Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken. Certain instructions (**zvselh**) (**evsel**) generate a pair of predicate bits that are both reported as consecutive bits in the history field.

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

75.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

75.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

75.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If DC1_{PTM} is set to ‘1’, indirect branch information is messaged out in the following format:

(1–32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

Figure 1854. Indirect branch message (history) format

75.12.2.2 Indirect branch messages (traditional)

If $DC1_{PTM}$ is cleared to '0', indirect branch information is messaged out in the following format:

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

Figure 1855. Indirect branch message format

75.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

(1–8 bits)	(4 bits)	(6 bits)
Sequence Count	Src. Proc.	TCODE (000011)

Max length = 18 bits; Min length = 11 bits

Figure 1856. Direct branch message format

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

75.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

75.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

75.12.3.2 Branch/Predicate Instruction History (HIST)

If DC1_{PTM} is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **zvselh** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 1721. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	bcctr, bcctrl, bclr, bclrl
Not taken direct branches	0	b, ba, bc, bca, bla, bcla, bl, bcl
Taken direct branches	1	b, ba, bc, bca, bla, bcla, bl, bcl⁽¹⁾
zvselh instruction	00,01,10, or 11	zvselh
evsel instruction	00,01,10, or 11	evsel

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

75.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that

the preceding instruction count and history information should be interpreted in a VLE context.

75.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

Max length = 46 bits; Min length = 15 bits

Figure 1857. Resource Full Message format

Table 1722 shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 1722. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch History. This type of packet is terminated by a stop bit set to 1 after the last history bit.

75.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to $MSR_{PMM}=0$ and $DC4_{PTMARK}=1$.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to [Table 1695](#) for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Figure 1858. Program Correlation message formats

75.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

75.12.6 Program Trace Overflow Error messages

an Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

75.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see [Table 1723](#)):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow '1'$ with $DC4_{PTMARK} = '1'$.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

Figure 1859. Program Trace Synchronization message format

Exception conditions that result in Program Trace Synchronization are summarized in [Table 1723](#).

Table 1723. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (j_trst_b), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (p_reset_b), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a nex_evti_b assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

75.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see [Table 1723](#)):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

Figure 1860. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. Messages is as follows:

(1–32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Figure 1861. Indirect Branch History w/ Sync message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in [Table 1724](#).

Table 1724. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync. Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the <i>next</i> Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCMPIDMSG → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A BTM Message from Instruction1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

75.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PMM} bit and the setting of DC4_{PTMARK}

75.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration)

Figure 1862. Program Trace — Indirect Branch message (Traditional)

Figure 1864. Program Trace — Direct Branch (traditional) & Error messages

Figure 1865. Program Trace — Indirect Branch w/ Sync message

75.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

75.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z425n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

75.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

75.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 1866. Data Write message format

75.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Figure 1867. Data Read message format

Note: . * Core (e200z425n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Core (e200z425n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

75.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see [Table 1725](#)):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

Figure 1868. Data Write/Read with Sync message format

Exception conditions that result in Data Trace Synchronization are summarized in [Table 1725](#).

Table 1725. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (j_trst_b), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.

Table 1725. Data Trace Exception summary (continued)

Exception Condition	Exception Handling
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a nex_evti_b assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCMPIDMSG → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

75.13.3 DTM operation

75.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

75.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

75.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and DC4_{DTMARK}.

75.13.3.4 Bus cycle special cases

Table 1726. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{\text{TEA}}$) ⁽¹⁾	Data Trace Message discarded
Bus cycle completed without error ⁽¹⁾	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored

Table 1726. Bus cycle special cases (continued)

Special case	Action
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC _{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) — both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0, or unless the misaligned access wraps over the end of a circular buffer when using the LSP specialized load or store with circular addressing. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z425n3) Core Debug Support chapter.)

Note: A store to the store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

75.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 1869. Data Trace — Data Write message

Figure 1870. Data Trace — Data Read w/ Sync message

75.14 Data Acquisition messaging

this section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

75.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

75.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

75.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z425n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

(1–32 bits)	(8 bits)	(4 bits)	(6 bits)
DQDATA	DQTAG	Src. Proc.	TCODE (011011)

Max length = 50 bits; Min length = 19 bits

Figure 1871. Data Acquisition message format

75.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z425n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the WMSK_{WEM} field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See [Table 1730](#) for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

(1–30 bits)	(4 bits)	(6 bits)
Watchpoint Source	Src. Proc.	TCODE (001111)

Variable length = 11–40 bits

Figure 1872. Watchpoint message format

The Watchpoint Source message field will contain a '1' for each asserted watchpoint. Leading zeros are truncated.

