not guarantee that PPA is updated before the next execution of the functional thread that uses it.

Mailbox method, on the other hand, makes the functional thread check for the existence of new data (Host to eTPU). It does not have to be responsible for the transfer, though: it may access the TPA directly, and a Transfer Service can then be used to copy data from TPA to PPA.

## 35.16.4 Programming Hints and Caveats

### 35.16.4.1 Atomic dual access after a call, return

A dual, back-to-back parameter access is not atomic after a call, a jump, or a return if they occurred in parallel with an odd SDM access. It is safer to make a pair of parameter accesses that must be coherent begin at the second instruction after a call/jump/return.

### 35.16.4.2 Resource polling

The use of polling while waiting for a condition or a resource (except semaphore lock) should be avoided in order not to hang the microengine in long loops. This general programming guideline is greatly enforced in eTPU, as a thread cannot be preempted for any reason. Safer polling, albeit with long and indeterministic latency, can be obtained if a thread issues a channel link to the serviced channel and terminates. The microengine is then free to other tasks, and the next poll happens at the next time the channel is serviced. This mechanism can be combined with finite (timed out) loops for better latency.

### 35.16.4.3 Changing channel function, parameter base, or entry table scheme

Channel function, parameter base address and entry table scheme are determined by the CFS, CPBA, and ETCS fields in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#). They cannot be changed when the channel is enabled. If the channel is disabled first, one may still have service requests from the previous function, so before the channel is enabled again one must be sure that:

- the first thread executed in the new function is the initialization one.
- the initialization thread of the new function clears any previously pending service request.

Here is a safe procedure for function changing:

1. Disable the channel (in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#), write CPR=00).
2. Change the function configuration (fields CFS and/or CPBA and/or ETCS in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#)).

3. Request the initialization thread, writing [eTPU Channel n Host Service Request Register for Engine 1 \(eTPU\\_CCCR\\_CnHSRR\\_ENG1\)](#) and [eTPU Channel n Host Service Request Register for Engine 2 \(eTPU\\_CCCR\\_CnHSRR\\_ENG2\)](#) with the initialization HSR (channel still disabled).
4. enable the channel (in [eTPU Channel n Configuration Register for Engine 1 \(eTPU\\_CCCR\\_CnCR\\_ENG1\)](#) and [eTPU Channel n Configuration Register for Engine 2 \(eTPU\\_CCCR\\_CnCR\\_ENG2\)](#) write  $CPR > 0$ ); the initialization HSR is serviced before any other formerly pending service requests, clearing them.

#### 35.16.4.4 Checking and Clearing Interrupts of a Stopped Engine

An Engine may be stopped with interrupts (or DMA requests) pending. This includes the case when the Engine's MDIS bit is set and a thread is still running: the thread will complete execution, possibly issuing an interrupt or DMA request before the engine stops, setting the STF bit.

As soon as the engine stops the channel registers become inaccessible, issuing bus errors when accessed. Interrupts and DMA requests can still be checked and cleared through the Global Channel Registers, though. DMA requests can also be cleared by the hardware handshaking with the DMA controller when the engine is stopped.

#### 35.16.5 Estimating Worst Case Latency

Reliable systems are designed to work under worst-case conditions. This section explains how to estimate worst-case latency (WCL) for any eTPU function in any system. The appendix covers the following topics:

- Introduction to Worst-Case Latency
- Using Worst-Case Latency Estimates to Evaluate Performance
- Priority Scheme Details used in WCL Analyses
- First-Pass WCL Analysis
- Second-Pass WCL Analysis

The first-pass WCL analysis is based on a deterministic, generalized formula that is easy to apply. Because of the generalizations in the formula, the first analysis result is almost always much worse than the real worst case. If the desired system performance is within the limits of this first analysis, then no further analysis is required; the system is well

within the performance limits of the eTPU. If the desired system performance exceeds that indicated by the first analysis, the second-pass WCL analysis should be applied. The second-pass analysis is not a generalized formula, but rather uses specific system details for a realistic worst-case estimation.

### 35.16.5.1 Introduction to Worst-Case Latency

#### Note

The latency calculation and examples refer to old TPU functions such as PWM, DIO etc. These functions use single action channels which have single transition and single match functionality. They are not optimized for the eTPU hardware enhancement which support various double action modes. These examples are for reference only. New eTPU functions which are optimized for the new hardware will impose different latency calculations.

Worst-case latency for a channel is the longest amount of time that can elapse between the execution of any two function threads on that channel. For example, if in a particular system, channel 5 is running PWM, the worst-case latency for channel 5 is the longest possible time between the execution of two PWM threads. The worst case time includes the time the execution unit takes to execute threads for other active channels, and other delays described later in this section. Refer to the following figure.

**Figure 35-335. Worst-Case Latency for PWM**

Worst-case latency for a channel depends both on the function running on that channel and on the activity on other channels. Since the 32 eTPU channels must all share the same execution unit, execution speed of a particular function varies with each system. The PWM thread response is faster if there are no other active channels than if other

channels are also active. In addition, changing the priority scheme and channel number assignments can change performance for a function even if the same set of functions are still active.

Each function is divided into threads, as shown in the figure below (see also [Functions and threads](#)). The eTPU Microengine executes one thread of a function at a time. For example, the Microengine might execute thread 1 of PWM, then thread 3 of DIO, then thread 2 of PWM, then thread 2 of SM, and so on. The amount of time the eTPU Microengine grants a function to execute a thread varies with the number of microcode instructions in the thread.

Since there is only one eTPU Microengine (in each eTPU Engine), the eTPU cannot actually execute the software for multiple functions simultaneously. However, the hardware for each of the channels is independent. This means that, for example, all 32 channel signals can change thread at the same moment, provided that the function software sets up the channel hardware to do so beforehand.

With Host CPU code, the system designer assigns functions to channels and initializes the functions. After initialization, functions typically run without Host intervention, except for eTPU channel interrupts to the Host to give or receive information. Most functions can run continuously with periodic servicing from the eTPU Microengine. As required, the channels request service from the eTPU Microengine, and the eTPU Scheduler determines the order in which the channels are serviced. Worst-case latency for a channel can be derived from the details of the priority scheme that the scheduler uses (see [Scheduler](#)).

**Figure 35-336. Function Threads**

### 35.16.5.2 Using Worst-Case Latency estimates to evaluate performance

Once WCL is found for a channel, the user must determine how to use this number to analyze performance. To analyze the performance of a channel running the PWM function, for example, some information about what happens in each thread is necessary.

The following example refers to old TPU PWM function, which is not optimized to the eTPU enhanced hardware. For PWM, thread 1 is the initialization thread, and threads 2 and 3 are used during normal function execution. (PWM threads 4, 5, and 6 are for special modes and will be assumed to be unused on channel 5). Thread 2 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from low to high at the time indicated in the match register (match time). At match time, the signal goes high and channel 5 requests service from the eTPU Microengine to execute thread 3. Thread 3 writes a time into the channel 5 match register and performs other operations that will cause the channel 5 signal to go from high to low at match time. At match time, the signal goes low and channel 5 requests service from the eTPU Microengine to execute thread 2. A PWM wave is kept running on the system by the eTPU executing thread 2, then thread 3, then thread 2, then thread 3, and so on.

Since the definition of worse-case latency assumes a fully loaded running system, initialization threads are not part of worst-case calculations. For the channel 5 example, the two PWM threads in [Figure 35-335](#) are thus the two normal running threads, threads 2 and 3.

[Figure 35-335](#) does not define which thread is thread 2 and which is thread 3. Since the worst-case latency derived from the first-pass analysis is the worst case between any 2 threads (not counting initialization threads), it is safe to say that the worst-case latency shown in [Figure 35-336](#) represents both the worst-case high time and the worst-case low time.

Notice in [Figure 35-335](#) that worst-case latency is drawn from the end of the execution of the first PWM thread to the end of the execution of the next PWM thread. It is drawn from end to end because the microcode instructions that make up the threads control the channel hardware. To make sure that all the microcode instructions needed to change the pin thread have been executed, it is necessary to include the execution time of the second thread.

Thread information for each function is found in the programming notes for individual TPU functions. See NXP Programming Note TPUPN00/D, Using the TPU Function Library and TPU Emulation Mode, for a list of available programming notes. Similar documentation will be provided for the eTPU new functions.

### 35.16.5.3 Priority Scheme Details Used in WCL Analysis

The user assigns functions to channel numbers and gives each active channel a priority level of high, middle, or low. The Scheduler uses the channel number and channel priority level to determine the order in which to grant service.

The scheduler allocates time slots to specific priority levels of high, middle, or low. One function thread is executed in each time slot. The length of a time slot varies according to the length of the executing thread. When fully loaded, the scheduler always assigns time slots in a seven-slot sequence (see the following table). After a seven-slot sequence is completed, another seven-slot sequence begins (see [Figure 35-338](#)). Note that in eTPU, when no service request exists, the scheduler goes to thread 1, but WCL calculation considers full load.

**Figure 35-337. Time-Slot Sequence**

This sequence scheme gives higher-priority channels more service time than lower-priority channels. High-priority channels are allocated four of seven time slots, middle-priority channels are allocated two of seven time slots, and low-priority channels are allocated one of seven time slots.

**Figure 35-338. Multiple Time-Slot Sequences**

#### 35.16.5.3.1 Priority Passing

If no channel of the priority level assigned to the time slot is requesting service, the eTPU scheduler can pass priority to other levels. If no high-level channel is requesting service during a high level time slot, a middle-level channel is granted service; or, if no middle level-channel is requesting service, a low-level channel is granted service. If no middle-level channel is requesting service during a middle-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a low-level channel is

granted service. If no low-level channel is requesting service during a low-level time slot, a high-level channel is granted service; or, if no high-level channel is requesting service, a middle-level channel is granted service. If no channel is requesting service, the time slot sequence is reset to state 1 and the scheduler idles until a request is received.

Priority passing is implemented in hardware and does not contribute to worst-case latency.

### 35.16.5.3.2 Time-slot transition

After each time slot, the eTPU must prepare for the next time slot. This preparation time between each time slot is called a time-slot transition. See [Time Slot Transition](#). Time-slot transitions can take from six up to ten eTPU clocks.

### 35.16.5.3.3 Channel Number Priority

If more than one channel of a priority level is requesting service, the lowest numbered channel is granted service first. For example, if channels 0, 5, and 9 are all high-level channels requesting service during a high time slot, channel 0 is granted service first. Continuing this example, if channel 0 requests service again immediately after being serviced, it is not serviced again until channels 5 and 9 are serviced. This scheme is implemented so that continuously-requesting low numbered channels do not take all the time on the eTPU execution unit and leave no time for other channels.

The scheduler uses registers to keep track of which channels have been serviced and which require servicing. Each channel has two register bit: a service request register (SRR) and a service grant register (SGR). The SRR is set when a channel requests service. After the channel has been granted service, the SGR is set and the SRR is cleared.

SGRs are not cleared individually by channel, but rather as priority level groups. The clearing of a group of SGRs begins a new cycle for that priority level. An SGR group is cleared on the condition that a channel of that priority level has just been serviced, and no other channel of that priority level is requesting service (has a set SRR) and has not been granted service (has a clear SGR).

For example, if a middle-priority channel has just been serviced (either in a middle-priority time slot or a high or low-priority time slot gained by priority passing), the SRRs and SGRs of all middle-priority channels are compared. If there is no middle-priority channel with its SRR set and SGR cleared, the scheduler clears all middle-level SGRs. If there is a middle-level channel with its SRR set and SGR cleared, the scheduler does not clear the SGR group, and the requesting middle-level channel is serviced on the next middle-level time slot (or possibly sooner by priority passing).

### 35.16.5.3.4 SDM Collision Rate

Most function threads read or write to the eTPU SDM at least once. Because both the eTPU Microengine and Host can access the SDM but not at the same time, the Microengine may suspend execution during the SDM access while waiting for the Host to finish accessing the SDM. At other times the Host may wait for the Microengine. Wait states can take up to two eTPU clocks, when the Host accesses the SDM directly, without using CDC. Microengine(s) wait-states must be added into the worst-case latency calculation. The system designer should estimate the percentage of SDM accesses in the system that will result in Microengine wait-states. This percentage is called the RAM collision rate (RCR). In each collision with direct Host accesses to the SDM the Microengine(s) wait for two eTPU clocks.

In eTPU the Coherent Dual-parameter Controller (CDC) may also access the SDM for atomic transfers of two parameters. eTPU Microengine may wait on this operation (if it is in service time) until the transfer is complete. CDC always transfers two parameters, making four consecutive accesses (read, write, read, write) of one eTPU clock each. The system designer should estimate the percentage of SDM accesses in the system that will result in a Microengine wait due to coherent transfer, and multiply it with the average number of eTPU clocks the Microengine waits for each transfer. This percentage is called Coherent Parameter Collision Rate (CPCR).

In addition, Microengine to Microengine multiple parameter coherent communication, using the hardware semaphores, may hold one Microengine which waits to lock the semaphore while the other Microengine is holding it. This waiting is due to a software loop, not hardware wait-states. Note that single parameter access of one Microengine does not affect the timing of the other Microengine due to SDM time interlace. This implies that single parameter Microengine to Microengine communication does not affect the performance. The Microengine which waits for the semaphore will loop until it is freed by the other Microengine. This time depends on the eTPU application. The system designer should estimate the percentage of Microengine to Microengine coherent parameter communication that will result in eTPU semaphore loops, and multiply it with the average number of eTPU clocks the Microengine loops for each such transfer. This percentage is called CCR (Communication Collision Rate).

A 100% collision rate for a system is the theoretical worst case. In many systems, however, the RCR, CPCR and CCR would be very low, sometimes even near 0%. This is because the eTPU is an independent processor capable of servicing most function needs, so that the Host rarely needs to access the eTPU SDM. Also coherent Microengine to Microengine communication of more than one parameter may be rare. To find a realistic

RCR, CPCR the system designer should evaluate the Host code and find the percentage of time it accesses the eTPU SDM with or without using the CDC. This percentage gives a good RCR and CPCR. The eTPU application provides a good estimation of CCR.

### Note

The programming practice of polling a flag in the eTPU SDM causes a very high RCR and should be avoided in high-performance systems.

After the collision rate for a system is found, it can be applied to the WCL calculations for each channel. The system designer can use the collision percentage and the number of SDM accesses (with and without semaphores) to estimate the eTPU loop time for a function. Note that in old TPU functions CPCR and CCR are both zero.

The estimation of eTPU wait time is as follows:

#### Variables:

$N1$  = Number of simple RAM accesses in the longest thread

$RCRWait$  = Maximal eTPU clocks wait time for simple RAM collision = 2

$CPCRWait$  = Average eTPU clocks for Coherent Parameter Transfer (using CDC).

$N2$  = Number of eTPU-eTPU semaphore RAM accesses in the longest thread

$CCRWait$  = Average eTPU clocks for Microengine-Microengine communication transfer.

#### Estimated Wait Time:

Function eTPU maximal wait time =

$$N1 * (RCR * RCRWait + CPCR * CPCRWait) + N2 * CCR * CCRWait$$

### 35.16.5.4 First-Pass Worst-Case Latency Analysis

Following is the first-pass calculation of worst-case latency for a channel. Remember that this analysis uses generalizations that usually produce a result much worse than the real worst case. If the worst-case result from the first analysis is too long for the desired performance, use the second analysis for a more realistic worst-case analysis.

### 35.16.5.4.1 Worst-case assumptions and formula

To estimate worst-case latency for a channel, assume this worst-case condition: the channel has just been serviced in a time slot of its priority level, and all other channels in the system are continuously requesting service and have cleared SGRs. The worst-case latency is the time from the end of the channel's service until the end of the channel's next service. See the following figure.

**Figure 35-339. First-pass Worst-Case Latency**

To estimate worst-case latency:

- Find the worst-case service time for each active channel.
- Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot.
- Add time for six-clock time-slot transitions.

#### 35.16.5.4.1.1 Finding the Worst-Case Service Time for Each Active Channel

A table for eTPU functions should list the longest threads (not counting initialization threads) for the functions, and the number of eTPU SDM accesses in the longest thread (semaphored and non semaphored). These figures will be used for estimating Microengine wait time. The table below is an example for old TPU functions in which there are only simple SDM accesses. It does not take into consideration the CDC operation and Microengine to Microengine communication.

The worst-case service time for each channel is: (CPCR=CCR=0)

Longest thread + ((number of RAM accesses in longest thread+1) \* RCR \* 2 clocks).

Note that the formula adds 1 RAM accesses for the parameter preload that occurs during TST. There are actually three accesses during TST, but only the first one can receive wait-states.

**Table 35-421. Longest Threads and RAM Accesses for old TPU Functions**

| Function | Longest Thread | RAM Accesses |
|----------|----------------|--------------|
| DIO      | 10             | 4            |

*Table continues on the next page...*

**Table 35-421. Longest Threads and RAM Accesses for old TPU Functions (continued)**

| Function         | Longest Thread               | RAM Accesses |
|------------------|------------------------------|--------------|
| ITC              | 40 (no linking) 42 (linking) | 7            |
| OC               | 40                           | 7            |
| PWM              | 24                           | 4            |
| SPWM             |                              |              |
| Mode 0           | 14                           | 4            |
| Mode1            | 18                           | 4            |
| Mode 2           | 20 (no linking)              | 4            |
|                  | 22 (linking)                 | 4            |
| PMA              | 94                           | 8            |
| PMM              | 94                           | 8            |
| PSP              |                              |              |
| Angle-Angle Mode | 76                           | 6            |
| Angle-Time Mode  | 50                           | 3            |
| SM <sup>1</sup>  | 160                          | 21           |
| PPWA             |                              |              |
| Mode 0           | 44                           | 9            |
| Mode 1           | 50 <sup>2</sup>              | 10           |
| Mode 2           | 44                           | 9            |
| Mode 3           | 50                           | 10           |

1. Assumes one master and one slave. For each additional slave
  1. Tab Add 32 clocks and 2 RAM accesses, and
  2. Tab Add (STEP\_RATE\_CNT \* two clocks)
2. With one channel linked. Add two clocks for each additional channel linked.

#### 35.16.5.4.1.2 Mapping the Channels for Each Time Slot

To determine when a channel will be serviced again, it is necessary to determine which other channels will be serviced first. Do this by assuming all channels are continuously requesting service and mapping the channels into the time-slot sequence.

#### 35.16.5.4.1.3 Adding Time for Time-Slot Transitions

Add six eTPU clocks for time-slot transitions which occur after each time slot.

#### 35.16.5.4.2 First-pass analysis Worst-Case Latency examples

The examples in this section assume the system configuration shown in the following table.

**Table 35-422. System configuration example**

| Channel | Priority | Function <sup>1, 2</sup>                    |
|---------|----------|---------------------------------------------|
| 0       | High     | PWM (driving a DC motor)                    |
| 1       | Middle   | PPWA (Mode 0, measuring the DC motor speed) |
| 2       | Low      | DIO (Input)                                 |

1. 9% RAM Collision Rate (RCR)

2. CPU clock rate = 40 MHz, or 25 ns per clock period

### 35.16.5.4.2.1 Finding the WCL for PWM on Channel 0

The following shows how to find the WCL for PWM on channel 0.

1. Find the worst-case service time for each active channel.

a. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

$24 + ((4 \text{ RAM accesses} + 1) * 0.09 * 2 \text{ CPU clock waits}) = 24.9 \text{ CPU clocks}$ ,  
rounded up to 25 CPU clocks (since there are no partial clock periods)

Channel 0 worst-case service time = 25 CPU clocks.

b. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

$44 + ((9 \text{ RAM accesses} + 1) * 0.09 * 2 \text{ CPU clock waits}) = 45.8 \text{ CPU clocks}$ ,  
rounded up to 46 CPU clocks

Channel 1 worst-case service time = 46 CPU clocks.

c. Longest thread of DIO is ten CPU clocks with four RAM accesses.

$10 + ((4 \text{ RAM accesses} + 1) * 0.09 * 2 \text{ CPU clock waits}) = 10.9 \text{ CPU clocks}$ ,  
rounded up to 11 CPU clocks

Channel 2 worst-case service time = 11 CPU clocks.

2. Assume channel 0 has just been serviced and that channels 1 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

Figure 35-340. Next Servicing for Channel 0

Channel 1 will be serviced in the middle-priority time slot before channel 0 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

A four-clock NOP occurs after each channel is serviced since there is one channel in each priority level, i.e., a new cycle for a priority level is started after each channel is serviced. Time-slot transitions occur after each time slot.

Table 35-423. Worst-Case Latency for Channel 0

|                                   |           |
|-----------------------------------|-----------|
| Channel 0 worst-case service time | 25 clocks |
| Channel 1 worst-case service time | 46 clocks |
| Two 6-clock time-slot transitions | 12 clocks |
| Total clocks                      | 83 clocks |

$83 \text{ clocks} * 25 \text{ ns/clock} = 2075 \text{ ns}$

Conclusion: in this system configuration PWM can run with a minimum high time or low time of 2075 ns.

Note that in double match eTPU system the PWM can be serviced once in each period, and there is no latency for minimum high time. The latency in eTPU PWM function will represent the minimum PWM period.

35.16.5.4.2.2 Finding the WCL for PPWA on Channel 1

The following shows how to find the WCL for PPWA on channel 1.

1. Find the worst-case service time for each active channel. See step 1 of previous example.
2. Assume channel 1 has just been serviced and that channels 0 and 2 are continuously requesting service. Using the H-M-H-L-H-M-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

**Figure 35-341. Next Servicing for Channel 1**

Channel 0 will be serviced twice and channel 2 once before channel 1 is serviced again.

3. Add time for the six-clock CPU time-slot transitions. See the above figure and the following table.

**Table 35-424. Worst Case Latency for Channel 1**

|                                        |            |
|----------------------------------------|------------|
| Two Channel 0 worst-case service times | 50 clocks  |
| Channel 1 worst-case service time      | 46 clocks  |
| Channel 2 worst-case service time      | 11 clocks  |
| Four 6-clock time-slot transitions     | 24 clocks  |
| Total clocks                           | 131 clocks |

$$131 \text{ clocks} * 25 \text{ ns/clock} = 3275 \text{ ns}$$

Conclusion: in this system configuration PPWA can measure a period or pulse of minimum 3275 ns.

Note that PPWA function optimized for eTPU hardware can use double transition mode to measure very narrow pulses with one service after the second transition, and latency will affect only the minimum gap between two input pulses. Also the function threads would have more efficient coding.

35.16.5.4.2.3 Finding the WCL for DIO on Channel 2

The following shows how to find the WCL for DIO on channel 2.

- 1. Find the worst-case service time for each active channel. See step 1 of previous examples.
- 2. Assume channel 2 has just been serviced and that channels 0 and 1 are continuously requesting service. Using the H-M-H-L-H-M-H-H-M-H-L-H time-slot sequence, map the channels that are granted for each time slot. See the following figure.

Figure 35-342. Next Servicing for Channel 2

Channel 0 will be serviced four times and channel 1 twice before channel 2 is serviced again.

- 3. Add time for the ten-clock CPU time-slot transitions and the four-clock NOPs. See the above figure and the following figure.

Table 35-425. Worst Case Latency for Channel 2

|                                         |            |
|-----------------------------------------|------------|
| Four Channel 0 worst-case service times | 100 clocks |
| Two Channel 1 worst-case service time   | 92 clocks  |
| Channel 2 worst-case service time       | 11 clocks  |
| Seven 6-clock time-slot transitions     | 42 clocks  |
| Total clocks                            | 245 clocks |

245 clocks \* 25 ns/clock = 6125 ns

Conclusion: in this system configuration DIO can keep track of the input level at a minimum of every 6125 ns.

Note that DIO function optimized for eTPU hardware can use double transition mode to measure two pin transitions at a time and reduce the service time, improving the overall system performance and latency.

### 35.16.5.5 Second-Pass Worst-Case Latency Analysis

Following is an example of a second-pass analysis for calculating worst-case latency for a channel. The second-pass analysis is useful for higher-performance systems, since it gives a more realistic worst-case latency result than first-pass analysis.

This example uses a relatively simple system in order to illustrate the basic principles of second-pass analysis. For a more complex example of second-pass analysis, refer to Multiphase Motor Commutation TPU Function (COMM)(TPUPN09/ D).

#### 35.16.5.5.1 Second-Pass Analysis Guidelines

Rather than use a fixed formula, a second-pass analysis relies on the application of the following guidelines.

1. The first-pass analysis makes the assumption that all channels in the system are continually requesting service. For many systems this is an unrealistic assumption. For example, if TCR1 is counting at a rate of 2 MHz (500 ns per count) and a channel is running the DIO function with a match rate of 20,000 TCR1 counts, the DIO will request service every 10 ms ( $20,000 * 500 \text{ ns} = 10,000,000 \text{ ns}$  or 10 ms). It is therefore unrealistic to assume that the channel running this DIO function is continuously requesting service. Figure out a realistic service request rate for each channel. Time slots can then be mapped to each channel at the real rate of request.
2. If a function is active during system initialization but not during the high-speed running mode of the system, then that system does not need to be included in the high-speed worst-case latency calculations.
3. Use a realistic SDM collision rate.
4. Be careful when assigning functions priority levels and channel numbers. Decide which function or functions will be most difficult to make perform at the desired level. Assign those channels high priority and low channel numbers. Try different priority and channel assignments to see how it affects the system.
5. The seven-slot sequence of || H | M | H | L | H | M | H || is asymmetrical when put back-to-back with other seven-slot sequences. Note that in the following sequence there are two high-priority slots next to each other:

|| H | M | H | L | H | M | H ||| H | M | H | L | H | M | H ||

6. Make sure that when mapping out channels to the sequence, you choose a worst-case slot to start the mapping. For example, when estimating WCL for a high-priority channel, do not start the mapping in the last high-priority slot in a seven-slot sequence, as that is a best case for a high-priority channel since another high-priority time slot is next.
7. Instead of always using the longest thread in the function as the worst-case thread, evaluate the threads in the function that will be used in the system and use the appropriate worst-case threads. For example, in the preceding example of first-pass analysis, the PWM was shown to be able to achieve a high time and low time of 2475 ns under worst-case conditions. This was derived using the longest PWM thread of 24 CPU clocks. This longest thread is actually thread 2, the thread that is entered after the pin has just gone high. Thread 3, the thread that is entered after the pin has just gone low, requires only 2 CPU clocks. Therefore, in the first-pass example, the high time was correctly derived, but the low time is actually shorter than was estimated.

### 35.16.5.5.2 Second-pass analysis example

This example requires three 50% PWM waveforms: one 5 kHz (200 ms/period) and two 50 kHz (20 ms/period), each running DC motors. (Remember that the PWM function requests service from the eTPU after each high time and after each low time, so the eTPU must handle a request every 100 ms for the 5 kHz PWM and every 10 ms for the 50 MHz PWM.)

#### Note

This example uses square waves for simplicity. Notice that to use a PWM waveform in the typical way, in which the pulse is modulated, the pulse must not be modulated in a way that violates the worst-case latency requirements.

This example also uses one DIO channel monitoring a signal level every millisecond and one PPWA channel in mode 0 monitoring the speed of the 5-kHz DC motor. The PPWA must measure periods of 5 kHz (200 ms/period).

The CPU is interrupted by the channel running the PPWA function after measuring 200 periods (every 40 ms). The interrupt service routine performs an averaging of the period accumulation and checks it against a known parameter. The interrupt service time is so short and infrequent that it is a tiny fraction of total system time. The interrupt service routine contains no polling of the SDM. Therefore a realistic RCR = 0%.

### 35.16.5.5.2.1 First-Try System Configuration

Try a system configuration that seems likely to work. If it does not, change priority levels or channel numbers.

The 5 kHz and 50 kHz PWMs are the most time-critical functions. Those are assigned high priority. PPWA is assigned middle priority. The DIO is low performance and is assigned low priority. Refer to the following table.

**Table 35-426. First-Try System Configuration**

| Channel | Priority | Function <sup>1, 2</sup>          |
|---------|----------|-----------------------------------|
| 0       | High     | PWM at 50 kHz (needs a 4-μs WCL)  |
| 1       | High     | PWM at 50 kHz (needs a 4-μs WCL)  |
| 2       | High     | PWM at 5 kHz (needs a 40-μs WCL)  |
| 8       | Middle   | PPWA at 5 kHz (needs a 80-μs WCL) |
| 15      | Low      | DIO as input at rate of 1 ms      |

1. 0% RAM collision rate

2. CPU clock rate = 40 MHz, or 60 ns per clock period

With this system configuration, worst-case service time for each active channel is determined as follows:

1. Longest thread of PWM is 24 CPU clocks with four RAM accesses.

$$24 + ((4 \text{ RAM accesses} + 1) * 0 * 2 \text{ CPU clock waits}) = 24 \text{ CPU clocks}$$

Channels 0-2 worst-case service time = 24 CPU clocks.

2. Longest thread of PPWA in mode 0 is 44 CPU clocks with nine RAM accesses.

$$44 + ((9 \text{ RAM accesses} + 1) * 0 * 2 \text{ CPU clock waits}) = 44 \text{ CPU clocks}$$

Channel 8 worst-case service time = 44 CPU clocks.

3. Longest thread of DIO is ten CPU clocks with four RAM accesses.

$$10 + ((4 \text{ RAM accesses} + 1) * 0 * 2 \text{ CPU clock waits}) = 10 \text{ CPU clocks}$$

Channel 15 worst-case service time = 10 CPU clocks.

To find the WCL for channel 0, assume channel 0 has just finished service.

Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

Figure 35-343. Worst-Case Latency for Channel 0 (First Try)

Conclusion: with this system configuration, worst-case latencies for channels 0 and 1 are too high (WCL for channel 1 is the same as WCL for channel 0). Try a different system configuration.

35.16.5.5.2.2 Second-Try System Configuration

The second-try system configuration is shown in the following table.

Table 35-427. Second-Try System Configuration

| Channel | Priority | Function <sup>1, 2</sup>          |
|---------|----------|-----------------------------------|
| 0       | High     | PWM at 50 kHz (needs a 4-μs WCL)  |
| 1       | High     | PWM at 50 kHz (needs a 4-μs WCL)  |
| 2       | Middle   | PWM at 5 kHz (needs a 40-μs WCL)  |
| 8       | Middle   | PPWA at 5 kHz (needs a 80-μs WCL) |
| 15      | Low      | DIO as input at rate of 1 ms      |

- 1. 0% RAM collision rate
- 2. CPU clock rate = 40 MHz, or 60 ns per clock period

To find the WCL for channel 0, assume channel 0 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

Figure 35-344. Worst-Case Latency for Channel 0 (Second Try)

Conclusion: with this system configuration, the WCL of both channel 0 and channel 1 is 3.85 ms, which is within the limit of 4 ms needed for a 50-kHz PWM.

Next, find the WCL for channel 2. Assume channel 2 has just finished service. Map the channels in the H-M-H-L-H-M-H sequence. See the following figure.

**Figure 35-345. Worst-Case Latency for Channel 2**

Conclusion: with this system configuration, the WCL for channels 2 and 8 is 4.7 ms, which is within the 40 and 80 ms WCL requirements.

Notice that channels 2 and 8 are well within their WCL requirements. The system could be reconfigured as shown in the following table to give channels 0 and 1 a larger margin while still keeping channels 2, 8 and 15 within their WCL requirements.

**Table 35-428. Second-Try System with Channel 0 and 1 Reconfigured**

| Channel | Priority | Function <sup>1, 2</sup>          |
|---------|----------|-----------------------------------|
| 0       | High     | PWM at 50 kHz (needs a 10-μs WCL) |
| 1       | High     | PWM at 50 kHz (needs a 10-μs WCL) |
| 2       | Middle   | PWM at 5 kHz (needs a 40-μs WCL)  |
| 8       | Low      | PPWA at 5 kHz (needs a 80-μs WCL) |
| 15      | Low      | DIO as input at rate of 1 ms      |

1. 0% RAM collision rate

2. CPU clock rate = 40 MHz, or 60 ns per clock period

## 35.16.6 Endianness

The following table shows the parameter addresses for big and little endian machines.

**Table 35-429. Parameter Addresses and Endianness**

| Parameter                                | byte address offset<br>(n = word address offset) |               |
|------------------------------------------|--------------------------------------------------|---------------|
|                                          | big endian                                       | little endian |
| 32-bit                                   | 4*n                                              |               |
| 24-bit                                   | 4*n + 1                                          | 4*n           |
| 32-bit parameter's most significant byte | 4*n                                              | 4*n + 3       |
| 24-bit parameter's most significant byte | 4*n + 1                                          | 4*n + 2       |
| least significant byte                   | 4*n + 3                                          | 4*n           |

### 35.16.7 Memory Error Service Procedures

Follows separate procedures for correctable and non-correctable error interrupt service routines. It is assumed that the non-correctable error ISR has higher priority, and cannot be preempted by the correctable error ISR. For memory error support details, see [Memory error support](#).

#### Note

The memory error support hardware does not (and is not intended to) guarantee that no error occurred will go unreported. However, combined with the procedures below, the information loss is minimized to statistical irrelevance on most scenarios.

#### 35.16.7.1 Non-correctable error service procedure

The basic procedure below can be followed in a Global Exception or a bus error machine check service routine. It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

1. Confirm/identify the error source, checking assertion of the [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) fields SCMERR and SDMERR.
2. Save the state(s) of [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) fields CRDIS/DRDIS.
3. Set the [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) CRDIS/DRDIS=1 to disable further updates to the respective report registers, guaranteeing coherency.

4. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the [eTPU Code Error Report Syndrome Register \(eTPU\\_MESR\\_CERSR\)](#) syndrome (for SCM) and/or the [eTPU Data Error Report Syndrome Register \(eTPU\\_MESR\\_DERSR\)](#) syndromes (for SDM, only those with the respective BE flags asserted). If it is a correctable error report, skip the steps 5 and 6 for the respective memory.
5. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR\_ACC in the register(s) [eTPU Code Error Report Address Register \(eTPU\\_MESR\\_CERAR\)](#) and [eTPU Data Error Report Address Register \(eTPU\\_MESR\\_DERAR\)](#); take or schedule the appropriate application-dependent recover actions.
6. Update error statistics as needed; it may include recording the access source, address, data and syndrome from:
  - [eTPU Code Error Report Address Register \(eTPU\\_MESR\\_CERAR\)](#)
  - [eTPU Data Error Report Address Register \(eTPU\\_MESR\\_DERAR\)](#)
  - [eTPU Code Error Report Data Register \(eTPU\\_MESR\\_CERDR\)](#)
  - [eTPU Data Error Report Data Register \(eTPU\\_MESR\\_DERDR\)](#)
  - [eTPU Code Error Report Syndrome Register \(eTPU\\_MESR\\_CERSR\)](#)
  - [eTPU Data Error Report Syndrome Register \(eTPU\\_MESR\\_DERSR\)](#)
7. Save the status of non-correctable error overflows flagged in the [eTPU Memory Error Status Register \(eTPU\\_MESR\\_MESR\)](#) fields CNCOVR/DNCOVR.
8. Set the [eTPU Memory Error Control Register \(eTPU\\_MESR\\_MECR\)](#) fields CRDIS/DRDIS to the state(s) saved in the step 2. That assures the access coherency of a preempted Correctable Error Service Procedure (which may have set CRDIS/DRDIS before this procedure) is not disturbed.
9. Clear the [eTPU Memory Error Status Register \(eTPU\\_MESR\\_MESR\)](#) fields CNCOVR/DNCOVR and CNCERR/DNCERR at once, in a single write to eTPU\_MESR\_MESR.
10. Use the overrun status saved on step 7 to update the error statistics, as needed.
11. Check the other Global Exception flags in [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#); take or schedule the appropriate (application dependent) recover actions.
12. Clear the Global Exception, programming [GEC](#) =1.

### 35.16.7.2 Correctable error service procedure

The basic procedure below can be followed in a Memory Error Interrupt service routine (see [Interrupts and data transfer requests](#)). It handles the service for both SCM and SDM errors, as they are symmetrical at this level. However, a real implementation is likely to split the procedure in two, one for each memory.

1. Confirm/identify the error source, checking assertion of the [eTPU Memory Error Status Register \(eTPU\\_MESR\\_MESR\)](#) fields CCERR/DCERR.
2. Program the [eTPU Memory Error Control Register \(eTPU\\_MESR\\_MECR\)](#) fields CRDIS=1 and/or DRDIS=1, to disable further updates to the respective report registers, guaranteeing coherency.
3. Check whether the report registers were updated by a correctable or non-correctable error; to do this, check the [eTPU Code Error Report Syndrome Register \(eTPU\\_MESR\\_CERSR\)](#) syndrome (for SCM) and/or the [eTPU Data Error Report Syndrome Register \(eTPU\\_MESR\\_DERSR\)](#) syndromes (for SDM, only those with the respective BE flags asserted). If it is a non-correctable error report, skip the steps 4 and 5 for the respective memory.
4. Identify the error source (host, microengine or MISC/CDC) by checking the field ERR\_ACC in [eTPU Code Error Report Address Register \(eTPU\\_MESR\\_CERAR\)](#) and [eTPU Data Error Report Address Register \(eTPU\\_MESR\\_DERAR\)](#); take or schedule the appropriate application-dependent recover actions, which may include soft-error fixing (see [Error fixing](#)).
5. Update error statistics as needed; it may include recording the access source, address, data and syndrome from:
  - [eTPU Code Error Report Address Register \(eTPU\\_MESR\\_CERAR\)](#)
  - [eTPU Data Error Report Address Register \(eTPU\\_MESR\\_DERAR\)](#)
  - [eTPU Code Error Report Data Register \(eTPU\\_MESR\\_CERDR\)](#)
  - [eTPU Data Error Report Data Register \(eTPU\\_MESR\\_DERDR\)](#)
  - [eTPU Code Error Report Syndrome Register \(eTPU\\_MESR\\_CERSR\)](#)
  - [eTPU Data Error Report Syndrome Register \(eTPU\\_MESR\\_DERSR\)](#)
6. Save the status of correctable error overflows flagged in the [eTPU Memory Error Status Register \(eTPU\\_MESR\\_MESR\)](#) fields CCOVR/DCOVR.
7. Program the [eTPU Memory Error Control Register \(eTPU\\_MESR\\_MECR\)](#) fields CRDIS/DRDIS=0.
8. Clear the [eTPU Memory Error Status Register \(eTPU\\_MESR\\_MESR\)](#) fields CCOVR/DCOVR and CCERR/DCERR at once, in a single write to [eTPU\\_MESR\\_MESR](#).

9. Use the saved overrun status to update the error statistics, as needed.

## **35.17 Appendices**

### **35.17.1 Microcycle and I/O timing**

#### **35.17.1.1 Execution and channel timing**

The following figure shows the main timings related to microinstruction execution when channels and timebases run on T2 timing.

Note: \*TCR clock/prescaler selection = 1 x eTPU clock

**Figure 35-346. Execution, timebase and channel T2 timing**

**Note:** \*TCR clock/prescaler selection = 4x eTPU clock

**Figure 35-347. Execution, timebase and channel T2/T4 timing**

The sequential occurrence of the four T states (T1-T4) constitutes a microcycle. Only T2 and T4 are taken as reference for timings, either internal or external. T2 and T4 have the timing of the positive eTPU clock pulses, and are used in most of the eTPU logic in an edge-triggered design style.

Two additional T states are derived from the eTPU clocks:  $\overline{T2}$  and  $\overline{T4}$ .  $\overline{T2}$  occurs when the eTPU loses SDM arbitration to a bus master.  $\overline{T4}$  occurs in halt state (due to a breakpoint or device debug request assertion, for instance), or in stall state (due to an NDEDI queue full); see [Development support features](#) for more details.

$\overline{T2}$  and  $\overline{T4}$  states are defined as microcycle timing states (not to be confounded with logic states) of one eTPU clock in which the T clocks continue to run, but the control signals associated with the clocks are unaffected. That is, no operation occurs during these states.

Both  $\overline{T2}$  and  $\overline{T4}$  states occur in multiples of two eTPU clocks to keep the microengine synchronized with the free running channels, which are unaffected and keep on working as in T2 and T4.

Thus, the eTPU has two types of timing states:

- $\overline{T2}$ : hold execution for SDM access, from clock pulse T2 until one of the next T2 clock pulses of another microcycle.
- $\overline{T4}$ : hold execution in debug mode or stall, from clock pulse T4 until one of the next T4 clock pulses of another microcycle.

The two following figures show the timing of  $\overline{T2}$  and  $\overline{T4}$  timing states, respectively.

Figure 35-348.  $\overline{T2}$  timing

Figure 35-349.  $\overline{T4}$  timing

### 35.17.1.2 Input/Output Signal Delays

The synchronizer, filter and edge detection logic delay the input signal transitions.

The Filter Delay varies with the filter clock ([eTPU Engine 1 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG1\)](#) and [eTPU Engine 2 Configuration Register \(eTPU\\_SCR\\_ECR\\_ENG2\)](#) field FPSCK) and the filter mode used, as shown in the [Table 35-355](#). For any given transition, it depends on the phase of the filter clock when the input transition happens. In integration mode (TCRCLK filtering only), it also depends on the state of the integrator counter. The Total Delay is defined as the number of eTPU clock rising edges between the input transition and the setting of TDLA/B, TCR1/2 incrementing, or EAC tooth sensing (TCRCLK) in angle mode. The synchronizer delay is 2 or 3 eTPU clocks, depending on the phase of the synchronizer when the input transition happens. The edge detection takes 1 more eTPU clock. The total delays are, thus:

```
Min. Total Delay = Min. Synchronizer Delay + Min. Filter Delay + Edge Detection Delay
Min. Total Delay = 3 + Min. Filter Delay
Max. Total Delay = Max. Synchronizer Delay + Max. Filter Delay + Edge Detection Delay
Max. Total Delay = 4 + Max. Filter Delay
```

The channel filters can be bypassed, so nullifying the filter delays in the equations above.

See the chip-specific eTPU information for connections between eTPU and input glitch filters.

The channel output flip-flops drive the eTPU output signals directly, without any synchronous delays.

## 35.17.2 Channel Mode Summary

The initial state considered for all submodes is channel flags MRLEA and MRLEB asserted, MRLA, MRLB, TDLA and TDLB negated. From initial state one can follow the table below and verify how each submode behaves in a determined sequence of events. Note that the actions performed by an event type depend on all previous events following the initial state, for a given channel submode.

There are three columns for each event: one for event type, one for enable/disable actions and one for capture. **Event type** column can be matchA, matchB, transA and transB (for double transition modes). **Enable/disable actions** column (identified as "[blocks] (enables)" in column head) specifies which other events are enabled or disabled. Initially disabled events (specified in "initially blocked" column) are usually enabled by other events.

In double transition submodes, the first transition detected is always considered transA and the second is considered transB. This means that transA event actually enables the detection of transB event. This is not explicit in the table, since it is a general behavior for all double transition submodes.

A sequence of four events (two matches and two transitions) are necessary to describe the behavior of some channel submodes. When a determined sequence of events has less than four events, the other event columns are left blank.

Cells in an "event type" column that have light-grayed background indicate that a service request is generated. More than one event in the same event sequence can issue service request.

### Note

The two tables below do not exhaust all possibilities of channel logic event sequences, because it does not account for possible microcode interventions. For instance, if matches are blocked by first transition and microcode resets TDLA, the matches become enabled again, and from this point on the channel behaves as if the first transition had never occurred.

**Table 35-430. Channel Mode Summary 1 of 2**

| Mode     | Initially Blocked | 1st Event              |                                 |         | 2nd Event  |                    |         |
|----------|-------------------|------------------------|---------------------------------|---------|------------|--------------------|---------|
|          |                   | Event Type             | [Blocks] (Enables) <sup>1</sup> | Capture | Event Type | [Blocks] (Enables) | Capture |
| em_nb_st | none              | match 1/2 <sup>2</sup> | none                            | 1/2     | match 2/1  | none               | 2/1     |

1. Transition 1 always enables Transition 2.
2. Shading indicates that a service request is generated.
3. sm\_st is compatible with TPU3 channel logic.
4. It is not possible to include all functionality of this submode in table.

### 35.17.3 MISC Algorithm

The MISC generator is based on the following polynomial:

$$G(x) = 1 + x^1 + x^2 + x^{22} + x^{31} \text{ (equivalent to feedback mask = 0x80400007)}$$

The MISC signature generation starts by clearing the MISC Accumulator value to 0 and preloading the MISC Counter with the highest SCM address. It then steps through each address decrementing the counter, reading 32 bit values and following the algorithm below:

```

If the least significant bit in MISC is 1 then
    MISC = MISC right shifted by 1 bit
    MISC = MISC XOR 0x80400007
else
    MISC = MISC right shifted by 1 bit
end if
MISC = MISC XOR RAM data

```

The code example below shows an excerpt of C code that calculates the MISC signature for a given array of data, based on the previous algorithm:

```

#define SCM_size    (MAX_SCM_ADDRESS / 4)    /* last byte address - converted to 32-bit word */
#define POLY        0x80400007               /* G(x) = 1 + x1 + x2 + x22 + x31 */
/*****
FUNCTION : void calc_misc()
PURPOSE : This function calculates the MISC value.
INPUTS NOTES : none
RETURNS NOTES : MISC value
GENERAL NOTES : the array 'unsigned int data[]' represents the actual memory
array, organized in 32-bit words.
*****/
unsigned int calc_misc (void)

```

```

{
    int j; /* loop counter */
    unsigned int misc = 0;
    for (j = (SCM_size-1); j >= 0 ; j--) { /* SCM_size has the number of 32-bit words in SCM
*/
        if (misc & 0x1) {
            misc >>= 1;
            misc ^= POLY;
        }
        else {
            misc >>= 1;
        }
        misc ^= data[j]; /* data[j] is the actual 32-bit word taken from the SCM
array
*/
    }
    return (misc); /* final signature calculated */
};

```

The value calculated by this algorithm must be loaded into [eTPU MISC Compare Register \(eTPU\\_SCR\\_MISCCMPR\)](#) prior to activating the SCM MISC calculator in eTPU. Once the MISC calculator is activated (bit SCMMISEN in register [eTPU Module Configuration Register \(eTPU\\_SCR\\_MCR\)](#) is written to 1) eTPU itself will start this procedure<sup>42</sup> reading the SCM whenever allowed by microengine. At the end of the cycle, when all the array has been read and the SCM signature is calculated, the Host CPU can be notified via Global Exception if the MISC Accumulator does not match the value in eTPU\_SCR\_MISCCMPR.

The average time taken by MISC to complete the signature of the whole SCM can be given by the formula:

$$\text{Average MISC period} = S / (4 * F * (1 - L))$$

where f is clock frequency, S is SCM size in bytes and L is eTPU load (as a percentage of execution clocks over a period of time, including TST clocks).

Further detail on MISC calculation can be found on [SCM Test - Multiple Input Signature Calculator](#). The application note **AN2192 - Detecting Errors in the Dual Port RAM (DPTRAM) Module** is also a good source of information (although it refers to TPU) on MISC signature.

42. eTPU MISC hardware is optimized to read 32-bit words from memory and to calculate this CRC in parallel, rather than shifting one bit at a time. The actual implementation inside eTPU, although bringing to the same results, does not match exactly the algorithm shown here.

## Chapter 36

# Input Glitch Filter (IGF)

### 36.1 Chip-specific IGF information

This chip has two instances of the IGF module: IGF\_0 and IGF\_1. They are in the eTPU clock domain. The two instances are located on different Peripheral Bridges.

#### 36.1.1 IGF channels and internal prescalers

The two IGF module instances support a combined total of 76 channels. Some channels of the instances implement internal prescalers.

Each channel has a 24-bit counter. Each internal prescaler is 9 bits wide.

The following table identifies the number of channels of each instance, the specific channel numbers that implement an internal prescaler, and the group of specific channel numbers that can use each implemented internal prescaler.

Each group of channel numbers that is associated with one implemented prescaler is a filter cluster.

**Table 36-1. IGF instance channels and internal prescalers**

| Instance | Channels supported | Channel number with prescaler | Filter cluster: channel numbers that use prescaler |
|----------|--------------------|-------------------------------|----------------------------------------------------|
| IGF_0    | 30                 | 0                             | 0-29                                               |
| IGF_1    | 46                 | 0                             | 0-31                                               |
|          |                    | 32                            | 32-45                                              |

### 36.1.2 IGF internal prescaler selection

Channels in a filter cluster that do not implement their own internal prescaler must select an "external" prescaler. This selection means the channel uses the prescaler of the preceding channel in the filter cluster.

Within a filter cluster, to enable a channel  $x$  to use the cluster's internal prescaler:

1. For the channel that implements the cluster's internal prescaler, select the internal prescaler by ensuring that the channel's  $MCR_n[PSSEL]$  field is 0.
2. For every channel between that channel and channel  $x$ , including channel  $x$  itself, select the "external" prescaler by setting the channel's  $MCR_n[PSSEL]$  field to 1.

#### 36.1.2.1 Example of internal prescaler selection

To select the applicable internal prescaler for IGF\_0 channel 3:

1. Because IGF\_0's channel 0 implements the cluster's internal prescaler, select the internal prescaler for channel 0 by ensuring that IGF\_0's  $MCR_0[PSSEL]$  field is 0.
2. Select the "external" prescaler for every channel between channel 0 and channel 3, including channel 3 itself:
  - a. Set IGF\_0's  $MCR_1[PSSEL]$  to 1.
  - b. Set IGF\_0's  $MCR_2[PSSEL]$  to 1.
  - c. Set IGF\_0's  $MCR_3[PSSEL]$  to 1.

#### 36.1.2.2 Restriction on prescaler selection for IGF\_1 channel 32

Do not set IGF\_1's  $MCR_{32}[PSSEL]$  field to 1.

This setting could cause timing failure for all IGF\_1 channels.

### 36.1.3 IGF interaction with other modules

The IGF modules interface with eTPU and eMIOS modules.

The following table shows the mapping of IGF\_0 channels.

**Table 36-2. IGF\_0 channel mapping**

| Filter channel | Primary function pin    | Module  |
|----------------|-------------------------|---------|
| 0              | TCRCLKC                 | eTPU_C  |
| 1-15           | ETPUC0-14               | eTPU_C  |
| 16-19          | EMIOS0_0-3 <sup>1</sup> | eMIOS_0 |
| 20-21          | EMIOS0_6-7              | eMIOS_0 |
| 22-29          | EMIOS0_16-23            | eMIOS_0 |

1. EMIOS0\_4 and EMIOS0\_5 do not have filters because the input channels are not connected directly from pads. They are connected from the DSPI\_B module.

The following table shows the mapping of IGF\_1 channels.