Table 1727. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
00000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1	Watchpoint #0 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1x	Watchpoint #1 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xx	Watchpoint #2 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxx	Watchpoint #3 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxx	Watchpoint #4 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxx	Watchpoint #5 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxx	Watchpoint #6 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #7 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #8 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #9 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #10 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #11 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #12 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #13 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #14 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #15 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #16 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #17 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #18 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #19 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #20 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #21 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #22 enabled for WTM

xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #24 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #25 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #26 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #27 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #28 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxxxxxx	Watchpoint #29 enabled for WTM

75.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 1873. Watchpoint Message & Watchpoint Error message

75.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect.

[Table 1728](#) details the external hardware trigger signals.

Table 1728. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 1728. External Hardware Trigger Signals (continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

75.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The RWCS_{ATTR} field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

75.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
 - a) Write Address → 32h'xxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure the bits as follows:
 - a) Access Control (AC) → 1b'1 (to indicate start access)
 - b) Map Select (MAP) → 3b'000 (primary memory map)
 - c) Access Priority (PR) → 2b'11 (highest priority)
 - d) Read/Write (RW) → 1b'1 (write access)
 - e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
 - f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
 - a) Write Data → 32h'xxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see [Table 1730](#) for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note: Only the **nex_ahb_start**, **nex_rdy_b**, and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

75.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in [Section 75.17.1, Single write access](#) to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has been cleared,

this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in [Section 75.17.1, Single write access](#) until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

75.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
 - a) Read Address → 32h'xxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure the bits as follows:
 - a) Access Control (AC) → 1b'1 (to indicate start access)
 - b) Map Select (MAP) → 3b'000 (primary memory map)
 - c) Access Priority (PR) → 2b'11 (highest priority)
 - d) Read/Write (RW) → 1b'0 (read access)
 - e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
 - f) Access Count (CNT) → 14h'0000 or 14h'0001 (single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see [Table 1730](#) for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#).

Note: Only the **nex_ahb_start**, **nex_rdy_b**, and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

75.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in [Section 75.17.3, Single read access](#) to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (see [Table 1730](#) for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see [Table 1730](#) for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#).
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in [Section 75.17.3, Single read access](#) until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

75.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

75.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

75.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
 - a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
 - b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

75.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

(5 bits)	(4 bits)	(6 bits)
Error Code (00011)	Src. Proc.	TCODE (001000)

Fixed length = 15 bits

Figure 1874. Error message format

75.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

75.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in [Table 1730](#). The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#) for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z425n3) Core Debug Support chapter.

Table 1729. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (j_tdo) pin is the serial output for test instructions and data. j_tdo is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. j_tdo changes on the falling edge of j_tclk .
j_tdi	I	The Test Data Input (j_tdi) pin receives serial test instruction and data. TDI is sampled on the rising edge of j_tclk .
j_tms	I	The Test Mode Select (j_tms) input pin is used to sequence the OnCE controller state machine. j_tms is sampled on the rising edge of j_tclk .
j_tclk	I	The Test Clock (j_tclk) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (j_trst_b) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in [Table 1730](#).

Table 1730. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (nex_mcko) is a free running output clock to development tools for timing of nex_mdo[n:0] & nex_mseo_b[1:0] pin functions. nex_mcko is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (nex_mdo[n:0]) are output pins used for OTM, BTM, and DTM. External latching of nex_mdo[n:0] shall occur on the rising edge of the Nexus3 clock (nex_mcko).
nex_mseo_b[1:0]	O	Message Start/End Out (nex_mseo_b[1:0]) are output pins that indicate when a message on the nex_mdo[n:0] pins has started, when a variable length packet has ended, and when the message has ended. External latching of nex_mseo_b[1:0] shall occur on the rising edge of the Nexus3 clock (nex_mcko). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (nex_rdy_b) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, nex_rdy_b remains deasserted
nex_err_b	O	Error (nex_err_b) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, nex_err_b remains deasserted
nex_evto_b	O	Event Out (nex_evto_b) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. nex_evto_b is held asserted for one (1) cycle of nex_mcko : 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01

Table 1730. Nexus 3 auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evti_b	I	Event In (nex_evti_b) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (nex_wevto[3:0]) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. nex_wevto[3:0] is held asserted for one (1) cycle of nex_mcko .
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to [Section 75.20, Auxiliary port arbitration](#), for detail on Nexus port arbitration.