**Table 36-3. IGF\_1 channel mapping**

| Filter channel | Primary function pin    | Module  |
|----------------|-------------------------|---------|
| 0              | TCRCLKA                 | eTPU_A  |
| 1-15           | ETPUA0-14               | eTPU_A  |
| 16             | TCRCLKB                 | eTPU_B  |
| 17-31          | ETPUB0-14               | eTPU_B  |
| 32-37          | EMIOS1_0-5 <sup>1</sup> | eMIOS_1 |
| 38-45          | EMIOS1_16-23            | eMIOS_1 |

1. EMIOS1\_6 and EMIOS1\_7 do not have filters because the input channels are not connected directly from pads. They are connected from the DSPI\_D module.

### 36.1.4 STOP mode system requests for IGF\_0 and IGF\_1

As described in [STOP mode](#), a STOP mode system request can stop the IGF module instances.

This chip also has inter-module STOP mode system requests that affect IGF\_0 and IGF\_1 individually:

- IGF\_0 automatically stops when eTPU\_C and eMIOS\_0 stop.
- IGF\_1 automatically stops when eTPU\_A/eTPU\_B and eMIOS\_1 stop.

## 36.2 Introduction

The Input Glitch Filter provides programmable glitch rejection filtering of digital input signals.

### 36.3 Block Diagram

The figure below is the block diagram for the Input Glitch Filter module.

Figure 36-1. Input Glitch Filter block diagram

### 36.4 Input Glitch Filter overview

The Input Glitch Filter receives an input signal usually from a device PAD. Signals generated externally to the device are affected by environmental noise or glitches. The signal level has to be evaluated with some criteria in order to remove the noise which could affect the measurements done over this signal, such as transition time, period and level.

In a typical application, the Input Glitch Filter interfaces with one or more timer peripherals.

The strategy to remove glitches from an input signal is to monitor the level of the signal during a wide time window thus the glitches can be evaluated and removed.

The input signal should be stable for a certain amount of time before it can be used as a trigger or by a timer input channel. This strategy implies a delay on detecting a transition in the signal.

There is another strategy which is based on removing the glitches by introducing a blanking period after an edge is detected. In this strategy there is no delay from the edge detection in the input signal to the filtered signal, in the filter output. The strategy also allows input signals with different filter periods to be measured at the same time.

### 36.4.1 Interaction with other peripherals

The figure below shows an example of how the Input Glitch Filter interacts with on-chip peripherals.

Figure 36-2. Input Glitch Filter application example

### 36.4.2 Mode of operation

The Input Glitch Filter has the following modes of operation:

- Configuration mode
- Normal mode
- Debug mode
- Low power mode

#### 36.4.2.1 Configuration mode

The configuration mode is the initial mode of the Input Glitch filter after system reset is applied. The configuration mode is selected when FGEN = '0' in the MCR register. The filter parameters such as rising and falling thresholds can be programmed when the filter

is in configuration mode without disturbing the internal device logic since the filter output is kept at logic '0' state. Once FGEN is programmed with logic '1' the filter enters the normal operating mode and is able to initiate the filtering process.

#### NOTE

The MDIS bit in the MCR register, if set to logic '1', makes the filter transition to low power mode independent of FGEN bit settings. Thus, in order to enter the configuration mode MDIS bit needs to be at logic '0'.

### 36.4.2.2 Normal mode

The normal mode of operation is entered when MCR register FGEN = '1'. In this mode the filter implements one of the filter types:

- Bypass filter
- Windowing filter
- Integrating filter
- Integrating-hold filter

These filter types are described in the following sections. Before entering the normal mode, the filter parameters, such as rise and fall thresholds, need to be programmed in the appropriate registers, as well as the type needs to be defined in the corresponding register.

#### NOTE

In the normal mode it is still possible to change the filter parameters, such as rise and fall thresholds. See section [On-the-fly filter reconfiguration](#) for more details.

### 36.4.2.3 Debug mode

The debug mode is entered when the MCR FRZ bit is set and a system level debug request occurs. Once the debug mode is entered, the internal filter counter is halted and the debug functions controlled by the FBP, FOH, and FOL bits are enabled. The filter output is frozen and remains at the state it was immediately before the debug mode was entered. The FOH and FOL MCR bits can be used to force the filter output to logic '1' or '0', respectively. These bits are self-negating, thus they always read as zero.

By setting the MCR FBP bit, the filter input state is copied to the filter output, thus allowing to control the filter output based on the filter input state. The output is forced during one clock cycle. After that the filter output remains at the new forced state until it is changed again by using a debug control bit or if the filter returns to the normal mode of operation.

### NOTE

The system level debug request occurs when a specific event, or a series of events, occurs in one of the device sub-modules and is interpreted by the device debug logic as a debug request. The Input Glitch Filter is not capable of generating an event that causes the assertion of the system level debug request.

#### 36.4.2.4 Low power mode

The low power mode is controlled by the MDIS bit in the MCR register or by the STOP signal which is the system level low power control signal. When entering low power mode the filter output remains unchanged at the state it was just before the low power mode was entered. Since the Input Glitch Filter clocks are stopped in this mode, the internal counter remains inactive. The description of this mode is covered in the Low Power Mode section of this document.

## 36.5 Memory map

The Input Glitch Filter registers are implemented in 32-bit. 8-bit write operations are allowed. The coherency in case of 8-bit access must be provided by the application software since there is no coherence mechanism built into the hardware.

### NOTE

RESERVED bit registers, when available for write operations, should be written always with logic '0'. Read access does not return meaningful data from RESERVED bit registers.

#### IGF memory map

| Address offset (hex) | Register name                            | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | Module Configuration Register (IGF_MCR0) | 32              | R/W    | 0000_0000h  | <a href="#">36.5.1/1650</a> |
| 4                    | Module Status Register (IGF_MSR0)        | 32              | R/W    | 0000_0000h  | <a href="#">36.5.2/1653</a> |

36.5.1 Module Configuration Register (IGF\_MCRn)

The Module Configuration register (MCR) provides access to low power, debug, and filter control bits.

Address: 0h base + 0h offset + (64d × i), where i=0d to 45d

IGF\_MCRn field descriptions

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 1<br>MDIS     | Module Disable<br><br>The MDIS bit forces the filter to enter a low power state. After this bit is asserted the clock for the module is removed thus filter operation is not possible. The access to filter registers is allowed.<br><br>0   Input Glitch Filter is not in low power mode due to MDIS bit<br>1   Input Glitch Filter is in low power mode                                                                                                                                                                                |
| 2<br>FRZ      | Freeze bit for debug operation<br><br>The FRZ bit enables the Input Glitch Filter to enter freeze mode (debug mode) when a system level signal request the module enters freeze (debug) mode. Once in freeze mode the filter operation is disabled meaning that transitions on the input signal will not propagate through the filter output. The bypass FBP bit can be used by the software to force the filter output to be the same as the filter input. In this mode FOH and FOL also can be used to define the filter output state. |

## IGF\_MCRn field descriptions (continued)

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | 0 Freeze mode disabled<br>1 Freeze mode enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3<br>FBP         | Force Bypass<br><br>This bit is self-negated thus is only read as zero. Writing 1 to this bit while in freeze mode forces the filter to bypass the value in the input to the filter output, thus allowing a software control on the filter. This bit is functional only in freeze mode.<br><br>0 no filter bypass<br>1 transfer input signal value to the filter output                                                                                                                                                                                                                                   |
| 4<br>FOH         | Force filter output high<br><br>If set, this bit forces the Input Glitch Filter output to '1'. This bit is functional only in debug mode. It is self-negated thus always read as zero.<br><br>0 no action<br>1 forces the filter output to '1'                                                                                                                                                                                                                                                                                                                                                            |
| 5<br>FOL         | Force filter output low<br><br>If set this bit forces the Input Glitch Filter output to '0'. This bit is functional only in debug mode. It is self-negated thus always read as zero.<br><br>0 no action<br>1 forces the filter output to '0'                                                                                                                                                                                                                                                                                                                                                              |
| 6–21<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 22<br>IMM        | Immediate edge propagation control bit<br><br>The IMM bit controls the propagation of an edge through the filter. If asserted, this bit defines that an edge at the filter input propagates through the filter output independent of the prescaler settings. In bypass mode the propagation delay is three system clock cycles. If negated, the signal propagation depends upon the prescaler settings. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN = 0<br><br>0 edge propagation depends on prescaler<br>1 edge propagation within three system clock cycles |
| 23<br>PSSEL      | Prescaler selection bit<br><br>The PSSEL selects if the prescaler used by the Input Glitch Filter is from internal source (internal prescaler counter) or from external source. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0.<br><br>0 internal prescaler selected<br>1 external prescaler selected                                                                                                                                                                                                                                                          |
| 24<br>POL        | Output polarity bit<br><br>This bit sets the polarity of the filter output to inverted or not inverted. The polarity control implemented by the POL bit is applied at the filter output stage thus also changing the reset state of the output, even if the filter is disabled by the FGEN bit. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0.                                                                                                                                                                                                                |

IGF\_MCR<sub>n</sub> field descriptions (continued)

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | 0 not inverted output<br>1 inverted output                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 25<br>FGEN     | Filter global enable<br><br>This control bit enables the filter operation, meaning that if the filter is enabled the filtering selected types are applied to the rising and falling edges of the input signal. If the filter is not enabled, then the filter output remains unchanged independent of the filter input signal. Note that the filter output state is affected by the POL bit when the filter is disabled.<br><br>0 filter is disabled: filter output keeps current state.<br>1 filter is enabled: filtering is applied to selected edges.   |
| 26<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 27–28<br>FFM   | Falling edge filter type selection<br><br>This bit field selects the filter type for the filter input signal falling edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0.<br><br>00 bypass: edge is propagated to filter output without any filtering in three system clock cycles<br>01 windowing: windowing filter is selected for the falling edge<br>10 integrating: integrating filter is selected for the falling edge<br>11 integrating-hold: integrating-hold filter is selected for the falling edge |
| 29<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 30–31<br>RFM   | Rising edge filter type selection<br><br>This bit field selects the filter type for the input signal rising edge. The filter hardware will only allow changes to this bit if the filter is disabled, FGEN=0.<br><br>00 bypass: edge is propagated to filter output without any filtering in three system clock cycles<br>01 windowing: windowing filter is selected for the rising edge<br>10 integrating: integrating filter is selected for the rising edge<br>11 integrating-hold: integrating-hold filter is selected for the rising edge             |

### 36.5.2 Module Status Register (IGF\_MSRn)

The Module status register (MSR) provides access to filter status bits and corresponding clear bits as well as access to the state of filter input and output signals.

Address: 0h base + 4h offset + (64d × i), where i=0d to 45d

|       |    |    |    |    |    |    |    |    |    |    |       |       |       |       |     |     |

## 36.6 Functional description

The following sections describe the Input Glitch Filter module functionality.

### 36.6.1 Input double sampling

The filter input is double sampled for clock domain translation thus avoiding asynchronous signals to propagate through the filter internal logic. This stage is composed by two flip-flops connected back to back. The delay caused by this logic is therefore two clock cycles.

Note that due to the synchronous nature of the Input Glitch Filter design, if a glitch smaller than one clock cycle occurs at the filter input it will not propagate to the filter internal logic and thus will not propagate to the filter output. Also, if clock is not applied to the filter (i.e. in low power mode) any transition at the filter input will not propagate to the filter output.

### 36.6.2 Filter types

The Input Glitch Filter implements three main filter types:

- Windowing
- Integrating
- Integrating hold

These filter types can be selected for the rising and falling edges independently, thus allowing different filter types to be selected for different edges (i.e. rising edge filtered with windowing filter and falling edge filtered with integrating).

#### 36.6.2.1 Windowing filter

This filter type detects an edge (positive or negative edge) at the filter input and then mask out detection of subsequent edges over a period of time, which is defined as the blanking period, thus effectively behaving as a high pass filter. After an edge is detected the level at the filter input is propagated to the filter output within three clock cycles. The delay is caused by the synchronization stage at the input and by the filter output register stage. During the blanking period any transition at the filter input is disregarded. After the blanking period has elapsed, the filter compares the input level state with the filter output state. In case they are different a transition is inferred and re-evaluate according to the filter type assigned to that transition (positive or negative edges). Since, in this example, the windowing filter type is programmed for both edges, the inferred negative edge is propagated to the filter output and another blanking period is initiated. The figure below describes the windowing filter type behavior.

Figure 36-148. Windowing filter type

### 36.6.2.2 Integrating filter

The integrating filter behaves like a low-pass filter, thus removing high frequency bursts from the input signal. The input and output signals are compared and if they are at different states an internal filter counter is enabled.

The direction of the counter (up or down counting) is defined by the states of the input and output filter signals as follows:

- Filter output is at the same state as the filter input: down-counting
- Filter output is at different state as the filter input: up-counting

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If filter counter reaches the selected threshold for the edge being filtered.

The figure below describes an example of the Integrating filter type operation.

**Figure 36-149. Integrating filter type**

### 36.6.2.3 Integrating-hold filter

The integrating-hold filter type is similar to the integrating filter. The difference is the counter, which only counts in up direction instead of up-down in the integrating mode. In this filter configuration the input and output signals are compared and if they are at different states the filter counter is enabled. This counter is controlled by the state of the filter input and filter output signals as follows:

- Filter output is at the same state as the filter input: counter is in hold state (no-counting).
- Filter output is at different state as the filter input: counter is counting up.

The counter is compared with the rising or falling threshold register according to:

- Rising threshold register is selected if the rising edge is being filtered.
- Falling threshold register is selected if the falling edge is being filtered.

The filter output changes state to the same state as the filter input:

- If the filter counter reaches the selected threshold for the edge being filtered.

The internal counter is disabled and cleared:

- If the filter counter reaches the selected threshold for the edge being filtered.

The figure below shows an example of the Integrating-hold filter type operation.

**Figure 36-150. Integrating-hold filter type**

### 36.6.2.4 Bypass filter

In the bypass filter type, the Input Glitch Filter immediately propagates any transition on the filter input to the filter output. This filter type does not provide any protection against glitches in the input signal. It is intended to be used in situations where the input signal is already filtered, or it is a glitch free signal, or the filter output is connected to a module that already has filtering capabilities. The bypass filter type is independently selected for rising or falling edges. Thus rising edges may be not filtered by the bypass filter type while the falling edges are filtered by any of the available filter types.

The bypass filter presents a delay in the edge propagation through the filter that is caused by the double sampling at the filter input and by the output filter register. Therefore, the total delay is three clock cycles.

### 36.6.2.5 Combined filter

The Input Glitch Filter allows the combination of filter types for different edges, positive and negative. As an example, the rising edges may be filtered using the windowing filter while the falling edges are filtered with an integrating filter. This configuration of the Input Glitch Filter is provided for situations where the noise present in the rising edges is different from the noise in the falling edges. Another use case is when the delay requirements of the input signal is different for rising and falling edges.

The figure below shows the combined filter operation. The windowing filter type is applied to the rising edges. The integrating filter is used for the falling edges.

**Figure 36-151. Combined filter type (windowing + integrating)**

### 36.6.3 Application

This section describes several applications for the Input Glitch filter module.

#### 36.6.3.1 Application use case 1: integrating filter

The integrating filter type is particularly useful in applications where glitches occur spuriously while the signal is expected to be in a steady state (either 1 or 0). Choosing correct up and down filter clock rates can ensure that the effects of spurious glitches can be completely eliminated, whilst minimizing propagation delays.

The application must be able to tolerate delays between the actual edge occurrence and the time that the signal is propagated through the filter logic. Because the delays are constants defined by the detection thresholds, application software may compensate for them, provided little or no noise occurs on the detected edge.

#### 36.6.3.2 Application use case 2: windowing filter

The windowing filter type is particularly useful for removing noise bounce produced by a switch or sensor when its signal changes state. In this case, there is no propagation delay (except for the filter input synchronization logic and output register) between the filter input and filter output signals. This type of filter would not necessarily provide much immunity to spurious noise that occurred during the steady state portion of the signal. In

order to optimize the characteristics of this filter, the blanking period should be of the same magnitude as the expected input signal rate. Signals that change frequency can be accommodated by software by dynamically updating the blanking period.

### **36.6.3.3 Application use case 3: windowing filter**

Safety applications may need to compare the inputs obtained from different input pins, but derived from a single external source. This form of redundancy may detect non-common mode faults that may occur in the portions of the SoC that route and process the incoming signal. Having two different instances of windowing filter used on each input pin will ensure that the signal edge timing for both input paths is equal. Applying different filter characteristics for each input path can enhance the ability to detect SoC fault conditions.

### **36.6.3.4 Application use case 4: combined filter**

Some applications may have rising edge signals that exhibit different characteristics to falling edge signals which might require different filtering to optimize the filtering effect. For example the “first” rising edge may represent a true real time event with a fast slew rate that must be captured without delay, while the falling edge signal may have a slow slew rate with many noisy transitions. The Input Glitch Filter can apply, for example, a windowing filter on the rising edge to ensure no loss of real time information and an integrating filter on the falling edge to eliminate noise from being detected as a new rising transition.

### **36.6.3.5 Application use case 5: prescaler settings in windowing filter**

The prescaler settings influence the timing for an edge to propagate through the filter. In windowing filter the IMM bit in the MCR register controls the way an edge is propagated through the filter. The figure below describes the windowing filter operation with regard to the IMM bit settings.

**Figure 36-152. Input signal propagation through the filter in windowing filter type**

If  $IMM = 0$  then the input signal edges are propagated according to the prescaler ticks. If  $IMM = 1$  then the input edges are propagated immediately (within 3 clock cycles) to the filter output.

### 36.6.3.6 Application use case 6: prescaler settings in bypass

The prescaler settings influence the timing for an input signal edge to propagate through the filter. In bypass, the  $IMM$  bit in the  $MCR$  register controls the way an edge is propagated through the filter. If  $IMM = 0$ , the prescaled clock is used to sample the input filter signal. The resolution the input signal is sampled is therefore related to the prescaler frequency. Glitches narrower than the prescaler period that are not aligned with the prescaler clock are not captured by the filter. If  $IMM = 1$ , the system clock is used to sample the filter input signal instead of the prescaled clock. In this case, the resolution of the sampled input signal is the system clock.

The figure below describes the filter input signal sampling behavior for  $IMM = 0$  and  $IMM = 1$ .

**Figure 36-153. Input signal propagation through the filter in bypass**

### 36.6.4 Programming guidelines

The following generalized procedure may be used to configure the Input Glitch Filter Block:

1. Program the SoC pin mux logic to route an external signal to the input of the selected glitch filter.
2. Enable the destination module to receive the Input Glitch filter output.
3. Enable the clock source at the SoC level.
4. Program the Glitch Filter counter prescaler(s) to the desired rate.
5. Select the filter type for each edge using MCR[FFM] and MCR[RFM].
6. Clear any status bits if necessary.
7. Enable the filter using MCR[FGEN]

### 36.6.5 On-the-fly filter reconfiguration

The architecture of the Input Glitch Filter allows for on the fly reconfiguration of filter parameters such as rise and fall threshold values.

If a parameter is changed it influences the filter operation immediately after the new parameter value was written. The main problem when changing parameters, such as a threshold value, when the filter is enabled is that the filter counter could lose a match due to the parameter change. A great or equal comparator is used in the threshold match logic which allows correct filter operation when the threshold parameters are changed. The figure below shows an example of changing the rising edge parameter value. Note that in this case the match occurs immediately after the parameter is changed since the new parameter value is below the current counter value.

**Figure 36-154. On-the-fly rising threshold parameter change**

In the case shown in the figure above the match occurs immediately after the new rising threshold is programmed at 'A'.

### NOTE

Note that when changing the threshold values the match may not occur when the counter is equal to the threshold value (the old or the new programmed value). Instead, the match may occur in between the old and new programmed thresholds when the threshold re-programming instant A is done when the counter is greater than the new value. This is a transitory effect which may occur when the threshold value is changed and should be considered by the application.

## 36.7 Power saving mode

The Input Glitch Filter implements power saving mode thus allowing to reduce power consumption when device inputs connected to the filter are not used or the filter is not necessary to be functioning in a specific SoC mode of operation.

### 36.7.1 STOP mode

There are two ways for the Input Glitch filter to enter low power mode:

- MDIS bit
- STOP mode system request

The MDIS control bit in the MCR register, when set, disables the filter logic by stopping the module clock signals and thus halting the internal filter counter which reduces the dynamic power consumption of the module. The MDIS bit provides a selective control of the low power operation of each one of the Input Glitch Filter instances in the device.

The STOP mode system request is similar to MDIS operation with exception that it applies to all Input Glitch Filter instances in the device. It does not need to be enabled by any control bit in the Input Glitch filter module. The low power mode in this case is controlled by the assertion of the STOP signal which is a system wide low power control signal.

## **Chapter 37**

### **FlexCAN (CAN)**

#### **37.1 Chip-specific FlexCAN information**

This chip has four FlexCAN modules.

Each FlexCAN instance supports 64 message buffers.

##### **37.1.1 FlexCAN RAM**

On this chip, each FlexCAN module instance has four 1.5 KB dedicated RAM blocks.

##### **37.1.2 FlexCAN reset**

The FlexCAN architecture has two sources of reset: one resets the entire FlexCAN system and the other resets only the Host Control Interface (CHI). This chip supports only the global reset, which is driven by the internal reset of the device.

##### **37.1.3 CAN\_MCR[SUPV] and access to FlexCAN registers**

On this chip, regardless of the value of CAN\_MCR[SUPV], all core accesses to FlexCAN registers occur in supervisor mode.

#### **37.2 Introduction**

The FlexCAN module is a communication controller implementing the CAN protocol according to the CAN 2.0 B protocol specification. A general block diagram is shown in the following figure, which describes the main subblocks implemented in the FlexCAN module, including one associated memory for storing message buffers, Receive (Rx)

Global Mask registers, Receive Individual Mask registers, Receive FIFO filters, and Receive FIFO ID filters. The functions of the submodules are described in subsequent sections.

**Figure 37-1. FlexCAN block diagram**

### 37.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, Version 2.0 B, which supports both standard and extended message frames. The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip.

The CAN Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
- Performing error handling

The Controller Host Interface (CHI) sub-module handles message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms.

The Bus Interface Unit (BIU) sub-module controls the access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs and test signals are accessed through the BIU.

## 37.2.2 FlexCAN module features

The FlexCAN module includes these distinctive legacy features:

- Full implementation of the CAN protocol specification, Version 2.0 B
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes of zero to eight bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling
- Transmission abort capability
- Programmable clock source to the CAN Protocol Interface, either bus clock or crystal oscillator
- Unused structures space can be used as general purpose RAM space

- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
- Time stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts
- Independence from the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes

New major features are also provided:

- Remote request frames may be handled automatically or by software
- CAN bit time settings and configuration bits can only be written in Freeze mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
- SYNCH bit available in Error in Status 1 register to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Rx FIFO Global Mask register
- Selectable priority between mailboxes and Rx FIFO during matching process
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
- 100% backward compatibility with previous FlexCAN version
- Supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors).

### 37.2.3 Modes of operation

The FlexCAN module has these functional modes:

- Normal mode (User or Supervisor):

In Normal mode, the module operates receiving and/or transmitting message frames, errors are handled normally, and all CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

- Freeze mode:

Freeze mode is enabled when the FRZ bit in MCR is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ\_ACK] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See [Freeze mode](#) for more information.

- Listen-Only mode:

The module enters this mode when the LOM field in the Control 1 Register is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- Loop-Back mode:

The module enters this mode when the LPB field in the Control 1 Register is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

For low-power operation, the FlexCAN module has:

- Module Disable mode:

This low-power mode is entered when the MDIS bit in the MCR Register is asserted by the CPU and the LPM\_ACK is asserted by the FlexCAN. When disabled, the module requests to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating the MDIS bit in the MCR register. See [Module Disable mode](#) for more information.

- Doze mode:

This low power mode is entered when the DOZE bit in MCR is asserted and Doze mode is requested at chip level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Doze mode, the module requests to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. Exit from this mode happens when the DOZE bit in MCR is negated, when the chip is removed from Doze mode. See [Doze mode](#) for more information.

- Stop mode:

This low power mode is entered when Stop mode is requested at chip level and the LPM\_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed. See [Stop mode](#) for more information.

## 37.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

**Table 37-1. FlexCAN signal descriptions**

| Signal | Description      | I/O    |
|--------|------------------|--------|
| CAN Rx | CAN Receive Pin  | Input  |
| CAN Tx | CAN Transmit Pin | Output |

### 37.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

### 37.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

## 37.4 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

### 37.4.1 FlexCAN memory mapping

The complete memory map for a FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming the SUPV field in the MCR register. These registers are identified as S/U in the Access column of [Table 37-2](#).

#### NOTE

An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register or accessing an invalid address.

**Table 37-2. Register access and reset information**

| Register                                     | Access type | Affected by hard reset | Affected by soft reset |
|----------------------------------------------|-------------|------------------------|------------------------|
| Module Configuration Register (MCR)          | S           | Yes                    | Yes                    |
| Control 1 register (CTRL1)                   | S/U         | Yes                    | No                     |
| Free Running Timer register (TIMER)          | S/U         | Yes                    | Yes                    |
| Rx Mailboxes Global Mask register (RXMGMASK) | S/U         | No                     | No                     |
| Rx Buffer 14 Mask register (RX14MASK)        | S/U         | No                     | No                     |
| Rx Buffer 15 Mask register (RX15MASK)        | S/U         | No                     | No                     |
| Error Counter Register (ECR)                 | S/U         | Yes                    | Yes                    |
| Error and Status 1 Register (ESR1)           | S/U         | Yes                    | Yes                    |

*Table continues on the next page...*

**Table 37-2. Register access and reset information (continued)**

| Register                                          | Access type | Affected by hard reset | Affected by soft reset |
|---------------------------------------------------|-------------|------------------------|------------------------|
| Interrupt Masks 2 register (IMASK2)               | S/U         | Yes                    | Yes                    |
| Interrupt Masks 1 register (IMASK1)               | S/U         | Yes                    | Yes                    |
| Interrupt Flags 2 register (IFLAG2)               | S/U         | Yes                    | Yes                    |
| Interrupt Flags 1 register (IFLAG1)               | S/U         | Yes                    | Yes                    |
| Control 2 Register (CTRL2)                        | S/U         | Yes                    | No                     |
| Error and Status 2 Register (ESR2)                | S/U         | Yes                    | Yes                    |
| CRC Register (CRCR)                               | S/U         | Yes                    | Yes                    |
| Rx FIFO Global Mask register (RXFGMASK)           | S/U         | No                     | No                     |
| Rx FIFO Information Register (RXFIR)              | S/U         | No                     | No                     |
| Message buffers                                   | S/U         | No                     | No                     |
| Rx Individual Mask Registers                      | S/U         | No                     | No                     |
| Memory Error Control Register (MECR)              | S/U         | Yes                    | Yes                    |
| Error Injection Address Register (ERRIAR)         | S/U         | Yes                    | Yes                    |
| Error Injection Data Pattern Register (ERRIDPR)   | S/U         | Yes                    | Yes                    |
| Error Injection Parity Pattern Register (ERRIPPR) | S/U         | Yes                    | Yes                    |
| Error Report Address Register (RERRAR)            | S/U         | Yes                    | Yes                    |
| Error Report Data Register (RERRDR)               | S/U         | Yes                    | Yes                    |
| Error Report Syndrome Register (RERRSYNR)         | S/U         | Yes                    | Yes                    |
| Error Status Register (ERRSR)                     | S/U         | Yes                    | Yes                    |

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

This module's memory map includes sixty-four 128-bit message buffers (MBs) that occupy the range from offset 0x80 to 0x47F .

### CAN memory map

| Address offset (hex) | Register name                                    | Width (in bits) | Access | Reset value | Section/ page               |
|----------------------|--------------------------------------------------|-----------------|--------|-------------|-----------------------------|
| 0                    | Module Configuration Register (CAN_MCR)          | 32              | R/W    | 5980_000Fh  | <a href="#">37.4.2/1679</a> |

## 37.4.2 Module Configuration Register (CAN\_MCR)

This register defines global system configurations, such as the module operation modes and the maximum message buffer configuration.

Address: 0h base + 0h offset = 0h

**CAN\_MCR field descriptions**

| Field     | Description                                                                                                                                                                                                                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>MDIS | <p>Module Disable</p> <p>This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface sub-modules. This is the only bit within this register not affected by soft reset.</p> <p>0 Enable the FlexCAN module.<br/>1 Disable the FlexCAN module.</p> |
| 1<br>FRZ  | <p>Freeze Enable</p> <p>The FRZ bit specifies the FlexCAN behavior when the HALT bit in the MCR Register is set or when Debug mode is requested at chip level . When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.</p>                                         |

**CAN\_MCR field descriptions (continued)**

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | 0 Not enabled to enter Freeze mode.<br>1 Enabled to enter Freeze mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 2<br>RFEN     | <b>Rx FIFO Enable</b><br><br>This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in the table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in section "Arbitration and Matching Timing"). This bit can be written only in Freeze mode because it is blocked by hardware in other modes.<br><br>0 Rx FIFO not enabled.<br>1 Rx FIFO enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3<br>HALT     | <b>Halt FlexCAN</b><br><br>Assertion of this bit puts the FlexCAN module into Freeze mode. The CPU should clear it after initializing the Message Buffers and Control Register. No reception or transmission is performed by FlexCAN before this bit is cleared. Freeze mode cannot be entered while FlexCAN is in a low power mode.<br><br>0 No Freeze mode request.<br>1 Enters Freeze mode if the FRZ bit is asserted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 4<br>NOTRDY   | <b>FlexCAN Not Ready</b><br><br>This read-only bit indicates that FlexCAN is either in Disable mode , Doze mode, Stop mode or Freeze mode. It is negated once FlexCAN has exited these modes.<br><br>0 FlexCAN module is either in Normal mode, Listen-Only mode or Loop-Back mode.<br>1 FlexCAN module is either in Disable mode , Doze mode, Stop mode or Freeze mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 5<br>Reserved | This field is reserved.<br>Always write 0 to this field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 6<br>SOFTTRST | <b>Soft Reset</b><br><br>When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER , ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected: CTRL1, CTRL2, all RXIMR registers, RXMGMASK, RX14MASK, RX15MASK, RXFGMASK, RXFIR, all Message Buffers .<br><br>The SOFTTRST bit can be asserted directly by the CPU when it writes to the MCR Register. Because soft reset is synchronous and has to follow a request/acknowledge procedure across clock domains, it may take some time to fully propagate its effect. The SOFTTRST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed.<br><br>Soft reset cannot be applied while clocks are shut down in a low power mode. The module should be first removed from low power mode, and then soft reset can be applied.<br><br>0 No reset request.<br>1 Resets the registers affected by soft reset. |
| 7<br>FRZACK   | <b>Freeze Mode Acknowledge</b><br><br>This read-only bit indicates that FlexCAN is in Freeze mode and its prescaler is stopped. The Freeze mode request cannot be granted until current transmission or reception processes have finished.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## CAN\_MCR field descriptions (continued)

| Field          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <p>Therefore the software can poll the FRZACK bit to know when FlexCAN has actually entered Freeze mode. If Freeze Mode request is negated, then this bit is negated after the FlexCAN prescaler is running again. If Freeze mode is requested while FlexCAN is in a low power mode, then the FRZACK bit will be set only when the low-power mode is exited. See Section "Freeze Mode".</p> <p><b>NOTE:</b> FRZACK will be asserted within 178 CAN bits from the freeze mode request by the CPU, and negated within 2 CAN bits after the freeze mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN not in Freeze mode, prescaler running.<br/>1 FlexCAN in Freeze mode, prescaler stopped.</p> |
| 8<br>SUPV      | <p>Supervisor Mode</p> <p>This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the Access Type column of the module memory map. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses.<br/>1 FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.</p>    |
| 9<br>Reserved  | <p>This field is reserved.<br/>Always write 0 to this field.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 10<br>WRNEN    | <p>Warning Interrupt Enable</p> <p>When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register. If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 TWRNINT and RWRNINT bits are zero, independent of the values in the error counters.<br/>1 TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.</p>                                               |
| 11<br>LPMACK   | <p>Low-Power Mode Acknowledge</p> <p>This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode.</p> <p><b>NOTE:</b> LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Section "Protocol Timing").</p> <p>0 FlexCAN is not in a low-power mode.<br/>1 FlexCAN is in a low-power mode.</p>                                                        |
| 12<br>Reserved | <p>This field is reserved.<br/>Always write 0 to this field.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 13<br>DOZE     | <p>Doze Mode Enable</p> <p>This bit defines whether FlexCAN is allowed to enter low-power mode when Doze mode is requested at chip level.</p> <p>0 FlexCAN is not enabled to enter low-power mode when Doze mode is requested.<br/>1 FlexCAN is enabled to enter low-power mode when Doze mode is requested.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |

## CAN\_MCR field descriptions (continued)

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 14<br>SRXDIS      | <p>Self Reception Disable</p> <p>This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Self reception enabled.<br/>1 Self reception disabled.</p>                                                                                                                                                                                                              |
| 15<br>IRMQ        | <p>Individual Rx Masking And Queue Enable</p> <p>This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMASK, RX14MASK and RX15MASK, RXFGMASK. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY.<br/>1 Individual Rx masking and queue feature are enabled.</p>                                                                                                                                                                                                   |
| 16<br>Reserved    | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 17<br>Reserved    | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 18<br>LPRIOEN     | <p>Local Priority Enable</p> <p>This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Local Priority disabled.<br/>1 Local Priority enabled.</p>                                                                                                                                                       |
| 19<br>AEN         | <p>Abort Enable</p> <p>This bit is supplied for backwards compatibility with legacy applications. When asserted, it enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> When MCR[AEN] is asserted, only the abort mechanism (see Section "Transmission Abort Mechanism") must be used for updating Mailboxes configured for transmission.</p> <p><b>CAUTION:</b> Writing the Abort code into Rx Mailboxes can cause unpredictable results when the MCR[AEN] is asserted.</p> <p>0 Abort disabled.<br/>1 Abort enabled.</p> |
| 20–21<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                | <p>This 2-bit field identifies the format of the Rx FIFO ID Filter Table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Section "Rx FIFO Structure". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>00 Format A: One full ID (standard and extended) per ID Filter Table element.</p> <p>01 Format B: Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID Filter Table element.</p> <p>10 Format C: Four partial 8-bit Standard IDs per ID Filter Table element.</p> <p>11 Format D: All frames rejected.</p>                                                                                                                                                                                                                           |
| 24<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 25–31<br>MAXMB | <p>Number Of The Last Message Buffer</p> <p>This 7-bit field defines the number of the last Message Buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Number of the last MB = MAXMB</p> <p><b>NOTE:</b> MAXMB must be programmed with a value smaller than the parameter NUMBER_OF_MB, otherwise the number of the last effective Message Buffer will be: (NUMBER_OF_MB - 1)</p> <p>Additionally, the value of MAXMB must encompass the FIFO size defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table "Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate" (in Section "Arbitration and Matching Timing").</p> |

## 37.4.3 Control 1 register (CAN\_CTRL1)

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit-rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior and interrupt enabling (Bus-Off, Error, Warning). It also determines the Division Factor for the clock prescaler.

Address: 0h base + 4h offset = 4h

## CAN\_CTRL1 field descriptions

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–7<br>PRES DIV | <p>Prescaler Division Factor</p> <p>This 8-bit field defines the ratio between the PE clock frequency and the Serial Clock (Sclck) frequency. The Sclck period defines the time quantum of the CAN protocol. For the reset value, the Sclck frequency is equal to the PE clock frequency. The Maximum value of this field is 0xFF, that gives a minimum Sclck frequency equal to the PE clock frequency divided by 256. See Section "Protocol Timing". This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><math>\text{Sclck frequency} = \text{PE clock frequency} / (\text{PRES DIV} + 1)</math></p>                       |
| 8–9<br>RJW      | <p>Resync Jump Width</p> <p>This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one re-synchronization. One time quantum is equal to the Sclck period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><math>\text{Resync Jump Width} = \text{RJW} + 1.</math></p>                                                                                                                                                                                                                                                                       |
| 10–12<br>PSEG1  | <p>Phase Segment 1</p> <p>This 3-bit field defines the length of Phase Buffer Segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><math>\text{Phase Buffer Segment 1} = (\text{PSEG1} + 1) \times \text{Time-Quanta}.</math></p>                                                                                                                                                                                                                                                                                                                           |
| 13–15<br>PSEG2  | <p>Phase Segment 2</p> <p>This 3-bit field defines the length of Phase Buffer Segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><math>\text{Phase Buffer Segment 2} = (\text{PSEG2} + 1) \times \text{Time-Quanta}.</math></p>                                                                                                                                                                                                                                                                                                                           |
| 16<br>BOFFMSK   | <p>Bus Off Mask</p> <p>This bit provides a mask for the Bus Off Interrupt.</p> <p>0 Bus Off interrupt disabled.<br/>1 Bus Off interrupt enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <p>internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p><b>NOTE:</b> In this mode, the MCR[SRXDIS] cannot be asserted because this will impede the self reception of a transmitted message.</p> <p>0 Loop Back disabled.<br/>1 Loop Back enabled.</p>                                                                                                                                                                                                                                                                                                                                              |
| 20<br>TWRNMSK     | <p>Tx Warning Interrupt Mask</p> <p>This bit provides a mask for the Tx Warning Interrupt associated with the TWRNINT flag in the Error and Status Register. This bit is read as zero when MCR[WRNEN] bit is negated. This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted.</p> <p>0 Rx Warning Interrupt disabled.<br/>1 Rx Warning Interrupt enabled.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 22–23<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 24<br>SMP         | <p>CAN Bit Sampling</p> <p>This bit defines the sampling mode of CAN bits at the Rx input. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Just one sample is used to determine the bit value.<br/>1 Three samples are used to determine the value of the received bit: the regular one (sample point) and 2 preceding samples; a majority rule is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 25<br>BOFFREC     | <p>Bus Off Recovery</p> <p>This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will re-synchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be re-asserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.</p> <p>0 Automatic recovering from Bus Off state enabled, according to CAN Spec 2.0 part B.<br/>1 Automatic recovering from Bus Off state disabled.</p> |

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 26<br>TSYN       | <p>Timer Sync</p> <p>This bit enables a mechanism that resets the free-running timer each time a message is received in Message Buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If the RFEN bit in MCR is set (Rx FIFO enabled), the first available Mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Timer Sync feature disabled<br/>1 Timer Sync feature enabled</p>                                                                                                                                                                                                                                                                          |
| 27<br>LBUF       | <p>Lowest Buffer Transmitted First</p> <p>This bit defines the ordering mechanism for Message Buffer transmission. When asserted, the LPRIEN bit does not affect the priority arbitration. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Buffer with highest priority is transmitted first.<br/>1 Lowest number buffer is transmitted first.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 28<br>LOM        | <p>Listen-Only Mode</p> <p>This bit configures FlexCAN to operate in Listen-Only mode. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error without changing the REC, as if it was trying to acknowledge the message.</p> <p>Listen-Only mode acknowledgement can be obtained by the state of ESR1[FLTCNF] field which is Passive Error when Listen-Only mode is entered. There can be some delay between the Listen-Only mode request and acknowledge.</p> <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Listen-Only mode is deactivated.<br/>1 FlexCAN module operates in Listen-Only mode.</p> |
| 29–31<br>PROPSEG | <p>Propagation Segment</p> <p>This 3-bit field defines the length of the Propagation Segment in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>Propagation Segment Time = (PROPSEG + 1) × Time-Quanta.<br/>Time-Quantum = one Sclock period.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**37.4.4 Free Running Timer (CAN\_TIMER)**

This register represents a 16-bit free running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

The timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop, and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted, the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure; see Section "Mailbox Lock Mechanism".

Address: 0h base + 8h offset = 8h

### 37.4.5 Rx Mailboxes Global Mask Register (CAN\_RXMGMASK)

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When the MCR[IRMQ] bit is negated, RXMGMASK is always in effect.
- When the MCR[IRMQ] bit is asserted, RXMGMASK has no effect.

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 10h offset = 10h

1. RTR bit of the Incoming Frame. It is saved into an auxiliary MB called Rx Serial Message Buffer (Rx SMB).
2. If the CTRL2[EACEN] bit is negated, the RTR bit of Mailbox is never compared with the RTR bit of the incoming frame.
3. If the CTRL2[EACEN] bit is negated, the IDE bit of Mailbox is always compared with the IDE bit of the incoming frame.

## 37.4.6 Rx 14 Mask register (CAN\_RX14MASK)

This register is located in RAM.

RX14MASK is provided for legacy application support. When the MCR[IRMQ] bit is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of Message Buffer 14.

This register can only be programmed while the module is in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 14h offset = 14h

## 37.4.7 Rx 15 Mask register (CAN\_RX15MASK)

This register is located in RAM.

RX15MASK is provided for legacy application support. When the MCR[IRMQ] bit is asserted, RX15MASK has no effect.

RX15MASK is used to mask the filter fields of Message Buffer 15.

This register can be programmed only while the module is in Freeze mode because it is blocked by hardware in other modes.

Address: 0h base + 18h offset = 18h

### 37.4.8 Error Counter (CAN\_ECR)

This register has two 8-bit fields reflecting the value of two FlexCAN error counters: Transmit Error Counter (TXERRCNT field) and Receive Error Counter (RXERRCNT field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module. Both counters are read-only except in Freeze mode, where they can be written by the CPU.

FlexCAN responds to any bus state as described in the protocol, for example, transmit Error Active or Error Passive flag, delay its transmission start time (Error Passive) and avoid any influence on the bus when in Bus Off state.

The following are the basic rules for FlexCAN bus state transitions:

- If the value of TXERRCNT or RXERRCNT increases to be greater than or equal to 128, the FLTCONF field in the Error and Status Register is updated to reflect 'Error Passive' state.
- If the FlexCAN state is 'Error Passive', and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLTCONF field in the Error and Status Register is updated to reflect 'Error Active' state.
- If the value of TXERRCNT increases to be greater than 255, the FLTCONF field in the Error and Status Register is updated to reflect 'Bus Off' state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
- If FlexCAN is in 'Bus Off' state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, the FLTCONF field in the Error and Status Register is updated to be 'Error Active' and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value.
- If during system start-up, only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to 'Error Passive' state, the TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the 'Bus Off' state.
- If the RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to 'Error Active' state.

## 37.4.9 Error and Status 1 register (CAN\_ESR1)

This register reflects various error conditions and some general status of the device. It is also the source of interrupts to the CPU.

A CPU read operation clears the following fields to 0, so these fields report error conditions that occurred after the last time the CPU read this register: BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, and STFERR. TXWRN, RXWRN, IDLE, TX, FLTCONF, and RX provide status information.

The following table shows the FlexCAN state variables and their meanings. Combinations not shown in the table are reserved.

| SYNCH | IDLE | TX | RX | FlexCAN state               |
|-------|------|----|----|-----------------------------|
| 0     | 0    | 0  | 0  | Not synchronized to CAN bus |
| 1     | 1    | x  | x  | Idle                        |
| 1     | 0    | 1  | 0  | Transmitting                |
| 1     | 0    | 0  | 1  | Receiving                   |

|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 29<br>BOFFINT  | <p>Bus Off Interrupt</p> <p>This bit is set when FlexCAN enters 'Bus Off' state. If the corresponding mask bit in the Control Register (BOFFMSK) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0 No such occurrence.<br/>1 FlexCAN module entered Bus Off state.</p>                                 |
| 30<br>ERRINT   | <p>Error Interrupt</p> <p>This bit indicates that at least one of the Error Bits (bits 15-10) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.</p> <p>0 No such occurrence.<br/>1 Indicates setting of any Error Bit in the Error and Status Register.</p> |
| 31<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                              |

## 37.4.10 Interrupt Masks 2 register (CAN\_IMASK2)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB63 to MB32. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG2 bit is set.

Address: 0h base + 24h offset = 24h

### 37.4.11 Interrupt Masks 1 register (CAN\_IMASK1)

This register allows any number of a range of the 32 Message Buffer Interrupts to be enabled or disabled for MB31 to MB0. It contains one interrupt mask bit per buffer, enabling the CPU to determine which buffer generates an interrupt after a successful transmission or reception, that is, when the corresponding IFLAG1 bit is set.

### 37.4.12 Interrupt Flags 2 register (CAN\_IFLAG2)

This register defines the flags for the 32 Message Buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB] field, CPU must service the IFLAG2 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

**37.4.13 Interrupt Flags 1 register (CAN\_IFLAG1)**

This register defines the flags for the 32 Message Buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When the bit MCR[RFEN] is set, the function of the 8 least significant interrupt flags BUF[7:0]I changes: BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, and the BUF4TO0I field is reserved.

Before enabling the RFEN, the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Section "Rx FIFO". Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN bit is negated, the FIFO flags must be cleared. The same care must be taken when an RFFN value is selected extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

Before updating MCR[MAXMB] field, CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

| 4–7<br>RFFN     | <p>Number Of Rx FIFO Filters</p> <p>This 4-bit field defines the number of Rx FIFO filters, as shown in the following table. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that make the number of Message Buffers occupied by Rx FIFO and ID Filter exceed the number of Mailboxes present, defined by MCR[MAXMB].</p> <p><b>NOTE:</b> Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available.</p> <p>Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows:</p> <p><math>(\text{SETUP\_MB} - 6) \times 4</math></p> <p>where SETUP_MB is the least between NUMBER_OF_MB and MAXMB.</p> <p>The number of remaining Mailboxes available will be:</p> <p><math>(\text{SETUP\_MB} - 8) - (\text{RFFN} \times 2)</math></p> <p>If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value (memory space available) the exceeding ones will not be functional.</p> <table><tr><th>RFFN[3:0]</th><th>Number of Rx FIFO filters</th><th>Message Buffers occupied by Rx FIFO and ID Filter Table</th><th>Remaining Available Mailboxes<sup>1</sup></th><th>Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks</th><th>Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask<sup>2</sup></th></tr><tr><td>0x0</td><td>8</td><td>MB 0-7</td><td>MB 8-63</td><td>Elements 0-7</td><td>none</td></tr><tr><td>0x1</td><td>16</td><td>MB 0-9</td><td>MB 10-63</td><td>Elements 0-9</td><td>Elements 10-15</td></tr><tr><td>0x2</td><td>24</td><td>MB 0-11</td><td>MB 12-63</td><td>Elements 0-11</td><td>Elements 12-23</td></tr><tr><td>0x3</td><td>32</td><td>MB 0-13</td><td>MB 14-63</td><td>Elements 0-13</td><td>Elements 14-31</td></tr><tr><td>0x4</td><td>40</td><td>MB 0-15</td><td>MB 16-63</td><td>Elements 0-15</td><td>Elements 16-39</td></tr><tr><td>0x5</td><td>48</td><td>MB 0-17</td><td>MB 18-63</td><td>Elements 0-17</td><td>Elements 18-47</td></tr><tr><td>0x6</td><td>56</td><td>MB 0-19</td><td>MB 20-63</td><td>Elements 0-19</td><td>Elements 20-55</td></tr></table> | RFFN[3:0]                                               | Number of Rx FIFO filters                  | Message Buffers occupied by Rx FIFO and ID Filter Table          | Remaining Available Mailboxes <sup>1</sup>                                    | Rx FIFO ID Filter Table Elements Affected by Rx Individual Masks | Rx FIFO ID Filter Table Elements Affected by Rx FIFO Global Mask <sup>2</sup> | 0x0 | 8 | MB 0-7 | MB 8-63 | Elements 0-7 | none | 0x1 | 16 | MB 0-9 | MB 10-63 | Elements 0-9 | Elements 10-15 | 0x2 | 24 | MB 0-11 | MB 12-63 | Elements 0-11 | Elements 12-23 | 0x3 | 32 | MB 0-13 | MB 14-63 | Elements 0-13 | Elements 14-31 | 0x4 | 40 | MB 0-15 | MB 16-63 | Elements 0-15 | Elements 16-39 | 0x5 | 48 | MB 0-17 | MB 18-63 | Elements 0-17 | Elements 18-47 | 0x6 | 56 | MB 0-19 | MB 20-63 | Elements 0-19 | Elements 20-55 |

| 8–12<br>TASD | <p><b>Tx Arbitration Start Delay</b><br/>This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. This field can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency.</p> <p>The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa.</p> <p>If TASD is 0 then the arbitration start is not delayed, thus the CPU has less time to configure a Tx MB for the next arbitration, but more time is reserved for arbitration. On the other hand, if TASD is 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration.</p> <p>If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is not the best to be transmitted.</p> <p>The optimal configuration for TASD can be calculated as:</p> $TASD = 25 - \left\{ f \times [MAXMB + 3 - \frac{CANCLK}{(RFEN \times 8)} - (RFEN \times RFFN \times 2)] \times 2 \right\} / \left\{ f \times [1 + (PSEG1+1) + \frac{SYS}{(PSEG2+1)} + (PROPSEG+1)] \times (PRES DIV+1) \right\}$ <p>where:</p> |                           |                                                         |                                            |                                                                  |                                                                               |

| 13<br>MRP         | <p>Mailboxes Reception Priority</p> <p>If this bit is set the matching process starts from the Mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Matching starts from Rx FIFO and continues on Mailboxes.<br/>1 Matching starts from Mailboxes and continues on Rx FIFO.</p>                                                                                                                                                                                                                                                                                   |
| 14<br>RRS         | <p>Remote Request Storing</p> <p>If this bit is asserted Remote Request Frame is submitted to a matching process and stored in the corresponding Message Buffer in the same fashion of a Data Frame. No automatic Remote Response Frame will be generated.</p> <p>If this bit is negated the Remote Request Frame is submitted to a matching process and an automatic Remote Response Frame is generated if a Message Buffer with CODE=0b1010 is found with the same ID.</p> <p>This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Remote Response Frame is generated.<br/>1 Remote Request Frame is stored.</p>                        |
| 15<br>EACEN       | <p>Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes</p> <p>This bit controls the comparison of IDE and RTR bits within Rx Mailboxes filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</p> <p>0 Rx Mailbox filter's IDE bit is always compared and RTR is never compared despite mask bits.<br/>1 Enables the comparison of both Rx Mailbox filter's IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply.</p>                                       |
| 16–31<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

1. The number of the last remaining available mailboxes is defined by the least value between the parameter NUMBER\_OF\_MB minus 1 and the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

### 37.4.15 Error and Status 2 register (CAN\_ESR2)

This register reflects various interrupt flags and some general status.

Address: 0h base + 38h offset = 38h

**CAN\_ESR2 field descriptions**

| Field           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–8<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 9–15<br>LPTM    | Lowest Priority Tx Mailbox<br><br>If ESR2[VPS] is asserted, this field indicates the lowest number inactive Mailbox (see the IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one that has the greatest arbitration value (see the "Highest priority Mailbox first" section). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.                                                                                                                                                                                                                                                                            |
| 16<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 17<br>VPS       | Valid Priority Status<br><br>This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the CPU writes to Control and Status word of a Mailbox that has already been scanned, that is, it is behind Tx Arbitration Pointer, during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox that is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox.<br><br><b>NOTE:</b> ESR2[VPS] is not affected by any CPU write into Control Status (C/S) of a MB that is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is being transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked.<br><br>0 Contents of IMB and LPTM are invalid.<br>1 Contents of IMB and LPTM are valid. |
| 18<br>IMB       | Inactive Mailbox<br><br>If ESR2[VPS] is asserted, this bit indicates whether there is any inactive Mailbox (CODE field is either 0b1000 or 0b0000). This bit is asserted in the following cases:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 17–31<br>TXCRC  | <p>CRC Transmitted</p> <p>This field indicates the CRC value of the last message transmitted. This field is updated at the same time the Tx Interrupt Flag is asserted.</p> |

### 37.4.17 Rx FIFO Global Mask register (CAN\_RXFGMASK)

This register is located in RAM.

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

Address: 0h base + 48h offset = 48h

1. If MCR[IDAM] field is equivalent to the format B only the fourteen most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] field is equivalent to the format C only the eight most significant bits of the Identifier of the incoming frame are compared with the Rx FIFO filter.

37.4.18 Rx FIFO Information Register (CAN\_RXFIR)

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. See Section "Rx FIFO" for instructions on reading this register.

Address: 0h base + 4Ch offset = 4Ch

|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–22<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                 |
| 23–31<br>IDHIT   | Identifier Acceptance Filter Hit Indicator<br><br>This field indicates which Identifier Acceptance Filter was hit by the received message that is in the output of the Rx FIFO. If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the IFLAG[BUF5I] is asserted. |

37.4.19 Rx Individual Mask Registers (CAN\_RXIMRn)

These registers are located in RAM.

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO. If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on the setting of CTRL2[RFFN].

RXIMR can only be written by the CPU while the module is in Freeze mode; otherwise, they are blocked by hardware.

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

Address: 0h base + 880h offset + (4d × i), where i=0d to 63d

## 37.4.20 Memory Error Control Register (CAN\_MECR)

This register contains control bits for memory error detection and correction (ECC).

### NOTE

When bit CTRL2[ECRWRE] is 0, this register is read-only and writes to this register result in bus transfer errors.

Address: 0h base + AE0h offset = AE0h

**37.4.21 Error Injection Address Register (CAN\_ERRIAR)**

This register holds the address where error is to be injected.

Use the following table to convert from the memory map address to the location in the physical FlexCAN RAM:

| RAM contents      | Injection address | Memory map |
|-------------------|-------------------|------------|
| FlexCAN Registers | Not mapped        | -          |

*Table continues on the next page...*

**37.4.24 Error Report Address Register (CAN\_RERRAR)**

Reports the address used for an access in which an error (correctable or non-correctable) was detected, and also reports the identification of the source of that access.

This address is always reported using a 32-bit alignment. Non-aligned accesses (ERRADDR[1:0] non-0) are reported with the address aligned and data is reported in RERRDR accordingly shifted. In case of errors detected in accesses larger than 32-bit (as performed by FlexCAN internal processes), the address of the 32-bit word in which the error was detected is reported. In case of errors detected in more than one 32-bit word, only the least significant address is reported.

Address: 0h base + AF0h offset = AF0h

**37.4.25 Error Report Data Register (CAN\_RERRDR)**

Reports the raw data (unmodified by the correction performed by ECC logic) read from memory with error. The value reported does not represent the transient values of the BUSY bit (see the “Message Buffer Code for Rx buffers” table) when reading a Message Buffer.

Address: 0h base + AF4h offset = AF4h

**CAN\_RERRDR field descriptions**

| Field         | Description                               |
|---------------|-------------------------------------------|
| 0–31<br>RDATA | Raw data word read from memory with error |

**37.4.26 Error Report Syndrome Register (CAN\_RERRSYNR)**

Holds the syndrome detected in a memory read with error. It also reports the bytes which were read in this 32-bit read transaction.

Each SYNDn field indicates the type of error and which bit in byte (n) is affected by the error. (SYND3 corresponds to the most significant byte in the data word read from memory; SYND0 corresponds to the least significant.)

**Table 37-94. Syndrome Definition**

| SYNDn (hex) | Type | Bit affected          |
|-------------|------|-----------------------|
| 00          | -    | none (no error)       |
| 01          | Code | 0                     |
| 02          | Code | 1                     |
| 04          | Code | 2                     |
| 07          | Data | 5                     |
| 08          | Code | 3                     |
| 0E          | Data | 7                     |
| 10          | Code | 4                     |
| 13          | Data | 2                     |
| 15          | Data | 6                     |
| 16          | Data | 1                     |
| 19          | Data | 3                     |
| 1A          | Data | 4                     |
| 1C          | Data | 0                     |
| All others  | -    | Non-correctable error |

Each BEN field indicates which byte in the 32-bit word reported was effectively read. The syndrome bits are calculated for all bytes, even for the non-read ones. Errors detected in non-read bytes are indicated (see the "Error Indication" section) and reported (see the "Error Reporting" section).

Address: 0h base + AF8h offset = AF8h

37.4.27 Error Status Register (CAN\_ERRSR)

Holds the status bits of the error correction and detection operations. After raised, these flags must be cleared by writing 1 to them. Writing 0 has no effect.

Address: 0h base + AFCh offset = AFCh

**37.4.28 Message buffer structure**

The message buffer structure used by the FlexCAN module is represented in the following figure. Both Extended (29-bit identifier) and Standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16 bytes.

The memory area from 0x80 to 0x47F is used by the mailboxes.

**Table 37-96. Message buffer structure**

|     | 0           | 1 | 2 | 3                      | 4                           | 7 | 8           | 9   | 10  | 11  | 12  | 13 | 14          | 15            | 16         | 23          | 24 | 31 |  |

**CODE** — Message Buffer Code

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in [Table 37-97](#) and [Table 37-98](#). See [Functional description](#) for additional information.

**Table 37-97. Message buffer code for Rx buffers**

| CODE description                        | Rx code BEFORE receive new frame | SRV <sup>1</sup> | Rx code AFTER successful reception <sup>2</sup> | RRS <sup>3</sup> | Comment                                                                                                                                                                                                                                                                                               |

|                                                                                                 |                                  | —                | —                                               | 1                | This code is ignored during matching and arbitration process. See <a href="#">Matching process</a> for details.     |
| CODE[0]=1b1: BUSY — FlexCAN is updating the contents of the MB. The CPU must not access the MB. | BUSY <sup>5</sup>                | —                | FULL                                            | —                | Indicates that the MB is being updated. It will be negated automatically and does not interfere with the next CODE. |
|                                                                                                 |                                  | —                | OVERRUN                                         | —                |                                                                                                                     |

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered a successful reception after the frame to be moved to MB (move-in process). See [Move-in](#) for details.
3. Remote Request Stored bit from CTRL2 register. See section "Control 2 Register (CTRL2)" for details.
4. Code 0b1010 is not considered Tx and an MB with this code should not be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

**Table 37-98. Message buffer code for Tx buffers**

| CODE Description                                                    | Tx Code BEFORE tx frame | MB RTR | Tx Code AFTER successful transmission | Comment                                                                                                                               |

|---------------------------------------------|-------------------------|--------|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frame from an incoming Remote Request Frame |                         |        |                                       | automatically written to the MB by the CHI as a result of a match to a remote request frame. The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See <a href="#">Matching process</a> and <a href="#">Arbitration process</a> for details. |

**SRR** — Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

**IDE** — ID Extended Bit

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

**RTR** — Remote Transmission Request

This bit affects the behavior of remote frames and is part of the reception filter. See [Table 37-97](#), [Table 37-98](#), and the description of the RRS bit in Control 2 Register (CTRL2) for additional details.

If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

### **DLC** — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see the [Table 37-96](#)). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see [Table 37-99](#)).

### **TIME STAMP** — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

### **PRI0** — Local priority

This 3-bit field is used only when LPRI0\_EN bit is set in MCR, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See [Arbitration process](#).

### **ID** — Frame Identifier

In standard frame format, only the 11 most significant bits (3 to 13) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

### **DATA BYTE 0–7** — Data Field

Up to eight bytes can be used for a data frame.

For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (*n*) is valid only if *n* is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

**Table 37-99. DATA BYTES validity**

| DLC | Valid DATA BYTES |
|-----|------------------|
| 0   | none             |
| 1   | DATA BYTE 0      |
| 2   | DATA BYTE 0–1    |
| 3   | DATA BYTE 0–2    |
| 4   | DATA BYTE 0–3    |
| 5   | DATA BYTE 0–4    |
| 6   | DATA BYTE 0–5    |
| 7   | DATA BYTE 0–6    |
| 8   | DATA BYTE 0–7    |

### 37.4.29 Rx FIFO structure

When the MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

**Table 37-100. Rx FIFO structure**

|      | 0           | 3 | 7           | 8           | 9   | 10  | 11  | 12  | 13 | 14 | 15          | 16         | 23          | 24 | 31          |  |
|------|-------------|---|-------------|-------------|-----|-----|-----|-----|----|----|-------------|------------|-------------|----|-------------|--|
| 0x80 |             |   |             |             | SRR | IDE | RTR | DLC |    |    |             | TIME STAMP |             |    |             |  |
| 0x84 |             |   | ID standard |             |     |     |     |     |    |    | ID extended |            |             |    |             |  |
| 0x88 | Data byte 0 |   |             | Data byte 1 |     |     |     |     |    |    |             |            | Data byte 2 |    | Data byte 3 |  |
| 0x8C | Data byte 4 |   |             | Data byte 5 |     |     |     |     |    |    |             |            | Data byte 6 |    | Data byte 7 |  |
| 0x90 | Reserved    |   |             |             |     |     |     |     |    |    |             |            |             |    |             |  |
| to   |             |   |             |             |     |     |     |     |    |    |             |            |             |    |             |  |
| 0xDC |             |   |             |             |     |     |     |     |    |    |             |            |             |    |             |  |

*Table continues on the next page...*

**Table 37-100. Rx FIFO structure (continued)**

|                     |                                   |
|---------------------|-----------------------------------|
| 0xE0                | ID filter table element 0         |
| 0xE4                | ID filter table element 1         |
| 0xE8<br>to<br>0x2D4 | ID filter table elements 2 to 125 |
| 0x2D8               | ID filter table element 126       |
| 0x2DC               | ID filter table element 127       |
|                     | = Unimplemented or reserved       |

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.

The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See [Rx FIFO](#) for more information.

**Table 37-101. ID table structure**

| Format | 0                           | 1   | 2                                             | 7 | 8                           | 15 | 16  | 17  | 18                                              | 23 | 24 | 30 | 31                           |
|--------|-----------------------------|-----|-----------------------------------------------|---|-----------------------------|----|-----|-----|-------------------------------------------------|----|----|----|------------------------------|
| A      | RTR                         | IDE | RXIDA<br>(standard = 2–12, extended = 2–30)   |   |                             |    |     |     |                                                 |    |    |    |                              |
| B      | RTR                         | IDE | RXIDB_0<br>(standard = 2–12, extended = 2–15) |   |                             |    | RTR | IDE | RXIDB_1<br>(standard = 18–28, extended = 18–31) |    |    |    |                              |
| C      | RXIDC_0<br>(std/ext = 0–7)  |     |                                               |   | RXIDC_1<br>(std/ext = 8–15) |    |     |     | RXIDC_2<br>(std/ext = 16–23)                    |    |    |    | RXIDC_3<br>(std/ext = 24–31) |
|        | = Unimplemented or Reserved |     |                                               |   |                             |    |     |     |                                                 |    |    |    |                              |

### **RTR** — Remote Frame

This bit specifies if Remote Frames are accepted into the FIFO if they match the target ID.

1 = Remote Frames can be accepted and data frames are rejected

0 = Remote Frames are rejected and data frames can be accepted

### **IDE** — Extended Frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

### **RXIDA** — Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (2 to 12) are used for frame identification. In the extended frame format, all bits are used.

### **RXIDB\_0, RXIDB\_1** — Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (2 to 12 and 18 to 28) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

### **RXIDC\_0, RXIDC\_1, RXIDC\_2, RXIDC\_3** — Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

## **37.5 Functional description**

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed by a set of Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see [Message buffer structure](#)). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed on its ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to [Table 37-97](#)). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to [Table 37-98](#)).

### 37.5.1 Transmit process

To transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the following procedure:

1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see [Transmission abort mechanism](#)). If backwards compatibility is desired (MCR[AEN] bit is negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see [Mailbox inactivation](#)).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control, and CODE fields of the Control and Status word to activate the MB.

When the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority. At the end of the successful transmission, the value of the Free Running Timer is written into the Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB (see [Table 37-97](#) and [Table 37-98](#) in [Message buffer structure](#)).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until the Interrupt Flag is negated by CPU. This means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

## 37.5.2 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest number Mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value.
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIOEN] bits settings.

### 37.5.2.1 Lowest-number Mailbox first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIOEN] bit has no effect when CTRL1[LBUF] is asserted.

### 37.5.2.2 Highest-priority Mailbox first

If CTRL1[LBUF] bit is negated, then the arbitration process searches the active Tx Mailbox with the highest priority, which means that this Mailbox's frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest-priority Tx Mailbox is the one that has the lowest arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values, the Mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIOEN] bit setting.

#### 37.5.2.2.1 Local Priority disabled

If MCR[LPRIOEN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the Local Priority is disabled.

**Table 37-102. Composition of the arbitration value when Local Priority is disabled**

| Format             | Mailbox Arbitration Value (32 bits) |             |             |                             |             |
|--------------------|-------------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | Standard ID (11 bits)               | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | Extended ID[28:18] (11 bits)        | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

#### 37.5.2.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIOEN] must be asserted. In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the following table).

**Table 37-103. Composition of the arbitration value when Local Priority is enabled**

| Format             | Mailbox Arbitration Value (35 bits) |                              |             |             |                             |             |
|--------------------|-------------------------------------|------------------------------|-------------|-------------|-----------------------------|-------------|
| Standard (IDE = 0) | PRIO (3 bits)                       | Standard ID (11 bits)        | RTR (1 bit) | IDE (1 bit) | - (18 bits)                 | - (1 bit)   |
| Extended (IDE = 1) | PRIO (3 bits)                       | Extended ID[28:18] (11 bits) | SRR (1 bit) | IDE (1 bit) | Extended ID[17:0] (18 bits) | RTR (1 bit) |

As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

### 37.5.2.3 Arbitration process (continued)

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the Data Length Code (DLC) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. T ASD value may be changed to optimize the arbitration start point.
- During CAN BusOff state from TX\_ERR\_CNT=124 to 128. T ASD value may be changed to optimize the arbitration start point.
- During C/S write by CPU in BusIdle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.
  - If there is a pending arbitration and BusIdle state starts then an arbitration process is triggered. In this case the first and second C/S write in BusIdle will not restart the arbitration process. It is possible that there is not enough time to finish arbitration in WaitForBusIdle state and the next state is Idle. In this case the scan is not interrupted, and it is completed during BusIdle state. During this arbitration C/S write does not cause arbitration restart.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze mode (first bit of the WaitForBusIdle state). If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled
- Arbitration winner inactivation or abort during any arbitration process
- There was not enough time to finish Tx arbitration process (for instance, when a deactivation was performed near the end of frame). In this case arbitration process is pending.
- Error or Overload flag in the bus
- Low Power or Freeze mode request in Idle state

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time
- C/S write during arbitration if write is performed in a MB whose number is lower than the Tx arbitration pointer
- Any C/S write if there is no Tx Arbitration process in progress
- Rx Match has just updated a Rx Code to Tx Code
- Entering Busoff state

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration pointer, the ongoing arbitration process will scan this MB as normal.

### 37.5.3 Receive process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the following steps:

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see [Mailbox inactivation](#)), preferably with a safe inactivation (see [Transmission abort mechanism](#)).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the *move-in* process (see [Move-in](#)) as follows:

1. The received Data field (8 bytes at most) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see [Table 37-97](#) and [Table 37-98](#) in Section [Message buffer structure](#)).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for CPU servicing (read) the frame received in an Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox.
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See [Mailbox lock mechanism](#).
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See [Move-in](#).
4. Acknowledge the proper flag at IFLAG registers.
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in [Table 37-97](#). If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior *safe inactivation*, a newly received frame matching the filter of that Mailbox may be lost.

### CAUTION

*In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.*

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in an Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRXDIS] bit is not asserted. If the MCR[SRXDIS] bit is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see [Rx FIFO](#)). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of the IFLAG[BUF5I] "Frames available in Rx FIFO" bit in the IMASK1 register), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional – needed only if a mask was used for IDE and RTR bits)
2. Read the ID field (optional – needed only if a mask was used)
3. Read the Data field
4. Read the RXFIR register (optional)
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory – releases the MB and allows the CPU to read the next Rx FIFO entry)

### 37.5.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame

- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the *matched structures*. The *matching winner* is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

**Table 37-104. Matching architecture**

| Structure         | SMB[RTR] | CTRL2[RRS] | CTRL2[EAC EN] | MB[IDE]          | MB[RTR]             | MB[ID <sup>1</sup> ] | MB[CODE]                 |
|-------------------|----------|------------|---------------|------------------|---------------------|----------------------|--------------------------|
| Mailbox           | 0        | -          | 0             | cmp <sup>2</sup> | no_cmp <sup>3</sup> | cmp_msk <sup>4</sup> | EMPTY or FULL or OVERRUN |
| Mailbox           | 0        | -          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 0          | -             | cmp              | no_cmp              | cmp                  | RANSWER                  |
| Mailbox           | 1        | 1          | 0             | cmp              | no_cmp              | cmp_msk              | EMPTY or FULL or OVERRUN |
| Mailbox           | 1        | 1          | 1             | cmp_msk          | cmp_msk             | cmp_msk              | EMPTY or FULL or OVERRUN |
| FIFO <sup>5</sup> | -        | -          | -             | cmp_msk          | cmp_msk             | cmp_msk              | -                        |

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no\_cmp: The SMB contents are not compared with the MB contents
4. cmp\_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is *free-to-receive* when any of the following conditions is satisfied:

- The CODE field of the Mailbox is EMPTY

- The CODE field of the Mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in [Mailbox lock mechanism](#))
- The CODE field of the Mailbox is either FULL or OVERRUN and an inactivation (see [Mailbox inactivation](#)) is performed
- The Rx FIFO is not full

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.

It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above

If the selected priority is Mailboxes first:

- If a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO
- If no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO
- If both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
  - If MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox
  - If MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox

See the following table for a summary of matching possibilities.

**Table 37-105. Matching possibilities and resulting reception structures**

| RFEN                                                               | IRMQ | MRP            | Matched in MB     | Matched in FIFO      | Reception structure | Description                             |
|--------------------------------------------------------------------|------|----------------|-------------------|----------------------|---------------------|-----------------------------------------|
| <b>No FIFO, only MB, match is always MB first</b>                  |      |                |                   |                      |                     |                                         |
| 0                                                                  | 0    | X <sup>1</sup> | None <sup>2</sup> | - <sup>3</sup>       | None                | Frame lost by no match                  |

| 1                                                                  | 1    | 0              | X                 | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 0              | None              | Full                 | None                | Frame lost by FIFO full (FIFO Overflow) |
| 1                                                                  | 1    | 0              | Free              | Full                 | FirstMB             |                                         |
| 1                                                                  | 1    | 0              | NotFree           | Full                 | LastMb              | Overrun                                 |
| 1                                                                  | 1    | 1              | None              | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 1              | Free              | X                    | FirstMB             |                                         |
| 1                                                                  | 1    | 1              | NotFree           | NotFull              | FIFO                |                                         |
| 1                                                                  | 1    | 1              | NotFree           | Full                 | LastMb              | Overrun                                 |

1. This is a don't care condition.

2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).

## Functional description

3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe Mailbox inactivation (see [Mailbox inactivation](#)) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not "free-to-receive", so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Refer to the description of the Rx Individual Mask Registers (RXIMRx). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXGMASK, RX14MASK, RX15MASK and RXFGMASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

### 37.5.5 Move process

There are two types of move process: move-in and move-out.

#### 37.5.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see [Matching process](#)) and all of the following conditions are true:

- The CAN bus has reached or let past either:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB
- There is no ongoing matching process
- The destination Mailbox is not locked by the CPU
- There is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished
- There is a previous pending move-in to the same destination Mailbox
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled (MCR[SRXDIS] bit is asserted)
- Any CAN protocol error is detected

Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It only stays on hold waiting for exiting Freeze and Low-Power mode and to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;
5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see [Mailbox inactivation](#)) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed to alert the CPU that the Message Buffer content is temporarily incoherent.

### **37.5.5.2 Move-out**

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Section "Arbitration process"). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.

### **37.5.6 Data coherence**

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in [Transmit process](#) and [Receive process](#).

### 37.5.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] bit must be asserted
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze mode
- The module enters in BusOff state
- There is an overload frame

If none of the conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register, and an interrupt to the CPU is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. On the other hand, if one of the above conditions is reached, the frame is not transmitted; therefore, the abort code is written into the CODE field, the interrupt flag is set in the IFLAG, and an interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU just needs to read the abort code to make sure the active MB was *safely inactivated*. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

- CPU checks the corresponding IFLAG and clears it, if asserted.

- CPU writes 0b1001 into the CODE field of the C/S word.
- CPU waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
- CPU reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
- It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

### 37.5.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on Mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission Mailboxes must be performed just when MCR[AEN] bit is deasserted.

If a Mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See [Transmit process](#) and [Receive process](#) for more detailed instruction on how to inactivate and reactivate a Mailbox.

To inactivate a Mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because the user is not able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can lead to undesirable results:

- A frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter
- A frame containing the message within the inactivated Tx Mailbox may be transmitted without notice

In order to eliminate such risk and perform a *safe inactivation* the CPU must use the following mechanism along with the inactivation itself:

- For Tx Mailboxes, the Transmission Abort (see [Transmission abort mechanism](#))

The inactivation automatically unlocks the Mailbox (see [Mailbox lock mechanism](#)).

#### NOTE

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by

FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.

### 37.5.6.3 Mailbox lock mechanism

Other than Mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending-move and potentially may lose a received message. The MB locking is done to prevent a new frame to be written into the MB while the CPU is reading it.

#### NOTE

The locking mechanism applies only to Rx MBs that are not part of FIFO and have a code different than INACTIVE (0b0000) or EMPTY<sup>1</sup> (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

---

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.

### Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Section "Free Running Timer Register (TIMER)"), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see [Modes of operation](#)) and it will take place only when the module resumes to Normal or Freeze modes.

## 37.5.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting the MCR[RFEN] bit. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both Message Buffers and FIFO engine) is described in [Rx FIFO structure](#). The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is only valid whilst the IFLAG[BUF5I] is asserted.

The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also [Rx FIFO structure](#)):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

### Note

A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid while the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If the IRMQ bit is negated, then the FIFO filter table is affected by RXFGMASK.

## 37.5.8 CAN protocol related features

This section describes the CAN protocol related features.

### 37.5.8.1 Remote frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.
- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.
- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

### 37.5.8.2 Overload frames

FlexCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

### 37.5.8.3 Time stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

The Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in the description of the Control 1 Register (CTRL1).

### 37.5.8.4 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source bit CLKSRC in the CTRL1 Register defines whether the internal clock is connected to the output of a crystal oscillator (Oscillator Clock) or to the Peripheral Clock. In order to guarantee reliable operation, the clock source should be selected while the module is in Disable Mode (bit MDIS set in the Module Configuration Register).

**Figure 37-92. CAN engine clocking scheme**

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The oscillator clock has better jitter performance.

The FlexCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW. See the description of the Control 1 Register (CTRL1).

The PRESDIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

$$f_{Tq} = \frac{f_{CANCLK}}{(\text{Prescaler Value})}$$

A bit time is subdivided into three segments<sup>1</sup> (see [Figure 37-93](#) and [Table 37-106](#)):

- SYNC\_SEG: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section
- Time Segment 1: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL1 Register so that their sum (plus 2) is in the range of 4 to 16 time quanta
- Time Segment 2: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL1 Register (plus 1) to be 2 to 8 time quanta long

$$\text{Bit Rate} = \frac{f_{Tq}}{(\text{number of Time Quanta})}$$

1. For further explanation of the underlying concepts, see ISO/DIS 11519–1, Section 10.3. See also the CAN 2.0A/B protocol specification for bit timing.

**Figure 37-93. Segments within the bit time**

Whenever CAN bit is used as a measure of duration (for example, MCR[FRZACK] and MCR[LPMACK]), the number of peripheral clocks in one CAN bit can be calculated as:

$$NCCP = \frac{f_{SYS} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRES DIV + 1)}{f_{CANCLK}}$$

where:

- NCCP is the number of peripheral clocks in one CAN bit;
- $f_{CANCLK}$  is the Protocol Engine (PE) Clock (see Figure "CAN Engine Clocking Scheme"), in Hz;
- $f_{SYS}$  is the frequency of operation of the system (CHI) clock, in Hz;
- PSEG1 is the value in CTRL1[PSEG1] field;
- PSEG2 is the value in CTRL1[PSEG2] field;
- PROPSEG is the value in CTRL1[PROPSEG] field;
- PRES DIV is the value in CTRL1[PRES DIV] field.

For example, 180 CAN bits = 180 x NCCP peripheral clock periods.

**Table 37-106. Time segment syntax**

| Syntax         | Description                                                                                                                                    |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| SYNC_SEG       | System expects transitions to occur on the bus during this period.                                                                             |
| Transmit Point | A node in transmit mode transfers a new value to the CAN bus at this point.                                                                    |
| Sample Point   | A node samples the bus at this point. If the three samples per bit option is selected, then this point marks the position of the third sample. |

The following table gives an overview of the CAN compliant segment settings and the related parameter values.

**Table 37-107. Bosch CAN 2.0B standard compliant bit time segment settings**

| Time segment 1 | Time segment 2 | Re-synchronization jump width |
|----------------|----------------|-------------------------------|
| 5 .. 10        | 2              | 1 .. 2                        |
| 4 .. 11        | 3              | 1 .. 3                        |
| 5 .. 12        | 4              | 1 .. 4                        |
| 6 .. 13        | 5              | 1 .. 4                        |
| 7 .. 14        | 6              | 1 .. 4                        |
| 8 .. 15        | 7              | 1 .. 4                        |
| 9 .. 16        | 8              | 1 .. 4                        |

### Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1). For bit time calculations, use an IPT (Information Processing Time) of 2, which is the value implemented in the FlexCAN module.

#### 37.5.8.5 Arbitration and matching timing

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.

**Figure 37-94. Matching and move-in time windows**

Figure 37-95. Arbitration and move-out time windows

Figure 37-96. Arbitration at the end of bus off and move-out time windows

**NOTE**

The matching and arbitration timing shown in the preceding figures do not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN sub-blocks.

When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time slot. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in [Table 37-107](#)
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, see [Clock domains and restrictions](#)
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table:

**Table 37-108. Minimum ratio between peripheral clock frequency and CAN bit rate**

| Number of Message Buffers | RFEN | Minimum number of peripheral clocks per CAN bit |
|---------------------------|------|-------------------------------------------------|
| 16 and 32                 | 0    | 16                                              |
| 64                        | 0    | 25                                              |
| 16                        | 1    | 16                                              |
| 32                        | 1    | 17                                              |

*Table continues on the next page...*

**Table 37-108. Minimum ratio between peripheral clock frequency and CAN bit rate (continued)**

| Number of Message Buffers | RFEN | Minimum number of peripheral clocks per CAN bit |
|---------------------------|------|-------------------------------------------------|
| 64                        | 1    | 30                                              |

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, therefore the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in the preceding table can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRES DIV, PROPSEG, PSEG1, PSEG2) contained in the Control 1 Register (CTRL1).

In case of synchronous operation (when the peripheral clock frequency is equal to the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by selecting an adequate value for PRES DIV in order to meet the requirement in the preceding table. In case of asynchronous operation (the peripheral clock frequency greater than the oscillator clock frequency), the number of peripheral clocks per CAN bit can be adjusted by both PRES DIV and/or the frequency ratio.

As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRES DIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

### 37.5.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The Bus Domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The Oscillator Domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CTRL1[CLKSRC] bit is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator domain clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the Bus Domain clock frequency must always be greater than the Oscillator Domain clock frequency.

### NOTE

Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

## 37.5.10 Modes of operation details

The FlexCAN module has functional modes and low-power modes. See [Modes of operation](#) for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

### CAUTION

“Permanent Dominant” failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a “Permanent Dominant”, the corresponding acknowledge can never be asserted.

### 37.5.10.1 Freeze mode

This mode is requested by the CPU through the assertion of the HALT bit in the MCR Register or when the chip is put into Debug mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in a low-power mode. The acknowledgement is obtained through the assertion by the FlexCAN of FRZ\_ACK bit in the same register. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off or Idle state
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores the Rx input pin and drives the Tx pin as recessive
- Stops the prescaler, thus halting all CAN protocol activities

- Grants write access to the Error Counters Register, which is read-only in other modes
- Sets the NOT\_RDY and FRZ\_ACK bits in MCR

After requesting Freeze mode, the user must wait for the FRZ\_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK\_SRC] bit that can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates the FRZ bit in the MCR Register
- The chip is removed from Debug Mode and/or the HALT bit is negated

The FRZ\_ACK bit is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

### **37.5.10.2 Module Disable mode**

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM\_ACK bit in the same register. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM\_ACK bit and negates the FRZ\_ACK bit.

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPM\_ACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

### 37.5.10.3 Doze mode

This is a system low power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, the DOZE bit in MCR Register needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion by the FlexCAN of the LPMACK bit in the same register. The CPU must only consider the FlexCAN in Doze mode when both request and acknowledgement conditions are satisfied.

If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the clocks to the PE and CHI sub-modules, sets the LPMACK bit and negates the FRZACK bit. If Doze Mode is triggered during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Shuts down the clocks to the PE and CHI sub-modules
- Sets the NOTRDY and LPMACK bits in MCR

The Bus Interface Unit continues to operate, enabling the CPU to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Doze Mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request
- CPU negating the DOZE bit of the MCR Register

### **37.5.10.4 Stop mode**

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and the acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets the LPMACK bit, negates the FRZACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets the NOTRDY and LPMACK bits in MCR
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop Mode request.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates the LPMACK bit. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

## 37.5.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Error, ECC Host Access Non-correctable Error, ECC FlexCAN Access Non-correctable Error, ECC Correctable Error, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes it to 1 (unless another interrupt is generated at the same time).

### Note

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled ( $\text{MCR}[\text{RFEN}] = 1$ ), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag," and bits 4-0 are unused. See the description of IFLAG1 for more information.

For a combined interrupt where multiple MB interrupt sources are ORed together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The interrupt sources for Bus Off, Error, Tx Warning, and Rx Warning generate interrupts like the MB interrupt sources, and they can be read from ESR1 and ESR2. The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in CTRL1.

The interrupt sources for ECC errors—Host Access with Non-correctable Interrupt Flag, FlexCAN Access with Non-correctable Interrupt Flag, and Correctable Error Interrupt Flag—can be read in ERRSR and the corresponding interrupts masks bits are located in MECR.

## 37.5.12 Bus interface

The CPU access to FlexCAN registers are subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table "Module Memory Map" in Supervisor Mode or with S only) results in access error.
- Read and write access to implemented reserved address space results in access error.
- Write access to positions whose bits are all currently read-only results in access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. Refer to register and bit descriptions for details.
- Read and write access to unimplemented address space results in access error.
- Read and write access to RAM located positions during Low Power Mode results in access error.
- If MAXMB is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN is configured with 16 MBs, RFFN is 0x0, and MAXMB is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one Individual Mask and the available memory in the Mask Registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.

## 37.5.13 Detection and Correction of Memory Errors

FlexCAN supports detection and correction of errors in memory read accesses. Each byte of FlexCAN memory is associated to 5 parity bits and the error correction mechanism assures that in this 13-bit word, errors in one bit can be corrected (corrected errors) and errors in 2 bits can be detected but not corrected (non-corrected errors). Errors in more than 2 bits may not be detected. When read, the parity bits are used to calculate a syndrome, which indicates the error in each byte.

Memory errors are indicated to Host through status register (Error Status Register (ERRSR)) and bus transfer errors, and reported through report registers (Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR)).

The error detection and correction mechanism can be activated or not, controlled by ECCDIS bit in Memory Error Control Register (MECR). When disabled, updates on indications and reporting registers are stopped, but the parity bits are still calculated and written along with data in memory write operations. It assures that memory has consistent parity bits associated to data.

### NOTE

All FlexCAN memory must be initialized before starting its operation in order to have the parity bits in memory properly updated. The WRMFRZ bit in Control 2 Register (CTRL2) grants write access to all memory positions from 0x080 to 0xADF.

To avoid that critical error correction configuration be accidentally changed, this protocol must be followed to enable the update of the Memory Error Control Register (MECR):

1. By default, ECRWRE bit in Control 2 Register (CTRL2) is 0 and ECRWRDIS bit in Memory Error Control Register (MECR) is 1.
2. Set ECRWRE bit in Control 2 Register (CTRL2).
3. Clear ECRWRDIS bit.
4. All writes to Memory Error Control Register (MECR) must keep ECRWRDIS cleared.
5. After configuration is done, lock the Memory Error Control Register (MECR) by either setting ECRWRDIS or clearing ECRWRE.

### 37.5.13.1 Sources of the Memory Access

The FlexCAN memory can be accessed by 2 major sources (or requestors):

- by Host (CPU): largest word accessed is 32-bit wide
- by FlexCAN internals processes (Match, Arbitration, RxMove on reception, TxMove on transmission): largest word accessed is 64-bit wide

The way that non-correctable errors are indicated and reported depends on the source of access.

### 37.5.13.2 Error Indication

Memory errors are indicated by flags HANCEIF, FANCEIF, CEIF in the Error Status Register (ERRSR). Non-correctable errors detected in memory reads requested by Host are indicated separately than the ones detected in requests by FlexCAN internal processes. Corrected errors indication makes no distinction of the source of the access. There are 3 independent flags for these 3 cases, and each flag will raise an interrupt unless it is masked by mask bits in Memory Error Control Register (MECR). If both non-corrected and corrected errors are found in different bytes in the same read operation both flags are set.

The non-corrected error detected in Host accesses are also indicated as a bus transfer error. A bus wait request may be asserted to extend the memory transaction to the moment the report registers are updated. This indication cannot be masked. If the flag bit HANCEIF is not masked, the same non-corrected error will raise a bus transfer error and an interrupt request.

Each indication flag has one Overrun flag in Error Status Register (ERRSR). The Overrun flags do not request interrupts. Overrun flags for non-correctable errors indicate that other errors of the same nature were detected after current error being treated, while overrun flags for correctable errors indicate that other errors of the same nature were detected before the current error being treated. This is the recommended handling sequence for error indication:

1. Get error report information from report registers
2. Use this information to take proper measures in the application
3. Clear the Interrupt flag
4. If the Overrun flag is active:
  - a. Alert application that at least one error could not be handled
  - b. Clear the Overrun flag

The FlexCAN internal processes can access memory in transactions larger than 32-bits. For the indication, this kind of access is considered a consecutive sequence of 32-bit accesses. If errors are found in 2 or more 32-bit words the Interrupt and Overrun flags are set simultaneously.

### 37.5.13.3 Error Reporting

Report registers Error Report Address Register (RERRAR), Error Report Data Register (RERRDR) and Error Report Syndrome Register (RERRSYNR) provide detailed information about the address read, raw data and syndrome read with error and indicated by the flags described in the “Error Indication” section. The address, data and syndrome registers are updated simultaneously along with the error flags, according to these rules.

1. If any of the 2 non-corrected error flags is currently set, does not update the registers (preserve the old non-corrected error reporting)
2. Else (no error flag is currently set or only the corrected error flag is currently set), update the report registers according to the new error; or according to the most severe of new errors if non-corrected and corrected errors are simultaneously detected

Reporting of errors detected in accesses larger than 32-bit follows the semantic described in the “Error Indication” section and in the Error Report Address Register (RERRAR) description.

The address reported in RERRAR and defined in ERRIAR are not the same listed in the module memory map. How the reported addresses correspond to locations in the module memory map is shown in the Error Injection Address Register (ERRIAR) description.

Addresses reported when reading memory portions organized as FIFOs, such as the Rx FIFO Structure and the Rx FIFO Information Register (RXFIR), refer to the address of the element accessed in the FIFO, not to the FIFO base address.

To assure coherence of the error report registers it is necessary to turn off the report update by clearing the MECR[RERRDIS] bit before reading the report registers.

### 37.5.13.4 Response to Errors

Correctable errors have no consequence on FlexCAN operation, once the corrected data is used by Host or FlexCAN internal processes. For host-initiated reads, a non-corrected error detected does not affect FlexCAN operation.

Non-corrected errors detected on memory reads requested by FlexCAN do not stop the FlexCAN processing and this may result in incorrect operation.

If a non-corrected error occurs during a reception process (Match or RxMove), an incorrect destination may be selected to store the incoming frame, a corrupted frame may be stored in the correct destination, or both. If a non-corrected error occurs during either an Arbitration or a TxMove process, either a non-highest priority frame may be mistakenly selected to be transmitted or no frame may be transmitted at all, when MECR[NCEFAFRZ] = 1.

The error report registers can provide information to the application for a customized handling of these situations. If the delay of this handling is not accepted and MECR[NCEFAFRZ] = 1, the FlexCAN stops operation automatically and enters Freeze mode when these errors are detected. See the Memory Error Control Register (MECR) description for more details.

### 37.5.13.5 Error Injection

The error injection registers ERRIAR, ERRIDPR, and ERRIPPR are used to inject errors in memory reads in order to force errors and consequently update the indication and reporting registers. How the error injection addresses correspond to locations in the module memory map is shown in the ERRIAR description.

The injection is done by flipping the data and parity bits correspondent to the bits in 1 in ERRIDPR and ERRIPPR. Injection can be selected specifically for memory accesses requested by Host or by FlexCAN internal processes.

In case of accesses larger than 32-bits, the EXTERRIE bit in Memory Error Control Register (MECR) extends the injection pattern, replicating it in 32-bit words to fill the width of the access.

#### NOTE

It is very unlikely, but error injection may correct a bit with error. This will not raise the error flags and reports as expected.

To ensure coherence among error injection registers and avoid spurious error injections, the HAERRIE and FAERRIE bits in Memory Error Control Register (MECR) must be cleared while configuring the memory injection registers.

## 37.6 Initialization/application information

This section provide instructions for initializing the FlexCAN module.

### 37.6.1 FlexCAN initialization sequence

The FlexCAN module may be reset as follows:

- Chip level hard reset, which resets all memory mapped registers asynchronously
- SOFTRST bit in MCR, which resets some of the memory mapped registers synchronously. See [Table 37-2](#) to see what registers are affected by soft reset.

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFTRST bit remains asserted while soft reset is pending, so software can poll this bit to

know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in a low power mode. The low power mode should be exited and the clocks resumed before applying soft reset.

The clock source (CLKSRC bit) should be selected while the module is in Disable mode. After the clock source is selected and the module is enabled (MDIS bit negated), FlexCAN automatically goes to Freeze mode. In Freeze mode, FlexCAN is unsynchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZACK and NOTRDY bits in the MCR Register are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN is put into Freeze mode; see [Freeze mode](#). The following is a generic initialization sequence applicable to the FlexCAN module:

- Initialize the Module Configuration Register
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRNEN bit
  - If required, disable frame self reception by setting the SRXDIS bit
  - Enable the Rx FIFO by setting the RFEN bit
  - Enable the abort mechanism by setting the AEN bit
  - Enable the local priority feature by setting the LPRIOEN bit
- Initialize the Control Register
  - Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  - Determine the bit rate by programming the PRESDIV field
  - Determine the internal arbitration mode (LBUF bit)
- Initialize the Message Buffers
  - The Control and Status word of all Message Buffers must be initialized
  - If Rx FIFO was enabled, the ID filter table must be initialized
  - Other entries in each Message Buffer should be initialized as required

- Initialize the Rx Individual Mask Registers
- When ECC is enabled, follow the initialization note in [Detection and Correction of Memory Errors](#)
- Set required interrupt mask bits in the IMASK Registers (for all MB interrupts) and in CTRL Register (for Bus Off and Error interrupts)
- Negate the HALT bit in MCR

Starting with the last event, FlexCAN attempts to synchronize to the CAN bus.

## **Chapter 38**

# **Modular CAN (M\_CAN)**

### **38.1 Chip-specific M\_CAN information**

#### **38.1.1 M\_CAN Message RAM allocation**

On this chip, each M\_CAN instance can address 1216 words in the Message RAM.

As a result, the Message RAM shared by the two M\_CAN instances supports 2432 words, or 9.5 KB.

#### **38.1.2 Introduction**

The M\_CAN subsystem includes:

- Two M\_CAN modules
- A Message RAM controller

The M\_CAN subsystem block diagram is shown in the following figure.

\*Refer to the Clocking chapter for M\_CAN clock details.

**Figure 38-1. M\_CAN subsystem block diagram**

## 38.1.3 Functional Description

### 38.1.3.1 Message RAM Controller

The Message RAM Controller has the arbiter for the accesses to the external Message RAM and the ECC (Error Code Correction) Controller for the external Message RAM data.

#### 38.1.3.1.1 Message RAM Arbiter

The Message RAM Arbiter is a dynamic round robin arbiter that selects which request is sent to the external Message RAM. These requests are made by the CPU, M\_CAN\_0, or M\_CAN\_1.

This arbiter ensures:

- 50% bandwidth for CPU accesses to the external Message RAM. The CPU does not wait for more than one clock cycle to access the external Message RAM (see examples 1 and 3).
- 50% bandwidth is shared between M\_CAN\_0 and M\_CAN\_1 accesses to the external Message RAM. Each M\_CAN waits at least one clock cycle to access the external Message RAM (see examples 1, 2, and 3).
- If there is no CPU request, all bandwidth is distributed to M\_CAN\_0 and M\_CAN\_1 (see example 2).
- If there are no M\_CAN\_0 and M\_CAN\_1 requests, all bandwidth is distributed to the CPU.
- If there are requests from only one M\_CAN, the other M\_CAN's bandwidth is distributed to the first M\_CAN (see example 1).

The following examples illustrate the dynamic arbiter scheme.

- **Example 1:** The following figure shows who accesses the external Message RAM when only CPU and M\_CAN\_0 try to access to it.

- **Example 2:** The following figure shows who accesses the external Message RAM when only M\_CAN\_0 and M\_CAN\_1 try to access to it.

- **Example 3:** The following figure shows who accesses the external Message RAM when the CPU, M\_CAN\_0, and M\_CAN\_1 try to access to it.

The read or write accesses to the external Message RAM use two clock cycles. In the first clock cycle, the address is available, and in the second, the data is available.

The arbiter has a pseudo address pre-fetching mechanism that allows the data of the previous access to overlap with the address of the current access. The pseudo address pre-fetching scheme saves multiple clock cycles when there are multiples accesses to the external Message RAM.

#### **38.1.3.1.2 ECC Controller**

The ECC Controller provides Single Error Correction / Double Error Detection (SECEDED). It guarantees single bit error correction and double bit error detection (without correction). The SECEDED code is not guaranteed to detect more than two bits with error.

Each 32 data bits of the external Message RAM is associated with 7 ECC bits. If all these 39 bits are zero or one, then it is flagged as non-correctable error.

For writes to the external Message RAM, the ECC bits (7-bit) are calculated using the data bits (32-bit). The data bits plus ECC bits (39-bit) are written into the specified memory address. The error detection and correction are performed on the reads from the external Message RAM.

When an M\_CAN accesses the external Message RAM, the ECC bits are calculated by the ECC Controller and they are sent to this M\_CAN.

#### **38.1.3.2 External Message RAM**

The external Message RAM supports only 32-bit write and read accesses.

The CPU can access the external Message RAM through the M\_CAN subsystem. In this case, the CPU can do 8/16/32-bit read accesses to the external Message RAM.

#### **38.1.3.3 Transfer Error**

The M\_CAN subsystem does not report any transfer error.

### **38.1.4 External Signals**

The M\_CAN subsystem external signals are shown in the following table.

**Table 38-1. M\_CAN subsystem external signals**

| Signal name | Direction | Description           |
|-------------|-----------|-----------------------|
| M_CAN_0_Rx  | input     | M_CAN_0 CAN Rx signal |
| M_CAN_0_Tx  | output    | M_CAN_0 CAN Tx signal |
| M_CAN_1_Rx  | input     | M_CAN_1 CAN Rx signal |
| M_CAN_1_Tx  | output    | M_CAN_1 CAN Tx signal |

## 38.2 Overview

The M\_CAN module is the new CAN Communication Controller IP-module that can be integrated as stand-alone device or as part of an ASIC. It is described in VHDL on RTL level, prepared for synthesis. The M\_CAN performs communication according to ISO11898-1 (Bosch CAN specification 2.0 part A,B) and to Bosch CAN FD specification V1.0. Additional transceiver hardware is required for connection to the physical layer.

The message storage is intended to be a single- or dual-ported Message RAM outside of the module. It is connected to the M\_CAN via the Generic Master Interface. Depending on the chosen ASIC integration, multiple M\_CAN controllers can share the same Message RAM.

All functions concerning the handling of messages are implemented by the Rx Handler and the Tx Handler. The Rx Handler manages message acceptance filtering, the transfer of received messages from the CAN Core to the Message RAM as well as providing receive message status information. The Tx Handler is responsible for the transfer of transmit messages from the Message RAM to the CAN Core as well as providing transmit status information.

Acceptance filtering is implemented by a combination of up to 128 filter elements where each one can be configured as a range, as a bit mask, or as a dedicated ID filter.

The M\_CAN can be connected to a wide range of Host CPUs via its 8/16/32-bit Generic Slave Interface. The M\_CAN's clock domain concept allows the separation between the high precision CAN clock and the Host clock, which may be generated by an FM-PLL.

### 38.2.1 Features

The following are the features of M\_CAN.

- Conforms with CAN protocol version 2.0 part A, B and ISO 11898-1

- CAN FD with up to 64 data bytes supported
- CAN Error Logging
- AUTOSAR support
- SAE J1939 support
- Improved acceptance filtering
- Two configurable Receive FIFOs
- Separate signalling on reception of High Priority Messages
- Up to 64 dedicated Receive Buffers
- Up to 32 dedicated Transmit Buffers
- Configurable Transmit FIFO
- Configurable Transmit Queue
- Configurable Transmit Event FIFO
- Direct Message RAM access for Host CPU
- Multiple M\_CANs may share the same Message RAM
- Programmable loop-back test mode
- Maskable module interrupts
- 8/16/32 bit Generic Slave Interface for connection customer-specific Host CPUs
- Two clock domains (CAN clock and Host clock)
- Power-down support
- Debug on CAN support

## 38.2.2 Block Diagram

Figure 38-2. M\_CAN Block Diagram

- **CAN Core:** CAN Protocol Controller and Rx/Tx Shift Register. Handles all ISO 11898-1 protocol functions. Supports 11-bit and 29-bit identifiers.
- **Sync:** Synchronizes signals from the Host clock domain to the CAN clock domain and vice versa.
- **Clk:** Synchronizes reset signal to the Host clock domain and to the CAN clock domain.
- **Cfg and Ctrl:** CAN Core related configuration and control bits.
- **Interrupt and Timestamp:** Interrupt control and 16-bit CAN bit time counter for receive and transmit timestamp generation.
- **Tx Handler:** Controls the message transfer from the external Message RAM to the CAN Core. A maximum of 32 Tx Buffers can be configured for transmission. Tx buffers can be used as dedicated Tx Buffers, as Tx FIFO, part of a Tx Queue, or as a combination of them. A Tx Event FIFO stores Tx timestamps together with the corresponding Message ID. Transmit cancellation is also supported.

- **Rx Handler:** Controls the transfer of received messages from the CAN Core to the external Message RAM. The Rx Handler supports two Receive FIFOs, each of configurable size, and up to 64 dedicated Rx Buffers for storage of all messages that have passed acceptance filtering. A dedicated Rx Buffer, in contrast to a Receive FIFO, is used to store only messages with a specific identifier. An Rx timestamp is stored together with each message. Up to 128 filters can be defined for 11-bit IDs and up to 64 filters for 29-bit IDs.
- Connects the M\_CAN to a customer specific Host CPU. The Generic Slave Interface is capable to connect to an 8/16/32-bit bus to support a wide range of interconnection structures.
- **Generic Master Interface:** Connects the M\_CAN access to an external 32-bit Message RAM. The maximum Message RAM size is 16 KB × 32-bit. A single M\_CAN can use at most 4.25K × 32 bit.
- All flags from the Interrupt Register IR as well as selected internal status and control signals are routed to this interface. The interface is intended for connection of the M\_CAN to a module-external interrupt unit or to other module-external components. The connection of these signals is optional.

### 38.2.3 Dual Clock Sources

To improve the EMC behavior, a spread spectrum clock can be used for the Host clock domain. Due to the high precision clocking requirements of the CAN Core, a separate clock without any modulation has to be provided as CAN clock.

Within the M\_CAN module there is a synchronization mechanism implemented to ensure save data transfer between the two clock domains.

#### Note

In order to achieve a stable function of the M\_CAN, the Host clock must always be faster than or equal to the CAN clock. Also, the modulation depth of a spread spectrum clock has to be regarded.

## 38.2.4 Dual Interrupt Lines

The module provides two interrupt lines. Interrupts can be routed either to M\_CAN interrupt 0 or to M\_CAN interrupt 1. By default all interrupts are routed to interrupt line M\_CAN interrupt 0. By programming ILE[EINT0] and ILE[EINT1], the interrupt lines can be enabled or disabled separately.

## 38.3 Memory Map and Register Description

After hardware reset, the registers of the M\_CAN hold the reset values listed in Table 1. Additionally the Bus\_Off state is reset and the output M\_CAN Tx is set to recessive (HIGH). The value 0x0001 (CCCR[INIT] = 1) in the CC Control Register enables software initialization. The M\_CAN does not influence the CAN bus until the CPU resets CCCR[INIT] to 0.

The M\_CAN module allocates an address space of 256 bytes. All registers are organized as 32-bit registers. The M\_CAN is accessible by the Host CPU via the Generic Slave Interface using a data width of 8 bit (byte access), 16 bit (half-word access), or 32 bit (word access). Write access by the Host CPU to registers/bits marked with “P=Protected Write” is possible only with CCCR[CCE]=1 AND CCCR[INIT]=1. There is a delay from writing to a command register until the update of the related status register bits due to clock domain crossing.

### CAUTION

In case the application software wants to access one of the reserved addresses in the M\_CAN register map (read or write access), interrupt flag IR[ARA] is set, and if enable the interrupt is signalled via the assigned interrupt line (m\_can\_int0 or m\_can\_int1).

**M\_CAN memory map**

| Address offset (hex) | Register name                                          | Width (in bits) | Access | Reset value                 | Section/ page               |
|----------------------|--------------------------------------------------------|-----------------|--------|-----------------------------|-----------------------------|
| 0                    | Core Release Register (M_CAN_CREL)                     | 32              | R      | <a href="#">See section</a> | <a href="#">38.3.1/1773</a> |

### M\_CAN\_ENDN field descriptions

| Field       | Description                                                       |
|-------------|-------------------------------------------------------------------|
| 0–31<br>ETV | Endianness Test Value<br>The endianness test value is 0x87654321. |

### 38.3.3 Data Bit Timing and Prescaler Register (M\_CAN\_DBTP)

This register is only writable if bits CCCR.CCE and CCCR.INIT are set. The CAN bit time may be programmed in the range of 4 to 49 time quanta. The CAN time quantum may be programmed in the range of 1 to 32 m\_can\_cclk periods.  $t_q = (DBRP + 1) \text{ mtq}$ .

DTSEG1 is the sum of Prop\_Seg and Phase\_Seg1. DTSEG2 is Phase\_Seg2.

Therefore the length of the bit time is (programmed values)  $[DTSEG1 + DTSEG2 + 3] t_q$  or (functional values)  $[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] t_q$ .

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

#### NOTE

With a M\_CAN clock of 8 MHz, the reset value of 0x00000A33 configures the M\_CAN for a data phase bit rate of 500 kBit/s.

#### NOTE

The bit rate configured for the CAN FD data phase via DBTP must be higher or equal to the bit rate configured for the arbitration phase via NBTP.

Address: 0h base + Ch offset = Ch

**38.3.4 Test Register (M\_CAN\_TEST)**

Write access to the Test Register has to be enabled by setting bit CCCR[TEST] to 1. All Test Register functions are set to their reset values when bit CCCR[TEST] is reset.

Loop Back Mode and software control of pin M\_CAN\_Tx are hardware test modes. Programming of TX other than 00 may disturb the message transfer on the CAN bus.

**38.3.5 RAM Watchdog Register (M\_CAN\_RWD)**

The RAM Watchdog monitors the READY output of the Message RAM. A Message RAM access via the M\_CAN's Generic Master Interface starts the Message RAM Watchdog Counter with the value configured by RWD[WDC]. The counter is reloaded with RWD[WDC] when the Message RAM signals successful completion by activating its READY output. In case there is no response from the Message RAM until the counter has counted down to zero, the counter stops and interrupt flag IR[WDI] is set. The RAM Watchdog Counter is clocked by the Host clock.

| 27<br>CSR  | <p>Clock Stop Request</p> <p>0 No clock stop is requested<br/>1 Clock stop requested. When clock stop is requested, first INIT and then CSA will be set after all pending transfer requests have been completed and the CAN bus reached idle.</p>                                                                                                                                                   |
| 28<br>CSA  | <p>Clock Stop Acknowledge</p> <p>0 No clock stop acknowledged<br/>1 M_CAN may be set in power down by stopping M_CAN input clocks.</p>                                                                                                                                                                                                                                                              |
| 29<br>ASM  | <p>Restricted Operation Mode</p> <p>Bit ASM can only be set by the Host when both CCE and INIT are set to '1'. The bit can be reset by the Host at any time. For a description of the Restricted Operation Mode see <a href="#">Restricted Operation Mode</a>.</p> <p>0 Normal CAN operation<br/>1 Restricted Operation Mode active</p>                                                             |
| 30<br>CCE  | <p>Configuration Change Enable</p> <p><b>NOTE:</b> This field has Protected Write status.</p> <p>0 The CPU has no write access to the protected configuration registers.<br/>1 The CPU has write access to the protected configuration registers (while CCCR[INIT] = 1)</p>                                                                                                                         |
| 31<br>INIT | <p>Initialization</p> <p><b>NOTE:</b> Due to the synchronization mechanism between the two clock domains, there may be a delay until the value written to INIT can be read back. Therefore the programmer has to assure that the previous value written to INIT has been accepted by reading INIT before setting INIT to a new value.</p> <p>0 Normal Operation<br/>1 Initialization is started</p> |

**38.3.7 Nominal Bit Timing and Prescaler Register (M\_CAN\_NBTP)**

This register is only writable if its CCCR[CCE] and CCCR[INIT] are set. The CAN bit time may be programmed in the range of 4 to 385 time quanta. The CAN time quantum may be programmed in the range of 1 to 512 m\_can\_cclk periods.  $tq = (NBRP + 1) mtq$ .

NTSEG1 is the sum of Prop\_Seg and Phase\_Seg1. NTSEG2 is Phase\_Seg2.

## Memory Map and Register Description

Therefore the length of the bit time is (programmed values)  $[NTSEG1 + NTSEG2 + 3] t_q$  or (functional values)  $[Sync\_Seg + Prop\_Seg + Phase\_Seg1 + Phase\_Seg2] t_q$ .

The Information Processing Time (IPT) is zero, meaning the data for the next bit is available at the first clock edge after the sample point.

### NOTE

With a CAN clock of 8 MHz, the reset value of 0x06000A03 configures the M\_CAN for a bit rate of 500 kBit/s.

#### M\_CAN\_ECR field descriptions

| Field           | Description                                                                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–7<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                           |
| 8–15<br>CEL     | CAN Error Logging<br>The counter is incremented each time when a CAN protocol error causes the Transmit Error Counter or the Receive Error Counter to be incremented. It is reset by read access to CEL. The counter stops at 0xFF; the next increment of TEC or REC sets interrupt flag IR[ELO]. |
| 16<br>RP        | Receive Error Passive<br>0 The Receive Error Counter is below the error passive level of 128<br>1 The Receive Error Counter has reached the error passive level of 128                                                                                                                            |
| 17–23<br>REC    | Receive Error Counter<br>Actual state of the Receive Error Counter, values between 0 and 127.                                                                                                                                                                                                     |
| 24–31<br>TEC    | Transmit Error Counter<br>Actual state of the Transmit Error Counter, values between 0 and 255.                                                                                                                                                                                                   |

### 38.3.13 Protocol Status Register (M\_CAN\_PSR)

#### NOTE

When a frame in CAN FD format has reached the data phase with BRS flag set, the next CAN event (error or valid frame) will be shown in DLEC instead of LEC. An error in a fixed stuff bit of a CAN FD CRC sequence will be shown as a Form Error, not Stuff Error.

#### NOTE

The Bus\_Off recovery sequence (see CAN Specification Rev. 2.0 or ISO11898-1) cannot be shortened by setting or resetting CCCR[INIT].

1. If the device goes Bus\_Off, it sets CCCR[INIT] and PSR[BO], stopping all bus activities.
2. After the user clears CCCR[INIT], the user must then wait for 129 occurrences of Bus Idle (129 \* 11 consecutive recessive bits) before normal CAN operation can resume.
  - During the waiting period, each time the device monitors a sequence of 11 recessive bits, a Bit0Error code (101b) is written to PSR[LEC].
  - These code writes enable the user to check readily whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the Bus\_Off recovery sequence.
  - ECR[REC] is used to count these sequences.
3. After the observation of the 129 occurrences of Bus Idle, the device clears PSR[BO].

Address: 0h base + 44h offset = 44h

| 29–31<br>LEC | Last Error Code<br>The LEC indicates the type of the last error to occur on the CAN bus. This field will be cleared to 0 when a message has been transferred (reception or transmission) without error.<br><b>NOTE:</b> This field is set by a read operation.<br>000 Error: No error occurred since LEC has been reset by successful reception or transmission<br>001 Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed<br>010 Form Error: A fixed format part of a received frame has the wrong format<br>011 AckError: The message transmitted by the M_CAN was not acknowledged by another node.<br>100 Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value 1), but the monitored bus value was dominant.<br>101 Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored bus value was recessive. During Bus_Off recovery this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceeding of the Bus_Off recovery sequence (indicating the bus is not stuck at dominant or continuously disturbed).<br>110 CRCError: The CRC check sum of a received message was incorrect. The CRC of an incoming message does not match with the CRC calculated from the received data.<br>111 NoChange: Any read access to the Protocol Status Register re-initializes the LEC to 7. When the LEC shows the value 7, no CAN bus event was detected since the last CPU read access to the Protocol Status Register. |

### 38.3.14 Transmitter Delay Compensation Register (M\_CAN\_TDCR)

Address: 0h base + 48h offset = 48h

#### M\_CAN\_TDCR field descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–16<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                               |
| 17–23<br>TDCO    | Transmitter Delay Compensation Offset.<br><br><b>NOTE</b><br>This field has Protected Write status.<br><br>0x00-0x7F Offset value defining the distance between the measured delay from M_CAN Tx to M_CAN Rx and the secondary sample point. Valid values are 0 to 127 mtq.                                                                                                                                           |
| 24<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                               |
| 25–31<br>TDCF    | Transmitter Delay Compensation Filter Window Length.<br><br><b>NOTE</b><br>This field has Protected Write status.<br><br>0x00-0x7F Defines the minimum value for the SSP position, dominant edges on M_CAN Rx that would result in an earlier SSP position are ignored for transmitter delay measurement. The feature is enabled when TDCF is configured to a value greater than TDCO. Valid values are 0 to 127 mtq. |

### 38.3.15 Interrupt Register (M\_CAN\_IR)

The flags are set when one of the listed conditions is detected (edge-sensitive). The flags remain set until the Host clears them. Aflag is cleared by writing a 1 to the corresponding bit position. Writing a 0 has no effect. Ahard reset will clear the register. The configuration of IE controls whether an interrupt is generated. The configuration of ILS controls on which interrupt line an interrupt is signalled.

Address: 0h base + 50h offset = 50h

**38.3.17 Interrupt Line Select Register (M\_CAN\_ILS)**

The Interrupt Line Select register assigns an interrupt generated by a specific interrupt flag from the Interrupt Register to one of the two module interrupt lines. For interrupt generation the respective interrupt line has to be enabled via ILE[EINT0] and ILE[EINT1]

0 = Interrupt assigned to interrupt line 0

1 = Interrupt assigned to interrupt line 1

Address: 0h base + 58h offset = 58h

| Field            | Description                                                                                                                                                                                                                                                                                                |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–25<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                    |
| 26–31<br>F1AI    | Rx FIFO 1 Acknowledge Index<br><br>After the CPU has read a message or a sequence of messages from Rx FIFO 1 it has to write the buffer index of the last element read from Rx FIFO 1 to F1AI. This will set the Rx FIFO 1 Get Index RXF1S[F1GI] to F1AI + 1 and update the FIFO 1 Fill Level RXF1S[F1FL]. |

### 38.3.33 Rx Buffer / FIFO Element Size Configuration Register (M\_CAN\_RXESC)

Configures the number of data bytes belonging to an Rx Buffer / Rx FIFO element. Data field sizes >8 bytes are intended for CAN FD operation only.

#### NOTE

In case the data field size of an accepted CAN frame exceeds the data field size configured for the matching Rx Buffer or Rx FIFO, only the number of bytes as configured by RXESC are stored to the Rx Buffer resp. Rx FIFO element. The rest of the frame's data field is ignored.

Address: 0h base + BCh offset = BCh

### 38.3.34 Tx Buffer Configuration Register (M\_CAN\_TXBC)

#### NOTE

Be aware that the sum of TFQS and NDTB may be not greater than 32. There is no check for erroneous configurations. The Tx Buffers section in the Message RAM starts with the dedicated Tx Buffers.

Address: 0h base + C0h offset = C0h

**38.3.35 Tx FIFO/Queue Status Register (M\_CAN\_TXFQS)**

The Tx FIFO/Queue status is related to the pending Tx requests listed in register TXBRP. Therefore the effect of Add/Cancellation requests may be delayed due to a running Tx scan (TXBRP not yet updated).

**NOTE**

In case of mixed configurations where dedicated Tx Buffers are combined with a Tx FIFO or a Tx Queue, the Put and Get Indices indicate the number of the Tx Buffer starting with the first dedicated Tx Buffers.

Example: For a configuration of 12 dedicated Tx Buffers and a Tx FIFO of 20 Buffers a Put Index of 15 points to the fourth buffer of the Tx FIFO.

Address: 0h base + C4h offset = C4h

**38.3.37 Tx Buffer Request Pending Register (M\_CAN\_TXBRP)****NOTE**

TXBRP bits which are set while a Tx scan is in progress are not considered during this particular Tx scan. In case a cancellation is requested for such a Tx Buffer, this Add Request is cancelled immediately, the corresponding TXBRP bit is reset.

|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | Each Tx Buffer has its own Cancellation Finished bit. The bits are set when the corresponding TXBRP bit is cleared after a cancellation was requested via TXBCR. In case the corresponding TXBRP bit was not set at the point of cancellation, CF is set immediately. The bits are reset when a new transmission is requested by writing 1 to the corresponding bit of register TXBAR. |
| 0     | No transmit buffer cancellation                                                                                                                                                                                                                                                                                                                                                        |

| 27–31<br>EFAI    | Event FIFO Acknowledge Index<br><br>After the CPU has read an element or a sequence of elements from the Tx Event FIFO it has to write the index of the last element read from Tx Event FIFO to EFAI. This will set the Tx Event FIFO Get Index TXEFS[EFGI] to EFAI + 1 and update the Event FIFO Fill Level TXEFS[EFFL]. |

38.4 Message RAM

For storage of Rx/Tx messages and for storage of the filter configuration a single- or dual-ported Message RAM has to be connected to the M\_CAN module.

NOTE

In case the MessageRAMis equipped with parity or ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing e.g. 0x00000000 to each Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR[BEC] (Bit Error Corrected) or IR[BEU] (Bit Error Uncorrected).

The Message RAM has a width of 32 bits. In case parity checking or ECC is used a respective number of bits has to be added to each word.

When operated in CAN FD mode the required Message RAM size strongly depends on the element size configured for Rx FIFO0, Rx FIFO1, Rx Buffers, and Tx Buffers via RXESC[F0DS], RXESC[F1DS], RXESC[RBDS], and TXESC[TBDS].

The M\_CAN module can be configured to allocate up to 4352 words in the Message RAM. For the actual amount of Message RAM on this chip, see the chip-specific M\_CAN information.

It is not necessary to configure each of the sections listed in the following figure, and there is no restriction with respect to the sequence of the sections.

**Figure 38-49. Message RAM configuration**

When the M\_CAN addresses the Message RAM it addresses 32-bit words, not single bytes. The configurable start addresses are 32-bit word addresses i.e. only bits 15 to 2 are evaluated, the two least significant bits are ignored.

### NOTE

The M\_CAN does not check for erroneous configuration of the Message RAM. Especially the configuration of the start addresses of the different sections and the number of elements of each section has to be done carefully to avoid falsification or loss of data.

## 38.4.1 Rx Buffer and FIFO Element

Up to 64 Rx Buffers and two Rx FIFOs can be configured in the Message RAM. Each Rx FIFO section can be configured to store up to 64 received messages. The structure of a Rx Buffer / FIFO element is shown in the following table. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register RXESC.

**Table 38-49. Rx Buffer and FIFO Element**

**NOTE**

Depending on the configuration of the element size (RXESC), between two and sixteen 32-bit words ( $R_n = 3 \dots 17$ ) are used for storage of a CAN message's data field.

**38.4.2 Tx Buffer Element**

The Tx Buffers section can be configured to hold dedicated Tx Buffers as well as a Tx FIFO / Tx Queue. In case that the Tx Buffers section is shared by dedicated Tx buffers and a Tx FIFO / Tx Queue, the dedicated Tx Buffers start at the beginning of the Tx Buffers section followed by the buffers assigned to the Tx FIFO or Tx Queue. The Tx Handler distinguishes between dedicated Tx Buffers and Tx FIFO / Tx Queue by evaluating the Tx Buffer configuration TXBC.TFQS and TXBC.NDTB. The element size can be configured for storage of CAN FD messages with up to 64 bytes data field via register TXESC.

**NOTE**

Depending on the configuration of the element size (TXESC), between two and sixteen 32-bit words (Tn = 3 ..17) are used for storage of a CAN message's data field.

**38.4.3 Tx Event FIFO Element**

Each element stores information about transmitted messages. By reading the Tx Event FIFO the Host CPU gets this information in the order the messages were transmitted. Status information about the Tx Event FIFO can be obtained from register TXEFS.

**Table 38-53. Tx Event FIFO Element**

### 38.4.4 Standard Message ID Filter Element

Up to 128 filter elements can be configured for 11-bit standard IDs. When accessing a Standard Message ID Filter element, its address is the Filter List Standard Start Address SIDFC[FLSSA] plus the index of the filter element (0...127).

**Table 38-55. Standard Message ID Filter Element**

|    |          |           |             |    |     |   |             |   |

|  | SFID2[8:6]: Is used to control the M_CAN filter event pins at the Extension Interface. A one at the respective bit position enables generation of a pulse at the related filter event pin with the duration of one Host clock period in case the filter matches. |
|  | SFID2[5:0]: Defines the offset to the Rx Buffer Start Address RXBC.RBSA for storage of a matching message.                                                                                                                                                       |

### 38.4.5 Extended Message ID Filter Element

Up to 64 filter elements can be configured for 29-bit extended IDs. When accessing an Extended Message ID Filter element, its address is the Filter List Extended Start Address XIDFC[FLESA] plus two times the index of the filter element (0...63).

**Table 38-57. Extended Message ID Filter Element**

## 38.5 Functional Description

### 38.5.1 Operating Modes

#### 38.5.1.1 Software Initialization

Software initialization is started by setting bit CCCR[INIT], either by software or by a hardware reset, when an uncorrected bit error was detected in the Message RAM, or by going Bus\_Off. While CCCR[INIT] is set, message transfer from and to the CAN bus is stopped, the status of the CAN bus output M\_CAN\_Tx is recessive (HIGH). The counters of the Error Management Logic EML are unchanged. Setting CCCR[INIT] does not change any configuration register. Resetting CCCR[INIT] finishes the software

initialization. Afterwards the Bit Stream Processor BSP synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (= Bus\_Idle) before it can take part in bus activities and start the message transfer.

Access to the M\_CAN configuration registers is only enabled when both bits CCCR[INIT] and CCCR[CCE] are set (protected write).

CCCR[CCE] can only be set/reset while CCCR[INIT] = 1. CCCR[CCE] is automatically reset when CCCR[INIT] is reset.

The following registers are reset when CCCR[CCE] is set

- HPMS – High Priority Message Status
- RXF0S – Rx FIFO 0 Status
- RXF1S – Rx FIFO 1 Status
- TXFQS – Tx FIFO/Queue Status
- TXBRP – Tx Buffer Request Pending
- TXBTO – Tx Buffer Transmission Occurred
- TXBCF – Tx Buffer Cancellation Finished
- TXEFS – Tx Event FIFO Status

The Timeout Counter value TOCV[TOC] is preset to the value configured by TOCC[TOP] when CCCR[CCE] is set.

In addition the state machines of the Tx Handler and Rx Handler are held in idle state while CCCR[CCE] = 1.

The following registers are only writable while CCCR[CCE] = 0

- TXBAR – Tx Buffer Add Request
- TXBCR – Tx Buffer Cancellation Request

CCCR[TEST] and CCCR[MON] can only be set by the Host while CCCR[INIT] = 1 and CCCR[CCE] = 1. Both bits may be reset at any time. CCCR[DAR] can only be set/reset while CCCR[INIT] = 1 and CCCR[CCE] = 1.

### **NOTE**

In case the Message RAM is equipped with parity or ECC functionality, it is recommended to initialize the Message RAM after hardware reset by writing e.g. 0x00000000 to each

Message RAM word to create valid parity/ECC checksums. This avoids that reading from uninitialized Message RAM sections will activate interrupt IR.BEC (Bit Error Corrected) or IR.BEU (Bit Error Uncorrected).

### 38.5.1.2 Normal Operation

Once the M\_CAN is initialized and CCCR.INIT is reset to zero, the M\_CAN synchronizes itself to the CAN bus and is ready for communication.

After passing the acceptance filtering, received messages including Message ID and DLC are stored into a dedicated Rx Buffer or into Rx FIFO 0 or Rx FIFO 1.

For messages to be transmitted dedicated Tx Buffers and/or a Tx FIFO or a Tx Queue can be initialized or updated. Automated transmission on reception of remote frames is not implemented.

### 38.5.1.3 CAN FD Operation

There are two variants in the CAN FD frame transmission, first the CAN FD frame without bit rate switching. The second variant is the CAN FD frame where control field, data field, and CRC field are transmitted with a higher bit rate than the beginning and the end of the frame.

The previously reserved bit in CAN frames with 11-bit identifiers and the first previously reserved bit in CAN frames with 29-bit identifiers will now be decoded as FDF bit. FDF = recessive signifies a CAN FD frame, FDF = dominant signifies a Classic CAN frame. In a CAN FD frame, the two bits following FDF, res and BRS, decide whether the bit rate inside of this CAN FD frame is switched. A CAN FD bit rate switch is signified by res = dominant and BRS = recessive. The coding of res = recessive is reserved for future expansion of the protocol. In case the M\_CAN receives a frame with FDF = recessive and res = recessive, it will signal a Protocol Exception Event by setting bit PSR[PXE]. When Protocol Exception Handling is enabled (CCCR[PXHD] = 0), this causes the operation state to change from Receiver (PSR[ACT] = 10) to Integrating (PSR[ACT] = 00) at the next sample point. In case Protocol Exception Handling is disabled (CCCR[PXHD] = 1), the M\_CAN will treat a recessive res bit as an form error and will respond with an error frame.

CAN FD operation is enabled by programming CCCR[FDOE]. In case CCCR[FDOE] = 1, transmission and reception of CAN FD frames is enabled. Transmission and reception of Classic CAN frames is always possible. Whether a CAN FD frame or a Classic CAN frame is transmitted can be configured via bit FDF in the respective Tx Buffer element.

With  $\text{CCCR}[\text{FDOE}] = 0$ , received frames are interpreted as Classic CAN frames, which leads to the transmission of an error frame when receiving a CAN FD frame. When CAN FD operation is disabled, no CAN FD frames are transmitted even if bit FDF of a Tx Buffer element is set.  $\text{CCCR}[\text{FDOE}]$  and  $\text{CCCR}[\text{BRSE}]$  can only be changed while  $\text{CCCR}[\text{INIT}]$  and  $\text{CCCR}[\text{CCE}]$  are both set.

With  $\text{CCCR}[\text{FDOE}] = 0$ , the setting of bits FDF and BRS is ignored and frames are transmitted in Classic CAN format. With  $\text{CCCR}[\text{FDOE}] = 1$  and  $\text{CCCR}[\text{BRSE}] = 0$ , only bit FDF of a Tx Buffer element is evaluated. With  $\text{CCCR}[\text{FDOE}] = 1$  and  $\text{CCCR}[\text{BRSE}] = 1$ , transmission of CAN FD frames with bit rate switching is enabled. All Tx Buffer elements with bits FDF and BRS set are transmitted in CAN FD format with bit rate switching.

A mode change during CAN operation is only recommended under the following conditions:

- The failure rate in the CAN FD data phase is significant higher than in the CAN FD arbitration phase. In this case disable the CAN FD bit rate switching option for transmissions.
- During system startup all nodes are transmitting Classic CAN messages until it is verified that they are able to communicate in CAN FD format. If this is true, all nodes switch to CAN FD operation.
- Wake-up messages in CAN Partial Networking have to be transmitted in Classic CAN format.
- End-of-line programming in case not all nodes are CAN FD capable. Non CAN FD nodes are held in Silent mode until programming has completed. Then all nodes switch back to Classic CAN communication.

In the CAN FD format, the coding of the DLC differs from the standard CAN format. The DLC codes 0 to 8 have the same coding as in standard CAN, the codes 9 to 15, which in standard CAN all code a data field of 8 bytes, are coded according to the following table.

**Table 38-59. Coding of DLC in CAN FD**

| DLC                  | 9  | 10 | 11 | 12 | 13 | 14 | 15 |
|----------------------|----|----|----|----|----|----|----|
| Number of data bytes | 12 | 16 | 20 | 24 | 32 | 48 | 64 |

In CAN FD frames, the bit timing will be switched inside the frame, after the BRS (Bit Rate Switch) bit, if this bit is recessive. Before the BRS bit, in the CAN FD arbitration phase, the standard CAN bit timing is used as defined by the Bit Timing and Prescaler Register BTP. In the following CAN FD data phase, the fast CAN bit timing is used as

defined by the Fast Bit Timing and Prescaler Register FBTP. The bit timing is switched back from the fast timing at the CRC delimiter or when an error is detected, whichever occurs first.

The maximum configurable bit rate in the CAN FD data phase depends on the CAN clock frequency. Example: with a CAN clock frequency of 20 MHz and the shortest configurable bit time of 4 tq, the bit rate in the data phase is 5 Mbit/s.

In both data frame formats, CAN FD long and CAN FD fast, the value of the bit ESI (Error Status Indicator) is determined by the transmitter's error state at the start of the transmission. If the transmitter is error passive, ESI is transmitted recessive, else it is transmitted dominant.

### 38.5.1.4 Transmitter Delay Compensation

During the data phase of a CAN FD transmission only one node is transmitting, all others are receivers. The length of the bus line has no impact. When transmitting via pin M\_CAN\_Tx the M\_CAN receives the transmitted data from its local CAN transceiver via M\_CAN\_Rx pin. The received data is delayed by the transmitter delay. In case this delay is greater than TSEG1 (time segment before sample point), a bit error is detected. In order to enable a data phase bit time that is even shorter than the transmitter delay, the delay compensation is introduced. Without transmitter delay compensation, the bit rate in the data phase of a CAN FD frame is limited by the transmitter delay.

#### 38.5.1.4.1 Description

The M\_CAN's protocol unit has implemented a delay compensation mechanism to compensate the transmitter delay, thereby enabling transmission with higher bit rates during the CAN FD data phase independent of the delay of a specific CAN transceiver.

To check for bit errors during the data phase of transmitting nodes, the delayed transmit data is compared against the received data at the Secondary Sample Point SSP. If a bit error is detected, the transmitter will react on this bit error at the next following regular sample point. During arbitration phase the delay compensation is always disabled.

The transmitter delay compensation enables configurations where the data bit time is shorter than the transmitter delay, it is described in detail in the new ISO11898-1. It is enabled by setting bit DBTP[TDC].

The received bit is compared against the transmitted bit at the SSP. The SSP position is defined as the sum of the measured delay from the M\_CAN's transmit output M\_CAN\_Tx through the transceiver to the receive input M\_CAN\_Rx plus the transmitter delay compensation offset as configured by TDCR[TDCO]. The transmitter delay

compensation offset is used to adjust the position of the SSP inside the received bit (e.g. half of the bit time in the data phase). The position of the secondary sample point is rounded down to the next integer number of mtq.

PSR[TDCV] shows the actual transmitter delay compensation value. PSR[TDCV] is cleared when CCCR[INIT] is set and is updated at each transmission of an FD frame while DBTP[TDC] is set.

The following boundary conditions have to be considered for the transmitter delay compensation implemented in the M\_CAN:

- The sum of the measured delay from M\_CAN\_Tx to M\_CAN\_Rx and the configured transmitter delay compensation offset TDCR[TDCO] has to be less than 6 bit times in the data phase.
- The sum of the measured delay from M\_CAN\_Tx to M\_CAN\_Rx and the configured transmitter delay compensation offset TDCR[TDCO] has to be less or equal 127 mtq. In case this sum exceeds 127 mtq, the maximum value of 127 mtq is used for transmitter delay compensation.
- The data phase ends at the sample point of the CRC delimiter, that stops checking of receive bits at the SSPs.

#### 38.5.1.4.2 Transmitter delay compensation measurement

If transmitter delay compensation is enabled by programming DBTP[TDC] = 1, the measurement is started within each transmitted CAN FD frame at the falling edge of bit FDF to bit res. The measurement is stopped when this edge is seen at the receive input M\_CAN\_Rx of the transmitter. The resolution of this measurement is one mtq.

Figure 38-50. Transmitter delay measurement

To avoid that a dominant glitch inside the received FDF bit ends the delay compensation measurement before the falling edge of the received res bit, resulting in a too early SSP position, the use of a transmitter delay compensation filter window can be enabled by programming TDCR[TDCF]. This defines a minimum value for the SSP position. Dominant edges on M\_CAN\_Rx, that would result in an earlier SSP position are ignored for transmitter delay measurement. The measurement is stopped when the SSP position is at least TDCR[TDCF] AND M\_CAN\_Rx is low.

### 38.5.1.5 Restricted Operation Mode

In Restricted Operation Mode the node is able to receive data and remote frames and to give acknowledge to valid frames, but it does not send data frames, remote frames, active error frames, or overload frames. In case of an error condition or overload condition, it does not send dominant bits, instead it waits for the occurrence of bus idle condition to resynchronize itself to the CAN communication. The error counters (ECR[REC], ECR[TEC]) are frozen while Error Logging (ECR[CEL]) is active. The Host can set the M\_CAN into Restricted Operation mode by setting bit CCCR[ASM]. The bit can only be set by the Host when both CCCR[CCE] and CCCR[INIT] are set to 1. The bit can be reset by the Host at any time.

Restricted Operation Mode is automatically entered when the Tx Handler was not able to read data from the Message RAM in time. To leave Restricted Operation Mode, the Host CPU has to reset CCCR[ASM].

The Restricted Operation Mode can be used in applications that adapt themselves to different CAN bit rates. In this case the application tests different bit rates and leaves the Restricted Operation Mode after it has received a valid frame.

#### NOTE

The Restricted Operation Mode must not be combined with the Loop Back Mode (internal or external).

### 38.5.1.6 Bus Monitoring Mode

The M\_CAN is set in Bus Monitoring Mode by programming CCCR.MON to one. In Bus Monitoring Mode (see ISO11898-1, 10.12 Bus monitoring), the M\_CAN is able to receive valid data frames and valid remote frames, but cannot start a transmission. In this mode, it sends only recessive bits on the CAN bus. If the M\_CAN is required to send a dominant bit (ACK bit, overload flag, active error flag), the bit is rerouted internally so that the M\_CAN monitors this dominant bit, although the CAN bus may remain in recessive state. In Bus Monitoring Mode, register TXBRP is held in reset state.

The Bus Monitoring Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits. The following figure shows the connection of signals M\_CAN Tx and Rx to the M\_CAN in Bus Monitoring Mode.

**Figure 38-51. Pin Control in Bus Monitoring Mode**

### 38.5.1.7 Disabled Automatic Retransmission

According to the CAN Specification (see ISO11898-1, 6.3.3 Recovery Management), the M\_CAN provides means for automatic retransmission of frames that have lost arbitration or that have been disturbed by errors during transmission. By default automatic retransmission is enabled. To support time-triggered communication as described in ISO 11898-1, chapter 9.2, the automatic retransmission may be disabled via CCCR[DAR].

#### 38.5.1.7.1 Frame Transmission in DAR mode

In DAR mode all transmissions are automatically cancelled after they started on the CAN bus. A Tx Buffer's Tx Request Pending bit TXBRP[TRPx] is reset after successful transmission, when a transmission has not yet been started at the point of cancellation, has been aborted due to lost arbitration, or when an error occurred during frame transmission.

- Successful transmission:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] not set
- Successful transmission in spite of cancellation:

- Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] set
- Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set
- Arbitration lost or frame transmission disturbed:
  - Corresponding Tx Buffer Transmission Occurred bit TXBTO[TOx] not set
  - Corresponding Tx Buffer Cancellation Finished bit TXBCF[CFx] set

In case of a successful frame transmission, and if storage of Tx events is enabled, a Tx Event FIFO element is written with Event Type ET = 10 (transmission in spite of cancellation).

### 38.5.1.8 Power Down (Sleep Mode)

The M\_CAN can be set into power down mode controlled by CC Control Register CCCR[CSR].

When all pending transmission requests have completed, the M\_CAN waits until bus idle state is detected. Then the M\_CAN sets then CCCR[INIT] to one to prevent any further CAN transfers. Now the M\_CAN acknowledges that it is ready for power down by setting CCCR[CSA] to one. In this state, before the clocks are switched off, further register accesses can be made. A write access to CCCR[INIT] will have no effect. Now the module input clocks: CAN clock and Host clock may be switched off.

To leave power down mode, the application has to turn on the module clocks before resetting CC Control Register flag CCCR[CSR]. The M\_CAN will acknowledge this by resetting output signal clock stop acknowledge and resetting CCCR[CSA]. Afterwards, the application can restart CAN communication by resetting bit CCCR[INIT].

### 38.5.1.9 Test Modes

To enable write access to register TEST, bit CCCR[TEST] has to be set to one. This allows the configuration of the test modes and test functions.

Four output functions are available for the CAN transmit pin M\_CAN\_Tx by programming TEST[TX]. Additionally to its default function – the serial data output – it can drive the CAN Sample Point signal to monitor the M\_CAN's bit timing and it can drive constant dominant or recessive values. The actual value at pin M\_CAN\_Rx can be read from TEST[RX]. Both functions can be used to check the CAN bus' physical layer.

Due to the synchronization mechanism between CAN clock and Host clock domain, there may be a delay of several Host clock periods between writing to TEST[TX] until the new configuration is visible at output pin M\_CAN\_Tx. This applies also when reading input pin M\_CAN\_Rx via TEST[RX].

### Note

Test modes should be used for production tests or self test only.  
The software control for pin M\_CAN\_Tx interferes with all CAN protocol functions. It is not recommended to use test modes for application.

#### 38.5.1.9.1 External Loopback Mode

The M\_CAN can be set in External Loopback Mode by programming TEST[LBCK] to one. In Loopback Mode, the M\_CAN treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into an Rx Buffer or an Rx FIFO. The following figure shows the connection of signals M\_CAN\_Tx and M\_CAN\_Rx to the M\_CAN in External Loopback Mode.

This mode is provided for hardware self-test. To be independent from external stimulation, the M\_CAN ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. In this mode the M\_CAN performs an internal feedback from its Tx output to its Rx input. The actual value of the input pin M\_CAN\_Rx is disregarded by the M\_CAN. The transmitted messages can be monitored at the pin M\_CAN\_Tx.

Figure 38-52. Pin Control in External Loopback Mode

### 38.5.1.9.2 Internal Loopback Mode

Internal Loopback Mode is entered by programming bits TEST[LBCK] and CCCR[MON] to one. This mode can be used for a "Hot Selftest", meaning the M\_CAN can be tested without affecting a running CAN system connected to the pins M\_CAN\_Tx and M\_CAN\_Rx. In this mode pin M\_CAN\_Rx is disconnected from the M\_CAN and pin M\_CAN\_Tx is held recessive. The following figure shows the connection of M\_CAN\_Tx and M\_CAN\_Rx to the M\_CAN in case of Internal Loopback Mode.

Figure 38-53. Pin Control in Internal Loopback Mode

### 38.5.2 Timestamp Generation

For timestamp generation the M\_CAN supplies a 16-bit wrap-around counter. A prescaler TSCC[TCP] can be configured to clock the counter in multiples of CAN bit times (1...16). The counter is readable via TSCV[TSC]. A write access to register TSCV resets the counter to zero. When the timestamp counter wraps around interrupt flag IR[TSW] is set.

On start of frame reception / transmission the counter value is captured and stored into the timestamp section of an Rx Buffer / Rx FIFO (RXTS[15:0]) or Tx Event FIFO (TXTS[15:0]) element.

### 38.5.3 Timeout Counter

To signal timeout conditions for Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO the M\_CAN supplies a 16-bit Timeout Counter. It operates as down-counter and uses the same prescaler controlled by TSCC[TCP] as the Timestamp Counter. The Timeout

Counter is configured via register TOCC. The actual counter value can be read from TOCV[TOC]. The Timeout Counter can only be started while CCCR[INIT] = 0. It is stopped when CCCR[INIT] = 1, e.g. when the M\_CAN enters Bus\_Off state.

The operation mode is selected by TOCC[TOS]. When operating in Continuous mode, the counter starts when CCCR[INIT] is reset. A write to TOCV presets the counter to the value configured by TOCC[TOP] and continues down-counting.

When the Timeout Counter is controlled by one of the FIFOs, an empty FIFO presets the counter to the value configured by TOCC[TOP]. Down-counting is started when the first FIFO element is stored. Writing to TOCV has no effect.

When the counter reaches zero, interrupt flag IR[TOO] is set. In Continuous Mode, the counter is immediately restarted at TOCC[TOP].

### **Note**

The clock signal for the Timeout Counter is derived from the CAN Core's sample point signal. Therefore the point in time where the Timeout Counter is decremented may vary due to the synchronization / re-synchronization mechanism of the CAN Core. If the baud rate switch feature in CAN FD is used, the timeout counter is clocked differently in arbitration and data field.

## **38.5.4 Rx Handling**

The Rx Handler controls the acceptance filtering, the transfer of received messages to the Rx Buffers or to one of the two Rx FIFOs, as well as the Rx FIFO's Put and Get Indices.

### **38.5.4.1 Acceptance filtering**

The M\_CAN offers the possibility to configure two sets of acceptance filters, one for standard identifiers and one for extended identifiers. These filters can be assigned to Rx Buffer or to Rx FIFO 0, 1. For acceptance filtering each list of filters is executed from element #0 until the first matching element. Acceptance filtering stops at the first matching element. The following filter elements are not evaluated for this message.

The main features are:

- Each filter element can be configured as
  - Range filter (from - to)

- Filter for one or two dedicated IDs
- Classic bit mask filter
- Each filter element is configurable for acceptance or rejection filtering
- Each filter element can be enabled / disabled individually
- Filters are checked sequentially, execution stops with the first matching filter element

Related configuration registers are:

- Global Filter Configuration (GFC)
- Standard ID Filter Configuration (SIDFC)
- Extended ID Filter Configuration (XIDFC)
- Extended ID AND Mask (XIDAM)

Depending on the configuration of the filter element (SFEC/EFEC) a match triggers one of the following actions:

- Store received frame in FIFO 0 or FIFO 1
- Store received frame in Rx Buffer
- Store received frame in Rx Buffer and generate pulse at filter event pin
- Reject received frame
- Set High Priority Message interrupt flag IR.HPM
- Set High Priority Message interrupt flag IR.HPM and store received frame in FIFO 0 or FIFO 1

Acceptance filtering is started after the complete identifier has been received. After acceptance filtering has completed, and if a matching Rx Buffer or Rx FIFO has been found, the Message Handler starts writing the received message data in portions of 32 bit to the matching Rx Buffer or Rx FIFO. If the CAN protocol controller has detected an error condition (e.g. CRC error), this message is discarded with the following impact on the affected Rx Buffer or Rx FIFO:

### **Rx Buffer**

New Data flag of matching Rx Buffer is not set, but Rx Buffer (partly) overwritten with received data. For error type see PSR[LEC] respectively PSR[DLEC].

### **Rx FIFO**

Put index of matching Rx FIFO is not updated, but related Rx FIFO element (partly) overwritten with received data. For error type see PSR[LEC] respectively PSR[DLEC]. In case the matching Rx FIFO is operated in overwrite mode, the boundary conditions described in "Rx FIFO Overwrite Mode" section have to be considered.

### **Note**

When an accepted message is written to one of the two Rx FIFOs, or into an Rx Buffer, the unmodified received identifier is stored independent of the filter(s) used. The result of the acceptance filter process is strongly depending on the sequence of configured filter elements.

#### **38.5.4.1.1 Range Filter**

The filter matches for all received frames with Message IDs in the range defined by SF1ID/SF2ID resp. EF1ID/EF2ID.

There are two possibilities when range filtering is used together with extended frames:

- EFT = "00": The Message ID of received frames is ANDed with the Extended ID AND Mask (XIDAM) before the range filter is applied
- EFT = "11": The Extended ID AND Mask (XIDAM) is not used for range filtering

#### **38.5.4.1.2 Filter for Specific IDs**

A filter element can be configured to filter for one or two specific Message IDs. To filter for one specific Message ID, the filter element has to be configured with SF1ID = SF2ID resp. EF1ID = EF2ID.

#### **38.5.4.1.3 Classic Bit Mask Filter**

Classic bit mask filtering is intended to filter groups of Message IDs by masking single bits of a received Message ID. With classic bit mask filtering SF1ID/EF1ID is used as Message ID filter, while SF2ID/EF2ID is used as filter mask.

A zero bit at the filter mask will mask out the corresponding bit position of the configured ID filter, e.g. the value of the received Message ID at that bit position is not relevant for acceptance filtering. Only those bits of the received Message ID where the corresponding mask bits are one are relevant for acceptance filtering.

In case all mask bits are one, a match occurs only when the received Message ID and the Message ID filter are identical. If all mask bits are zero, all Message IDs match.

#### 38.5.4.1.4 Standard Message ID Filtering

The following figure shows the flow for standard Message ID (11-bit Identifier) filtering. The Standard Message ID Filter element is described in [Standard Message ID Filter Element](#).

Controlled by the Global Filter Configuration GFC and the Standard ID Filter Configuration SIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

Figure 38-54. Standard Message ID Filter Path

### 38.5.4.1.5 Extended Message ID Filtering

The figure below shows the flow for extended Message ID (29-bit Identifier) filtering. The Extended Message ID Filter element is described in [Extended Message ID Filter Element](#).

Controlled by the Global Filter Configuration GFC and the Extended ID Filter Configuration XIDFC Message ID, Remote Transmission Request bit (RTR), and the Identifier Extension bit (IDE) of received frames are compared against the list of configured filter elements.

The Extended ID AND Mask XIDAM is ANDed with the received identifier before the filter list is executed.

**Figure 38-55. Extended Message ID Filter Path**

### 38.5.4.1.6 Rx FIFOs

Rx FIFO 0 and Rx FIFO 1 can be configured to hold up to 64 elements each. Configuration of the two Rx FIFOs is done via registers RXF0C and RXF1C.

Received messages that passed acceptance filtering are transferred to the Rx FIFO as configured by the matching filter element. For a description of the filter mechanisms available for Rx FIFO 0 and Rx FIFO 1 see [Acceptance filtering](#). The Rx FIFO element is described in [Rx Buffer and FIFO Element](#).

To avoid an Rx FIFO overflow, the Rx FIFO watermark can be used. When the Rx FIFO fill level reaches the Rx FIFO watermark configured by RXFnC[FnWM], interrupt flag IR[RFnW] is set. When the Rx FIFO Put Index reaches the Rx FIFO Get Index an Rx FIFO Full condition is signalled by RXFnS[FnF]. In addition interrupt flag IR[RFnF] is set.

**Figure 38-56. Rx FIFO Status**

When reading from an Rx FIFO, Rx FIFO Get Index RXFnS[FnGI] x FIFO Element Size has to be added to the corresponding Rx FIFO start address RXFnC[FnSA].

**Table 38-60. Rx Buffer / FIFO Element Size**

| RXESC.RBDS[2:0] RXESC.FnDS[2:0] | Data Field [bytes] | FIFO Element Size [RAM words] |
|---------------------------------|--------------------|-------------------------------|
| 000                             | 8                  | 4                             |
| 001                             | 12                 | 5                             |
| 010                             | 16                 | 6                             |
| 011                             | 20                 | 7                             |
| 100                             | 24                 | 8                             |
| 101                             | 32                 | 10                            |
| 110                             | 48                 | 14                            |
| 111                             | 64                 | 18                            |

#### 38.5.4.1.6.1 Rx FIFO Blocking Mode

The Rx FIFO blocking mode is configured by  $RXFnC[FnOM] = 0$ . This is the default operation mode for the Rx FIFOs.

When an Rx FIFO full condition is reached ( $RXFnS[FnPI] = RXFnS[FnGI]$ ), no further messages are written to the corresponding Rx FIFO until at least one message has been read out and the Rx FIFO Get Index has been incremented. An Rx FIFO full condition is signalled by  $RXFnS[FnF] = 1$ . In addition interrupt flag  $IR[RFnF]$  is set.

In case a message is received while the corresponding Rx FIFO is full, this message is discarded and the message lost condition is signalled by  $RXFnS[RFnL] = 1$ . In addition interrupt flag  $IR[RFnL]$  is set.

#### 38.5.4.1.6.2 Rx FIFO Overwrite Mode

The Rx FIFO overwrite mode is configured by  $RXFnC[FnOM] = 1$ .

When an Rx FIFO full condition ( $RXFnS[FnPI] = RXFnS[FnGI]$ ) is signalled by  $RXFnS[FnF] = 1$ , the next message accepted for the FIFO will overwrite the oldest FIFO message. Put and get index are both incremented by one.

When an Rx FIFO is operated in overwrite mode and an Rx FIFO full condition is signalled, reading of the Rx FIFO elements should start at least at get index + 1. The reason for that is, that it might happen, that a received message is written to the Message RAM (put index) while the CPU is reading from the Message RAM (get index). In this case inconsistent data may be read from the respective Rx FIFO element. Adding an offset to the get index when reading from the Rx FIFO avoids this problem. The offset depends on how fast the CPU accesses the Rx FIFO. The following figure shows an offset of two with respect to the get index when reading the Rx FIFO. In this case the two messages stored in element 1 and 2 are lost.

Figure 38-57. Rx FIFO Overflow Handling

After reading from the Rx FIFO, the number of the last element read has to be written to the Rx FIFO Acknowledge Index RXFnA[FnA]. This increments the get index to that element number. In case the put index has not been incremented to this Rx FIFO element, the Rx FIFO full condition is reset (RXFnS[FnF] = 0).

38.5.4.1.7 Dedicated Rx Buffers

The M\_CAN supports up to 64 dedicated Rx Buffers. The start address of the dedicated Rx Buffer section is configured via RXBC[RBSA].

For each Rx Buffer a Standard or Extended Message ID Filter Element with SFEC / EFEC = 111 and SFID2 / EFID2[10:9] = 00 has to be configured (see [Standard Message ID Filter Element](#) and [Extended Message ID Filter Element](#))

After a received message has been accepted by a filter element, the message is stored into the Rx Buffer in the Message RAM referenced by the filter element. The format is the same as for an Rx FIFO element. In addition the flag IR[DRX] (Message stored in Dedicated Rx Buffer) in the interrupt register is set.

Table 38-61. Example Filter Configuration for Rx buffers

| Filter Element | SFID1[10:0] EFID1[28:0] | SFID2[10:9] EFID2[10:9] | SFID2[5:0] EFID2[5:0] |
|----------------|-------------------------|-------------------------|-----------------------|
| 0              | ID message 1            | 00                      | 00 0000               |
| 1              | ID message 2            | 00                      | 00 0001               |
| 2              | ID message 3            | 00                      | 00 0010               |

After the last word of a matching received message has been written to the Message RAM, the respective New Data flag in register NDAT1,2 is set. As long as the New Data flag is set, the respective Rx Buffer is locked against updates from received matching frames. The New Data flags have to be reset by the Host by writing a 1 to the respective bit position.

While an Rx Buffer's New Data flag is set, a Message ID Filter Element referencing this specific Rx Buffer will not match, causing the acceptance filtering to continue. Following Message ID Filter Elements may cause the received message to be stored into another Rx Buffer, or into an Rx FIFO, or the message may be rejected, depending on filter configuration

#### **38.5.4.1.7.1 Rx Buffer Handling**

- Reset interrupt flag IR[DRX]
- Read New Data registers
- Read messages from Message RAM
- Reset New Data flags of processed messages

#### **38.5.4.1.8 Debug on CAN Support**

Debug messages are stored into Rx Buffers. For debug handling three consecutive Rx buffers (e.g. #61, #62, #63) have to be used for storage of debug messages A, B, and C. The format is the same as for an Rx Buffer or an Rx FIFO element.

Advantage: Fixed start address for the DMA transfers (relative to RXBC[RBSA]), no additional configuration required.

For filtering of debug messages Standard / Extended Filter Elements with SFEC / EFEC = 111 have to be set up. Messages matching these filter elements are stored into the Rx Buffers addressed by SFID2 / EFID2[5:0].

After message C has been stored, the DMA request output m\_can\_dma\_req is activated and the three messages can be read from the Message RAM under DMA control. The RAM words holding the debug messages will not be changed by the M\_CAN while m\_can\_dma\_req is activated. The behaviour is similar to that of an Rx Buffers with its New Data flag set.

After the DMA has completed the DMA unit sets m\_can\_dma\_ack. This resets m\_can\_dma\_req. Now the M\_CAN is prepared to receive the next set of debug messages.

### 38.5.4.1.8.1 Filtering for Debug Messages

Filtering for debug messages is done by configuring one Standard / Extended Message ID Filter Element for each of the three debug messages. To enable a filter element to filter for debug messages SFEC / EFEC has to be programmed to 111. In this case fields SFID1 / SFID2 and EFID1 / EFID2 have a different meaning (see [Standard Message ID Filter Element](#) and [Extended Message ID Filter Element](#)). While SFID2 / EFID2[10:9] controls the debug message handling state machine, SFID2 / EFID2[5:0] controls the location for storage of a received debug message.

When a debug message is stored, neither the respective New Data flag nor IR[DRX] are set. The reception of debug messages can be monitored via RXF1S[DMS].

**Table 38-62. Example Filter Configuration for Debug Messages**

| Filter Element | SFID1[10:0] EFID1[28:0] | SFID2[10:9] EFID2[10:9] | SFID2[5:0] EFID2[5:0] |
|----------------|-------------------------|-------------------------|-----------------------|
| 0              | ID debug message A      | 01                      | 11 1101               |
| 1              | ID debug message B      | 10                      | 11 1110               |
| 2              | ID debug message C      | 11                      | 11 1111               |

### 38.5.4.1.8.2 Debug Message Handling

The debug message handling state machine assures that debug messages are stored to three consecutive Rx Buffers in correct order. In case of missing messages the process is restarted. The DMA request is activated only when all three debug messages A, B, C have been received in correct order.

The status of the debug message handling state machine is signaled via RXF1S[DMS].

**Figure 38-58. Debug Message Handling State Machine**

T0: reset m\_can\_dma\_req output, enable reception of debug messages A, B, and C

T1: reception of debug message A

T2: reception of debug message A

T3: reception of debug message C

T4: reception of debug message B

T5: reception of debug messages A, B

T6: reception of debug message C

T7: DMA transfer completed

T8: reception of debug message A,B,C (message rejected)

### 38.5.5 Tx Handling

The Tx Handler handles transmission requests for the dedicated Tx Buffers, the Tx FIFO, and the Tx Queue. It controls the transfer of transmit messages to the CAN Core, the Put and Get Indices, and the Tx Event FIFO. Up to 32 Tx Buffers can be set up for message transmission. The CAN mode for transmission (Classic CAN or CAN FD) can be configured separately for each Tx Buffer element. The Tx Buffer element is described in [Tx Buffer Element](#). The table below describes the possible configurations for frame transmission.

**Table 38-63. Possible configurations for frame transmission**

| CCCR    |      | Tx Buffer Element |         | Frame Transmission            |
|---------|------|-------------------|---------|-------------------------------|
| BRSE    | FDOE | FDF               | BRS     |                               |
| ignored | 0    | ignored           | ignored | Classic CAN                   |
| 0       | 1    | 0                 | ignored | Classic CAN                   |
| 0       | 1    | 1                 | ignored | FD without bit rate switching |
| 1       | 1    | 0                 | ignored | Classic CAN                   |
| 1       | 1    | 1                 | 0       | FD without bit rate switching |
| 1       | 1    | 1                 | 1       | FD with bit rate switching    |

#### Note

AUTOSAR requires at least three Tx Queue Buffers and support of transmit cancellation.

The Tx Handler starts a Tx scan to check for the highest priority pending Tx request (Tx Buffer with lowest Message ID) when the Tx Buffer Request Pending register TXBRP is updated, or when a transmission has been started.

### 38.5.5.1 Transmit Pause

The transmit pause feature is intended for use in CAN systems where the CAN message identifiers are (permanently) specified to specific values and cannot easily be changed. These message identifiers may have a higher CAN arbitration priority than other defined messages, while in a specific application their relative arbitration priority should be inverse. This may lead to a case where one ECU sends a burst of CAN messages that cause another ECU's CAN messages to be delayed because that other messages have a lower CAN arbitration priority.

If, for example, CAN ECU-1 has the transmit pause feature enabled and is requested by its application software to transmit four messages, it will, after the first successful message transmission, wait for two CAN bit times of bus idle before it is allowed to start the next requested message. If there are other ECUs with pending messages, those messages are started in the idle time, they would not need to arbitrate with the next message of ECU-1. After having received a message, ECU-1 is allowed to start its next transmission as soon as the received message releases the CAN bus.

The transmit pause feature is controlled by bit CCCR.TXP. If the bit is set, the M\_CAN will, each time it has successfully transmitted a message, pause for two CAN bit times before starting the next transmission. This enables other CAN nodes in the network to transmit messages even if their messages have lower prior identifiers. Default is transmit pause disabled (CCCR[TXP] = 0).

This feature looses up burst transmissions coming from a single node and it protects against “babbling idiot” scenarios where the application program erroneously requests too many transmissions.

### 38.5.5.2 Dedicated Tx Buffers

Dedicated Tx Buffers are intended for message transmission under complete control of the Host CPU. Each Dedicated Tx Buffer is configured with a specific Message ID. In case that multiple Tx Buffers are configured with the same Message ID, the Tx Buffer with the lowest buffer number is transmitted first.

If the data section has been updated, a transmission is requested by an Add Request via TXBAR[ARn]. The requested messages arbitrate internally with messages from an optional Tx FIFO or Tx Queue and externally with messages on the CAN bus, and are sent out according to their Message ID.

A Dedicated Tx Buffer allocates Element Size 32-bit words in the Message RAM (see the following table). Therefore the start address of a Dedicated Tx Buffer in the Message RAM is calculated by adding transmit buffer index (0...31) x Element Size to the Tx Buffer Start Address TXBC[TBSA].

**Table 38-64. Tx Buffer / FIFO / Queue Element Size**

| TXESC.TBDS[2:0] | Data Field [bytes] | Element Size [RAM words] |
|-----------------|--------------------|--------------------------|
| 000             | 8                  | 4                        |
| 001             | 12                 | 5                        |
| 010             | 16                 | 6                        |
| 011             | 20                 | 7                        |
| 100             | 24                 | 8                        |
| 101             | 32                 | 10                       |
| 110             | 48                 | 14                       |
| 111             | 64                 | 18                       |

### 38.5.5.3 Tx FIFO

Tx FIFO operation is configured by programming TXBC[TFQM] to 0. Messages stored in the Tx FIFO are transmitted starting with the message referenced by the Get Index TXFQS[TFGI]. After each transmission the Get Index is incremented cyclically until the Tx FIFO is empty. The Tx FIFO enables transmission of messages with the same Message ID from different Tx Buffers in the order these messages have been written to the Tx FIFO. The M\_CAN calculates the Tx FIFO Free Level TXFQS[TFFL] as difference between Get and Put Index. It indicates the number of available (free) Tx FIFO elements.

New transmit messages have to be written to the Tx FIFO starting with the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request increments the Put Index to the next free Tx FIFO element. When the Put Index reaches the Get Index, Tx FIFO Full (TXFQS[TFQF] = 1) is signalled. In this case no further messages should be written to the Tx FIFO until the next message has been transmitted and the Get Index has been incremented.

When a single message is added to the Tx FIFO, the transmission is requested by writing a 1 to the TXBAR bit related to the Tx Buffer referenced by the Tx FIFO's Put Index.

When multiple (n) messages are added to the Tx FIFO, they are written to n consecutive Tx Buffers starting with the Put Index. The transmissions are then requested via TXBAR. The Put Index is then cyclically incremented by n. The number of requested Tx buffers should not exceed the number of free Tx Buffers as indicated by the Tx FIFO Free Level.

When a transmission request for the Tx Buffer referenced by the Get Index is cancelled, the Get Index is incremented to the next Tx Buffer with pending transmission request and the Tx FIFO Free Level is recalculated. When transmission cancellation is applied to any other Tx Buffer, the Get Index and the FIFO Free Level remain unchanged.

A Tx FIFO element allocates Element Size 32-bit words in the Message RAM (See [Table 38-64](#)). Therefore the start address of the next available (free) Tx FIFO Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS.TFQPI (0...31) x Element Size to the Tx Buffer Start Address TXBC[TBSA].

#### 38.5.5.4 Tx Queue

Tx Queue operation is configured by programming TXBC[TFQM] to 1. Messages stored in the Tx Queue are transmitted starting with the message with the lowest Message ID (highest priority). In case that multiple Queue Buffers are configured with the same Message ID, the Queue Buffer with the lowest buffer number is transmitted first.

New messages have to be written to the Tx Buffer referenced by the Put Index TXFQS[TFQPI]. An Add Request cyclically increments the Put Index to the next free Tx Buffer. In case that the Tx Queue is full (TXFQS[TFQF] = 1), the Put Index is not valid and no further message should be written to the Tx Queue until at least one of the requested messages has been sent out or a pending transmission request has been cancelled.

The application may use register TXBRP instead of the Put Index and may place messages to any Tx Buffer without pending transmission request.

A Tx Queue Buffer allocates Element Size 32-bit words in the Message RAM (see [Table 38-64](#)). Therefore the start address of the next available (free) Tx Queue Buffer is calculated by adding Tx FIFO/Queue Put Index TXFQS[TFQPI] (0...31) x Element Size to the Tx Buffer Start Address TXBC[TBSA].

### 38.5.5.5 Mixed Dedicated Tx Buffers / Tx FIFO

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx FIFO. The number of Dedicated Tx Buffers is configured by TXBC[NDTB]. The number of Tx Buffers assigned to the Tx FIFO is configured by TXBC[TFQS]. In case TXBC[TFQS] is programmed to zero, only Dedicated Tx Buffers are used.

**Figure 38-59. Example of mixed Configuration Dedicated Tx Buffers / Tx FIFO**

Tx prioritization:

- Scan Dedicated Tx Buffers and oldest pending Tx FIFO Buffer (referenced by TXFS[TFGI])
- Buffer with lowest Message ID gets highest priority and is transmitted next

### 38.5.5.6 Mixed Dedicated Tx Buffers / Tx Queue

In this case the Tx Buffers section in the Message RAM is subdivided into a set of Dedicated Tx Buffers and a Tx Queue. The number of Dedicated Tx Buffers is configured by TXBC.NDTB. The number of Tx Queue Buffers is configured by TXBC.TFQS. In case TXBC.TFQS is programmed to zero, only Dedicated Tx Buffers are used.

**Figure 38-60. Example of mixed Configuration Dedicated Tx Buffers / Tx Queue**

Tx prioritization:

- Scan all Tx Buffers with activated transmission request
- Tx Buffer with lowest Message ID gets highest priority and is transmitted next

### 38.5.5.7 Transmit Cancellation

The M\_CAN supports transmit cancellation. This feature is especially intended for gateway applications and AUTOSAR based applications. To cancel a requested transmission from a dedicated Tx Buffer or a Tx Queue Buffer the Host has to write a 1 to the corresponding bit position (= number of Tx Buffer) of register TXBCR. Transmit cancellation is not intended for Tx FIFO operation.

Successful cancellation is signalled by setting the corresponding bit of register TXBCF to 1.

In case a transmit cancellation is requested while a transmission from a Tx Buffer is already ongoing, the corresponding TXBRP bit remains set as long as the transmission is in progress. If the transmission was successful, the corresponding TXBTO and TXBCF bits are set. If the transmission was not successful, it is not repeated and only the corresponding TXBCF bit is set.

#### Note

In case a pending transmission is cancelled immediately before this transmission could have been started, there follows a short time window where no transmission is started even if another message is also pending in this node. This may enable another node to transmit a message which may have a lower priority than the second message in this node.

### 38.5.5.8 Tx Event Handling

To support Tx event handling the M\_CAN has implemented a Tx Event FIFO. After the M\_CAN has transmitted a message on the CAN bus, Message ID and timestamp are stored in a Tx Event FIFO element. To link a Tx event to a Tx Event FIFO element, the Message Marker from the transmitted Tx Buffer is copied into the Tx Event FIFO element.

The Tx Event FIFO can be configured to a maximum of 32 elements. The Tx Event FIFO element is described in [Tx Event FIFO Element](#).

The purpose of the Tx Event FIFO is to decouple handling transmit status information from transmit message handling i.e. a Tx Buffer holds only the message to be transmitted, while the transmit status is stored separately in the Tx Event FIFO. This has the advantage, especially when operating a dynamically managed transmit queue, that a Tx Buffer can be used for a new message immediately after successful transmission. There is no need to save transmit status information from a Tx Buffer before overwriting that Tx Buffer.

When a Tx Event FIFO full condition is signalled by IR[TEFF], no further elements are written to the Tx Event FIFO until at least one element has been read out and the Tx Event FIFO Get Index has been incremented. In case a Tx event occurs while the Tx Event FIFO is full, this event is discarded and interrupt flag IR[TEFL] is set.

To avoid a Tx Event FIFO overflow, the Tx Event FIFO watermark can be used. When the Tx Event FIFO fill level reaches the Tx Event FIFO watermark configured by TXEFC[EFWM], interrupt flag IR[TEFW] is set.

When reading from the Tx Event FIFO, two times the Tx Event FIFO Get Index TXEFS[EFGI] has to be added to the Tx Event FIFO start address TXEFC[EFSA].

### 38.5.6 FIFO Acknowledge Handling

The Get Indices of Rx FIFO 0, Rx FIFO 1, and the Tx Event FIFO are controlled by writing to the corresponding FIFO Acknowledge Index (see the registers RXF0A, RXF1A, and TXEFA). Writing to the FIFO Acknowledge Index will set the FIFO Get Index to the FIFO Acknowledge Index plus one and thereby updates the FIFO Fill Level. There are two use cases:

- When only a single element has been read from the FIFO (the one being pointed to by the Get Index), this Get Index value is written to the FIFO Acknowledge Index.
- When a sequence of elements has been read from the FIFO, it is sufficient to write the FIFO Acknowledge Index only once at the end of that read sequence (value: Index of the last element read), to update the FIFO's Get Index.

Due to the fact that the CPU has free access to the M\_CAN's Message RAM, special care has to be taken when reading FIFO elements in an arbitrary order (Get Index not considered). This might be useful when reading a High Priority Message from one of the two Rx FIFOs. In this case the FIFO's Acknowledge Index should not be written because this would set the Get Index to a wrong position and also alters the FIFO's Fill Level. In this case some of the older FIFO elements would be lost.

### Note

The application has to ensure that a valid value is written to the FIFO Acknowledge Index. The M\_CAN does not check for erroneous values.

# Chapter 39

## Deserial Serial Peripheral Interface (DSPI)

### 39.1 Chip-specific DSPI information

This chip implements five instances of the DSPI module. Some feature details vary among the instances.

The following table summarizes the feature differences. The table does not list feature details that all instances share.

**Table 39-1. DSPI instance feature differences**

| Feature                                                                                                    | DSPI_A | DSPI_B | DSPI_C | DSPI_D     | DSPI_E          |
|------------------------------------------------------------------------------------------------------------|--------|--------|--------|------------|-----------------|
| Serialization mechanisms defined in the SIU chapter                                                        | Yes    | Yes    | Yes    | Yes        | No <sup>1</sup> |
| Serial Data In (SIN) signals                                                                               | Yes    | Yes    | Yes    | Yes        | No              |
| PISRs and bit muxes are implemented                                                                        | Yes    | Yes    | Yes    | Yes        | No <sup>2</sup> |
| Hardware Trigger (HT)                                                                                      | Yes    | Yes    | Yes    | Yes        | No              |
| Clock and data signals (SCK and SOUT) are available on LVDS pairs to support microsecond bus functionality | No     | No     | Yes    | Yes        | No              |
| Output serialization bits used                                                                             | None   | [15:0] | [15:0] | [15:4,1:0] | None            |

1. DSPI\_E does not support serialization, except what is provided by the ASDR register.

2. The registers PSIR0, PSIR1, PSIR2, and PISR3 do not exist for DSPI\_E.

#### 39.1.1 DSPI and eMIOS direct connections

The following table shows direct connections between eMIOS and DSPI module instances.

**Table 39-2. DSPI and eMIOS direct connections**

| Source | Destination | Description                                                                |
|--------|-------------|----------------------------------------------------------------------------|
| DSPI_B | eMIOS_0     | Connection from DSPI_B deserial data out bit 14 to eMIOS_0 input channel 5 |
| DSPI_B | eMIOS_0     | Connection from DSPI_B deserial data out bit 15 to eMIOS_0 input channel 4 |
| DSPI_D | eMIOS_1     | Connection from DSPI_D deserial data out bit 14 to eMIOS_1 input channel 7 |
| DSPI_D | eMIOS_1     | Connection from DSPI_D deserial data out bit 15 to eMIOS_1 input channel 6 |

### 39.1.2 DSPI connections with SIU, eTPU, and eMIOS modules

Some DSPI deserialized outputs can be used to trigger external interrupt requests via the External Interrupt Input Multiplexing sub-block in the SIU. See [External IRQ Input Select Register \(SIU\\_EIISR\)](#) for details.

DSPI\_A, DSPI\_B, DSPI\_C, and DSPI\_D connect via SIU registers to channels of eTPU and eMIOS modules as well as GPO data registers. See [Pin serialization for DSPI](#) for more information. The following table lists the applicable SIU registers for each DSPI instance.

**Table 39-3. SIU registers for DSPI pin serialization**

| DSPI instance | SIU registers                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 39.2 Introduction

The deserial serial peripheral interface (DSPI) module provides a synchronous serial bus for communication between a chip and an external peripheral device. The module supports chip pin count reduction through serialization and deserialization of chip internal signals transmitted over the D SPI serial link.

### 39.2.1 Block Diagram

The block diagram of this module is as follows:

#### NOTE

SPI is used for both SPI Mode and DSI mode in this diagram.

Figure 39-1. DSPI Block Diagram

### 39.2.2 Features

The module supports the following features:

- Full-duplex, three-wire synchronous transfers
- Master mode
- Slave mode
- Data streaming operation in Slave mode with continuous slave selection
- Buffered transmit operation using the transmit first in first out (TX FIFO) with depth of 4 entries

- Buffered receive operation using the receive FIFO (RX FIFO) with depth of 4 entries
- Asynchronous clocking scheme for Register and Protocol Interfaces
- TX and RX FIFOs can be disabled individually for low-latency updates to DSPI queues
- Visibility into TX and RX FIFOs for ease of debugging
- Programmable transfer attributes on a per-frame basis:
  - eight transfer attribute registers
  - Serial clock (SCK) with programmable polarity and phase
  - Various programmable delays
  - Programmable serial frame size: 4 to 32
    - DSPI frames longer than 16 bits can be supported using the continuous selection format.
  - Continuously held chip select capability
  - Parity control
- 6 peripheral chip selects (PCSeS), expandable to 64 with external demultiplexer
- Deglitching support for up to 32 peripheral chip selects (PCSeS) with external demultiplexer
- DMA support for adding entries to TX FIFO and removing entries from RX FIFO:
  - TX FIFO is not full (TFFF)
  - RX FIFO is not empty (RFDF)
- Interrupt conditions:
  - End of Queue reached (EOQF)
  - TX FIFO is not full (TFFF)
  - Transfer of current frame complete (TCF)
  - Attempt to transmit with an empty Transmit FIFO (TFUF)
  - RX FIFO is not empty (RFDF)
  - Frame received while Receive FIFO is full (RFOF)
  - DSPI Parity Error (SPEF)

- Modified DSPI transfer formats for communication with slower peripheral devices
- Power-saving architectural features:
  - Support for Stop mode

The DSPI also supports pin reduction through serialization and deserialization if enabled for the module.

- Two sources of serialized data:
  - The module memory-mapped register
  - Parallel Input signals
  - Programmable selection of source data on bit basis
- Deserialized data is provided as Parallel Output signals and as bits in a memory-mapped register
- Interrupt conditions:
  - Deserialized data matches pre-programmed pattern (DDIF)
  - DSI Parity Error (DPEF)
- Transfer initiation conditions:
  - Continuous
  - Edge sensitive hardware trigger
  - Change in data
- Pin serialization/deserialization with interleaved DSPI frames for control and diagnostics
- Continuous serial communications clock

DSPI supports a combined DSPI and DSI modes of operation known as the Combined Serial Interface (CSI). It also supports the downstream Micro Second Channel in the Timed Serial Bus (TSB) configuration.

- Transmission of frames is done at frame boundaries
- Frames from DSPI and DSI are identifiable by a bit transmitted at the start of each frame
- Separate interrupts for frame completion from DSPI and DSI

### 39.2.3 Interface configurations

#### 39.2.3.1 DSPI configuration

The Serial Peripheral Interface DSPI configuration allows the module to send and receive serial data. This configuration allows the module to operate as a basic DSPI block with internal FIFOs supporting external queue operation. Transmitted data and received data reside in separate FIFOs. The host CPU or a DMA controller read the received data from the Receive FIFO and write transmit data to the Transmit FIFO.

For queued operations, the SPI queues can reside in system RAM, external to the module. Data transfers between the queues and the module FIFOs are accomplished by a DMA controller or host CPU. The following figure shows a system example with DMA, DSPI, and external queues in system RAM.

#### NOTE

SPI is used for both DSPI Mode and DSI mode in this diagram.

Figure 39-2. SPI with queues and DMA

#### 39.2.3.2 DSI configuration

In the Deserial Serial Interface (DSI) configuration, DSPI serializes up to 32 parallel input signals or register bits. DSPI also deserializes the received data to parallel output signals or to a memory-mapped register. DSPI transfers the data using an DSPI-like protocol.

Timed Serial Bus (TSB) mode provides the MicroSecond Channel (MSC) downstream support, serializing from 4 to 32 parallel input signals or register bits. For more information on TSB mode, see [Timed Serial Bus \(TSB\)](#).

### **39.2.3.3 CSI configuration**

The Combined Serial Interface (CSI) configuration supports further configuration as follows:

- Normal: A combination of the DSPI and DSI configurations. The DSPI interleaves DSI data frames with data frames. Interleaving is done on the frame boundaries.
- TSB: Transmission of DSPI data has higher priority than DSI data.

## **39.2.4 Modes of Operation**

The module supports the following modes of operation that can be divided into two categories:

- Module-specific modes:
  - Master mode
  - Slave mode
  - Module Disable mode
- Chip-specific modes:
  - External Stop mode

The module enters module-specific modes when the host writes a module register. The chip-specific modes are controlled by signals external to the module. The chip-specific modes are modes that a chip may enter in parallel to the block-specific modes.

### **39.2.4.1 Master Mode**

Master mode allows the module to initiate and control serial communication. In this mode, these signals are controlled by the module and configured as outputs:

- SCK
- PCS[x]

### 39.2.4.2 Slave Mode

Slave mode allows the module to communicate with DSPI/DSI bus masters. In this mode, the module responds to externally controlled serial transfers. The SCK signal and the PCS[0]/ $\overline{\text{SS}}$  signals are configured as inputs and driven by an SPI bus master.

### 39.2.4.3 Module Disable Mode

The Module Disable mode can be used for chip power management. The clock to the non-memory mapped logic in the module can be stopped while in the Module Disable mode.

### 39.2.4.4 External Stop Mode

External Stop mode is used for chip power management. The module supports the Peripheral Bus Stop mode mechanism. When a request is made to enter External Stop mode, it acknowledges the request and completes the transfer that is in progress. When the module reaches the frame boundary, it signals that the protocol clock to the module may be shut off.

#### NOTE

In master mode, if a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. In slave mode, this module waits until its chip select input signal goes high before it is ready to have its clocks shut off. It should be noted that the CS0 pad must be correctly configured to allow it to return to high when no transfer is occurring. If the pad is tied low then this could prevent the module from being correctly disabled.

## 39.3 Module signal descriptions

This table describes the signals on the boundary of the module that may connect off chip (in alphabetical order).

**Table 39-4. Module signal descriptions**

| Signal  | Master mode                  | Slave mode       | I/O |
|---------|------------------------------|------------------|-----|
| HT      | Hardware Trigger             | Hardware Trigger | I   |
| PCS0/SS | Peripheral Chip Select 0 (O) | Slave Select (I) | I/O |

*Table continues on the next page...*

**Table 39-4. Module signal descriptions (continued)**

| Signal                         | Master mode                                             | Slave mode       | I/O |
|--------------------------------|---------------------------------------------------------|------------------|-----|
| PCS[1:3]                       | Peripheral Chip Selects 1–3                             | (Unused)         | O   |
| PCS4                           | Peripheral Chip Select 4                                | (Unused)         | O   |
| PCS5/ $\overline{\text{PCSS}}$ | Peripheral Chip Select 5 /Peripheral Chip Select Strobe | (Unused)         | O   |
| SCK                            | Serial Clock (O)                                        | Serial Clock (I) | I/O |
| SIN                            | Serial Data In                                          | Serial Data In   | I   |
| SOUT                           | Serial Data Out                                         | Serial Data Out  | O   |

### 39.3.1 HT—Hardware Trigger

Master mode: Hardware Trigger (I)—Honored only when the module is configured for the DSI or CSI configuration (MCR[DCONF]), hardware-trigger reception is enabled (DSICR0[TRRE] or TRIG[TRRE]), and the module is in the Running state (SR[TXRXS]). Receives hardware triggers that initiate data transfers. DSICR0[TPOL] specifies whether the module uses rising or falling edges of HT as hardware triggers.

Slave mode: Hardware Trigger (I)—Honored only when the module is configured for the DSI or CSI configuration (MCR[DCONF]), hardware-trigger reception is enabled (DSICR0[TRRE] or TRIG[TRRE]), and the module is in the Running state (SR[TXRXS]). DSICR0[TPOL] specifies whether the module uses rising or falling edges of HT as hardware triggers.

### 39.3.2 PCS0/ $\overline{\text{SS}}$ —Peripheral Chip Select/Slave Select

Master mode: Peripheral Chip Select 0 (O)—Selects an DSPI slave to receive data transmitted from the module.

Slave mode: Slave Select (I)—Selects the module to receive data transmitted from an DSPI master.

#### NOTE

Do not tie the DSPI slave select pin to ground. Otherwise, DSPI cannot function properly.

### 39.3.3 PCS1–PCS3—Peripheral Chip Selects 1–3

Master mode: Peripheral Chip Selects 1–3 (O)—Select an DSPI slave to receive data transmitted by the module.

Slave mode: Unused

### 39.3.4 PCS4—Peripheral Chip Select 4

Master mode: Peripheral Chip Select 4 (O)—Selects an DSPI slave to receive data transmitted by the module.

Slave mode: Unused

### 39.3.5 PCS5/ $\overline{\text{PCSS}}$ —Peripheral Chip Select 5/Peripheral Chip Select Strobe

Master mode:

- Peripheral Chip Select 5 (O)—Used only when the peripheral-chip-select strobe is disabled (MCR[PCSSE]). Selects an DSPI slave to receive data transmitted by the module.
- Peripheral Chip Select Strobe (O)—Used only when the peripheral-chip-select strobe is enabled (MCR[PCSSE]). Strokes an off-module peripheral-chip-select demultiplexer, which decodes the module's PCS signals other than PCS5, preventing glitches on the demultiplexer outputs.

Slave mode: Unused

### 39.3.6 SCK—Serial Clock

Master mode: Serial Clock (O)—Supplies a clock signal from the module to DSPI slaves.

Slave mode: Serial Clock (I)—Supplies a clock signal to the module from an DSPI master.

### 39.3.7 SIN—Serial Input

Master mode: Serial Input (I)—Receives serial data.

Slave mode: Serial Input (I)—Receives serial data.

### 39.3.8 SOUT—Serial Output

Master mode: Serial Output (O)—Transmits serial data.

Slave mode: Serial Output (O)—Transmits serial data.

## 39.4 Memory Map/Register Definition

Register accesses to memory addresses that are reserved or undefined result in a transfer error. Any Write access to the POPR and RXFRn also results in a transfer error.

### NOTE

While the module is in the running state, do not write to these registers:

- PISRn
- DIMRn, DPIRn, and SSRn

#### DSPI memory map

| Address offset (hex) | Register name                                                             | Width (in bits) | Access | Reset value | Section/page                |

## 39.4.1 Module Configuration Register (DSPI\_MCR)

Contains bits to configure various attributes associated with the module operations. The HALT and MDIS bits can be changed at any time, but the effect takes place only on the next frame boundary. Only the HALT and MDIS bits in the MCR can be changed, while the module is in the Running state.

Address: 0h base + 0h offset = 0h

|       |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

## DSPI\_MCR field descriptions (continued)

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                  | <p>Determines the inactive state of PCSx. Refer to the chip-specific D SPI information for the number of PCS signals used in this chip.</p> <p><b>NOTE:</b> The effect of this bit only takes place when module is enabled. Ensure that this bit is configured correctly before enabling the DSPI interface.</p> <p>0 The inactive state of PCSx is low.<br/>1 The inactive state of PCSx is high.</p>                                                                                                     |
| 16<br>Reserved   | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 17<br>MDIS       | <p>Module Disable</p> <p>Allows the clock to be stopped to the non-memory mapped logic in the module effectively putting it in a software-controlled power-saving state. The reset value of the MDIS bit is parameterized, with a default reset value of 0. When the module is used in Slave Mode, it is recommended to leave this bit 0, because a slave doesn't have control over master transactions.</p> <p>0 Enables the module clocks.<br/>1 Allows external logic to disable the module clocks.</p> |
| 18<br>DIS_TXF    | <p>Disable Transmit FIFO</p> <p>When the TX FIFO is disabled, the transmit part of the module operates as a simplified double-buffered SPI. This bit can be written only when the MDIS bit is cleared.</p> <p>0 TX FIFO is enabled.<br/>1 TX FIFO is disabled.</p>                                                                                                                                                                                                                                         |
| 19<br>DIS_RXF    | <p>Disable Receive FIFO</p> <p>When the RX FIFO is disabled, the receive part of the module operates as a simplified double-buffered D SPI. This bit can only be written when the MDIS bit is cleared.</p> <p>0 RX FIFO is enabled.<br/>1 RX FIFO is disabled.</p>                                                                                                                                                                                                                                         |
| 20<br>CLR_TXF    | <p>Clear TX FIFO</p> <p>Flushes the TX FIFO. Writing a 1 to CLR_TXF clears the TX FIFO Counter. The CLR_TXF bit is always read as zero.</p> <p>0 Do not clear the TX FIFO counter.<br/>1 Clear the TX FIFO counter.</p>                                                                                                                                                                                                                                                                                    |
| 21<br>CLR_RXF    | <p>Clear RX FIFO</p> <p>Flushes the RX FIFO. Writing a 1 to CLR_RXF clears the RX Counter. |-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>DSPI_TCNT | DSPI Transfer Counter<br><br>Counts the number of SPI transfers the module makes. The DSPI_TCNT field increments every time the last bit of an DSPI frame is transmitted. A value written to DSPI_TCNT presets the counter to that value. DSPI_TCNT is reset to zero at the beginning of the frame when the CTCNT field is set in the executing SPI command. The Transfer Counter wraps around; incrementing the counter past 65535 resets the counter to zero. |
| 16–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                         |

### 39.4.3 Clock and Transfer Attributes Register (In Master Mode) (DSPI\_CTAR<sub>n</sub>)

CTAR registers are used to define different transfer attributes. Do not write to the CTAR registers while the module is in the Running state.

In Master mode, the CTAR registers define combinations of transfer attributes such as frame size, clock phase and polarity, data bit ordering, baud rate, and various delays. In slave mode, a subset of the bitfields in CTAR0 and CTAR1 are used to set the slave transfer attributes.

When the module is configured as a DSPI master, the CTAS field in the command portion of the TX FIFO entry selects which of the CTAR registers is used. When the module is configured as an DSPI bus slave, it uses the CTAR0 register.

When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used. When the module is configured as a DSI bus slave, the CTAR1 register is used.

In CSI Configuration, the transfer attributes are selected based on whether the current frame is DSPI data or DSI data. DSPI transfers in CSI Configuration follow the protocol described for DSPI Configuration, and DSI transfers in CSI Configuration follow the protocol described for DSI Configuration. CSI Configuration is valid only in conjunction with master mode.

TSB mode sets some limitations on transfer attributes:

- Clock phase is forced to be CPHA = 1 and the CPHA bit setting has no effect.
- PCS lines are driven at the driving edge of the SCK clock together with SOUT, so PCS assertion and negation delays control is unavailable and PCSSCK, PASC, CSSCK and ASC fields have no effect.
- Delay after transfer can be set from 1 to 64 serial clocks with help of PDT and DT fields

| 1           | 1                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | 11  | 57/43          |     |                |   |     |     |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |
| 1–4<br>FMSZ | <p>Frame Size</p> <p>The number of bits transferred per frame is equal to the FMSZ value plus 1. Regardless of the transmission mode, the minimum valid frame size value is 4. There is a constraint on the minimum allowable Frame size, which depends on the ratio of the Register Read/Write clock to the Protocol clock. The minimum Frame size (FMSZ + 1) is determined by the following equation. Upper Ceiling must be applied for non-integer values.</p> <p>Minimum Frame Size = ( ( 4 x f<sub>p</sub> ) + ( 3 x f<sub>r</sub> ) ) / ( n x f<sub>r</sub> )</p> <p>f<sub>p</sub> = Protocol clock frequency</p> <p>f<sub>r</sub> = Register interface clock frequency</p> <p>n = (PBR x BR) / ( 1 + DBR) = Multiple of protocol clock required to get Baud (SCK) Clock</p> <p>However, the minimum frame size can never be less than 4. There is no constraint on the maximum programmable frame size. Also note that 'fp' can be equal to, less than or greater than 'fr' purely based on user requirement.</p>                                                                                                                                                                                                                                                                                                                                                                                              |     |                |     |                |   |     |     |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |   |   |    |       |

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5<br>CPOL     | <p>Clock Polarity</p> <p>Selects the inactive state of the Serial Communications Clock (SCK). This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock polarities. When the Continuous Selection Format is selected, switching between clock polarities without stopping the module can cause errors in the transfer due to the peripheral device interpreting the switch of clock polarity as a valid clock edge.</p> <p><b>NOTE:</b> In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed.</p> <p>0 The inactive state value of SCK is low.<br/>1 The inactive state value of SCK is high.</p> |
| 6<br>CPHA     | <p>Clock Phase</p> <p>Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1.</p> <p>0 Data is captured on the leading edge of SCK and changed on the following edge.<br/>1 Data is changed on the leading edge of SCK and captured on the following edge.</p>                                                                                                                                                                    |
| 7<br>LSBFE    | <p>LSB First</p> <p>Specifies whether the LSB or MSB of the frame is transferred first.</p> <p>0 Data is transferred MSB first.<br/>1 Data is transferred LSB first.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 8–9<br>PCSSCK | <p>PCS to SCK Delay Prescaler</p> <p>Selects the prescaler value for the delay between assertion of PCS and the first edge of the SCK. See the CSSCK field description for information on how to compute the PCS to SCK Delay. Refer <a href="#">PCS to SCK Delay (t<sub>CSC</sub>)</a> for more details.</p> <p>00 PCS to SCK Prescaler value is 1.<br/>01 PCS to SCK Prescaler value is 3.<br/>10 PCS to SCK Prescaler value is 5.<br/>11 PCS to SCK Prescaler value is 7.</p>                                                                                                                                                                                                                                                                        |
| 10–11<br>PASC | <p>After SCK Delay Prescaler</p> <p>Selects the prescaler value for the delay between the last edge of SCK and the negation of PCS. See the ASC field description for information on how to compute the After SCK Delay. In the TSB mode, the PASC field has no effect. Refer <a href="#">After SCK Delay (t<sub>ASC</sub>)</a> for more details.</p> <p>00 Delay after Transfer Prescaler value is 1.<br/>01 Delay after Transfer Prescaler value is 3.<br/>10 Delay after Transfer Prescaler value is 5.<br/>11 Delay after Transfer Prescaler value is 7.</p>                                                                                                                                                                                        |
| 12–13<br>PDT  | <p>Delay after Transfer Prescaler</p> <p>Selects the prescaler value for the delay between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame. The PDT field is only used in master mode. See</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|                | <p>the DT field description for details on how to compute the Delay after Transfer. Refer <a href="#">Delay after Transfer (t<sub>DT</sub>)</a> for more details.</p> <p>00 Delay after Transfer Prescaler value is 1.<br/> 01 Delay after Transfer Prescaler value is 3.<br/> 10 Delay after Transfer Prescaler value is 5.<br/> 11 Delay after Transfer Prescaler value is 7.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |             |                    |      |   |      |   |      |   |      |    |      |    |      |    |      |     |      |     |      |     |      |      |      |      |      |      |      |      |      |       |      |       |      |       |
| 14–15<br>PBR   | <p>Baud Rate Prescaler</p> <p>Selects the prescaler value for the baud rate. This field is used only in master mode. The baud rate is the frequency of the SCK. The protocol clock is divided by the prescaler value before the baud rate selection takes place. See the BR field description for details on how to compute the baud rate.</p> <p>00 Baud Rate Prescaler value is 2.<br/> 01 Baud Rate Prescaler value is 3.<br/> 10 Baud Rate Prescaler value is 5.<br/> 11 Baud Rate Prescaler value is 7.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |             |                    |      |   |      |   |      |   |      |    |      |    |      |    |      |     |      |     |      |     |      |      |      |      |      |      |      |      |      |       |      |       |      |       |
| 16–19<br>CSSCK | <p>PCS to SCK Delay Scaler</p> <p>Selects the scaler value for the PCS to SCK delay. This field is used only in master mode. In the TSB mode the field has no effect. The PCS to SCK Delay is the delay between the assertion of PCS and the first edge of the SCK. The delay is a multiple of the protocol clock period, and it is computed according to the following equation:</p> $t_{CSC} = (1/f_P) \times PCSSCK \times CSSCK.$ <p>The following table lists the delay scaler values.</p> <p style="text-align: center;"><b>Table 39-14. Delay Scaler Encoding</b></p> <table> <tr> <th>Field Value</th><th>Delay Scaler Value</th></tr> <tr><td>0000</td><td>2</td></tr> <tr><td>0001</td><td>4</td></tr> <tr><td>0010</td><td>8</td></tr> <tr><td>0011</td><td>16</td></tr> <tr><td>0100</td><td>32</td></tr> <tr><td>0101</td><td>64</td></tr> <tr><td>0110</td><td>128</td></tr> <tr><td>0111</td><td>256</td></tr> <tr><td>1000</td><td>512</td></tr> <tr><td>1001</td><td>1024</td></tr> <tr><td>1010</td><td>2048</td></tr> <tr><td>1011</td><td>4096</td></tr> <tr><td>1100</td><td>8192</td></tr> <tr><td>1101</td><td>16384</td></tr> <tr><td>1110</td><td>32768</td></tr> <tr><td>1111</td><td>65536</td></tr> </table> | Field Value | Delay Scaler Value | 0000 | 2 | 0001 | 4 | 0010 | 8 | 0011 | 16 | 0100 | 32 | 0101 | 64 | 0110 | 128 | 0111 | 256 | 1000 | 512 | 1001 | 1024 | 1010 | 2048 | 1011 | 4096 | 1100 | 8192 | 1101 | 16384 | 1110 | 32768 | 1111 | 65536 |

|              | Refer <a href="#">PCS to SCK Delay (t<sub>CSC</sub>)</a> for more details.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |           |                        |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |     |      |     |      |     |      |      |      |      |      |      |
| 20–23<br>ASC | <p>After SCK Delay Scaler</p> <p>Selects the scaler value for the After SCK Delay. This field is used only in master mode. The After SCK Delay is the delay between the last edge of SCK and the negation of PCS. The delay is a multiple of the protocol clock period, and it is computed according to the following equation:</p> $t_{ASC} = (1/f_P) \times PASC \times ASC$ <p>See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values. Refer <a href="#">After SCK Delay (t<sub>ASC</sub>)</a> for more details.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |           |                        |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |     |      |     |      |     |      |      |      |      |      |      |
| 24–27<br>DT  | <p>Delay After Transfer Scaler</p> <p>Selects the Delay after Transfer Scaler. This field is used only in master mode. The Delay after Transfer is the time between the negation of the PCS signal at the end of a frame and the assertion of PCS at the beginning of the next frame.</p> <p>In the Continuous Serial Communications Clock operation, the DT value is fixed to one SCK clock period, The Delay after Transfer is a multiple of the protocol clock period, and it is computed according to the following equation:</p> $t_{DT} = (1/f_P) \times PDT \times DT$ <p>See Delay Scaler Encoding table in CTARn[CSSCK] bit field description for scaler values.</p> <p>In the TSB mode, the Delay after Transfer is equal to a number formed by concatenation of the PDT and DT fields plus 1 of the SCK clock periods. Refer <a href="#">Delay after Transfer (t<sub>DT</sub>)</a> for more details.</p>                                                                                                                 |           |                        |      |   |      |   |      |   |      |   |      |    |      |    |      |    |      |     |      |     |      |     |      |      |      |      |      |      |
| 28–31<br>BR  | <p>Baud Rate Scaler</p> <p>Selects the scaler value for the baud rate. This field is used only in master mode. The prescaled protocol clock is divided by the Baud Rate Scaler to generate the frequency of the SCK. The baud rate is computed according to the following equation:</p> $SCK \text{ baud rate} = (f_P / PBR) \times [(1+DBR)/BR]$ <p>The following table lists the baud rate scaler values.</p> <p style="text-align: center;"><b>Table 39-13. ### 39.4.4 Clock and Transfer Attributes Register (In Slave Mode) (DSPI\_CTAR<sub>n</sub>\_SLAVE)

When the module is configured as an SPI bus slave, the CTAR0 register is used.

When the module is configured as a DSI master, the DSICTAS field in the DSI Configuration Register 0 (DSICR0), selects which of the CTAR register is used. When the module is configured as a DSI bus slave, the CTAR1 register is used.

Address: 0h base + Ch offset + (4d × i), where i=0d to 1d

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | <p><b>NOTE:</b> In case of Continuous SCK mode, when the module goes in low power mode(disabled), inactive state of SCK is not guaranteed.</p> <p>0 The inactive state value of SCK is low.</p> <p>1 The inactive state value of SCK is high.</p>                                                                                                                                                                                                                                                                                                                                       |
| 6<br>CPHA         | <p>Clock Phase</p> <p>Selects which edge of SCK causes data to change and which edge causes data to be captured. This bit is used in both master and slave mode. For successful communication between serial devices, the devices must have identical clock phase settings. In Continuous SCK mode or TSB mode, the bit value is ignored and the transfers are done as if the CPHA bit is set to 1.</p> <p>0 Data is captured on the leading edge of SCK and changed on the following edge.</p> <p>1 Data is changed on the leading edge of SCK and captured on the following edge.</p> |
| 7<br>PE           | <p>Parity Enable</p> <p>Enables parity bit transmission and reception for the frame.</p> <p>0 No parity bit included/checked.</p> <p>1 Parity bit is transmitted instead of last data bit in frame, parity checked for received frame.</p>                                                                                                                                                                                                                                                                                                                                              |
| 8<br>PP           | <p>Parity Polarity</p> <p>Controls polarity of the parity bit transmitted and checked.</p> <p>0 Even Parity: the number of 1 bits in the transmitted frame is even. The SR[SPEF] bit is set if the number of 1 bits is odd in the received frame.</p> <p>1 Odd Parity: the number of 1 bits in the transmitted frame is odd. The SR[SPEF] bit is set if the number of 1 bits is even in the received frame.</p>                                                                                                                                                                         |
| 9<br>Reserved     | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 10–31<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 39.4.5 Status Register (DSPI\_SR)

SR contains status and flag bits. The bits reflect the status of the module and indicate the occurrence of events that can generate interrupt or DMA requests. Software can clear flag bits in the SR by writing a 1 to them. Writing a 0 to a flag bit has no effect. This register may not be writable in Module Disable mode due to the use of power saving mechanisms.

Address: 0h base + 2Ch offset = 2Ch

## DSPI\_SR field descriptions (continued)

| Field         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1<br>TXRXS    | <p>TX and RX Status</p> <p>Reflects the run status of the module.</p> <p>0 Transmit and receive operations are disabled (The module is in Stopped state).</p> <p>1 Transmit and receive operations are enabled (The module is in Running state).</p>                                                                                                                                                                                                                                                                                                                                                |
| 2<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 3<br>EOQF     | <p>End of Queue Flag</p> <p>Indicates that the last entry in a queue has been transmitted when the module is in Master mode. The EOQF bit is set when the TX FIFO entry has the EOQ bit set in the command halfword and the end of the transfer is reached. The EOQF bit remains set until cleared by writing a 1 to it. When the EOQF bit is set, the TXRXS bit is automatically cleared.</p> <p>0 EOQ is not set in the executing command.</p> <p>1 EOQ is set in the executing SPI command.</p>                                                                                                  |
| 4<br>TFUF     | <p>Transmit FIFO Underflow Flag</p> <p>Indicates an underflow condition in the TX FIFO. The transmit underflow condition is detected only for DSPI blocks operating in Slave mode and DSPI configuration. TFUF is set when the TX FIFO of the module operating in SPI Slave mode is empty and an external DSPI master initiates a transfer. The TFUF bit remains set until cleared by writing 1 to it.</p> <p>0 No TX FIFO underflow.</p> <p>1 TX FIFO underflow has occurred.</p>                                                                                                                  |
| 5<br>Reserved | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 6<br>TFFF     | <p>Transmit FIFO Fill Flag</p> <p>Indicates whether there is an available location to be filled in the FIFO. Either a DMA request or an interrupt indication can be used to add another entry to the FIFO. Note that this bit is set if at least one location is free in the FIFO. The TFFF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller to the TX FIFO full request, when the TX FIFO is full.</p> <p><b>NOTE:</b> The reset value of this bit is 0 when the module is disabled, (MCR[MDIS]=1).</p> <p>0 TX FIFO is full.</p> <p>1 TX FIFO is not full.</p> |
| 7<br>Reserved | <p>This field is reserved.</p> <p>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Field</b>       | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | Indicates that a DSPI frame with parity error had been received. The bit remains set until it is cleared by writing a 1 to it.<br><br>0 No parity error.<br>1 Parity error has occurred.                                                                                                                                                                                                                                                                    |
| 11<br>DDIF         | DSI Data Received with Active Bits<br><br>Indicates that a DSI frame had been received with bits selected by DIMR with active polarity, defined by the DPIR register. The bit remains set until it is cleared by writing a 1 to it.<br><br>0 No DSI data with active bits was received.<br>1 DSI data with active bits was received.                                                                                                                        |
| 12<br>RFOF         | Receive FIFO Overflow Flag<br><br>Indicates an overflow condition in the RX FIFO. The field is set when the RX FIFO and shift register are full and a transfer is initiated. The bit remains set until it is cleared by writing a 1 to it.<br><br>0 No Rx FIFO overflow.<br>1 Rx FIFO overflow has occurred.                                                                                                                                                |
| 13<br>Reserved     | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                     |
| 14<br>RFDF         | Receive FIFO Drain Flag<br><br>Indicates whether there is an available location to be drained from the FIFO. Either a DMA request or an interrupt indication can be used to read from the FIFO. Note that this bit is set if at least one location can be read from the FIFO. The RFDF bit can be cleared by writing 1 to it or by acknowledgement from the DMA controller when the RX FIFO is empty.<br><br>0 RX FIFO is empty.<br>1 RX FIFO is not empty. |
| 15<br>Reserved     | This field is reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 16–19<br>TXCTR     | TX FIFO Counter<br><br>Indicates the number of valid entries in the TX FIFO. The TXCTR is incremented every time the PUSHHR is written. The TXCTR is decremented every time an DSPI command is executed and the DSPI data is transferred to the shift register.                                                                                                                                                                                             |
| 20–23<br>TXNXTPTR  | Transmit Next Pointer<br><br>Indicates which TX FIFO entry is transmitted during the next transfer. The TXNXTPTR field is updated every time SPI data is transferred from the TX FIFO to the shift register.                                                                                                                                                                                                                                                |
| 24–27<br>RXCTR     | RX FIFO Counter<br><br>Indicates the number of entries in the RX FIFO. The RXCTR is decremented every time the POPR is read. The RXCTR is incremented every time data is transferred from the shift register to the RX FIFO.                                                                                                                                                                                                                                |
| 28–31<br>POPNXTPTR | Pop Next Pointer<br><br>Contains a pointer to the RX FIFO entry to be returned when the POPR is read. The POPNXTPTR is updated when the POPR is read.                                                                                                                                                                                                                                                                                                       |

### 39.4.6 DMA/Interrupt Request Select and Enable Register (DSPI\_RSER)

RSER controls DMA and interrupt requests. Do not write to the RSER while the module is in the Running state.

Address: 0h base + 30h offset = 30h

**39.4.7 PUSH TX FIFO Register In Master Mode (DSPI\_PUSHR)**

Specifies data to be transferred to the TX FIFO and CMD FIFO. User must write 16-bits data into TXDATA field. An 8- or 16-bit write access to the TXDATA field transfers 16 bits of data bus to the TX FIFO. A write access to the command fields transfers the 16 bits of command information to the CMD FIFO. In Master mode, the register transfers 16 bits of data to the TX FIFO and 16 bits of command information to the CMD FIFO.

The TX FIFO and CMD FIFO must be filled simultaneously. In other words, you must perform write accesses to both the data and command fields for every PUSHR operation. Because both the TX FIFO and CMD FIFO are written to and read from simultaneously, they behave as a single 32 bit FIFO.

A read access of PUSHR returns the topmost TX FIFO and CMD FIFO entries concatenated.

When the module is disabled, writing to this register does not update the FIFO. Therefore, any reads performed while the module is disabled return the last PUSHR write performed while the module was still enabled.

Address: 0h base + 34h offset = 34h

**39.4.8 PUSH TX FIFO Register In Slave Mode (DSPI\_PUSHR\_SLAVE)**

Specifies data to be transferred to the TX FIFO in slave mode. An 8- or 16-bit write access to PUSHR transfers the 16-bit TXDATA field to the TX FIFO.

Address: 0h base + 34h offset = 34h

**39.4.9 POP RX FIFO Register (DSPI\_POPR)**

POPR is used to read the RX FIFO. Eight- or sixteen-bit read accesses to the POPR have the same effect on the RX FIFO as 32-bit read accesses. A write to this register will generate a Transfer Error.

Address: 0h base + 38h offset = 38h

**39.4.13 DSI Serialization Data Register 0 (DSPI\_SDR0)**

SDR0 contains the states of the 32 LSB Parallel Input signals. The states of the Parallel Input signals are latched into the SDR0 on the rising edge of every bus clock. The SDR0 is read-only. When the TXSS bit in the DSICR0 is cleared, the data in the SDR0 is used as the source of the DSI frames.

| 0–31<br>SER_DATA | Serialized Data<br>Contains the signal states of the 32 LSB Parallel Input signals. |

**39.4.14 DSI Alternate Serialization Data Register 0 (DSPI\_ASDR0)**

ASDR0 is used by host software to write the 32 LSB of the data to be serialized. When the TXSS bit in the DSICR0 is set, the data in the ASDR0 is the source of the DSI frames. Writes to the ASDR0 take effect on the next frame boundary.

**39.4.18 DSI Serialization Source Select Register 0 (DSPI\_SSR0)**

SSR0 is used to create a combined frame for transmission that contains bits from ASDR0 and SDR0. Each bit in the SSR0 register selects a corresponding bit to be serialized. When DSICR0[TXSS] is set, the SSR0 register value has no effect.

Each SS bit selects data for a corresponded bit in the transmitted frame.<br><br>0 The bit in the transmitted frame is taken from the Parallel Input pin.<br>1 The bit in the transmitted frame is taken from the ASDR0 register |

**39.4.19 DSI Parallel Input Select Register 0 (DSPI\_PISR0)**

PISR0–3 select each data bit for the transmitted frame from 32 parallel input pins. Each Input Pin Select (IPS) field controls one bit in the transmitted frame. Each register contains control fields for 8 bits in the frame. The select field value is defined as a 4-bit signed integer number. The selected parallel input pin number is defined as a difference between the sum of the field number and the field value.

For example, if IPS16 is equal to the binary number 1111 (minus 1 decimal), then bit 16 in the frame is taken from parallel input pin number 15. When the IPS0 is equal to -1, then bit 0 in the frame is taken from parallel input 31. When the IPS0 is equal to +1, then bit 0 in the frame is taken from Parallel Input 1 and so on.

Note that PISR0–3 only preselect the Parallel Input pins. The final selection to the transmitted frame is made with the SSR0-1 register bits or the DSICR0[TXSS] bit.

## 39.5 Functional description

The module supports full-duplex, synchronous serial communications between chips and peripheral devices. The module can also be used to reduce the number of pins required for I/O by serializing and deserializing Parallel Input/Output signals. All communications are done with SPI-like protocol.

The module has the following configurations

- The DSPI Configuration in which the module operates as a basic DSPI or a queued SPI.
- DSI Configuration in which the module serializes and deserializes Parallel Input/Output signals or bits from memory-mapped registers
- When Master mode is enabled, the module also supports CSI Configuration, which combines the functionality of the DSPI and DSI configurations.

The DCONF field in the Module Configuration Register (MCR) determines the module Configuration. See [Module Configuration Register \(DSPI\\_MCR\)](#) for the DSPI configuration values.

The CTAR<sub>n</sub> registers hold clock and transfer attributes. The DSPI configuration allows to select which CTAR to use on a frame by frame basis by setting a field in the DSPI command.

The DSI configuration statically selects which CTAR to use. In CSI, Configuration priority logic determines if DSPI data or DSI data is transferred and dictates what CTAR register is used for the data transfer. See [Clock and Transfer Attributes Register \(In Master Mode\) \(DSPI\\_CTAR<sub>n</sub>\)](#) for information on the fields of CTAR registers.

Typical master to slave connections are shown in the following figure. When a data transfer operation is performed, data is serially shifted a predetermined number of bit positions. Because the modules are linked, data is exchanged between the master and the slave. The data that was in the master shift register is now in the shift register of the slave, and vice versa. At the end of a transfer, the Transfer Control Flag(TCF) bit in the Shift Register(SR) is set to indicate a completed frame transfer.

**NOTE**

SPI is used for both SPI Mode and DSI mode in this diagram.

**Figure 39-45. Serial protocol overview**

Generally, more than one slave device can be connected to the module master. 6 Peripheral Chip Select (PCS) signals of the module masters can be used to select which of the slaves to communicate with. Refer to the chip specific section for details on the number of PCS signals used in this chip.

The three DSPI configurations share transfer protocol and timing properties which are described independently of the configuration in [Transfer formats](#). The transfer rate and delay settings are described in [Module baud rate and clock delay generation](#).

### 39.5.1 Start and Stop of module transfers

The module has two operating states: Stopped and Running. Both the states are independent of it's configuration. The default state of the module is Stopped. In the Stopped state, no serial transfers are initiated in Master mode and no transfers are responded to in Slave mode. The Stopped state is also a safe state for writing the various configuration registers of the module without causing undetermined results. In the Running state serial transfers take place.

The TXRXS bit in the SR indicates the state of module. The bit is set if the module is in Running state.

The module starts or transitions to Running when all of the following conditions are true:

- SR[EOQF] bit is clear
- Chip is not in the Debug mode or the MCR[FRZ] bit is clear
- MCR[HALT] bit is clear

The module stops or transitions from Running to Stopped after the current frame when any one of the following conditions exist:

- SR[EOQF] bit is set
- Chip in the Debug mode and the MCR[FRZ] bit is set
- MCR[HALT] bit is set

State transitions from Running to Stopped occur on the next frame boundary if a transfer is in progress, or immediately if no transfers are in progress.

## 39.5.2 Serial Peripheral Interface DSPI configuration

The DSPI configuration transfers data serially using a shift register and a selection of programmable transfer attributes. The module is in DSPI configuration when the DCONF field in the MCR is 0b00. The DSPI frames can be 32 bits long. The host CPU or a DMA controller transfers the DSPI data from the external to the module RAM queues to a TX FIFO buffer. The received data is stored in entries in the RX FIFO buffer. The host CPU or the DMA controller transfers the received data from the RX FIFO to memory external to the module. The operation of FIFO buffers is described in the following sections:

- [Transmit First In First Out \(TX FIFO\) buffering mechanism](#)
- [Command First In First Out \(CMD FIFO\) Buffering Mechanism](#)
- [Receive First In First Out \(RX FIFO\) buffering mechanism](#)

The interrupt and DMA request conditions are described in [Interrupts/DMA requests](#).

The DSPI configuration supports two block-specific modes—Master mode and Slave mode. In Master mode the module initiates and controls the transfer according to the fields of the executing DSPI Command. In Slave mode, the module responds only to transfers initiated by a bus master external to it and the DSPI command field space is reserved.

### 39.5.2.1 Master mode

In DSPI Master mode, the module initiates the serial transfers by controlling the SCK and the PCS signals. The executing DSPI Command determines which CTARs will be used to set the transfer attributes and which PCS signals to assert. The command field also contains various bits that help with queue management and transfer protocol. See [PUSH TX FIFO Register In Master Mode \(DSPI\\_PUSHR\)](#) for details on the DSPI command fields. The data in the executing TX FIFO entry is loaded into the shift register and

shifted out on the Serial Out (SOUT) pin. In DSPI Master mode, each DSPI frame to be transmitted has a command associated with it, allowing for transfer attribute control on a frame by frame basis.

### 39.5.2.2 Slave mode

In DSPI Slave mode the module responds to transfers initiated by an DSPI bus master. It does not initiate transfers. Certain transfer attributes such as clock polarity, clock phase, and frame size must be set for successful communication with an DSPI master. The DSPI Slave mode transfer attributes are set in the CTAR0. The data is shifted out with MSB first. Shifting out of LSB is not supported in this mode.

### 39.5.2.3 FIFO disable operation

The FIFO disable mechanisms allow DSPI transfers without using the TX FIFO, CMD FIFO or RX FIFO. The module operates as a double-buffered simplified DSPI when the FIFOs are disabled. The Transmit and Receive side of the FIFOs are disabled separately. Setting the MCR[DIS\_TXF] bit disables the TX FIFO and CMD FIFO, and setting the MCR[DIS\_RXF] bit disables the RX FIFO.

The FIFO disable mechanisms are transparent to the user and to host software. Transmit data and commands are written to the PUSHHR and received data is read from the POPR.

When the TX FIFO and CMD FIFO are disabled:

- SR[TFFF], SR[TFUF] and SR[TXCTR] behave as if there is a one-entry FIFO
- The contents of TXFRs, SR[TXNXTPTR] are undefined

Similarly, when the RX FIFO is disabled, the RFDF, RFOF, and RXCTR fields in the SR behave as if there is a one-entry FIFO, but the contents of the RXFR registers and POPNXTPTR are undefined.

### 39.5.2.4 Transmit First In First Out (TX FIFO) buffering mechanism

The TX FIFO functions as a buffer of DSPI data for transmission. The TX FIFO holds 4 words, each consisting of DSPI data. The number of entries in the TX FIFO is device-specific. DSPI data is added to the TX FIFO by writing to the Data Field of module PUSH FIFO Register (PUSHHR). TX FIFO entries can only be removed from the TX FIFO by being shifted out or by flushing the TX FIFO.

The TX FIFO Counter field (TXCTR) in the module Status Register (SR) indicates the number of valid entries in the TX FIFO. The TXCTR is updated every time a 8- or 16-bit write takes place to PUSHHR[TXDATA] or DSPI data is transferred into the shift register from the TX FIFO.

The TXNXTPTR field indicates the TX FIFO Entry that will be transmitted during the next transfer. The TXNXTPTR field is incremented every time DSPI data is transferred from the TX FIFO to the shift register. The maximum value of the field is equal to the maximum implemented TXFR number and it rolls over after reaching the maximum.

#### 39.5.2.4.1 Filling the TX FIFO

Host software or other intelligent blocks can add (push) entries to the TX FIFO and CMD FIFO by writing to the PUSHHR. When the TX FIFO is not full, the TX FIFO Fill Flag (TFFF) in the SR is set. The TFFF bit is cleared when TX FIFO is full and the DMA controller indicates that a write to PUSHHR is complete. Writing a '1' to the TFFF bit also clears it. The TFFF can generate a DMA request or an interrupt request. See [Transmit FIFO Fill Interrupt or DMA Request](#) for details.

The module ignores attempts to push data to a full TX FIFO, and the state of the TX FIFO does not change and no error condition is indicated.

#### 39.5.2.4.2 Draining the TX FIFO

The TX FIFO entries are removed (drained) by shifting DSPI data out through the shift register. Entries are transferred from the TX FIFO to the shift register and shifted out as long as there are valid entries in the TX FIFO. Every time an entry is transferred from the TX FIFO to the shift register, the TX FIFO Counter decrements by one. At the end of a transfer, the TCF bit in the SR is set to indicate the completion of a transfer. The TX FIFO is flushed by writing a '1' to the CLR\_TXF bit in MCR.

If an external bus master initiates a transfer with a module slave while the slave's TX FIFO is empty, the Transmit FIFO Underflow Flag (TFUF) in the slave's SR is set. See [Transmit FIFO Underflow Interrupt Request](#) for details.

#### 39.5.2.5 Command First In First Out (CMD FIFO) Buffering Mechanism

The CMD FIFO functions as a buffer of DSPI command used for DSPI data transmission. The TX FIFO and CMD FIFO must be filled together, i.e. write enables should be given for both the Data and Command fields while performing a PUSHHR operation.

The CMD FIFO holds 4 words, each representing DSPI command fields. The number of entries in the CMD FIFO is device-specific. DSPI Command is added to the CMD FIFO by writing to the command field of DSPI PUSH FIFO Register (PUSHR). CMD FIFO entries can only be removed from the CMD FIFO by being shifted out (to help transmit DSPI data) or by flushing the CMD FIFO.

Every CMD FIFO entry has a corresponding single TX FIFO entry attached to it because both these FIFO's are filled simultaneously.

### **39.5.2.6 Receive First In First Out (RX FIFO) buffering mechanism**

The RX FIFO functions as a buffer for data received on the SIN pin. The RX FIFO holds 4 received DSPI data frames. The number of entries in the RX FIFO is device-specific. DSPI data is added to the RX FIFO at the completion of a transfer when the received data in the shift register is transferred into the RX FIFO. DSPI data are removed (popped) from the RX FIFO by reading the module POP RX FIFO Register (POPR). RX FIFO entries can only be removed from the RX FIFO by reading the POPR or by flushing the RX FIFO.

The RX FIFO Counter field (RXCTR) in the module's Status Register (SR) indicates the number of valid entries in the RX FIFO. The RXCTR is updated every time the POPR is read or DSPI data is copied from the shift register to the RX FIFO.

The POPNXTPTR field in the SR points to the RX FIFO entry that is returned when the POPR is read. The POPNXTPTR contains the positive offset from RXFR0 in a number of 32-bit registers. For example, POPNXTPTR equal to two means that the RXFR2 contains the received DSPI data that will be returned when the POPR is read. The POPNXTPTR field is incremented every time the POPR is read. The maximum value of the field is equal to the maximum implemented RXFR number and it rolls over after reaching the maximum.

#### **39.5.2.6.1 Filling the RX FIFO**

The RX FIFO is filled with the received DSPI data from the shift register. While the RX FIFO is not full, DSPI frames from the shift register are transferred to the RX FIFO. Every time an DSPI frame is transferred to the RX FIFO, the RX FIFO Counter is incremented by one.

If the RX FIFO and shift register are full and a transfer is initiated, the RFOF bit in the SR is set indicating an overflow condition. Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

### 39.5.2.6.2 Draining the RX FIFO

Host CPU or a DMA can remove (pop) entries from the RX FIFO by reading the module POP RX FIFO Register (POPR). A read of the POPR decrements the RX FIFO Counter by one. Attempts to pop data from an empty RX FIFO are ignored and the RX FIFO Counter remains unchanged. The data, read from the empty RX FIFO, is undetermined.

When the RX FIFO is not empty, the RX FIFO Drain Flag (RFDF) in the SR is set. The RFDF bit is cleared when the RX\_FIFO is empty and the DMA controller indicates that a read from POPR is complete or by writing a 1 to it.

## 39.5.3 Deserial Serial Interface (DSI) Configuration

The DSI Configuration supports pin count reduction by serializing Parallel Input signals or register bits and shifting them out in a DSPI-like protocol. The timing and transfer protocol is described in [Transfer formats](#). The received serial frames are converted to a parallel form (deserialized) and placed on the Parallel Output signals or in the DSPI\_DDR register. The various features of the DSI Configuration are set in DSPI DSI Configuration Registers (DSPI\_DSICR0/1).

The DSI frames can be from 4 to 32 bits.

### 39.5.3.1 DSI Master Mode

In DSI master mode the DSPI/DSPI initiates and controls the DSI transfers. The DSI master has different conditions that can initiate a transfer:

- Continuous
- Change in data
- Trigger signal
- Trigger signal combined with a change in data

These transfer initiation conditions are described in [DSI Transfer Initiation Control](#) . Transfer attributes are set during initialization. The DSICTAS field in the DSPI\_DSICR0 determines which of the DSPI\_CTAR registers will control the transfer attributes.

### 39.5.3.2 Slave Mode

In DSI slave mode the DSPI responds to transfers initiated by a DSPI or DSI bus master. In this mode the DSPI does not initiate DSI transfers. Certain transfer attributes such as clock polarity and phase must be set for successful communication with a DSI master. The DSI slave mode transfer attributes are set in the DSPI\_CTAR1. The data is shifted out with MSB first.

### 39.5.3.3 DSI Serialization

In the DSI Configuration, up to 32 bits can be serialized using two different sources. The TXSS bit in the DSPI\_DSICR0 selects between the DSPI DSI Serialization Data Register (DSPI\_SDR0) and the DSPI DSI Alternate Serialization Data Register (DSPI\_ASDR0) as the source of the serialized data. The DSPI\_SDR0 holds the latest 32 Parallel Input signal values which is sampled at every rising edge of the bus clock. The DSPI\_ASDR0 register is written by host software and used as an alternate source of serialized data.

The DSPI has to sample the inputs (from SDR0 or ASDR0) before it transmits a DSI frame. Due to the asynchronous clocking structure within DSPI, the sampled data (from SDR0 or ASDR0) must be synchronized into the Protocol Domain before being loaded into the Shift Register for transmission.

To prevent Clock Domain Crossing issues, inputs from SDR0 or ASDR0 should not change while they are being sampled into the Protocol Domain. This is ensured in the following manner for the ASDR0 inputs. The initial write performed on ASDR0 register will cause the 32-bit ASDR0 input to be latched into a temporary register which is then locked (further latching is prevented) until this data gets synchronized into the Protocol Domain. Once synchronized, the lock is removed and the next ASDR0 write will again trigger this process. If there was a write performed on ASDR0 while the lock was asserted, this will be taken into consideration as soon as the previous synchronization process completes and lock gets de-asserted. In case, multiple writes were performed on ASDR0 when lock was asserted, only the latest value will be considered for synchronization once the lock gets de-asserted.

The entire process explained above is also true for the SDR0 input, the only difference being that SDR0 inputs are delayed internally by a single Bus clock (register interface clock) to detect a change in the parallel input pins.

Once the synchronization process for a particular De-serial input begins, it takes up to 5 Bus clock (register interface clock) periods and 5 Protocol clock periods before the synchronization process for the next De-serial input can begin. Hence the writes performed on ASDR0 and SDR0 are constrained with this timing.

The DSPI\_PISR0-3 registers allow to change relative position of the Parallel input pins in the transmitted frame. Each transmitted frame bit can be selected from 16 adjacent Parallel Inputs by writing IPSn fields. The IPSn field is treated as 4 bit integer number, representing numbers from -8 to 7. The Parallel Input pin number, selected by IPSn field is defined by the difference between the IPSn field number (n) and the IPSn field value. If the operation result is negative the number 32 should be added. If the result is higher than 32, 32 should be subtracted from the result.

For example, IPS0, set to minus 1 (binary 1111), preselects Parallel Input 1 to 0 position in the transmitted frame.

IPS6, set to 3 (binary 0011), preselects Parallel Input 3 to be bit number 6 in the transmitted frame. The value minus 2 (1110) preselects Parallel Input 8.

IPS31, set to minus 8 (binary 1000), preselects Parallel Input 7 to be bit number 31 in the transmitted frame.

### Note

The Parallel Input pin state, to be transmitted, should be selected by TXSS or DSPI\_SSR0 register and the frame size should be higher than the bit position in the preselected frame.

DSPI\_SSR0 register provides additional way to create the frame for transmission. Each bit from this register is OR'd with the TXSS bit and controls individual transmitted bit source. This way, the transmitted frame can have any combination of the DSPI\_SDR0 and DSPI\_ASDR0 bits. This feature allows control DSPI based devices, requiring control and data fields in the frame. Control field may come from DSPI\_ASDR0 register, set by the device's CPU, while data field can be generated by device peripheral modules, like PWM timers.

A copy of the last DSI frame shifted out of the Shift Register is stored in the DSPI DSI Transmit Comparison Register (DSPI\_COMPR0). This register provides added visibility for debugging and it serves as a reference for transfer initiation control. The following figure shows the DSI Serialization logic.

**NOTE**

SPI is used for both SPI Mode and DSI mode in the following diagrams.

**Figure 39-46. DSI Serialization Diagram**

### 39.5.3.4 DSI Deserialization

When all bits in a DSI frame have been shifted in, the frame is copied to the DSPI DSI Deserialization Data Register (DSPI\_DDR0). This register presents the deserialized data as Parallel Output signal values. DSPI\_DDR0 is memory mapped to allow host software to read the deserialized data directly.

The received data is bit-wise compared to the value of the DSI Deserialized Data Polarity Interrupt Register (DSPI\_DPIR0), bit-wise AND'ed with DSI Deserialized Interrupt Mask Register (DSPI\_DIMR0) and the results OR'ed to produce DDIF flag in the DSPI\_SR register; which in turn can cause DDI interrupt request or DMA request based on RSER[DDIF\_RE] and RSER[DDIF\_DIRS] bits and/or stop DSI frame transmissions if DSICR0[DMS] bit is set.

The following figure shows the DSI Deserialization logic.

**NOTE**

SPI is used for both SPI Mode and DSI mode in this diagram.

Figure 39-47. DSI Deserialization Diagram

### 39.5.3.5 DSI Transfer Initiation Control

Data transfers for a D SPI in DSI configuration are initiated by a condition. The transfer initiation conditions are selected by the TRRE and CID bits in the DSPI\_DSICR0. The following table lists the four transfer initiation conditions.

Table 39-75. DSI Data Transfer Initiation Control

| D SPI _DSICR0 Bits |     | Transfer Initiation Control |
|--------------------|-----|-----------------------------|
| TRRE               | CID |                             |
| 0                  | 0   | Continuous                  |
| 0                  | 1   | Change in Data              |
| 1                  | 0   | Triggered                   |
| 1                  | 1   | Triggered or Change in Data |

#### 39.5.3.5.1 Continuous Control

For Continuous Control a new DSI frame shifts out when the previous transfer cycle has completed and the Delay after Transfer ( $t_{DT}$ ) has elapsed. This has no effect when DSPI is in Slave Mode.

#### 39.5.3.5.2 Change In Data Control

For change in data control a transfer is initiated when the data to be serialized has changed since the transfer of the last DSI frame. A copy of the previously transferred DSI data is stored in DSPI\_COMPR0. When the data selected for the transfer from the DSPI\_SDR0 and DSPI\_AS DR0 registers is different from the data in DSPI\_COMPR0 a new DSI frame is transmitted.

## NOTE

It is not advisable to configure a DSPI slave with the combination DSICR0[DCONT] = 1, DSICR0[CID] = 1 ; since the following statement then holds true.

Once slave select is asserted, there is a very small window (of up to t module clocks) after every SOF (Start of Frame) during which if a write on ASDR/SDR registers occur, the next frame to be transmitted would be loaded into the shift register. However, it is not feasible that such a write be initiated and completed within this short span of time; hence the data transmitted by DSPIslave would lag by one data frame.

### 39.5.3.5.3 Triggered Control

For Triggered Control initiation of a transfer is controlled by the Hardware Trigger signal (HT). The TPOL bit in the DSPI\_DSICR0 selects the active edge of HT. For HT to have any affect, the TRRE bit in the DSPI\_DSICR0 must be set.

### 39.5.3.5.4 Triggered or Change In Data Control

For Triggered or Change in Data Control, initiation of a transfer is controlled by the HT signal or by the detection of a change in data to be serialized.

## 39.5.4 Combined Serial Interface (CSI) Configuration

The CSI Configuration of the DSPI is used to support DSPISPI and DSI functions on a frame by frame basis. CSI Configuration allows interleaving of DSI data frames from the parallel input signals with SPI data frames from the TX FIFO. The data returned from the bus slave is either used to drive the Parallel Output signals or it is stored in the RX FIFO. The CSI Configuration allows serialized data and configuration or diagnostic data to be transferred to a slave device using only one serial link. The DSPI is in CSI Configuration when the DCONF field in the DSPI\_MCR is 0b10. The following figure shows an example of how a DSPI can be used with a deserializing peripheral that supports SPI control for control and diagnostic frames.

## NOTE

SPI is used for both DSPISPI Mode and DSI mode in this diagram.

**Figure 39-48. Example of System using DSPI in CSI Configuration**

In CSI Configuration the DSPI transfers DSI data based on [DSI Transfer Initiation Control](#).

When SPI commands are in the TX FIFO, the SPI frames have priority over the DSI frames. When the TX FIFO or CMD FIFO is empty, DSI transfer resumes.

Two peripheral chip select signals indicate whether DSI data or DSPISPI data is transmitted. The user must configure the DSPI so that the two CTAR registers associated with DSI data and DSPISPI data assert different peripheral chip select signals denoted in the figure as PCSx and PCSy. The CSI Configuration is only supported in master mode.

Data returned from the external slave while a DSI frame is transferred is placed on the Parallel Output signals. Data returned from the external slave while a DSPISPI frame is transferred is moved to the RX FIFO. The TX FIFO, CMD FIFO and RX FIFO are fully functional in CSI mode.

### 39.5.4.1 CSI Serialization

Serialization in the CSI configuration is similar to serialization in DSI Configuration. The transfer attributes for DSPI frames are determined by the DSPI\_CTAR register selected by the CTAS field in the DSPI command halfword. The transfer attributes for the DSI frames are determined by the DSPI\_CTAR register selected by the DSICTAS field in the DSPI\_DSICR0.

The Parallel Inputs signal states are latched into the DSPI DSI Serialization Data Register (DSPI\_SDR0) and serialized based on the transfer initiation control settings in the DSPI\_DSICR0. When SPI frames are written to the TX FIFO (and when CMD FIFO is not empty) they have priority over DSI data from the DSPI\_SDR and are transferred at the next frame boundary. A copy of the most recently transferred DSI frame is stored in DSPI\_COMPR0. The Transfer Priority Logic selects the source of the serialized data and asserts the appropriate PCS signal.

Separate frame completion interrupts are available to indicate frame transmission completion from DSPI and DSI frames.

39.5.4.2 CSI Deserialization

The deserialized frames in CSI Configuration go into the DSPI\_DDR0 or the RX FIFO based on the transfer priority logic. When DSI frames are transferred the returned frames are deserialized and latched into the DSPI\_DDR0. When DSPI frames are transferred the returned frames are deserialized and written to the RX FIFO.

39.5.5 Module baud rate and clock delay generation

The SCK frequency and the delay values for serial transfer are generated by dividing the protocol clock frequency by a prescaler and a scaler with the option for doubling the baud rate. The following figure shows conceptually how the SCK signal is generated.

Figure 39-49. Communications clock prescalers and scalers

39.5.5.1 Baud rate generator

The baud rate is the frequency of the SCK. The protocol clock is divided by a prescaler (PBR) and scaler (BR) to produce SCK with the possibility of halving the scaler division. The DBR, PBR, and BR fields in the CTARs select the frequency of SCK by the formula in the BR field description. The following table shows an example of how to compute the baud rate.

Table 39-76. Baud rate computation example

| f <sub>p</sub> | PBR  | Prescaler | BR     | Scaler | DBR | Baud rate |
|----------------|------|-----------|--------|--------|-----|-----------|
| 100 MHz        | 0b00 | 2         | 0b0000 | 2      | 0   | 25 Mb/s   |
| 20 MHz         | 0b00 | 2         | 0b0000 | 2      | 1   | 10 Mb/s   |

NOTE

The clock frequencies mentioned in the preceding table are given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 39.5.5.2 PCS to SCK Delay ( $t_{csc}$ )

The PCS to SCK delay is the length of time from assertion of the PCS signal to the first SCK edge. See [Figure 39-51](#) for an illustration of the PCS to SCK delay. The PCSSCK and CSSCK fields in the CTAR<sub>x</sub> registers select the PCS to SCK delay by the formula in the CSSCK field description. The following table shows an example of how to compute the PCS to SCK delay.

**Table 39-77. PCS to SCK delay computation example**

| $f_{sys}$ | PCSSCK | Prescaler | CSSCK  | Scaler | PCS to SCK Delay |
|-----------|--------|-----------|--------|--------|------------------|
| 100 MHz   | 0b01   | 3         | 0b0100 | 32     | 0.96 $\mu$ s     |

PCSSCK and CSSCK fields have no effect in TSB configuration.

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 39.5.5.3 After SCK Delay ( $t_{asc}$ )

The After SCK Delay is the length of time between the last edge of SCK and the negation of PCS. See [Figure 39-51](#) and [Figure 39-52](#) for illustrations of the After SCK delay. The PASC and ASC fields in the CTAR<sub>x</sub> registers select the After SCK Delay by the formula in the ASC field description. The following table shows an example of how to compute the After SCK delay.

**Table 39-78. After SCK Delay computation example**

| $f_p$   | PASC | Prescaler | ASC    | Scaler | After SCK Delay |
|---------|------|-----------|--------|--------|-----------------|
| 100 MHz | 0b01 | 3         | 0b0100 | 32     | 0.96 $\mu$ s    |

PASC and ASC fields have no effect in TSB configuration.

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

### 39.5.5.4 Delay after Transfer ( $t_{DT}$ )

The Delay after Transfer is the minimum time between negation of the PCS signal for a frame and the assertion of the PCS signal for the next frame. See [Figure 39-51](#) for an illustration of the Delay after Transfer. The PDT and DT fields in the CTARx registers select the Delay after Transfer by the formula in the DT field description. The following table shows an example of how to compute the Delay after Transfer.

**Table 39-79. Delay after Transfer computation example**

| $f_p$   | PDT  | Prescaler | DT     | Scaler | Delay after Transfer |
|---------|------|-----------|--------|--------|----------------------|
| 100 MHz | 0b01 | 3         | 0b1110 | 32768  | 0.98 ms              |

#### NOTE

The clock frequency mentioned in the preceding table is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

When in Non-Continuous Clock mode the  $t_{DT}$  delay is configured according to the equation specified in the CTAR[DT] field description. When in Continuous Clock mode and TSB is not enabled, the delay is fixed at 1 SCK period.

In TSB mode the Delay after Transfer is equal to a number formed by concatenation of PDT and DT fields plus 1 of the SCK clock periods. See detailed information on [Timed Serial Bus \(TSB\)](#)".

### 39.5.5.5 Peripheral Chip Select Strobe Enable ( $\overline{PCSS}$ )

The  $\overline{PCSS}$  signal provides a delay to allow the PCS signals to settle after a transition occurs thereby avoiding glitches. When the Module is in Master mode and the PCSSE bit is set in the MCR,  $\overline{PCSS}$  provides a signal for an external demultiplexer to decode peripheral chip selects other than PCS5 into glitch-free PCS signals. The following figure shows the timing of the  $\overline{PCSS}$  signal relative to PCS signals.

**Figure 39-50. Peripheral Chip Select Strobe timing**

The delay between the assertion of the PCS signals and the assertion of  $\overline{\text{PCSS}}$  is selected by the PCSSCK field in the CTAR based on the following formula:

$$t_{\text{PCSSCK}} = \frac{1}{f_{\text{P}}} \times \text{PCSSCK}$$

At the end of the transfer, the delay between  $\overline{\text{PCSS}}$  negation and PCS negation is selected by the PASC field in the CTAR based on the following formula:

$$t_{\text{PASC}} = \frac{1}{f_{\text{P}}} \times \text{PASC}$$

The following table shows an example of how to compute the  $t_{\text{pcssck}}$  delay.

**Table 39-80. Peripheral Chip Select Strobe Assert computation example**

| $f_{\text{P}}$ | PCSSCK | Prescaler | Delay before Transfer |
|----------------|--------|-----------|-----------------------|
| 100 MHz        | 0b11   | 7         | 70.0 ns               |

The following table shows an example of how to compute the  $t_{\text{pasc}}$  delay.

**Table 39-81. Peripheral Chip Select Strobe Negate computation example**

| $f_{\text{P}}$ | PASC | Prescaler | Delay after Transfer |
|----------------|------|-----------|----------------------|
| 100 MHz        | 0b11 | 7         | 70.0 ns              |

The  $\overline{\text{PCSS}}$  signal is not supported when Continuous Serial Communication SCK or TSB mode is enabled.

### NOTE

The clock frequency mentioned in the preceding tables is given as an example. Refer to the clocking chapter for the frequency used to drive this module in the device.

## 39.5.6 Transfer formats

The DSPI serial communication is controlled by the Serial Communications Clock (SCK) signal and the PCS signals. The SCK signal provided by the master device synchronizes shifting and sampling of the data on the SIN and SOUT pins. The PCS signals serve as enable signals for the slave devices.

In Master mode, the CPOL and CPHA bits in the Clock and Transfer Attributes Registers (CTARn) select the polarity and phase of the serial clock, SCK.

- CPOL - Selects the idle state polarity of the SCK
- CPHA - Selects if the data on SOUT is valid before or on the first SCK edge

Even though the bus slave does not control the SCK signal, in Slave mode the values of CPOL and CPHA must be identical to the master device settings to ensure proper transmission. In DSPI Slave mode, only CTAR0 is used. In DSI slave mode, only CTAR1 is used.

The module supports four different transfer formats:

- Classic DSPI with CPHA=0
- Classic DSPI with CPHA=1
- Modified Transfer Format with CPHA = 0
- Modified Transfer Format with CPHA = 1

A modified transfer format is supported to allow for high-speed communication with peripherals that require longer setup times. The module can sample the incoming data later than halfway through the cycle to give the peripheral more setup time. The MTFE bit in the MCR selects between Classic DSPI Format and Modified Transfer Format.

In the interface configurations, the module provides the option of keeping the PCS signals asserted between frames. See [Continuous Selection Format](#) for details.

### **39.5.6.1 Classic SPI Transfer Format (CPHA = 0)**

The transfer format shown in following figure is used to communicate with peripheral DSPI slave devices where the first data bit is available on the first clock edge. In this format, the master and slave sample their SIN pins on the odd-numbered SCK edges and change the data on their SOUT pins on the even-numbered SCK edges.

**Figure 39-51. Module transfer timing diagram (MTFE=0, CPHA=0, FMSZ=8)**

The master initiates the transfer by placing its first data bit on the SOUT pin and asserting the appropriate peripheral chip select signals to the slave device. The slave responds by placing its first data bit on its SOUT pin. After the  $t_{CSC}$  delay elapses, the master outputs the first edge of SCK. The master and slave devices use this edge to sample the first input data bit on their serial data input signals. At the second edge of the SCK, the master and slave devices place their second data bit on their serial data output signals. For the rest of the frame the master and the slave sample their SIN pins on the odd-numbered clock edges and changes the data on their SOUT pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signals. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 39.5.6.2 Classic DSPI Transfer Format (CPHA = 1)

This transfer format shown in the following figure is used to communicate with peripheral DSPI slave devices that require the first SCK edge before the first data bit becomes available on the slave SOUT pin. In this format, the master and slave devices change the data on their SOUT pins on the odd-numbered SCK edges and sample the data on their SIN pins on the even-numbered SCK edges.

**Figure 39-52. Module transfer timing diagram (MTFE=0, CPHA=1, FMSZ=8)**

The master initiates the transfer by asserting the PCS signal to the slave. After the  $t_{CSC}$  delay has elapsed, the master generates the first SCK edge and at the same time places valid data on the master SOUT pin. The slave responds to the first SCK edge by placing its first data bit on its slave SOUT pin.

At the second edge of the SCK the master and slave sample their SIN pins. For the rest of the frame the master and the slave change the data on their SOUT pins on the odd-numbered clock edges and sample their SIN pins on the even-numbered clock edges. After the last clock edge occurs, a delay of  $t_{ASC}$  is inserted before the master negates the PCS signal. A delay of  $t_{DT}$  is inserted before a new frame transfer can be initiated by the master.

### 39.5.6.3 Modified DSPI DSI Transfer Format (MTFE = 1, CPHA = 0)

In this Modified Transfer Format both the master and the slave sample later in the SCK period than in Classic DSPI mode to allow the logic to tolerate more delays in device pads and board traces. These delays become a more significant fraction of the SCK period as the SCK period decreases with increasing baud rates.

The master and the slave place data on the SOUT pins at the assertion of the PCS signal. After the PCS to SCK delay has elapsed the first SCK edge is generated. The slave samples the master SOUT signal on every odd numbered SCK edge. The DSPI in the slave mode when the MTFE bit is set also places new data on the slave SOUT on every odd numbered clock edge. Regular external slave, configured with CPHA=0 format drives its SOUT output at every even numbered SCK clock edge.

The DSPI master places its second data bit on the SOUT line one protocol clock after odd numbered SCK edge if the protocol clock frequency to SCK frequency ratio is higher than three. If this ratio is below four the master changes SOUT at odd numbered SCK edge. The point where the master samples the SIN is selected by the DSPI\_MCR[SMPL\_PT] field. The master sample point can be delayed by one or two protocol clock cycles. The SMPL\_PT field should be set to 0 if the protocol to SCK frequency ratio is less than 4. However if this ratio is less than 4, the actual sample point is delayed by one protocol clock cycle automatically by the design.

The following timing diagrams illustrate the DSPI operation with MTFE=1. Timing delays shown are:

- $T_{csc}$  - PCS to SCK assertion delay
- $T_{acs}$  - After SCK PCS negation delay
- $T_{su_{ms}}$  - master SIN setup time
- $T_{hd_{ms}}$  - master SIN hold time
- $T_{vd_{sl}}$  - slave data output valid time, time between slave data output SCK driving edge and data becomes valid.
- $T_{su_{sl}}$  - data setup time on slave data input
- $T_{hd_{sl}}$  - data hold time on slave data input
- $T_{sys}$  - protocol clock period.

The following figure shows the modified transfer format for CPHA = 0 and Fsys/Fsck = 4. Only the condition where CPOL = 0 is illustrated. Solid triangles show the data sampling clock edges. The two possible slave behavior are shown.

- Signal, marked "SOUT of Ext Slave", presents regular DSPI slave serial output.
- Signal, marked "SOUT of DSPI Slave", presents DSPI in the slave mode with MTFE bit set.

Other MTFE = 1 diagrams show DSPI SIN input as being driven by a regular external DSPI slave, configured according DSPI master CPHA programming.

**Note**

In the following diagrams,  $f_{sys}$  represents the protocol clock frequency from which the Baud frequency  $f_{sck}$  is derived.

**NOTE**

DSPI is used for both DSPI Mode and DSI mode in the following diagrams.

**Figure 39-53. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/4$ )**

**Figure 39-54. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/2$ )**

Figure 39-55. DSPI Modified Transfer Format (MTFE=1, CPHA=0,  $f_{sck} = f_{sys}/3$ )

#### 39.5.6.4 Modified SPI/DSI Transfer Format (MTFE = 1, CPHA = 1)

The following figures show the Modified Transfer Format for CPHA = 1. Only the condition, where CPOL = 0 is shown. At the start of a transfer the DSPI asserts the PCS signal to the slave device. After the PCS to SCK delay has elapsed the master and the slave put data on their SOUT pins at the first edge of SCK

#### NOTE

SPI is used for both DSPI Mode and DSI mode in the following diagrams.

. The slave samples the master SOUT signal on the even numbered edges of SCK. The master samples the slave SOUT signal on the odd numbered SCK edges starting with the third SCK edge. The slave samples the last bit on the last edge of the SCK. The master samples the last slave SOUT bit one half SCK cycle after the last edge of SCK. No clock edge will be visible on the master SCK pin during the sampling of the last bit. **The SCK to PCS delay and the After SCK delay must be greater or equal to half of the SCK period.**

Figure 39-56. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/2$ )

Figure 39-57. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/3$ )

**Figure 39-58. DSPI Modified Transfer Format (MTFE=1, CPHA=1,  $f_{sck} = f_{sys}/4$ )**

### 39.5.6.5 Continuous Selection Format

Some peripherals must be deselected between every transfer. Other peripherals must remain selected between several sequential serial transfers. The Continuous Selection Format provides the flexibility to handle both the following cases. The Continuous Selection Format is enabled for the DSPI configuration by setting the CONT bit in the DSPI command. Continuous Selection is enabled for the DSI Configuration by setting the DCONT bit in the DSICR0. The behavior of the PCS signals in the two configurations is identical so only DSPI configuration will be described.

When the CONT bit = 0, the module drives the asserted Chip Select signals to their idle states in between frames. The idle states of the Chip Select signals are selected by the PCSISn bits in the MCR. The following timing diagram is for two four-bit transfers with CPHA = 1 and CONT = 0.

**Figure 39-59. Example of non-continuous format (CPHA=1, CONT=0)**

When the CONT bit = 1, the PCS signal remains asserted for the duration of the two transfers. The Delay between Transfers ( $t_{DT}$ ) is not inserted between the transfers. The following figure shows the timing diagram for two four-bit transfers with CPHA = 1 and CONT = 1.

**Figure 39-60. Example of continuous transfer (CPHA=1, CONT=1)**

When using the module with continuous selection follow these rules:

- All transmit commands must have the same PCSn bits programming.
- The CTARs, selected by transmit commands, must be programmed with the same transfer attributes. Only FMSZ field can be programmed differently in these CTARs.

- When transmitting multiple frames in this mode, the user software must ensure that the last frame has the PUSHHR[CONT] bit deasserted in Master mode and the user software must provide sufficient frames in the TX\_FIFO to be sent out in Slave mode and the master deasserts the PCSn at end of transmission of the last frame.
- PUSHHR[CONT] and DSICR0[DCONT] must be deasserted before asserting MCR[HALT] in master mode. This will make sure that the PCSn signals are deasserted. Asserting MCR[HALT] during continuous transfer will cause the PCSn signals to remain asserted and hence Slave Device cannot transition from Running to Stopped state.

### NOTE

User must fill the TX FIFO with the number of entries that will be concatenated together under one PCS assertion for both master and slave before the TX FIFO becomes empty.

When operating in Slave mode, ensure that when the last entry in the TX FIFO is completely transmitted, that is, the corresponding TCF flag is asserted and TXFIFO is empty, the slave is deselected for any further serial communication; otherwise, an underflow error occurs.

## 39.5.7 Continuous Serial Communications Clock

The module provides the option of generating a Continuous SCK signal for slave peripherals that require a continuous clock.

Continuous SCK is enabled by setting the CONT\_SCKE bit in the MCR. Enabling this bit generates the Continuous SCK only if MCR[HALT] bit is low. Continuous SCK is valid in all configurations.

Continuous SCK is only supported for CPHA=1. Clearing CPHA is ignored if the CONT\_SCKE bit is set. Continuous SCK is supported for Modified Transfer Format.

Clock and transfer attributes for the Continuous SCK mode are set according to the following rules:

- When the module is in DSPI configuration, CTAR0 is used initially. At the start of each DSPI frame transfer, the CTAR specified by the CTAS for the frame is used.
- When the module is in DSI configuration, the CTAR specified by the DSICTAS field is used at all times.

- When the module is in CSI configuration, the CTAR selected by the DSICTAS field is used initially.
- At the start of a DSPI frame transfer, the CTAR specified by the CTAS value for the frame is used.
- At the start of a DSI frame transfer, the CTAR specified by the DSICTAS field is used.
- In all configurations, the currently selected CTAR remains in use until the start of a frame with a different CTAR specified, or the Continuous SCK mode is terminated.

It is recommended to keep the baud rate the same while using the Continuous SCK. Switching clock polarity between frames while using Continuous SCK can cause errors in the transfer. Continuous SCK operation is not guaranteed if the module is put into the External Stop mode or Module Disable mode.

Enabling Continuous SCK disables the PCS to SCK delay and the Delay after Transfer ( $t_{DT}$ ) is fixed to one SCK cycle. When TSB configuration is enabled the  $t_{DT}$  is programmable from 1 to 64 SCK cycles. The following figure is the timing diagram for Continuous SCK format with Continuous Selection disabled.

### NOTE

In Continuous SCK mode, for the DSPI transfer CTAR0 should always be used, and the TX FIFO must be cleared using the MCR[CLR\_TXF] field before initiating transfer.

**Figure 39-61. Continuous SCK Timing Diagram (CONT=0)**

If the CONT bit in the TX FIFO entry is set or the DCONT in DSICR0 is set, PCS remains asserted between the transfers. Under certain conditions, SCK can continue with PCS asserted, but with no data being shifted out of SOUT, that is, SOUT pulled high. This can cause the slave to receive incorrect data. Those conditions include:

- Continuous SCK with CONT bit set, but no data in the TX FIFO.
- Continuous SCK with CONT bit set and entering Stopped state (refer to [Start and Stop of module transfers](#)).
- Continuous SCK with CONT bit set and entering Stop mode or Module Disable mode.

The following figure shows timing diagram for Continuous SCK format with Continuous Selection enabled.

**Figure 39-62. Continuous SCK timing diagram (CONT=1)**

### 39.5.8 Slave Mode Operation Constraints

Slave mode logic shift register is buffered. This allows data streaming operation, when the module is permanently selected and data is shifted in with a constant rate.

The transmit data is transferred at second SCK clock edge of the each frame to the shift register if the  $\overline{SS}$  signal is asserted and any time when transmit data is ready and  $\overline{SS}$  signal is negated.

Received data is transferred to the receive buffer at last SCK edge of each frame, defined by frame size programmed to the CTAR0/1 register. Then the data from the buffer is transferred to the RXFIFO or DDR register.

If the  $\overline{SS}$  negates before that last SCK edge, the data from shift register is lost.

### 39.5.9 Timed Serial Bus (TSB)

The DSPI can be programmed in Timed Serial Bus configuration by setting the TSBC bit in the DSPI\_DSICR0 register. See DSPI DSI Configuration Register 0 (DSPI\_DSICR0) for details.

TSB configuration provides the Micro Second Channel (MSC) downstream channel support.

The MSC upstream channel is not supported by the DSPI, but can be supported by any available Serial Communication Controller (SCI or UART) in the SoC.

The DSI Continuous Frame Selection Format is not supported by the TSB Mode (DSICR0[DCONT] bit cannot not be asserted).

To work in TSB mode the DSPI must be in master mode and in DSI (DCONF = 0b01) or CSI (DCONF = 0b10) configuration. Both Continuous and Non Continuous Serial Communication Clock (controlled by the DSPI\_MCR[CONT\_SCKE] bit) are supported in the TSB mode.

The following figure shows the signals used in the TSB interface.

In the TSB configuration the DSPI is able to send from 4 to 34 bits MSC data frames (4 to 32 serialized data bits and up to 2 Data Selection zero bits). The serialized data bits source can be either:

- the DSPI DSI Alternate Serialization Data Register (DSPI\_ASDR0), written by the host software,
- Parallel Input pin states latched into the DSPIDSI Serialization Data Register (DSPI\_SDR0).

DSPI\_DSICR0 TXSS bit or DSPI\_SSR0 register bits define the source of the data.

The Least Significant Bits of the DSPI\_ASDR0 or DSPI\_SDR0 registers are selected to be serialized if the data frame is set to less than 32 bits.

#### NOTE

SPI is used for both DSPI Mode and DSI mode in this diagram.

**Figure 39-63. DSPI usage in the TSB Configuration**

The PCS signals are driven together with SOUT. The  $t_{CSC}$  and  $t_{ASC}$  delays are not available. Delay after Transfer (DT) is set in SCK clock periods as a binary number formed by concatenation of the DSPI\_CTARn PDT and DT fields plus one, allowing to set DT from 1 to 64 serial clock periods. DT field provides least significant bits and PDT field provides most significant bits of the Delay after Transfer.

**Figure 39-64. TSB Downstream Frames**

Above figure shows the two types of MSC downstream frames - command frame, and data frame.

The first transmitted bit, called the selection bit, determines the frame type:

- The selection bit "0" indicates a data frame
- The selection bit "1" indicates a command frame

Data frame may contain up to 2 selection bits to support two external slave devices, (so called dual receiver configuration) or no selection bits at all.

The command frame can be written by software, through DSPI TX FIFO, using one or two FIFO entries with help of the CONT bit. The data frame consists of up to 32 bits from the SDR0 or ASDR0 registers and up to two selection bits (0). Number of data bits in the data frame is defined by the DSCICR1[TSBCNT] field.

The selection bit of the MSC command frames (1) can be implemented by software.

The selection bits in the data frames are enabled by DSPI\_DSICR1 DSE0 and DSE1 bits. Each DSEn bit set increases the data frame size by one bit.

To comply with MSC specification, set DSPI\_CTARn[LSBFE] to transmit least significant bit first.

Regardless the LSBFE bit setting, the Data Frame Selection Bits, if enabled, are always transmitted first, before corresponded data sub frames.

### **39.5.9.1 MSC Dual Receiver Support with PCS Switch Over**

When in TSB mode it is possible to switch the set of PCS signals that are driven during the first part of the frame to a different set of PCS signals during the second part of the frame. The bit, at which this switch over occurs, is defined by FMSZ field of the DSPI\_CTARn register, selected by DSICTAS field of the DSICR0 register.

Number of the bits, not including the Data Selection Bit, in the first part of the frame is equal to value of the FMSZ field plus one. During this part of the frame the PCS signal levels are controlled by DSPI\_DSICR0 DPCS<sub>n</sub> bits, after that by DSPI\_DSICR1 DPCS1<sub>n</sub> bits.

The PCS switch over occurs at driving edge of the SCK clock output.

The second Data Selection Bit is inserted after the PCS switch over if enabled.

Data Frame with PCS switch over is shown in the following figure.

**Figure 39-65. TSB Data Frame Format for MSC Dual Receiver Operation**

### 39.5.10 Parity Generation and Check

The module can generate and check parity in the serial frame. The parity bit replaces the last transmitted bit in the frame. The parity is calculated for all transmitted data bits in frame, not including the last data bit that would be transmitted. The parity generation/control is done on frame basis. The registers field setting frame size defines the total number of bits in the frame, including the parity bit. Thus, to transmit/receive the same number of data bits with parity check, increase the frame size by one versus the same data size frame without the parity check.

Parity can be selected as odd or even. Parity Errors in the received frame set Parity Error flags in the Status register. The Parity Error Interrupt Requests are generated if enabled. The module can be programmed to stop frame transmission in case of a frame reception with parity error.

#### 39.5.10.1 Parity for DSPI Frames

When the module is in the master mode the parity generation is controlled by PE and PP bits of the CMD FIFO entries (PUSHR). Setting the PE bit enables parity generation for transmitted DSPI frames and parity check for received frames. PP bit defines polarity of the parity bit.

When continuous PCS selection is used to transmit DSPI data, two parity generation scenarios are available:

- Generate/check parity for the whole frame
- Generate/check parity for each sub-frame separately.

To generate/check parity for the whole frame set PE bit only in the last command/TX FIFO entry, forming this frame (with the PUSHR register).

To generate/check parity for each sub-frame set PE bit in each command/TX FIFO entry, forming this frame.

If the parity error occurs for received DSPI frame, the SR[SPEF] bit is set. If MCR[PES] bit is set, the module stops DSPI frames transmission. To resume DSPI operation clear the SR[SPEF] or the MCR[PES] bits.

In slave mode the parity is controlled by the PE and PP bits of the CTAR0 register similar to the master mode parity generation without continuous PCS selection.

### 39.5.10.2 Parity for DSI Frames

When DSPI is in Master Mode, parity generation is controlled by PE and PP bits of the DSPI\_DSICR0 register similar to the DSPI frames. The parity is calculated and checked for each DSI frame. DSPI\_DSICR0[DCONT] bit has no effect on parity generation. In slave mode the parity is controlled by the PE and PP bits of the CTAR1 register.

If the parity error occurs for received DSI frame, the DSPI\_SR[DPEF] bit is set. If DSPI\_DSICR0[PES] bit is set, the DSPI stops DSI frames transmission. To resume DSI operation clear the DSPI\_SR[DPEF] or the DSPI\_DSICR0[PES] bits.

### 39.5.11 Interrupts/DMA requests

The module has several conditions that can generate only interrupt requests and two conditions that can generate interrupt or DMA requests. The following table lists these conditions.

**Table 39-82. Interrupt and DMA request conditions**

| Condition                   | Flag | Interrupt | DMA |
|-----------------------------|------|-----------|-----|
| End of Queue (EOQ)          | EOQF | Yes       | -   |
| TX FIFO Fill                | TFFF | Yes       | Yes |
| Transfer Complete           | TCF  | Yes       | -   |
| TX FIFO Underflow           | TFUF | Yes       | -   |
| RX FIFO Drain               | RFDF | Yes       | Yes |
| RX FIFO Overflow            | RFOF | Yes       | -   |
| DSPI Parity Error           | SPEF | Yes       | -   |
| DSI Parity Error            | DPEF | Yes       | -   |
| DSI Deserialized Data Match | DDIF | Yes       | -   |

Each condition has a flag bit in the module Status Register (SR) and a Request Enable bit in the DMA/Interrupt Request Select and Enable Register (RSER). Certain flags (as shown in above table) generate interrupt requests or DMA requests depending on configuration of RSER register.

### 39.5.11.1 End Of Queue interrupt request

The End Of Queue (EOQ) interrupt request indicates that the end of a transmit queue is reached. The module generates the interrupt request when EOQ interrupt requests are enabled (RSER[EOQF\_RE]) and the EOQ bit in the executing DSPI command is 1.

The module generates the interrupt request when the last bit of the DSPI frame with EOQ bit set is transmitted.

### 39.5.11.2 Transmit FIFO Fill Interrupt or DMA Request

The Transmit FIFO Fill Request indicates that the TX FIFO is not full. The Transmit FIFO Fill Request is generated when the number of entries in the TX FIFO is less than the maximum number of possible entries, and the TFFF\_RE bit in the RSER is set. The TFFF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated.

#### NOTE

TFFF flag clears automatically when DMA is used to fill TX FIFO. Configure the DMA to fill only one FIFO location per transfer.

To clear TFFF when not using DMA, follow these steps for every PUSH performed using CPU to fill TX FIFO:

1. Wait until TFFF = 1.
2. Write data to PUSHR using CPU.
3. Clear TFFF by writing a 1 to its location. If TX FIFO is not full, this flag will not clear.

### 39.5.11.3 Transfer Complete Interrupt Request

The Transfer Complete Request indicates the end of the transfer of a serial frame. The Transfer Complete Request is generated at the end of each frame transfer when the TCF\_RE bit is set in the RSER.

#### **39.5.11.4 Transmit FIFO Underflow Interrupt Request**

The Transmit FIFO Underflow Request indicates that an underflow condition in the TX FIFO has occurred. The transmit underflow condition is detected only for the module operating in Slave mode and DSPI configuration. The TFUF bit is set when the TX FIFO of the module is empty, and a transfer is initiated from an external SPI master. If the TFUF bit is set while the TFUF\_RE bit in the RSER is set, an interrupt request is generated.

#### **39.5.11.5 Receive FIFO Drain Interrupt or DMA Request**

The Receive FIFO Drain Request indicates that the RX FIFO is not empty. The Receive FIFO Drain Request is generated when the number of entries in the RX FIFO is not zero, and the RFDF\_RE bit in the RSER is set. The RFDF\_DIRS bit in the RSER selects whether a DMA request or an interrupt request is generated. Configure the DMA to drain only one FIFO location per transfer.

#### **39.5.11.6 Receive FIFO Overflow Interrupt Request**

The Receive FIFO Overflow Request indicates that an overflow condition in the RX FIFO has occurred. A Receive FIFO Overflow request is generated when RX FIFO and shift register are full and a transfer is initiated. The RFOF\_RE bit in the RSER must be set for the interrupt request to be generated.

Depending on the state of the ROOE bit in the MCR, the data from the transfer that generated the overflow is either ignored or shifted in to the shift register. If the ROOE bit is set, the incoming data is shifted in to the shift register. If the ROOE bit is cleared, the incoming data is ignored.

#### **39.5.11.7 DSPI Frame Parity Error Interrupt Request**

The SPI Frame Parity Error Flag indicates that a DSPI frame with parity error had been received. The SPEF\_RE bit in the RSER must be set for the interrupt request to be generated.

### 39.5.11.8 DSI Frame Parity Error Interrupt Request

The DSI Frame Parity Error Flag indicates that a DSI frame with parity error has been received. The DPEF\_RE bit in the DSPI\_RSER must be set for the interrupt request to be generated.

### 39.5.11.9 Deserialized Data Match Interrupt Request

The Deserialized Data Match Flag (DDIF) indicates that a DSI frame matches DSPI\_DPIR0 data, masked with DSPI\_DIMR0, had been received. The DDIF\_RE bit in the DSPI\_RSER must be set for the request to be generated.

## 39.5.12 Power saving features

The module supports following power-saving strategies:

- External Stop mode
- Module Disable mode – Clock gating of non-memory mapped logic

### 39.5.12.1 Stop mode (External Stop mode)

This module supports the Stop mode protocol. When a request is made to enter External Stop mode, the module acknowledges the request. If a serial transfer is in progress, then this module waits until it reaches the frame boundary before it is ready to have its clocks shut off. While the clocks are shut off, this module's memory-mapped logic is not accessible. This also puts the module in STOPPED state. The SR[TXRXS] bit is cleared to indicate STOPPED state. The states of the interrupt and DMA request signals cannot be changed while in External Stop mode.

### 39.5.12.2 Module Disable mode

Module Disable mode is a block-specific mode that the module can enter to save power. Host CPU can initiate the Module Disable mode by setting the MDIS bit in the MCR. The Module Disable mode can also be initiated by hardware.

When the MDIS bit is set, the module negates the Clock Enable signal at the next frame boundary. Once the Clock Enable signal is negated, it is said to have entered Module Disable Mode. This also puts the module in STOPPED state. The SR[TXRXS] bit is

cleared to indicate STOPPED state. If implemented, the Clock Enable signal can stop the clock to the non-memory mapped logic. When Clock Enable is negated, the module is in a dormant state, but the memory mapped registers are still accessible. Certain read or write operations have a different effect when the module is in the Module Disable mode. Reading the RX FIFO Pop Register does not change the state of the RX FIFO. Similarly, writing to the PUSHHR Register does not change the state of the TX FIFO or CMD FIFO. Clearing either of the FIFOs has no effect in the Module Disable mode. Changes to the DIS\_TXF and DIS\_RXF fields of the MCR have no effect in the Module Disable mode. In the Module Disable mode, all status bits and register flags in the module return the correct values when read, but writing to them has no effect. Writing to the TCR during Module Disable mode has no effect. Interrupt and DMA request signals cannot be cleared while in the Module Disable mode.

## 39.6 Initialization/application information

This section describes how to initialize the module.

### 39.6.1 How to manage queues

The queues are not part of the module, but it includes features in support of queue management. Queues are primarily supported in DSPI configuration.

1. When module executes last command word from a queue, the EOQ bit in the command word is set to indicate it that this is the last entry in the queue.
2. At the end of the transfer, corresponding to the command word with EOQ set is sampled, the EOQ flag (EOQF) in the SR is set.
3. The setting of the EOQF flag disables serial transmission and reception of data, putting the module in the Stopped state. The TXRXS bit is cleared to indicate the Stopped state.
4. The DMA can continue to fill TX FIFO until it is full or step 5 occurs.
5. Disable DMA transfers by disabling the DMA enable request for the DMA channel assigned to TX FIFO (and CMD FIFO) and RX FIFO. This is done by clearing the corresponding DMA enable request bits in the DMA Controller.
6. Ensure all received data in RX FIFO has been transferred to memory receive queue by reading the RXCNT in SR or by checking RFDF in the SR after each read operation of the POPR.

7. Modify DMA descriptor of TX and RX channels for new queues
8. Flush TX FIFO (and CMD FIFO) by writing a 1 to the CLR\_TXF bit in the MCR. Flush RX FIFO by writing a '1' to the CLR\_RXF bit in the MCR.
9. Clear transfer count either by setting CTCNT bit in the command word of the first entry in the new queue or via CPU writing directly to DSPI\_TCNT field in the TCR.
10. Enable DMA channel by enabling the DMA enable request for the DMA channel assigned to the module TX FIFO, (and CMD FIFO) and RX FIFO by setting the corresponding DMA set enable request bit.
11. Enable serial transmission and serial reception of data by clearing the EOQF bit.

### 39.6.2 Switching Master and Slave mode

When changing modes in the module, follow the steps below to guarantee proper operation.

1. Halt it by setting MCR[HALT].
2. Clear the transmit and receive FIFOs by writing a 1 to the CLR\_TXF and CLR\_RXF bits in MCR.
3. Set the appropriate mode in MCR[MSTR] and enable it by clearing MCR[HALT].

### 39.6.3 Initializing Module in Master/Slave Modes

Once the appropriate mode in MCR[MSTR] is configured, the module is enabled by clearing MCR[HALT]. It should be ensured that module Slave is enabled before enabling it's Master. This ensures the Slave is ready to be communicated with, before Master initializes communication.

### 39.6.4 Baud rate settings

The following table shows the baud rate that is generated based on the combination of the baud rate prescaler PBR and the baud rate scaler BR in the CTARs. The values calculated assume a 100 MHz protocol frequency and the double baud rate DBR bit is cleared.

**Table 39-83. Baud rate values (bps)**

|                         |       | Baud rate divider prescaler values |       |       |       |
|-------------------------|-------|------------------------------------|-------|-------|-------|
|                         |       | 2                                  | 3     | 5     | 7     |
| Baud Rate Scaler Values | 2     | 25.0M                              | 16.7M | 10.0M | 7.14M |
|                         | 4     | 12.5M                              | 8.33M | 5.00M | 3.57M |
|                         | 6     | 8.33M                              | 5.56M | 3.33M | 2.38M |
|                         | 8     | 6.25M                              | 4.17M | 2.50M | 1.79M |
|                         | 16    | 3.12M                              | 2.08M | 1.25M | 893k  |
|                         | 32    | 1.56M                              | 1.04M | 625k  | 446k  |
|                         | 64    | 781k                               | 521k  | 312k  | 223k  |
|                         | 128   | 391k                               | 260k  | 156k  | 112k  |
|                         | 256   | 195k                               | 130k  | 78.1k | 55.8k |
|                         | 512   | 97.7k                              | 65.1k | 39.1k | 27.9k |
|                         | 1024  | 48.8k                              | 32.6k | 19.5k | 14.0k |
|                         | 2048  | 24.4k                              | 16.3k | 9.77k | 6.98k |
|                         | 4096  | 12.2k                              | 8.14k | 4.88k | 3.49k |
|                         | 8192  | 6.10k                              | 4.07k | 2.44k | 1.74k |
|                         | 16384 | 3.05k                              | 2.04k | 1.22k | 872   |
|                         | 32768 | 1.53k                              | 1.02k | 610   | 436   |

### 39.6.5 Delay settings

The following table shows the values for the Delay after Transfer ( $t_{DT}$ ) and CS to SCK Delay ( $T_{CSC}$ ) that can be generated based on the prescaler values and the scaler values set in the CTARs. The values calculated assume a 100 MHz protocol frequency.

#### NOTE

The clock frequency mentioned above is given as an example in this chapter. See the clocking chapter for the frequency used to drive this module in the device.

This table does not apply for TSB Continuous mode.

**Table 39-84. Delay values**

|                     |       | Delay prescaler values |               |               |               |
|---------------------|-------|------------------------|---------------|---------------|---------------|
|                     |       | 1                      | 3             | 5             | 7             |
| Delay scaler values | 2     | 20.0 ns                | 60.0 ns       | 100.0 ns      | 140.0 ns      |
|                     | 4     | 40.0 ns                | 120.0 ns      | 200.0 ns      | 280.0 ns      |
|                     | 8     | 80.0 ns                | 240.0 ns      | 400.0 ns      | 560.0 ns      |
|                     | 16    | 160.0 ns               | 480.0 ns      | 800.0 ns      | 1.1 $\mu$ s   |
|                     | 32    | 320.0 ns               | 960.0 ns      | 1.6 $\mu$ s   | 2.2 $\mu$ s   |
|                     | 64    | 640.0 ns               | 1.9 $\mu$ s   | 3.2 $\mu$ s   | 4.5 $\mu$ s   |
|                     | 128   | 1.3 $\mu$ s            | 3.8 $\mu$ s   | 6.4 $\mu$ s   | 9.0 $\mu$ s   |
|                     | 256   | 2.6 $\mu$ s            | 7.7 $\mu$ s   | 12.8 $\mu$ s  | 17.9 $\mu$ s  |
|                     | 512   | 5.1 $\mu$ s            | 15.4 $\mu$ s  | 25.6 $\mu$ s  | 35.8 $\mu$ s  |
|                     | 1024  | 10.2 $\mu$ s           | 30.7 $\mu$ s  | 51.2 $\mu$ s  | 71.7 $\mu$ s  |
|                     | 2048  | 20.5 $\mu$ s           | 61.4 $\mu$ s  | 102.4 $\mu$ s | 143.4 $\mu$ s |
|                     | 4096  | 41.0 $\mu$ s           | 122.9 $\mu$ s | 204.8 $\mu$ s | 286.7 $\mu$ s |
|                     | 8192  | 81.9 $\mu$ s           | 245.8 $\mu$ s | 409.6 $\mu$ s | 573.4 $\mu$ s |
|                     | 16384 | 163.8 $\mu$ s          | 491.5 $\mu$ s | 819.2 $\mu$ s | 1.1 ms        |
|                     | 32768 | 327.7 $\mu$ s          | 983.0 $\mu$ s | 1.6 ms        | 2.3 ms        |
|                     | 65536 | 655.4 $\mu$ s          | 2.0 ms        | 3.3 ms        | 4.6 ms        |

### 39.6.6 Calculation of FIFO pointer addresses

Complete visibility of the FIFO contents is available through the FIFO registers, and valid entries can be identified through a memory-mapped pointer and counter for each FIFO. The pointer to the first-in entry in each FIFO is memory mapped. For the TX FIFO the first-in pointer is the Transmit Next Pointer (TXNXTPTR). For the CMD FIFO the first-in pointer is the Command Next Pointer (CMDNXTPTR). For the RX FIFO the first-in pointer is the Pop Next Pointer (POPNXTPTR). The following figure illustrates the concept of first-in and last-in FIFO entries along with the FIFO Counter. The TX FIFO is chosen for the illustration, but the concepts carry over. See [Transmit First In First Out \(TX FIFO\) buffering mechanism](#), [Command First In First Out \(CMD FIFO\) Buffering Mechanism](#) and [Receive First In First Out \(RX FIFO\) buffering mechanism](#) for details on the FIFO operation.

Figure 39-66. TX FIFO pointers and counter

### 39.6.6.1 Address Calculation for the First-in Entry and Last-in Entry in the TX FIFO

The memory address of the first-in entry in the TX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the TX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

TX FIFO Base - Base address of TX FIFO

TXCTR - TX FIFO Counter

TXNXTPTR - Transmit Next Pointer

TX FIFO Depth - Transmit FIFO depth, implementation specific

### 39.6.6.2 Address Calculation for the First-in Entry and Last-in Entry in the CMD FIFO

The memory address of the first-in entry in the CMD FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{TXFIFOBase} + (4 \times \text{TXNXTPTR})$$

The memory address of the last-in entry in the CMD FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{TXFIFOBase} + 4 \times (\text{TXCTR} + \text{TXNXTPTR} - 1) \bmod (\text{TXFIFOdepth})$$

CMD FIFO Base - Base address of CMD FIFO

CMDCTR - CMD FIFO Counter

CMDNXTPTR - Command Next Pointer

CMD FIFO Depth - Command FIFO depth, implementation specific

### 39.6.6.3 Address Calculation for the First-in Entry and Last-in Entry in the RX FIFO

The memory address of the first-in entry in the RX FIFO is computed by the following equation:

$$\text{First-in EntryAddress} = \text{RX FIFOBase} + (4 \times \text{POPNXTPTR})$$

The memory address of the last-in entry in the RX FIFO is computed by the following equation:

$$\text{Last-inEntryaddress} = \text{RX FIFO Base} + 4 \times (\text{RXCTR} + \text{POPNXTPTR} - 1) \bmod (\text{RXFIFOdepth})$$

RX FIFO Base - Base address of RX FIFO

RXCTR - RX FIFO counter

POPNXTPTR - Pop Next Pointer

RX FIFO Depth - Receive FIFO depth, implementation specific

## Chapter 40

# Fast Ethernet Controller (FEC)

### 40.1 Chip-specific FEC information

This chip has one instance of the FEC module.

#### 40.1.1 FEC interface selection

On this chip, the FEC can operate using MII-Lite or RMII interfaces.

#### 40.1.2 FEC clocking

See [Ethernet clocking](#) for information about FEC clocking restrictions on this chip.

### 40.2 Introduction

The Fast Ethernet Controller (FEC) is a communication controller that supports 10 and 100 Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports five different standard MAC-PHY (physical) interfaces for connection to an external Ethernet transceiver. The FEC supports the 10/100 Mbps MII, 10/100 Mbps MII-Lite, 10/100 Mbps reduced MII, and the 10 Mbps-only 7-wire interface.

#### 40.2.1 Block diagram

[Figure 40-1](#) shows the block diagram of the FEC. The FEC is implemented with a combination of hardware and microcode. The off-chip (Ethernet) interfaces are compliant with industry and IEEE 802.3 standards.

## NOTE

When MII-Lite is used on this chip, the FEC\_TXER, FEC\_RXER, FEC\_COL, and FEC\_CRS signals shown in [Figure 40-1](#) are not used.

### Figure 40-1. FEC block diagram

The following table provides a brief description of the blocks in the previous figure.

### Table 40-1. FEC sub-block descriptions

| Block                              | Description                                                                          |
|------------------------------------|--------------------------------------------------------------------------------------|
| Control and status registers (CSR) | Provides global control (Ethernet reset and enable) and interrupt managing registers |

*Table continues on the next page...*

**Table 40-1. FEC sub-block descriptions (continued)**

| Block                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Descriptor controller             | <p>A RISC-based controller providing these functions in the FEC:</p> <ul style="list-style-type: none"> <li>• Initialization (those internal registers not initialized by you or hardware)</li> <li>• High-level control of the DMA channels (initiating DMA transfers)</li> <li>• Interpreting buffer descriptors</li> <li>• Address recognition for receive frames</li> <li>• Random number generation for transmit collision backoff timer</li> </ul> |
| DMA block                         | <p>Provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to all run independently</p> <p><b>Note:</b> In this document, "DMA" refers to the DMA block within the FEC, and is not related to any other DMA controllers that may be present on the chip.</p>                                                                                                                                |
| Media independent interface (MII) | <p>Provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of:</p> <ul style="list-style-type: none"> <li>• The management data clock (FEC_MDC)</li> <li>• The management data input/output lines (FEC_MDIO) of the MII interface</li> </ul>                                                                                                                      |
| Message information block (MIB)   | <p>Maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC, but provides valuable counters for network management.</p> <p>The counters supported are:</p> <ul style="list-style-type: none"> <li>• The RMON (RFC 1757) Ethernet Statistics group</li> <li>• Some of the IEEE 802.3 counters</li> </ul>                                                                                           |
| RAM                               | <p>Serves as the focal point of all data flow in the Fast Ethernet controller and divides into transmit and receive FIFOs. The FIFO boundaries are programmable using the FRSR register.</p> <p>User data flows to/from the DMA block from/to the receive/transmit FIFOs.</p> <p>Transmit data flows from the transmit FIFO into the transmit block.</p> <p>Receive data flows from the receive block into the receive FIFO.</p>                         |
| Transmit and receive blocks       | Provide the Ethernet MAC functionality (with some assist from microcode)                                                                                                                                                                                                                                                                                                                                                                                 |

## 40.2.2 Features

The FEC incorporates the following features:

- Support for the following Ethernet physical interfaces:<sup>1</sup>
  - 100-Mbps IEEE 802.3 MII
  - 10-Mbps IEEE 802.3 MII
  - 100-Mbps IEEE 802.3 MII-Lite

1. For interface selection options, see the chip-specific FEC information.

- 10-Mbps IEEE 802.3 MII-Lite
- 100-Mbps reduced media independent interface (RMII)
- 10-Mbps reduced media independent interface (RMII)
- 10-Mbps 7-wire interface (industry standard)
- IEEE 802.3 full duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority
- Support for full-duplex operation (200 Mbps throughput) with a minimum internal bus clock rate of 50 MHz
- Support for half-duplex operation (100 Mbps throughput) with a minimum internal bus clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
  - Frames with broadcast address may be always accepted or always rejected
  - Exact match for single 48-bit individual (unicast) address
  - Hash (64-bit hash) check of individual (unicast) addresses
  - Hash (64-bit hash) check of group (multicast) addresses
  - Promiscuous mode

### **40.2.3 Clocking requirements**

The FEC system clock frequency must be equal to or greater than the FEC protocol reference clock frequency (for example, 25 MHz system frequency for 100 Mbps protocol frequency). This requirement is true regardless of the reference selected by the application.

## **40.3 Modes of operation**

This section describes the FEC operating modes.

### 40.3.1 Full and half duplex operation

Full duplex mode is for use on point-to-point links between switches or end node to switch. Half duplex mode works in connections between an end node and a repeater or between repeaters. TCR[FDEN] controls duplex mode selection.

When configured for full duplex mode, flow control may be enabled. For more details, see:

- The RFC\_PAUSE and TFC\_PAUSE fields in the TCR
- The RCR[FCE] field
- [Full duplex flow control](#)

### 40.3.2 Interface options

The following interface options are supported<sup>2</sup>. A detailed discussion of the interface configurations is provided in [Network interface options](#).

#### 40.3.2.1 10 Mbps and 100 Mbps MII interface

The IEEE 802.3 standard defines the media independent interface (MII) for 10/100 Mbps operation. The MAC-PHY interface may be configured to operate in MII mode by programming RCR[MII\_MODE]=1.

The operation speed is determined by the FEC\_TXCLK and FEC\_RXCLK pins driven by the external transceiver. The transceiver auto-negotiates the speed or software controls it via the serial management interface (FEC\_MDC/FEC\_MDIO pins) to the transceiver. Refer to the MMFR and MSCR register descriptions, as well as the section on the MII, for a description of how to read and write registers in the transceiver via this interface.

#### 40.3.2.2 10 Mbps and 100 Mbps MII-Lite interface

MII-Lite refers to MII without the following signals:

- FEC\_COL
- FEC\_CRs

---

2. For interface selection options, see the chip-specific FEC information.

- FEC\_RXER
- FEC\_TXER

The MII-Lite connection is for PHYs that do not have all the MII pins and signals that are available for MII.

The following table provides additional information on the behavior of these signals when MII-Lite is used.

**Table 40-2. MII signals not used in MII-Lite**

| Signal   | Information                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEC_COL  | This signal is asserted by the PHY when there has been a collision. With full-duplex links, this would always be low, so this signal's absence implies either that the link is full-duplex or that collisions are handled internally within the PHY. The signal is only asserted high on simultaneous Rx and Tx on half-duplex links. As this must be handled by the PHY if the signal is not available, it can be safely pulled low. |
| FEC CRS  | Carrier sense is asserted high by the PHY to indicate that receive medium is non-idle. As in the case with the COL signal, this never occurs with full-duplex links. Again, it is recommended that this signal be pulled low using an external pulldown.                                                                                                                                                                              |
| FEC_RXER | This signal is asserted high by the PHY to signal an error to the MAC. However, in these circumstances the PHY will deliberately corrupt the CRC of the incoming frame before passing to the MAC. This input to the FEC can therefore be pulled low and any RXER can be detected by a CRC error in the received frame where the CR bit is set in the receive buffer descriptor (RxBd).                                                |
| FEC_TXER | This FEC output can be left unconfigured and unused. The signal was originally included for the test case in some PHY designs where the MAC layer in the FEC can demand that the PHY corrupt data during transmission. However, it is readily possible to do this within the MAC by setting the ABC (Append Bad CRC) bit in the transmit buffer descriptor (TxBD) for the frame being sent.                                           |

### 40.3.2.3 10 Mbps and 100 Mbps RMII interface

The reduced media independent interface (RMII) is a low-cost alternative to the IEEE802.3 MII standard. This interface provides the functionality of the MII interface on a total of 8 pins instead of 18. The RMII interface for 10/100 Ethernet MAC-PHY interface was defined by an industry consortium and is not currently included in the IEEE 802.3 standard. This functionality is selected as described in the chip configuration chapter, and is reflected in the read-only RCR[RMII\_MODE] bit. The RCR[RMII\_10T] bit determines the speed of operation. The reference clock for RMII is always 50 MHz, but this clock can be divided by 10 within the RCR register to support 10 Mbps operation. The PHY must be configured accordingly.

### 40.3.2.4 10 Mbps 7-wire interface operation

The FEC supports 7-wire interface used by many 10 Mbps Ethernet transceivers. The RCR[MII\_MODE] bit controls this functionality. If this bit is cleared, MII mode is disabled and the 10 Mbps 7-wire mode is enabled.

### 40.3.3 Address recognition options

The address options supported are:

- Promiscuous
- Broadcast reject
- Individual address (hash or exact match)
- Multicast hash match

Address recognition options are discussed in detail in [Ethernet address recognition](#).

### 40.3.4 Internal loopback

Internal loopback mode is selected via RCR[LOOP]. Loopback mode is discussed in detail in [MII internal and external loopback](#).

## 40.4 External signal description

The following table describes the various FEC signals, as well as indicating which signals work in available modes.

**Table 40-3. FEC signal descriptions**

| Signal name | MII            | 7-wire | RMII | Description                                                                                                                                                                                                                                                 |
|-------------|----------------|--------|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEC_COL     | X <sup>1</sup> | X      | —    | Asserted upon detection of a collision and remains asserted while the collision persists. This signal is not defined for full-duplex mode.                                                                                                                  |
| FEC_CRG     | X <sup>1</sup> | —      | —    | Carrier sense. When asserted, indicates transmit or receive medium is not idle. In RMII mode, this signal is present on the FEC_RXDV pin.                                                                                                                   |
| FEC_MDC     | X              | —      | X    | Output clock provides a timing reference to the PHY for data transfers on the FEC_MDIO signal.                                                                                                                                                              |
| FEC_MDIO    | X              | —      | X    | Transfers control information between the external PHY and the media-access controller. Data is synchronous to FEC_MDC. This signal is an input after reset. When the FEC operates in 10Mbps 7-wire interface mode, this signal should be connected to VSS. |

*Table continues on the next page...*

**Table 40-3. FEC signal descriptions (continued)**

| Signal name                                                                                                          | MII            | 7-wire | RMII | Description                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------------------------------------------|----------------|--------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FEC_RXCLK                                                                                                            | X              | X      | —    | Provides a timing reference for FEC_RXDV, FEC_RXD[3:0], and FEC_RXER.                                                                                                                                                                                                                                                            |
| FEC_RXDV                                                                                                             | X              | X      | X    | Asserting the FEC_RXDV input indicates PHY has valid nibbles present on the MII. FEC_RXDV must remain asserted from the first recovered nibble of the frame through to the last nibble. Assertion of FEC_RXDV must start no later than the SFD and exclude any EOF.<br><br>In RMII mode, this pin also generates the CRS signal. |
| FEC_RXD0                                                                                                             | X              | X      | X    | This pin contains the Ethernet input data transferred from PHY to the media-access controller when FEC_RXDV is asserted.                                                                                                                                                                                                         |
| FEC_RXD1                                                                                                             | X              | —      | X    | This pin contains the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.                                                                                                                                                                                                         |
| FEC_RXD[3:2]                                                                                                         | X              | —      | —    | These pins contain the Ethernet input data transferred from PHY to the media access controller when FEC_RXDV is asserted.                                                                                                                                                                                                        |

| FEC_TXD1                                                                                                             | X              | —      | X    | This pin contains the serial output Ethernet data and valid only during assertion of FEC_TXEN.                                                                                                                                                                                                                                   |
| FEC_TXD[3:2]                                                                                                         | X              | —      | —    | These pins contain the serial output Ethernet data and valid only during assertion of FEC_TXEN.                                                                                                                                                                                                                                  |
| FEC_TXEN                                                                                                             | X              | X      | X    | Indicates when valid nibbles are present on the MII. This signal is asserted with the first nibble of a preamble and is negated before the first FEC_TXCLK following the final nibble of the frame.                                                                                                                              |
| FEC_TXER                                                                                                             | X <sup>1</sup> | —      | —    | When asserted for one or more clock cycles while FEC_TXEN is also asserted, PHY sends one or more illegal symbols. FEC_TXER has no effect at 10 Mbps or when FEC_TXEN is negated.                                                                                                                                                |
| Note: Interface selection is chip-specific; see the chapter that describes how modules are configured and connected. |                |        |      |                                                                                                                                                                                                                                                                                                                                  |

1. This signal is not available in the MII-Lite interface.

## 40.5 Memory map and register definition

The FEC is programmed by a combination of control/status registers (CSRs) and buffer descriptors. The CSRs control operation modes and extract global status information. The descriptors pass data buffers and related buffer information between the hardware and software.

Each FEC implementation requires a 1 KB memory map space, which is divided into two sections of 512 bytes each for:

- Control/status registers
- Event/statistic counters held in the MIB block

The following table defines the top-level memory map.

**Table 40-4. FEC memory map**

| Address offset | Function                 |
|----------------|--------------------------|
| 000h–1FFh      | Control/status registers |
| 200h–3FFh      | MIB block counters       |

The following table shows the FEC register map. Any address offset not explicitly mentioned in this table is reserved. Do not modify the content of reserved fields. All accesses to and from the registers must be via 32-bit accesses. There is no support for accesses other than 32-bit. Accessing reserved or unimplemented register spaces in the FEC will not return transfer errors.

The MIB counters (shown in the following table) define the locations in the MIB RAM space where hardware-maintained counters reside. The counters are divided into two groups:

- RMON counters include the Ethernet statistics counters defined in RFC 1757
- Truncated frames counter (only frames with lengths up to 2047 bytes are supported)

The transmit and receive RMON counters are independent, which ensures accurate network statistics when operating in full duplex mode.

The included IEEE counters support the mandatory and recommended counter packages defined in Section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The FEC supports IEEE Basic Package objects, but these do not require counters in the MIB block. In addition, some of the recommended package objects supported do not require MIB counters. Counters for transmit and receive full duplex flow control frames are also included.

**FEC memory map**

**40.5.1 Interrupt Event Register (FEC\_EIR)**

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

These interrupts can be divided into operational interrupts, transceiver/network error interrupts, and internal error interrupts. Interrupts which may occur in normal operation are GRA, TXF, TXB, RXF, RXB, and MII. Interrupts resulting from errors/problems detected in the network or transceiver are HBERR, BABR, BABT, LC, and RL. Interrupts resulting from internal errors are HBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters:

- HBERR - IEEE\_T\_SQE
- BABR - RMON\_R\_OVERSIZE (good CRC), RMON\_R\_JAB (bad CRC)
- BABT - RMON\_T\_OVERSIZE (good CRC), RMON\_T\_JAB (bad CRC)
- LATE\_COL - IEEE\_T\_LCOL
- COL\_RETRY\_LIM - IEEE\_T\_EXCOL
- XFIFO\_UN - IEEE\_T\_MACERR

Software may choose to mask off these interrupts because these errors are visible to network management via the MIB counters.

|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>HBERR | Heartbeat error. Indicates TCR[HBC] is set and that the COL input was not asserted within the heartbeat window following a transmission.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 1<br>BABR  | Babbling receive error. Indicates a frame was received with length in excess of RCR[MAX_FL] bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2<br>BABT  | Babbling transmit error. Indicates the transmitted frame length exceeds RCR[MAX_FL] bytes. Usually this condition is caused by a frame that is too long is placed into the transmit data buffer(s). Truncation does not occur.                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3<br>GRA   | Graceful stop complete. Indicates the graceful stop is complete. During graceful stop the transmitter is placed into a pause state after completion of the frame currently being transmitted. This bit is set by one of these conditions: <ul style="list-style-type: none"> <li>A graceful stop initiated by the setting of the TCR[GTS] bit is now complete.</li> <li>A graceful stop initiated by the setting of the TCR[TFC_PAUSE] bit is now complete.</li> <li>A graceful stop initiated by the reception of a valid full duplex flow control pause frame is now complete. See <a href="#">Full duplex flow control</a>.</li> </ul> |
| 4<br>TXF   | Transmit frame interrupt. Indicates a frame has been transmitted and the last corresponding buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 5<br>TXB   | Transmit buffer interrupt. Indicates a transmit buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 6<br>RXF   | Receive frame interrupt. Indicates a frame has been received and the last corresponding buffer descriptor has been updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 7<br>RXB   | Receive buffer interrupt. Indicates a receive buffer descriptor not the last in the frame has been updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 8<br>MII   | MII interrupt. Indicates the MII has completed the data transfer requested.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 9<br>EBERR | Ethernet bus error. Indicates a system bus error occurred when a DMA transaction is underway. When the EBERR bit is set, ECR[ETHER_EN] is cleared, halting frame processing by the FEC. When this occurs, software needs to ensure that the FIFO controller and DMA also soft reset.                                                                                                                                                                                                                                                                                                                                                      |

Table continues on the next page...

**FEC\_EIR field descriptions (continued)**

| Field             | Description                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10<br>LC          | Late collision. Indicates a collision occurred beyond the collision window (slot time) in half duplex mode. The frame truncates with a bad CRC and the remainder of the frame is discarded.                                                                  |
| 11<br>RL          | Collision retry limit. Indicates a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. This error can only occur in half duplex mode. |
| 12<br>UN          | Transmit FIFO underrun. Indicates the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.                                                         |
| 13–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                      |

**40.5.2 Interrupt Mask Register (FEC\_EIMR)**

The EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR bit (write 1 to clear) or a 0 is written to the EIMR bit.

Each bit in this register corresponds to an interrupt source defined by the EIR. The corresponding EIMR bit determines whether an interrupt condition can generate an interrupt. At every processor clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR bit reflects the state of the interrupt signal even if the corresponding EIMR bit is set.

**40.5.3 Receive Descriptor Active Register (FEC\_RDAR)**

RDAR is a command register, written by the user, indicating the receive descriptor ring is updated (the driver produced empty receive buffers with the empty bit set).

When the register is written, the RDAR bit is set. This is independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (if ECR[ETHER\_EN] is also set). After the FEC polls a receive descriptor whose empty bit is not set, FEC clears the RDAR bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors are placed into the receive descriptor ring.

The RDAR is cleared at reset and when ECR[ETHER\_EN] is cleared.

Address: 0h base + 10h offset = 10h

| 7<br>RDAR        | Set to 1 when this register is written, regardless of the value written. Cleared by the FEC when no additional empty descriptors remain in the receive ring. Also cleared when ECR[ETHER_EN] is cleared. |
| 8–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                  |

40.5.4 Transmit Descriptor Active Register (FEC\_TDAR)

The TDAR is a command register which the user writes to indicate the transmit descriptor ring is updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

When the register is written, the TDAR field is set. This value is independent of the data actually written by the user. When set, the FEC polls the transmit descriptor ring and processes transmit frames (provided ECR[ETHER\_EN] is also set). After the FEC polls a transmit descriptor that is a ready bit not set, FEC clears the TDAR field and ceases transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors are placed into the transmit descriptor ring.

The TDAR field is cleared when any of the following events occur:

- Chip reset
- When ECR[ETHER\_EN] is cleared
- When ECR[RESET] is set

Address: 0h base + 14h offset = 14h

## 40.5.5 Ethernet Control Register (FEC\_ECR)

ECR is a read/write user register, though hardware may alter fields in this register as well. The ECR enables/disables the FEC.

Address: 0h base + 24h offset = 24h

| 30<br>ETHER_EN   | When this bit is set, FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is cleared, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware alters the ETHER_EN bit under the following conditions: <ul style="list-style-type: none"> <li>• ECR[RESET] is set by software, in which case ETHER_EN is cleared.</li> <li>• An error condition causes the EIR[EBERR] bit to set, in which case ETHER_EN is cleared.</li> </ul> |
| 31<br>RESET      | When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC. ECR[ETHER_EN] is cleared and all other FEC registers take their reset values. Also, any transmission/reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately eight internal bus clock cycles after this bit is set.                                                                                                                                                                                                                                                                                                                                   |

### 40.5.6 MII Management Frame Register (FEC\_MMFR)

The MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to the MMFR causes a management frame to be sourced unless the MSCR is programmed to 0. If MSCR is cleared while MMFR is written and then MSCR is written with a non-zero value, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

The MMFR does not reset to any predefined value.

To perform a read or write operation on the MII Management Interface, write the MMFR. To generate a valid read or write management frame, ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame is generated, but does not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compliant MII Management Interface write frame (write to a PHY register), write {01 01 PHYAD REGAD 10 DATA} to the MMFR. Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the write management frame operation completes, the MII interrupt is generated. At this time, contents of the MMFR match the original value written.

To generate an MII management interface read frame (read a PHY register), write {01 10 PHYAD REGAD 10 XXXX} to the MMFR (the content of the DATA field is unimportant). Writing this pattern causes the control logic to shift out the data in the MMFR following a preamble generated by the control state machine. During this time, contents of the MMFR register are altered as the contents are serially shifted and are unpredictable if read by the user. After the read management frame operation completes, the MII interrupt is generated. At this time, the contents of the MMFR register match the original value written except for the DATA field whose contents are replaced by the value read from the PHY register.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the MII interrupt to avoid writing to the MMFR while frame generation is in progress.

Address: 0h base + 40h offset = 40h

| 4–8<br>PA     | PHY address. This field specifies one of up to 32 attached PHY devices.                                                                                                                                                                           |
| 9–13<br>RA    | Register address. This field specifies one of up to 32 registers within the specified PHY device.                                                                                                                                                 |
| 14–15<br>TA   | Turn around. This field must be programmed to 10 to generate a valid MII management frame.                                                                                                                                                        |
| 16–31<br>DATA | Management frame data. This is the field for data to be written to or read from the PHY register.                                                                                                                                                 |

## 40.5.7 MII Speed Control Register (FEC\_MSCR)

The MSCR:

- Provides control of the MII clock (FEC\_MDC pin) frequency
- Allows a preamble drop on the MII management frame

The MII\_SPEED field must be programmed with a value to provide an FEC\_MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII\_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be set to 0 to turn off the FEC\_MDC. The FEC\_MDC generated has a 50% duty cycle except when MII\_SPEED changes during operation (change takes effect following a rising or falling edge of FEC\_MDC).

If the internal bus clock is 25 MHz, programming this register to 0000\_0005h results in an FEC\_MDC as stated the equation below.

$$25 \text{ MHz} \times \frac{1}{52} = 2.5 \text{ MHz}$$

**Figure 40-9. FEC\_MDC example**

[Table 40-13](#) shows optimum values for MII\_SPEED as a function of internal bus clock frequency.

**Table 40-13. Programming examples for MSCR**

| Internal FEC clock frequency | MSCR[MII_SPEED] | FEC_MDC frequency |
|------------------------------|-----------------|-------------------|
| 25 MHz                       | 5h              | 2.50 MHz          |
| 33 MHz                       | 7h              | 2.36 MHz          |
| 40 MHz                       | 8h              | 2.50 MHz          |
| 50 MHz                       | Ah              | 2.50 MHz          |
| 66 MHz                       | Eh              | 2.36 MHz          |
| 80 MHz                       | 10h             | 2.50 MHz          |
| 83 MHz                       | 10h             | 2.59 MHz          |

Address: 0h base + 44h offset = 44h

**FEC\_MSCR field descriptions**

| Field              | Description                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–23<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                |
| 24<br>DIS_PRE      | Setting this bit causes the preamble (32 ones) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.                                                                                                                  |
| 25–30<br>MII_SPEED | Controls the frequency of the MII management interface clock (FEC_MDC) relative to the internal bus clock. A value of 0 in this field turns off the FEC_MDC and leaves it in low voltage state. Any non-zero value results in the FEC_MDC frequency of $1/(\text{MII\_SPEED} \times 2)$ of the internal bus frequency. |
| 31<br>Reserved     | This field is reserved.<br>Reserved                                                                                                                                                                                                                                                                                    |

**40.5.8 MIB Control Register (FEC\_MIBC)**

The MIBC is a read/write register controlling and observing the state of the MIB block. User software accesses this register if there is a need to disable the MIB block operation. For example, to clear all MIB counters in RAM:

1. Disable the MIB block

2. Clear all the MIB RAM locations
3. Enable the MIB block

The MIB\_DIS bit is reset to 1. See the memory map for the locations of the MIB counters.

Address: 0h base + 64h offset = 64h

### FEC\_MIBC field descriptions

| Field            | Description                                                                             |
|------------------|-----------------------------------------------------------------------------------------|
| 0<br>MIB_DIS     | If MIB_DIS = 1, the MIB logic halts and not update any MIB counters.                    |
| 1<br>MIB_IDLE    | If MIB_IDLE = 1, the MIB block is not currently updating any MIB counters.              |
| 2–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

40.5.9 Receive Control Register (FEC\_RCR)

RCR controls the operational mode of the receive block and must be written only when ECR[ETHER\_EN] is cleared (initialization time).

Address: 0h base + 84h offset = 84h

FEC\_RCR field descriptions

| Field           | Description                                                                                                                                                                                                                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–4<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                              |
| 5–15<br>MAX_FL  | Maximum frame length. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL causes the BABT interrupt to occur. Receive frames longer than MAX_FL causes the BABR interrupt to occur and sets the LG bit in the end of frame receive buffer descriptor. |

Table continues on the next page...

## FEC\_RCR field descriptions (continued)

| Field             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                   | The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported.                                                                                                                                                                                                                                                                                                                                                                                                      |
| 16–19<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 20<br>RMII_ECHO   | RMII Echo. Enables RMII echo mode. RMII 2-bit receive data is processed through the RMII receive logic to the FEC and also routes through the RMII's transmit logic to become RMII 2-bit transmit data out.<br><br>0 Normal operation.<br>1 RMII echo mode enabled.<br><br><b>NOTE:</b> When RMII_ECHO is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_LOOP = 0 and LOOP = 0.                                                                                              |
| 21<br>RMII_LOOP   | RMII loopback. Enables RMII loopback mode. Causes the MII transmit outputs from the Ethernet controller to loop back to the Ethernet controllers's MII receive inputs through the RMII transmit/receive logic.<br><br>0 Normal operation.<br>1 RMII loopback mode enabled.<br><br><b>NOTE:</b> When RMII_LOOP is set, proper operation is guaranteed only when RMII_MODE = 1, RMII_ECHO = 0, LOOP = 0, and TCR <i>n</i> [FDEN] = 1.                                                             |
| 22<br>RMII_10T    | RMII 10-Base T. Enables 10Mbps mode of the RMII. Determines the clock frequency of the clock source to the FEC logic to support 10/100Mbps operations.<br><br>0 100 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is sent to the RMII, while a divided-by-2 version (25 MHz) is sent to the FEC.<br>1 10 Mbps operation. The 50 MHz RMII reference clock on FEC_TXCLK is divided by 10 (5 MHz) and sent to the RMII, while a divided-by-20 version (2.5 MHz) is sent to the FEC. |
| 23<br>RMII_MODE   | RMII Mode. Indicates if the FEC is in RMII or MII/7-wire mode. See the chip configuration chapter for more details.<br><br><b>NOTE:</b> Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.<br><br>0 FEC is in true MII mode.<br>1 FEC is in RMII mode.                                                                                                                                                                              |
| 24–25<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 26<br>FCE         | Flow control enable. If asserted, the receiver detects PAUSE frames. Upon PAUSE frame detection, the transmitter stops transmitting data frames for a given duration.                                                                                                                                                                                                                                                                                                                           |
| 27<br>BC_REJ      | Broadcast frame reject. If asserted, frames with DA (destination address) equal to FFFF_FFFF_FFFF are rejected unless the PROM bit is set. If BC_REJ and PROM are set, frames with broadcast DA are accepted and the M (MISS) is set in the receive buffer descriptor.                                                                                                                                                                                                                          |
| 28<br>PROM        | Promiscuous mode. All frames are accepted regardless of address matching.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 29<br>MII_MODE    | Media independent interface mode. Selects the external interface mode for transmit and receive blocks.<br><br><b>NOTE:</b> Interface selection is chip-specific; see the chapter that describes how modules are configured and connected.<br><br>0 7-wire mode (used only for serial 10 Mbps)<br>1 MII or RMII mode as indicated by the RMII_MODE bit                                                                                                                                           |

FEC\_RCR field descriptions (continued)

| Field      | Description                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 30<br>DRT  | Disable receive on transmit.<br><br>0 Receive path operates independently of transmit (use for full duplex or to monitor transmit activity in half duplex mode).<br>1 Disable reception of frames while transmitting (normally used for half duplex mode). |
| 31<br>LOOP | Internal loopback. If set, transmitted frames are looped back internal to the device and transmit output signals are not asserted. The internal bus clock substitutes for the FEC_TXCLK when LOOP is asserted. DRT must be set to 0 when setting LOOP.     |

40.5.10 Transmit Control Register (FEC\_TCR)

The TCR configures the transmit block.

Address: 0h base + C4h offset = C4h

## FEC\_TCR field descriptions

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–26<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 27<br>RFC_PAUSE  | Receive frame control pause. This read-only status bit is asserted when a full duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This bit automatically clears when the pause duration is complete.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 28<br>TFC_PAUSE  | Transmit frame control pause. Transmits a PAUSE frame when asserted. When this bit is set, the MAC stops transmission of data frames after the current transmission is complete. At this time, GRA interrupt in the EIR is asserted. With transmission of data frames stopped, MAC transmits a MAC Control PAUSE frame. Next, the MAC clears the TFC_PAUSE bit and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC Control PAUSE frame.                                                                                                                                                    |
| 29<br>FDEN       | Full duplex enable. If set, frames transmit independent of carrier sense and collision inputs. This field must be modified only when ECR[ETHER_EN] = 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 30<br>HBC        | Heartbeat control. If set, the heartbeat check performs following end of transmission and the HB bit in the status register is set if the collision input does not assert within the heartbeat window. This field must be modified only when ECR[ETHER_EN] = 0.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 31<br>GTS        | Graceful transmit stop. When this bit is set, MAC stops transmission after any frame currently transmitted is complete and GRA interrupt in the EIR is asserted. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this situation, program ECR[ETHER_EN] = 0 following the GRA interrupt. |

## 40.5.11 Physical Address Low Register (FEC\_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the 6-byte source address field when transmitting PAUSE frames.

This register is not reset and you must initialize it.

Address: 0h base + E4h offset = E4h

## FEC\_PALR field descriptions

| Field          | Description                                                                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>PADDR1 | Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8), and 3 (bits 7:0) of the 6-byte individual address are used for exact match and the source address field in PAUSE frames. |

40.5.12 Physical Address High Register and Type Field (FEC\_PAUR)

PAUR contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to compare with the DA (destination address) field of receive frames with an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte Source Address field when transmitting PAUSE frames. Bits 15:0 of PAUR contain a constant type field (8808h) for transmission of PAUSE frames. The upper 16 bits of this register are not reset and you must initialize them.

Address: 0h base + E8h offset = E8h

- \* Notes:
- u = Unaffected by reset.

FEC\_PAUR field descriptions

| Field          | Description                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 0–15<br>PADDR2 | Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address used for exact match, and the source address field in PAUSE frames. |
| 16–31<br>TYPE  | Type field in PAUSE frames. These 16 read-only bits are a constant value of 8808h.                                                           |

40.5.13 Opcode/Pause Duration (FEC\_OPD)

The OPD contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0001h. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field.

The lower 16 bits of this register are not reset and you must initialize them.

Address: 0h base + ECh offset = ECh

\* Notes:

- x = Undefined at reset.

### FEC\_OPD field descriptions

| Field              | Description                                                                    |
|--------------------|--------------------------------------------------------------------------------|
| 0–15<br>OPCODE     | Opcode field used in PAUSE frames. These read-only bits are a constant, 0001h. |
| 16–31<br>PAUSE_DUR | Pause Duration field used in PAUSE frames.                                     |

## 40.5.14 Descriptor Individual Upper Address Register (FEC\_IAUR)

IAUR contains the upper 32 bits of the 64-bit individual address hash table. The address recognition process uses this table to check for a possible match with the destination address (DA) field of receive frames with an individual DA.

This register is not reset and you must initialize it.

Address: 0h base + 118h offset = 118h

|       |        |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |

### FEC\_GALR field descriptions

| Field          | Description                                                                                                                                                                                                                                          |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>GADDR2 | The GADDR2 register contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0. |

## 40.5.18 Transmit FIFO Watermark (FEC\_TFWR)

The TFWR controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement (worst case bus access latency by the transmit data DMA channel).

Address: 0h base + 144h offset = 144h

**40.5.20 FIFO Receive Start Register (FEC\_FRSR)**

FRSR indicates the starting address of the receive FIFO. FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FRSR. The receive FIFO uses addresses from FRSR to FRBR inclusive.

Hardware initializes the FRSR at reset. FRSR only needs to be written to change the default value.

Address: 0h base + 150h offset = 150h

## 40.5.21 Receive Descriptor Ring Start Register (FEC\_ERDSR)

ERDSR points to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 0h base + 180h offset = 180h

**40.5.22 Transmit Buffer Descriptor Ring Start Register (FEC\_ETDSR)**

ETSDR provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 32-bit aligned; however, it is recommended it be made 128-bit aligned (evenly divisible by 16). You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions.

This register is undefined at reset and must be initialized prior to operation.

Address: 0h base + 184h offset = 184h

| 30–31<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0. |

**40.5.23 Receive Buffer Size Register (FEC\_EMRBR)**

The EMRBR dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, EMRBR must be set to RCR[MAX\_FL] or larger. To properly align the buffer, EMRBR must be evenly divisible by 16. To ensure this, bits 3-0 are forced low.

To minimize bus utilization (descriptor fetches), it is recommended that EMRBR be greater than or equal to 256 bytes.

The EMRBR is undefined at reset and must be initialized by the user.

Address: 0h base + 188h offset = 188h

| 0–31<br>IEEE_R_OCTETS_OK | Octet count for frames received without error |

## 40.5.79 Using the RMON and IEEE registers

In order to use the RMON and IEEE registers to monitor FEC performance, you must prepare them using the sequence below:

1. Write zeros to the registers.
2. Enable the FEC.

Until you complete this sequence, the registers are read/write, and their reset value is undefined. After you complete this sequence, the registers become read-only, and you may read them as necessary.

## 40.6 Functional description

This section describes the operation of the FEC, beginning with the description of two different types of MII frames, the buffer descriptors, the hardware and software initialization sequence, then the software (Ethernet driver) interface for transmitting and receiving frames.

Following the software initialization and operation sections are sections providing a detailed description of the functions of the FEC.

### 40.6.1 MII data frame

Ethernet/802.3 data frames transmitted across the MII have the format specified in [Figure 40-81](#) and [Table 40-85](#).

<inter-frame> <preamble> <sfd> <data> <efd>

**Figure 40-81. MII data frame format**

**Table 40-85. MII data frame components**

| Component     | Description                                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <inter-frame> | Inter-frame period. This is an unspecified amount of time during which no data activity occurs on the MII. The de-assertion of RX_DV and TX_EN indicate the absence of data activity. |
| <preamble>    | Preamble that begins a frame. It has the following value:<br>10101010 10101010 10101010 10101010 10101010 10101010 10101010<br>The leftmost 1 represents the LSB of the byte.         |
| <sfd>         | Start of a frame. It has the value 10101011.                                                                                                                                          |
| <data>        | Data portion of the frame. It consists of N octets which corresponds to 2N nibbles being transmitted. The order of each nibble is defined in <a href="#">Figure 40-82</a> .           |
| <efd>         | End-of-frame delimiter.                                                                                                                                                               |

Table 40-85. MII data frame components

| Component | Description                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
|           | For TXD data, it is indicated by the de-assertion of the TX_EN signal.<br>For RXD data, it is indicated by the de-assertion of the RX_DV signal. |

Figure 40-82. MII nibble/octet to octet/nibble mapping

40.6.2 MII management frame structure

A transceiver management frame being transmitted on the MII management interface uses the MDIO and MDC pins. A transaction or frame on this serial interface has the format specified in [Figure 40-83](#) and [Table 40-86](#).

<preamble> <st> <op> <phyad> <regad> <ta> <data> <idle>

Figure 40-83. MII management frame format

Table 40-86. MII management frame components

| Component  | Description                                                                                                            |
|------------|------------------------------------------------------------------------------------------------------------------------|
| <preamble> | Optional preamble, consisting of a sequence of 32 continuous logic 1's.                                                |
| <st>       | Start of frame, consisting of a 01 pattern.                                                                            |
| <op>       | Operation code.<br>01 Write operation<br>10 Read instruction                                                           |
| <phyad>    | Five-bit field that allows up to 32 PHYs to be addressed. The first address bit transmitted is the MSB of the address. |

Table continues on the next page...

**Table 40-86. MII management frame components (continued)**

| Component | Description                                                                                                                                               |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <regad>   | Five-bit field that allows for 32 registers to be addressed within each PHY. The first register bit transmitted is the MSB of the address.                |
| <ta>      | Two-bit field that provides spacing between the register address field and the data field to avoid contention on the MDIO signal during a read operation. |
| <data>    | 16-bit data field. Bit 15 is the first data bit transmitted and received.                                                                                 |
| <idle>    | Idle condition (MDIO is in the high-impedance state).                                                                                                     |

The MII management register set located in the PHY may consist of a basic register set and an extended register set as defined in [Table 40-87](#).

**Table 40-87. MII management register set**

| Register address | Register name                  | Register set |
|------------------|--------------------------------|--------------|
| 0                | Control                        | Basic        |
| 1                | Status                         |              |
| 2-3              | PHY identifier                 | Extended     |
| 4                | Auto-negotiation advertisement |              |
| 5                | AN link partner ability        |              |
| 6                | AN expansion                   |              |
| 7                | AN next page transmit          |              |

### 40.6.3 Buffer descriptors

This section provides a description of the operation of the driver/DMA via the buffer descriptors. It is followed by a detailed description of the receive and transmit descriptor fields.

#### 40.6.3.1 Driver/DMA operation with buffer descriptors

The data for the FEC frames resides in one or more memory buffers external to the FEC. Associated with each buffer is a buffer descriptor (BD), which contains a starting address (32-bit aligned pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read by the FEC DMA engine.

Software produces buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit produces the buffer. Software writing to TDAR or RDAR tells the FEC that a buffer is placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and consumes the buffers after they have been produced. After the data DMA is complete and the DMA engine writes the buffer descriptor status bits, hardware clears RxBD[E] or TxBD[R] to signal the buffer has been consumed. Software may poll the BDs to detect when the buffers are consumed or may rely on the buffer/frame interrupts. The driver may process these buffers, and they can return to the free list.

The ECR[ETHER\_EN] bit operates as a reset to the BD/DMA logic. When ECR[ETHER\_EN] is cleared, the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before ECR[ETHER\_EN] is set.

The buffer descriptors operate as two separate rings. ERDSR defines the starting address for receive BDs and ETDSR defines the starting address for transmit BDs. The wrap (W) bit defines the last buffer descriptor in each ring. When W is set, the next descriptor in the ring is at the location pointed to by ERDSR and ETDSR for the receive and transmit rings, respectively. Buffer descriptor rings must start on a 32-bit boundary; however, it is recommended they be 128-bit aligned.

#### 40.6.3.1.1 Driver/DMA operation with transmit BDs

Typically, a transmit frame is divided between multiple buffers. An example is to have an application payload in one buffer, TCP header in a second buffer, IP header in a third buffer, and Ethernet/IEEE 802.3 header in a fourth buffer. The Ethernet MAC does not prepend the Ethernet header (destination address, source address, length/type field(s)), so the driver must provide this in one of the transmit buffers. The Ethernet MAC can append the Ethernet CRC to the frame. TxBD[TC], which must be set by the driver, determines whether the MAC or driver appends the CRC.

The driver (TxBD software producer) should set up Tx BDs so a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, the BDs should be initialized with pointer, length, and control (W, L, TC, ABC) and then the TxBD[R] bit should be set in reverse order (third, second, then first BD) to ensure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA controller could DMA the first BD before the second was made available, potentially causing a transmit FIFO underrun.

In the FEC, the driver notifies the DMA that new transmit frame(s) are available by writing to TDAR. When this register is written to (data value is not significant), the FEC RISC tells the DMA to read the next transmit BD in the ring. After started, the RISC + DMA continues to read and interpret transmit BDs in order and DMA the associated buffers until a transmit BD is encountered with the R bit cleared. At this point, the FEC polls this BD one more time. If the R bit is cleared the second time, RISC stops the transmit descriptor read process until software sets up another transmit frame and writes to TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

#### 40.6.3.1.2 Driver/DMA operation with receive BDs

Unlike transmit, the length of the receive frame is unknown by the driver ahead of time. Therefore, the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the EMRBR register.

The driver (RxBD software producer) should set up some number of empty buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive DMA) consumes these buffers by filling them with data as frames are received and clearing the E bit and writing to the L bit (1 indicates last buffer in frame), the frame status bits (if L is set), and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD is written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end-of-frame buffers, the receive BD is written with L set and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame should be discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer is written with the length of the entire frame, not only the length of the last buffer.

For simplicity, the driver may assign a large enough default receive buffer length to contain an entire frame, keeping in mind that a malfunction on the network or out-of-spec implementation could result in giant frames. Frames of 2K (2048) bytes or larger are truncated by the FEC at 2047 bytes so software never sees a receive frame larger than 2047 bytes.

Similar to transmit, the FEC polls the receive descriptor ring after the driver sets up receive BDs and writes to the RDAR register. As frames are received, the FEC fills receive buffers and updates the associated BDs, then reads the next BD in the receive

descriptor ring. If the FEC reads a receive BD and finds the E bit cleared, it polls this BD once more. If RxB<sub>D</sub>[E] is clear a second time, FEC stops reading receive BDs until the driver writes to RDAR.

### 40.6.3.2 Ethernet Receive Buffer Descriptor (RxB<sub>D</sub>)

In the RxB<sub>D</sub>, the user initializes the E and W bits in the first longword and the pointer in the second longword. When the buffer has been DMA'd, the Ethernet controller modifies the E, L, M, BC, MC, LG, NO, CR, OV, and TR bits and writes the length of the used portion of the buffer in the first longword. The M, BC, MC, LG, NO, CR, OV, and TR bits in the first longword of the buffer descriptor are only modified by the Ethernet controller when the L bit is set.

**Table 40-88. Receive Buffer Descriptor (RxB<sub>D</sub>)**

|          | 15                                | 14  | 13 | 12  | 11 | 10 | 9 | 8 | 7  | 6  | 5  | 4  | 3 | 2  | 1  | 0  |

| Offset + 0 | W     | Wrap. Written by user.<br>0: The next buffer descriptor is found in the consecutive location<br>1: The next buffer descriptor is found at the location defined in ERDSR.                                                                                                                                                                                                                                                          |
| Offset + 0 | RO2   | Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.                                                                                                                                                                                                                                                                      |
| Offset + 0 | L     | Last in frame. Written by the FEC.<br>0: The buffer is not the last in a frame.<br>1: The buffer is the last in a frame.                                                                                                                                                                                                                                                                                                          |
| Offset + 0 | M     | Miss. Written by the FEC. This bit is set by the FEC for frames accepted in promiscuous mode, but flagged as a miss by the internal address recognition. Therefore, while in promiscuous mode, you can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set.<br>0: The frame was received because of an address recognition hit. |

*Table continues on the next page...*

**Table 40-89. Receive Buffer Descriptor field descriptions (continued)**

| Word       | Field       | Description                                                                                                                                                                                                                                                                                             |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            |             | 1: The frame was received because of promiscuous mode.                                                                                                                                                                                                                                                  |
| Offset + 0 | BC          | Set if the DA is broadcast (FFFF_FFFF_FFFF).                                                                                                                                                                                                                                                            |
| Offset + 0 | MC          | Set if the DA is multicast and not BC.                                                                                                                                                                                                                                                                  |
| Offset + 0 | LG          | Rx frame length violation. Written by the FEC. A frame length greater than RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.                                                                     |
| Offset + 0 | NO          | Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set, the CR bit is not set. |
| Offset + 0 | CR          | Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.                                                                                                                                       |
| Offset + 0 | OV          | Overrun. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and are zero. This bit is valid only if the L-bit is set.                                                               |
| Offset + 0 | TR          | Set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set, the frame must be discarded and the other error bits must be ignored as they may be incorrect.                                                                                                                 |
| Offset + 2 | Data Length | Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L equals 0 (the value is equal to EMRBR), or the length of the frame including CRC if L is set. It is written by the FEC once as the BD is closed.                                |
| Offset + 4 | A[31:16]    | RX data buffer pointer, bits [31:16] <sup>1</sup>                                                                                                                                                                                                                                                       |
| Offset + 6 | A[15:0]     | RX data buffer pointer, bits [15:0]                                                                                                                                                                                                                                                                     |

1. The receive buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 16. The buffer must reside in memory external to the FEC. The Ethernet controller never modifies this value.

### Note

When the software driver sets an E bit in one or more receive descriptors, the driver should follow with a write to RDAR.

### 40.6.3.3 Ethernet Transmit Buffer Descriptor (TxBD)

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. The Ethernet controller confirms transmission by clearing the ready bit (TxBD[R]) when DMA of the buffer is complete. In the TxBD, the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword and the buffer pointer in the second longword.

The FEC clears the R bit when the buffer is transferred. Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is indicated via individual interrupt bits (error conditions) and in statistic counters in the MIB block.

**Table 40-90. Transmit Buffer Descriptor (TxBD)**

| Offset + 2 | Data Length | Data length, written by user.<br><br>Data length is the number of octets the FEC should transmit from this BD's data buffer. It is never modified by the FEC.                                                                                                                                                                                                                                                                                                           |
| Offset + 4 | A[31:16]    | Tx data buffer pointer, bits [31:16]<br><br>1                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Offset + 6 | A[15:0]     | Tx data buffer pointer, bits [15:0]                                                                                                                                                                                                                                                                                                                                                                                                                                     |

1. The transmit buffer pointer, containing the address of the associated data buffer, must always be evenly divisible by 4. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

### Note

After the software driver has set up the buffers for a frame, it should set up the corresponding BDs. The last step in setting up the BDs for a transmit frame is setting the R bit in the first BD for the frame. The driver must follow that with a write to TDAR that triggers the FEC to poll the next BD in the ring.

## 40.6.4 Initialization sequence

This section describes which registers are reset due to hardware reset, which registers are reset by the FEC RISC, and what locations you must initialize prior to enabling the FEC.

### 40.6.4.1 Hardware Controlled Initialization

In the FEC, hardware resets registers and control logic that generate interrupts. A hardware reset negates output signals and resets general configuration bits.

Other registers reset when the ECR[ETHER\_EN] bit is cleared (which is accomplished by a hard reset or software to halt operation). By clearing ECR[ETHER\_EN], configuration control registers such as the TCR and RCR are not reset, but the entire data path is reset.

**Table 40-92. ECR[ETHER\_EN] De-Assertion Effect on FEC**

| Register/Machine            | Reset Value                                |
|-----------------------------|--------------------------------------------|
| XMIT block                  | Transmission is aborted (bad CRC appended) |
| RECV block                  | Receive activity is aborted                |
| DMA block                   | All DMA activity is terminated             |
| RDAR                        | Cleared                                    |
| TDAR                        | Cleared                                    |
| Descriptor Controller block | Halt operation                             |

### 40.6.5 User initialization (Prior to Setting ECR[ETHER\_EN])

You need to initialize portions the FEC prior to setting the ECR[ETHER\_EN] bit. The exact values depend on the particular application. The sequence is not important.

The following registers require initialization:

- EIMR
- EIR (clear by writing FFFF\_FFFFh)
- TFWR (optional)
- IALR / IAUR
- GAUR / GALR
- PALR / PAUR (only needed for full duplex flow control)
- OPD (only needed for full duplex flow control)
- RCR
- TCR
- MSCR (optional)
- MIB\_RAM (clear)
- FRSR (optional)
- EMRBR
- ERDSR
- ETDSR
- Transmit Descriptor ring (empty)
- Receive Descriptor ring (empty)

### **40.6.6 Microcontroller initialization**

In the FEC, the descriptor control RISC initializes some registers after ECR[ETHER\_EN] is asserted. After the microcontroller initialization sequence is complete, hardware is ready for operation.

The sequence is as follows:

1. Initialize the backoff random number seed.
2. Activate receiver.
3. Activate transmitter.
4. Clear transmit FIFO.

5. Clear receive FIFO.
6. Initialize the transmit ring pointer.
7. Initialize the receive ring pointer.
8. Initialize FIFO count registers.

### 40.6.7 User initialization (after setting ECR[ETHER\_EN])

After setting ECR[ETHER\_EN], you can set up the buffer/frame descriptors and write to TDAR and RDAR. See [Buffer descriptors](#), for more details.

### 40.6.8 Network interface options

The FEC supports an MII and reduced MII interface for 10/100 Mbps Ethernet, as well as a 7-wire serial interface for 10 Mbps Ethernet. The RCR[MII\_MODE] and RCR[RMII\_MODE] bits select the interface mode. In MII mode (RCR[MII\_MODE]=1 and RCR[RMII\_MODE]=0), there are 18 signals defined by the IEEE 802.3 standard and supported by the EMAC. The following table shows these signals.

**Table 40-93. MII mode**

| Signal description           | EMAC pin     |
|------------------------------|--------------|
| Transmit Clock               | FEC_TXCLK    |
| Transmit Enable              | FEC_TXEN     |
| Transmit Data                | FEC_TXD[3:0] |
| Transmit Error               | FEC_TXER     |
| Collision                    | FEC_COL      |
| Carrier Sense                | FEC_CRS      |
| Receive Clock                | FEC_RXCLK    |
| Receive Data Valid           | FEC_RXDV     |
| Receive Data                 | FEC_RXD[3:0] |
| Receive Error                | FEC_RXER     |
| Management Data Clock        | FEC_MDC      |
| Management Data Input/Output | FEC_MDIO     |

In RMII mode (RCR[MII\_MODE]=1 and RCR[RMII\_MODE]=1), the EMAC supports 8 external signals. These signals are shown in the table below.

**Table 40-94. RMII mode configuration**

| Signal description | EMAC pin     |
|--------------------|--------------|
| Reference Clock    | FEC_TXCLK    |
| Transmit Enable    | FEC_TXEN     |
| Transmit Data      | FEC_TXD[1:0] |
| Receive Data Valid | FEC_RXDV     |
| Receive Data       | FEC_RXD[1:0] |
| Receive Error      | FEC_RXER     |

The 7-wire serial mode interface (RCR[MII\_MODE]=1 and RCR[RMII\_MODE]=0 or 1) is generally referred to as AMD mode. The following table shows the 7-wire mode connections to the external transceiver.

**Table 40-95. 7-Wire mode configuration**

| Signal description | EMAC pin   |
|--------------------|------------|
| Transmit Clock     | FEC_TXCLK  |
| Transmit Enable    | FEC_TXEN   |
| Transmit Data      | FEC_TXD[0] |
| Collision          | FEC_COL    |
| Receive Clock      | FEC_RXCLK  |
| Receive Data Valid | FEC_RXDV   |
| Receive Data       | FEC_RXD[0] |

### 40.6.9 FEC frame transmission

The Ethernet transmitter is designed to work with almost no intervention from software. After ECR[ETHER\_EN] is set and data appears in the transmit FIFO, the Ethernet MAC can transmit onto the network. The Ethernet controller transmits bytes least significant bit (lsb) first.

When the transmit FIFO fills to the watermark (defined by TFWR), MAC transmit logic asserts FEC\_TXEN and starts transmitting the (PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller defers the transmission if the network is busy (FEC\_CRS is asserted). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense stays inactive for 60 bit times. If so, transmission begins after waiting an additional 36 bit times (96 bit times after carrier sense originally became inactive). See "Transmission errors" for more details.

If a collision occurs during transmission of the frame (half duplex mode), the Ethernet controller follows the specified backoff procedures and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least the first 64 bytes of the transmit frame, so they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data is transmitted, FCS (frame check sequence) or 32-bit cyclic redundancy check (CRC) bytes are appended if the TC bit is set in the transmit frame control word. If the ABC bit is set in the transmit frame control word, a bad CRC is appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status information to the MIB block. Transmit logic automatically pads short frames (if the TC bit in the transmit buffer descriptor for the end of frame buffer is set).

Settings in the EIMR determine interrupts generated to the buffer (TXB) and frame (TXF).

The transmit error interrupts are HBERR, BABT, LC, RL, and UN. If the transmit frame length exceeds MAX\_FL bytes, BABT interrupt is asserted. However, the entire frame is transmitted (no truncation).

To pause transmission, set TCR[GTS] (graceful transmit stop). The FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current frame finishes or terminates with a collision. After the transmitter has stopped, the GRA (graceful stop complete) interrupt is asserted. If TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

#### 40.6.9.1 Duplicate frame transmission

The FEC fetches transmit buffer descriptors (TxBDs) and the corresponding transmit data continuously until the transmit FIFO is full. It does not determine whether the TxBD to be fetched is already being processed internally (as a result of a wrap). As the FEC nears the end of the transmission of one frame, it begins to DMA the data for the next frame. To remain one BD ahead of the DMA, it also fetches the TxBD for the next frame. It is possible that the FEC fetches from memory a BD that has already been processed but not yet written back (it is read a second time with the R bit remains set). In this case, the data is fetched and transmitted again.

Using at least three TxBDs fixes this problem for large frames, but not for small frames. To ensure correct operation for large or small frames, one of the following must be true:

- The FEC software driver ensures that there is always at least one TxBD with the ready bit cleared.
- Every frame uses more than one TxBD and every TxBD but the last is written back immediately after the data is fetched.
- The FEC software driver ensures a minimum frame size,  $n$ . The minimum number of TxBDs is then  $(\text{Tx FIFO Size} \div (n+4))$  rounded up to the nearest integer (though the result cannot be less than three). The default Tx FIFO size is 192 bytes; this size is programmable.

## 40.6.10 FEC frame reception

The FEC receiver works with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking. The Ethernet controller receives serial data lsb first.

When the driver enables the FEC receiver by setting ECR[ETHER\_EN], it immediately starts processing receive frames. When FEC\_RXDV is asserted, the receiver first checks for a valid PA/SFD header. If the PA/SFD is valid, it is stripped and the receiver processes the frame. If a valid PA/SFD is not found, the frame is ignored.

In serial mode, the first 16 bit times of RX\_D0 following assertion of FEC\_RXDV are ignored. Following the first 16 bit times, the data sequence is checked for alternating 1/0s. If a 11 or 00 data sequence is detected during bit times 17 to 21, the remainder of the frame is ignored. After bit time 21, the data sequence is monitored for a valid SFD (11). If a 00 is detected, the frame is rejected. When a 11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes may occur, but if a 00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame are received, the FEC performs address recognition on the frame.

After a collision window (64 bytes) of data is received and if address recognition has not rejected the frame, the receive FIFO signals the frame is accepted and may be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to reject the frame. Therefore, no collision fragments are presented to you except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and after the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV, and TR status bits, and the frame length. See "Reception errors" for more details.

Receive buffer (RXB) and frame interrupts (RFINT) may be generated if enabled by the EIMR register. A receive error interrupt is a babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX\_FL); however, the BABR interrupt occurs and the LG bit in the receive buffer descriptor (RxBD) is set. See [Ethernet Receive Buffer Descriptor \(RxBD\)](#), for more details.

When the receive frame is complete, the FEC sets the L-bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E-bit. The Ethernet controller next generates a maskable interrupt (RFINT bit in EIR, maskable by RFIEN bit in EIMR), indicating that a frame is received and is in memory. The Ethernet controller then waits for a new frame.

### 40.6.11 Ethernet address recognition

The FEC filters the received frames based on destination address (DA) type — individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the destination address field. A flowchart for address recognition on received frames appears in the figures below.

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in [Figure 40-84](#) illustrates the address recognition decisions made by the receive block, while [Figure 40-85](#) illustrates the decisions made by the microcontroller.

If the DA is a broadcast address and broadcast reject (RCR[BC\_REJ]) is cleared, then the frame is accepted unconditionally, as shown in [Figure 40-84](#). Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in [Figure 40-85](#).

If the DA is a group (multicast) address and flow control is disabled, then the microcontroller performs a group hash table lookup using the 64-entry hash table programmed in GAUR and GALR. If a hash match occurs, the receiver accepts the frame.

If flow control is enabled, the microcontroller does an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines the received frame is a valid PAUSE frame, the frame is rejected. The receiver detects a PAUSE frame with the DA field set to the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that you program in the PALR and PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, IAUR and IALR. In the case of an individual hash match, the frame is accepted. Again, the receiver accepts or rejects the frame based on PAUSE frame detection, shown in [Figure 40-84](#).

If neither a hash match (group or individual) nor an exact match (group or individual) occur, and if promiscuous mode is enabled (RCR[PROM] set), the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

Similarly, if the DA is a broadcast address, broadcast reject (RCR[BC\_REJ]) is asserted, and promiscuous mode is enabled, the frame is accepted and the MISS bit in the receive buffer descriptor is set; otherwise, the frame is rejected.

In general, when a frame is rejected, it is flushed from the FIFO.

**Notes:**

BC\_REJ - field in RCR register (BroadCast REJect)

PROM - field in RCR register (PROMiscuous mode)

Pause Frame - valid PAUSE frame received

**Figure 40-84. Ethernet address recognition—receive block decisions**

**Notes:**

FCE - field in RCR register (flow control enable)

I/G - Individual/Group bit in destination address (lsb in first byte received in MAC frame)

**Figure 40-85. Ethernet address recognition—microcode decisions**

## 40.6.12 Hash algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits stored in GAUR, GALR (group address hash match), or IAUR, IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63. The msb of the CRC result selects GAUR (msb = 1) or GALR (msb = 0). The five least significant bits of the hash result select the bit within the selected register. If the CRC generator selects a bit set in the hash table, the frame is accepted; otherwise, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

**Figure 40-86. CRC32 polynomial for hash computation**

The following table contains example destination addresses and corresponding hash values.

**Table 40-96. Destination address to 6-bit hash**

| 48-BIT DA      | 6-bit hash<br>(in hex) | Hash decimal value |
|----------------|------------------------|--------------------|
| 65FF_FFFF_FFFF | 0h                     | 0                  |
| 55FF_FFFF_FFFF | 1h                     | 1                  |
| 15FF_FFFF_FFFF | 2h                     | 2                  |
| 35FF_FFFF_FFFF | 3h                     | 3                  |

### 40.6.13 Full duplex flow control

Full-duplex flow control allows you to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, MAC data frame transmission stops for a given pause duration.

To enable PAUSE frame detection, the FEC must operate in full-duplex mode (TCR[FDEN] set) with flow control (RCR[FCE] set). The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown in the following table. In addition, the receive status associated with the frame should indicate that the frame is valid.

**Table 40-97. PAUSE frame field specification**

|                                   |                                     |
|-----------------------------------|-------------------------------------|
| <b>48-bit destination address</b> | 0180_C200_0001h or Physical Address |
| <b>48-bit source address</b>      | Any                                 |
| <b>16-bit type</b>                | 8808h                               |
| <b>16-bit opcode</b>              | 0001h                               |
| <b>16-bit PAUSE duration</b>      | 0000h — FFFFh                       |

The receiver and microcontroller modules perform PAUSE frame detection. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, TCR[GTS] is set by the FEC internally. When transmission has paused, the EIR[GRA] interrupt is asserted and the pause timer begins to increment. The pause timer uses the transmit backoff timer hardware for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments once every slot time, until OPD[PAUSE\_DUR] slot times have expired. On OPD[PAUSE\_DUR] expiration, TCR[GTS] is cleared allowing MAC data frame transmission to resume. The receive flow control pause status bit (TCR[RFC\_PAUSE]) is set while the transmitter pauses due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and you must set flow control pause (TCR[TFC\_PAUSE]). After TCR[TFC\_PAUSE] is set, the transmitter sets TCR[GTS] internally. When the transmission of data frames stops, the EIR[GRA] (graceful stop complete) interrupt asserts and the pause frame is transmitted. TCR[TFC\_PAUSE,GTS] are then cleared internally.

You must specify the desired pause duration in the OPD register.

When the transmitter pauses due to receiver/microcontroller pause frame detection, TCR[TFC\_PAUSE] may remain set and cause the transmission of a single pause frame. In this case, the EIR[GRA] interrupt is not asserted.

### 40.6.14 Inter-Packet Gap (IPG) time

The minimum inter-packet gap time for back-to-back transmission is 96 bit times. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96 bit time IPG counter. Frame transmission may begin 96 bit times after carrier sense is negated if it stays negated for at least 60 bit times. If carrier sense asserts during the last 36 bit times, it is ignored and a collision occurs.

The receiver accepts back-to-back frames with a minimum spacing of at least 28 bit times. If an inter-packet gap between receive frames is less than 28 bit times, the receiver may discard the following frame.

### 40.6.15 Collision managing

If a collision occurs during frame transmission, the Ethernet controller continues the transmission for at least 32 bit times, transmitting a JAM pattern consisting of 32 ones. If the collision occurs during the sequence, a JAM pattern is sent after the end of the preamble sequence.

If a collision occurs within 512 bit times (one slot time), the retry process is initiated. The transmitter waits a random number of slot times. If a collision occurs after 512 bit times, then no retransmission is performed and the end of frame buffer is closed with a Late Collision (LC) error indication.

### 40.6.16 MII internal and external loopback

Internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Internal and external loopback are configured using combinations of the RCR[LOOP, DRT] and TCR[FDEN] bits.

Set FDEN for internal and external loopback.

For internal loopback, set RCR[LOOP] and clear RCR[DRT]. FEC\_TXEN and FEC\_TXER do not assert during internal loopback. During internal loopback, the transmit/receive data rate is higher than in normal operation because the transmit and receive blocks use the internal bus clock instead of the clocks from the external transceiver. This causes an increase in the required system bus bandwidth for transmit

and receive data being DMA'd to/from external memory. It may be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underruns and receive FIFO overflows.

For external loopback, clear RCR[LOOP] and RCR[DRT], and configure the external transceiver for loopback.

### 40.6.17 RMII loopback

The FEC also supports RMII loopback. In this mode, transmit data is sent to the RMII receive logic and out the FEC\_TXD[1:0] pins. To enable RMII loopback mode, set RCR[RMII\_MODE, RMII\_LOOP] and TCR[FDEN] and clear RCR[RMII\_ECHO, LOOP].

Figure 40-87. RMII loopback mode

### 40.6.18 RMII echo

The Ethernet controller also supports RMII echo mode, which transmits data on FEC\_TXD[1:0] as it is received on FEC\_RXD[1:0]. To enable RMII echo mode, set RCR[RMII\_MODE, RMII\_ECHO] bits and clear RCR[RMII\_LOOP, LOOP].

Figure 40-88. RMII echo mode

## 40.6.19 Ethernet error-managing procedure

The Ethernet controller reports frame reception and transmission error conditions using the MIB block counters, the FEC RxBDs, and the EIR register.

### 40.6.19.1 Transmission errors

#### 40.6.19.1.1 Transmitter underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error and stops transmitting. All remaining buffers for that frame are then flushed and closed, and EIR[UN] is set. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame. The UN interrupt is asserted if enabled in the EIMR register.

#### 40.6.19.1.2 Retransmission attempts limit expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[RL] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The RL interrupt is asserted if enabled in the EIMR register.

#### 40.6.19.1.3 Late collision

When a collision occurs after the slot time (512 bits starting at the Preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and EIR[LC] is set. The FEC then continues to the next transmit buffer descriptor and begins transmitting the next frame. The LC interrupt is asserted if enabled in the EIMR register.

#### 40.6.19.1.4 Heartbeat

Some transceivers have a self-test feature called heartbeat or signal quality error. To signify a good self-test, the transceiver indicates a collision to the FEC within four microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver continues to function properly. This is the heartbeat condition.

If TCR[HBC] is set and the heartbeat condition is not detected by the FEC after a frame transmission, a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets EIR[HB], and generates the HBERR interrupt if it is enabled.

## 40.6.19.2 Reception errors

### 40.6.19.2.1 Overrun error

If the receive block has data to put into the receive FIFO and the receive FIFO is full, FEC sets RxBD[OV]. All subsequent data in the frame is discarded and subsequent frames may also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. The driver must discard this frame.

### 40.6.19.2.2 Non-octet error (dribbling bits)

The Ethernet controller manages up to seven dribbling bits when the receive frame terminates past a non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, the frame non-octet aligned (NO) error is reported in the RxBD. If there is no CRC error, no error is reported.

### 40.6.19.2.3 CRC error

When a CRC error occurs with no dribble bits, FEC closes the buffer and sets RxBD[CR]. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

### 40.6.19.2.4 Frame length violation

When the receive frame length exceeds MAX\_FL bytes the BABR interrupt is generated, and RxBD[LG] is set. The frame is not truncated unless the frame length exceeds 2047 bytes.

### 40.6.19.2.5 Truncation

When the receive frame length exceeds 2047 bytes, frame is truncated and RxBD[TR] is set.

# Chapter 41

## SENT Receiver (SRX)

### 41.1 Chip-specific SRX information

This chip has two instances of the SRX module.

**Table 41-1. SRX module instances**

| Instance | Input/receive channels | FIFO depth |
|----------|------------------------|------------|
| SRX_0    | 6                      | 16         |
| SRX_1    | 6                      | 16         |

### 41.2 Introduction

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver for receiving serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled "SENT - Single Edge Nibble Transmission for Automotive Applications" and released on January 27, 2010 (<http://www.sae.org>), Apr2007 and Feb2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

### 41.2.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. See the device configuration details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA
  - Programmable option per channel to support reading of messages via DMA or Interrupt
  - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process
  - A FIFO for storing the received Fast Messages from all channels that are to be read out via DMA. FIFO depth is device-specific. See the device configuration section for details.
  - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow Serial Messages)
  - Separate buffers for storing Fast and Slow Serial Messages
  - Separate DMA and Interrupts generated for Fast and Slow Serial Messages
- Supports compensation for variation in SENT Tx Clock up to  $\pm 25\%$  and adjusts its measurement for drift in the Transmitter and Receiver clocks per channel
  - Calibration pulse correction factor per channel is available for use by software
- Implements for each channel all receiver diagnostics as specified by the SAE Specifications
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT Specification) for both Fast and Short Serial Message per channel
- Internal 6-bit CRC calculator for Enhanced Serial Messages per channel

- Supports all bit rates by having per channel configurable Rx clock periods from 3  $\mu$ s to 90  $\mu$ s
- Support for configurable number of data nibbles per channel
- Option to disable individual channel via programmable control bit
- Time stamping on start of each valid message (i.e. without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings
- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.
- 32-bit register interface for programming the module's registers and reading the received messages
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See [Clocks and resets](#) for more details on the clocks.

## 41.2.2 Modes of operation

Modes of operation.

### 41.2.2.1 Debug mode

In debug mode, message reception will be halted (without waiting for the current message being received to be completed) and all existing status and messages will be retained. DBG\_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL\_LEN\_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

### 41.2.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL\_LEN\_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.

**Modes where both system bus clock and protocol clock are gated:** In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

**Modes where frequency of system bus clock is changed:** For reduced power consumption the system bus clock can be reduced but not below a minimum value (See [System bus clock requirements](#)) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See [High frequency receiver clock \(protocol clock\) requirements](#)) for accurate receive operations.

#### Note

Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

#### NOTE

If the SOC requests entry to debug or stop mode, the message being received currently is discarded and the SOC enters debug/stop mode immediately. This does not affect the messages received completely prior to entering debug mode and will still be present on the message buffer and registers until they are read out.

#### NOTE

The message read registers [Channel 'n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn\_FMSG\_DATA), Channel 'n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn\_FMSG\_CRC), Channel 'n' Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn\_FMSG\_TS), Channel 'n' Serial Message Read Register (Bit 3) (n = 0 to (CH-1))

(CHn\_SMSG\_BIT3), Channel 'n' Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn\_SMSG\_BIT2), Channel 'n' Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn\_SMSG\_TS), DMA Fast Message Data Read Register (DMA\_FMSG\_DATA), DMA Fast Message CRC Read Register (DMA\_FMSG\_CRC), DMA Fast Message Time Stamp Read Register (DMA\_FMSG\_TS), DMA Slow Serial Message Bit3 Read Register (DMA\_SMSG\_BIT3), DMA Slow Serial Message Bit2 Read Register (DMA\_SMSG\_BIT2) and DMA Slow Serial Message Time Stamp Read Register (DMA\_SMSG\_TS)] will appear to lose their contents in the following conditions:

- The very first message is being received but not yet completely received and the MCU enters debug or freeze mode, the current message reception will get discarded and message read registers (as mentioned above) will read zeros
- Auto clear functionality is enabled (GBL\_CTRL[FAST\_CLR] = 1). In this case, when first message is read, it will get clear the message read registers (due to auto clear functionality being enabled). On reading again, the message read registers (as mentioned above) might read zeros.

If the MCU requests entry to debug or stop mode, the message being received currently by SENT Receiver is discarded and the MCU enters debug/stop mode immediately. This does not affect the messages received completely, prior to entering debug mode and these messages will still be present on the message buffer and registers until they are read out. Thus allow one message to be received completely and do not enable "Auto Clear" (GBL\_CTRL[FAST\_CLR] = 0), to allow messages to be read in debug or stop mode.

## 41.2.3 Block diagram

**Figure 41-1. SENT Receiver block diagram**

## 41.2.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. [Figure 41-1](#) shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and Adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages. A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the DMA FIFOs (for channels which are selected to be connected to the DMA) or in corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the FIFOs or buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

### 41.2.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message FIFOs or buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the DMA FIFO or message buffer as described in the subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel's status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the FIFOs or buffers on high frequency receiver clock. The module's message read logic synchronizes all these messages on the bus clock and pops out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast Messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see [Functional description](#).

## 41.3 External signal description

This section lists all inputs to the SENT Receiver block.

### 41.3.1 SENT\_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT Receiver channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

### Note

The value of CH is device-specific. See the device configuration details.

## 41.4 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT Receiver block.

The following table gives an overview on all SENT Receiver registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module is in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

### NOTE

Register Address = Base Address + Address Offset, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. See the device configuration section for details.

### NOTE

The value of the CH is device-specific. See the device configuration section for details.

### 41.4.1 Global Control Register (SRX\_GBL\_CTRL)

This register provides the global control and setting for the SENT Receiver Module. The SENT\_EN bit must be programmed after all other modules settings and control bits have been written to.

Address: 0h base + 0h offset = 0h

|       |                   |    |    |    |    |        |        |        |        |         |    |          |    |         |    |         |

**SRX\_GBL\_CTRL field descriptions**

| Field            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–7<br>TSPRSC    | Time Stamp Prescaler Value. Value in number of clock cycles of high frequency receiver clock set in order to obtain a clock frequency for the time stamp counter block.<br><br>0 to 255 - Time Stamp Clock = (High Frequency Clock)/(Value + 1). Value set by user software should be such that the clock period is at least 1 $\mu$ s.<br><br>If the high frequency clock input is 75 MHz, then the value set in this field would be 0x4A (or 74) to obtain a 1 $\mu$ s clock.<br><br>Note: Since the time stamp clock is common for all channels, the timestamp clock frequency must be at least twice the fastest receiver channel in the application. This is to ensure that the time stamp clock is fast enough to show change in timestamp from message to message. |
| 8–10<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 11–15<br>FIFOWM  | DMA Read FIFO Water Mark Level. Indicates the number of Fast Messages to be stored in FIFO before a DMA request is asserted. Default = 1 message.<br><br>0 Invalid Value. Should not be used<br>1 to 31 Valid water mark levels. Value fixed by user software.<br><br><b>NOTE:</b> The number of bytes to be transferred set in the DMA Controller's TCD must be set equal to the number of bytes corresponding to the set water mark value.                                                                                                                                                                                                                                                                                                                              |

| 31<br>SENT_EN  | SENT Receiver Global Enable. This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0.<br><br>0 Entire module is disabled<br>1 Module is enabled |

**41.4.2 Channel Enable Register (SRX\_CHNL\_EN)**

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

**NOTE**

Reads of bits beyond those for the supported number of channels should be ignored, and these bits must be written to 0.

| 24–31<br>Reserved | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                               |

**41.4.4 Fast Message Ready Status Register (SRX\_FMSG\_RDY)**

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via [Fast Message DMA Control Register \(SRX\\_FDMA\\_CTRL\)](#) ), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via [Fast Message Ready Interrupt Control Register \(SRX\\_FRDY\\_IE\)](#) ) and the channel is enabled, the message ready status bit in this register will be asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST\_CLR bit in the [Global Control Register \(SRX\\_GBL\\_CTRL\)](#) .

**NOTE**

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

| Field | Description                                                                                                                                                                                                                                                                                                                          |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). |
|       | <b>NOTE:</b> These bits are either "write 1 to clear" (w1c) or self-clearing depending on the value of the FAST_CLR BIT in the Global Control Register (GBL_CTRL).                                                                                                                                                                   |
|       | The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section <a href="#">Global Control Register (SRX_GBL_CTRL)</a> for details on FAST_CLR bit.                                                                                                                           |
|       | <b>NOTE:</b> When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported.                                     |
|       | <b>NOTE:</b> When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.                                                                                                                                                                                                           |
|       | 0 No Fast Message is available to be read out via Interrupt                                                                                                                                                                                                                                                                          |
|       | 1 Fast Message is available to be read out via Interrupt                                                                                                                                                                                                                                                                             |

#### 41.4.5 Slow Serial Message Ready Status Register (SRX\_SMSG\_RDY)

The bits of this register are asserted when a Slow Serial Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via [Fast Message DMA Control Register \(SRX\\_FDMA\\_CTRL\)](#) and [Slow Serial Message DMA Control Register \(SRX\\_SDMA\\_CTRL\)](#)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via [Fast Message Ready Interrupt Control Register \(SRX\\_FRDY\\_IE\)](#) and [Slow Serial Message Ready Interrupt Enable Register \(SRX\\_SRDY\\_IE\)](#)) and the channel is enabled, the message ready status bit in this register will be asserted on Slow Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Erroneous flow can happen if neither is selected.

These bits can be configured to be cleared via "Write 1 to Clear" or "Fast Clearing Mechanism". The configuration is done by writing to the FAST\_CLR bit in the [Global Control Register \(SRX\\_GBL\\_CTRL\)](#).

#### NOTE

Reads of bits beyond those for the supported number of channels should be ignored. Writes to these bits is ignored by the Receiver.

| 26–31<br>SRDY_IE | Enable for Slow Serial Message Ready Interrupt on channels 5 to 0 . These bits are writable when corresponding DMA enable bits are set to 0 in the Slow Serial DMA Control Register. The availability of message is indicated via assertion of corresponding bit in Slow Serial Message Ready Status Register irrespective of the value set in corresponding interrupt enable bit and DMA is not enabled. When a bit in this register is asserted, an interrupt for corresponding channel is generated.<br><br>0 Interrupt on reception of Slow Serial Messages is disabled<br>1 Interrupt on reception of Slow Serial Messages is enabled |

### 41.4.11 DMA Fast Message Data Read Register (SRX\_DMA\_FMSG\_DATA)

DMA Source Size must be set to 32 bits when reading this register (DMA\_FMSG\_DATA) via DMA. When FIFO is enabled, the DMA must read the complete message using this register only. Three read accesses must be made to read complete message.

Address: 0h base + 40h offset = 40h

#### 41.4.12 DMA Fast Message CRC Read Register (SRX\_DMA\_FMSG\_CRC)

DMA Source Size must be set to 32 bits when reading this register (DMA\_FMSG\_CRC) via DMA. When FIFO is enabled, fast messages are read out from FIFO through the DMA Fast Message Data Read register only. Reading this register will generate an access error.

Address: 0h base + 44h offset = 44h

### 41.4.13 DMA Fast Message Time Stamp Read Register (SRX\_DMA\_FMSG\_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the [Global Control Register \(SRX\\_GBL\\_CTRL\)](#) register. DMA Source Size must be set to 32 bits when reading this register (DMA\_FMSG\_TS) via DMA. When FIFO is enabled, fast messages are read out from FIFO through the DMA Fast Message Data Read register only. Reading this register will generate an access error.

Address: 0h base + 48h offset = 48h

**SRX\_DMA\_FMSG\_TS field descriptions**

| Field      | Description                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>TS | Time Stamp for received message. Indicates the relative time when the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) was detected |

### 41.4.14 DMA Slow Serial Message Bit3 Read Register (SRX\_DMA\_SMSG\_BIT3)

The above register (DMA\_SMSG\_BIT3) is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced Serial Messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in [Table 41-83](#), [Table 41-84](#) and [Table 41-85](#). [Table 41-83](#) and [Table 41-84](#) shows the enhanced serial messages format to be used when reading this register for these two types of messages. [Table 41-85](#) shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

#### NOTE

If the TYPE bit in the register reads '0', then remainder bits (for CFG, ID and DATA) will be redundant and read zeros. The short serial message will be located in DMA\_SMSG\_BIT2 register fields. If TYPE bit is '1', then the message in register is

Enhanced Serial Message and using CFG bit, software can decode the ID and DATA fields.

Address: 0h base + 50h offset = 50h

### 41.4.15 DMA Slow Serial Message Bit2 Read Register (SRX\_DMA\_SMSG\_BIT2)

This register (DMA\_SMSG\_BIT2) is common for all types of slow serial messages. Hence, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in [Table 41-83](#), [Table 41-84](#) and [Table 41-85](#). [Table 41-83](#), and [Table 41-84](#) shows the enhanced serial messages format to be used when reading this register for these two types of messages. [Table 41-85](#) shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Address: 0h base + 54h offset = 54h

### 41.4.16 DMA Slow Serial Message Time Stamp Read Register (SRX\_DMA\_SMSG\_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the [Global Control Register \(SRX\\_GBL\\_CTRL\)](#) register.

DMA Source Size must be set to 32 bits when reading this register (DMA\_SMSG\_TS) via DMA.

Memory map and register definition

Address: 0h base + 58h offset = 58h

SRX\_DMA\_SMSG\_TS field descriptions

| Field      | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>TS | Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received. |

41.4.17 Channel 'n' Clock Control Register (n = 0 to (CH-1)) (SRX\_CHn\_CLK\_CTRL)

NOTE

The value of the CH is device-specific. See the device configuration section for details.

The SENT Receiver module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations and clock drift that might occur in the Sensor Tx Clock. See [Adjustment for variation in sensor \(Tx\) clock](#) for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the [Channel Enable Register \(SRX\\_CHNL\\_EN\)](#) .

Address: 0h base + 60h offset + (16d × i), where i=0d to 5d

| 0<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 1–15<br>CM_PRSC | Compensated Prescaler Value. This is the compensated prescaler value calculated by Clock Compensation logic and this value is used to compensate for sensor Tx clock variation. This value is indicated as a read only field for use by user software, if needed. This is a 15-bit value.<br><br>'= Rx Prescaler Value' No variation, hence no compensation or Compensation is disabled<br>'< Rx Prescaler Value' Tx Clock is SLOWER than the programmed receive clock<br>'> Rx Prescaler Value' Tx Clock is FASTER than the programmed receive clock<br>Thus, the new Receiver Clock Tick Period can be computed by software as<br>Compensated Prescaler Value x High Frequency Receiver Clock Period<br>Note: The value provided in this field is ceil value of actual tick period as measured by the Receiver.                                                                                                                                                                                        |
| 16<br>COMP_EN   | Compensation Enable. To enable compensation logic to adjust the receiver clock against variation in Tx clock on this channel. User must set the Prescaler Value before enabling this bit.<br><br>0 Compensation is disabled<br>1 Compensation is enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 17<br>Reserved  | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 18–31<br>PRSC   | Rx Prescaler Value. This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (Trx_clk) is not divisible by the high frequency receiver clock (protocol clock) period (Thf_clk), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value.<br><br>0 Prescaler is bypassed. Should not be used.<br>Non-Zero Value Enables Prescaler<br>The required value is computed by software as follows:<br>$\text{Prescaler\_value} = \text{floor}\left(\frac{T_{\text{rx\_clk}}}{T_{\text{hf\_clk}}}\right)$ (both clock periods taken in μs).<br>Please see <a href="#">High frequency receiver clock (protocol clock) requirements</a> before setting this value. |

Table continues on the next page...

**SRX\_CHn\_CLK\_CTRL field descriptions (continued)**

| Field | Description                                                                                                                                                                                                                                       |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|       | e.g. if the required receiver clock tick period is 43 $\mu$ s and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 $\mu$ s) then,<br>Prescaler Value = $43/0.016 = 2687.5$ . Hence user must program 2687 in this register. |

#### 41.4.18 Channel 'n' Status Register (n=0 to (CH-1)) (SRX\_CHn\_STATUS)

This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal event) happened in the recent past. Messages are automatically discarded when an error is detected.

User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in the [Channel Enable Register \(SRX\\_CHNL\\_EN\)](#) bit for the corresponding channel.

**NOTE**

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 64h offset + (16d  $\times$  i), where i=0d to 5d

|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0<br>BUS_IDLE   | <p>Bus Idle Status. This bit indicates that the sensor interface has been idle for more than the period defined by the programmed Bus Idle Count value(in <a href="#">Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX_CHn_CONFIG)</a> ). CPU should write 1 to this clear this bit once it is read.</p> <p>0 Bus is not idle<br/>1 Channel has been idle for more than the allowed value</p>                                                                                             |
| 1-3<br>Reserved | <p>This field is reserved.<br/>This read-only field is reserved and always has the value 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                  |
| 4<br>CAL_RESYNC | <p>Successive Calibration Check (Option 2 of SAE SENT Spec) Resynchronized. This bit indicates that Successive Calibration Check (Option 2 of SAE Spec) has failed three times and has resynchronized to assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected).</p> <p>0 No interrupt<br/>1 Interrupt Status condition has occurred</p>                       |
| 5<br>CAL_20_25  | <p>Calibration Variation 20 - 25% Interrupt Status. This bit indicates that the calibration pulse received on this channel has variation in between <math>\pm 20\%</math> to <math>\pm 25\%</math> from 56 ticks.</p> <p>0 No Interrupt<br/>1 Interrupt Status condition has occurred</p>                                                                                                                                                                                                        |
| 6<br>MSG_OFLW   | <p>Slow Serial Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow will cause state machine to halt stopping reception of new messages.</p> <p>0 No Interrupt<br/>1 Interrupt Status condition has occurred</p>                                                                                                                                                                                                                                              |
| 7<br>FMSG_OFLW  | <p>Fast Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written.</p> <p>0 No Interrupt<br/>1 Interrupt Status condition has occurred</p> |

**SRX\_CHn\_STATUS field descriptions (continued)**

| Field               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8<br>Reserved       | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                    |
| 9<br>PP_DIAG_ERR    | This diagnostic checks status bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than $\pm 1.5625\%$ between two messages. This check is valid only for messages with pause pulse. This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                                                            |
| 10<br>CAL_LEN_ERR   | This diagnostic checks status bit indicates that Calibration pulse is more than 56 ticks $\pm 25\%$ . This bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                                                                                                                                                                                                    |
| 11<br>CAL_DIAG_ERR  | Successive Calibration pulses differ by $\pm 1.56\%$ . SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (See <a href="#">High frequency receiver clock (protocol clock) requirements</a> ). This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                             |
| 12<br>NIB_VAL_ERR   | Any nibble data value $<0$ or $>15$ . This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                                                                                                                                                                                                                                           |
| 13<br>MSG_CRC_ERR   | Checksum error in Slow Serial Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                                                                                                                                                                                                                                          |
| 14<br>FMSG_CRC_ERR  | Checksum error in Fast Message. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel, and is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed                                                                                                                                                                                                                                                 |
| 15<br>NUM_EDGES_ERR | Not the expected number of negative edges between calibration pulse. This diagnostic checks status bit indicates whether this diagnostic has failed or passed on this channel. This bit will not set in case of "Option 2" for successive calibration pulse check is selected. This error will only set when "Option 1" for successive calibration check is selected (SUCC_CAL_CHK). This bit is cleared by writing a 1 to it.<br><br>0 Error Check has passed<br>1 Error Check has failed |
| 16–31<br>Reserved   | This field is reserved.<br>This read-only field is reserved and always has the value 0.                                                                                                                                                                                                                                                                                                                                                                                                    |

### 41.4.19 Channel 'n' Configuration Register (n=0 to (CH-1)) (SRX\_CHn\_CONFIG)

This register (CHn\_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in [Channel 'n' Status Register \(n=0 to \(CH-1\)\) \(SRX\\_CHn\\_STATUS\)](#) and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the [Channel Enable Register \(SRX\\_CHNL\\_EN\)](#).

#### NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 68h offset + (16d × i), where i=0d to 5d

| Field                     | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4<br>IE_CAL_<br>RESYNC    | Successive Calibration Check Resynchronized Interrupt Enable: This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of "Option 2" being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                         |
| 5<br>IE_CAL_20_25         | Calibration Variation 20 - 25% Interrupt Enable. This bit enables interrupt assertion when corresponding status bit is set.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                                                 |
| 6<br>IE_SMSG_OFLW         | Slow Serial Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                      |
| 7<br>IE_FMSG_OFLW         | Fast Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                   |
| 8<br>FCRC_CHK_<br>OFF     | Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message<br><br>0 Check is enabled<br>1 Check is disabled/off                                                                                                                                                                                                                                                                        |
| 9<br>IE_PP_DIAG_<br>ERR   | Ratio of calibration pulse length to message length varies by more than $\pm 1.5625\%$ between two frames. Valid for messages with pause pulse. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                               |
| 10<br>IE_CAL_LEN_<br>ERR  | Calibration pulse is wider than 56 ticks $\pm 25\%$ . This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                         |
| 11<br>IE_CAL_DIAG_<br>ERR | Successive Calibration pulses differ by more than $\pm 1.56\%$ . SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55%. This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled |
| 12<br>IE_NIB_VAL_<br>ERR  | Any nibble data value $<0$ or $>15$ . This bit enables interrupt assertion when its respective diagnostic check fails on the corresponding channel.<br><br>0 Interrupt is disabled<br>1 Interrupt is enabled                                                                                                                                                                                                         |

**41.4.22 Channel 'n' Fast Message Time Stamp Read Register (n=0 to (CH-1)) (SRX\_CHn\_FMSG\_TS)**

Address offset:  $0x0168 + 0x18 \times n$

This is register CHn\_FMSG\_TS. The contents of this register are same as [DMA Fast Message Time Stamp Read Register \(SRX\\_DMA\\_FMSG\\_TS\)](#).

## Memory map and register definition

Address: 0h base + 168h offset + (24d × i), where i=0d to 5d

### SRX\_CHn\_FMSG\_TS field descriptions

| Field      | Description                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0–31<br>TS | Time Stamp for received message. Indicates the relative time when the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) was detected |

## 41.4.23 Channel 'n' Serial Message Read Register (Bit 3) (n=0 to (CH-1)) (SRX\_CHn\_SMSG\_BIT3)

Address offset: 0x016C + 0x18 × n

This is register CHn\_SMSG\_BIT3. The contents of this register are same as [DMA Slow Serial Message Bit3 Read Register \(SRX\\_DMA\\_SMSG\\_BIT3\)](#) .

### NOTE

The value of the CH is device-specific. See the device configuration section for details.

Address: 0h base + 16Ch offset + (24d × i), where i=0d to 5d