Table 1731. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (nex_aux_req[1:0]) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 1733 .)
nex_aux_busy	O	Nexus Auxiliary Busy (nex_aux_busy) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (nar_aux_grant) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (ext_multi_nex_sel) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

75.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in [Table 1732](#). Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the SPC57EM80xx.

Table 1732. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

Figure 1875 illustrates the state diagram for single pin MSEO transfers.

Figure 1875. Single pin MSEO transfers

Note that the “End Message” state does not contain valid data on the **nex_mdo[n:0]** pins. Also, It is not possible to have two consecutive “End Packet” messages. This implies the minimum packet size for a variable length packet is 2x the number of **nex_mdo[n:0]** pins. This ensures that a false end of message state is not entered by emitting two consecutive ‘1’s on the **nex_mseo_b** pin before the actual end of message.

Figure 1876 illustrates the state diagram for dual pin MSEO transfers.

Figure 1876. Dual pin MSEO transfers

The dual pin MSEO option is more robust than the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive “End Packet” states. This can be an advantage when small, variable sized packets are transferred.

Note: The “End Message” state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

75.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is impossible to know which bit is from the last packet and which bit is from the next packet.)
- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

75.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level. The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in [Table 1733](#) below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in [Section 75.18.2, Pin protocol](#). The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the MSEO state machine reaches the “End Message” state.

Table 1733. MDO request encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

75.21 Examples

The following are examples of Program Trace and Data Trace Messages.

[Table 1734](#) illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. [Table 1735](#) illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- lx = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 1734. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 1735. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	M A P	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

[Table 1736](#) and [Table 1737](#) illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 1736. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 1737. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

[Table 1738](#) illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and [Table 1739](#) illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 1738. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)

Table 1738. Data write message example (8 MDO / 1 MSEO) (continued)

Clock	nex_mdo[7:0]									nex_mseo_b	State
1	S1	S0	T5	T4	T3	T2	T1	T0		0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2		1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0		0	Normal Transfer
4	0	0	0	0	0	0	0	0		1	End Packet
5	0	0	0	0	0	0	0	0		1	End Message

Table 1739. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]									nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0		0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2		0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0		1	1	End Packet/ End Message

75.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the SPC57EM80xx Data Sheet.

75.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

75.23.1 JTAG sequence for accessing internal Nexus registers

Table 1740. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value

Table 1740. Accessing internal Nexus 3 registers via JTAG/OnCE (continued)

Step #	TMS Pin	Description
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

75.23.2 JTAG sequence for read access of memory-mapped resources

Table 1741. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of nex_rdy_b or nex_err_b pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

75.23.3 JTAG sequence for write access of memory-mapped resources

Table 1742. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of nex_rdy_b or nex_err_b pin
8	—	If CNT > 0, go back to Step #5

76 GTM Development Interface (GTMDI)

76.1 Introduction

Figure 1877 shows a block diagram of the Generic Timer Module (GTM) Development Interface.

Figure 1877. GTMDI block diagram

76.2 Overview

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including Multi-Channel Sequencer (MCS) cores, Advanced Routing Unit (ARU) data trace, input channel filters trace, output timer channels, DPLL and Sensor Pattern Evaluation (SPE) sub-modules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules to implement complex debug features. Trace capability is also provided along with a global time-stamp which allows real time trace for several GTM sub-module events.

The GTMDI implements a Nexus Client standard interface and a JTAG standard Port Controller to provide communication capability with the JTAG and NAR on-chip modules. The Nexus standard is only used for the physical interfaces. Due to specific requirements for the GTM debug, the Nexus standard is not followed.

[Figure 1878](#) describes the interconnection between the GTMDI and GTM modules. The GTMDI selects which signal or bus to monitor since it does not have the capability to monitor all signals in parallel. The multiplexing architecture is described in the following sections.

Figure 1878. GTMDI and GTM interface

Note: [Figure 1878](#) does not show all of the GTM internal modules. It shows only the modules that interface to the GTMDI debug module.

The number of ATOM, TIM, TOM, MCS and SPE modules in [Figure 1878](#) is shown in [Table 1743](#).

Table 1743. GTM Sub-module instances

Module	Number of instances
ATOM	5
TIM	4
TOM	3
MCS	numMCS
SPE	2

[Figure 1879](#) shows the Watchpoint Triggers (WPT) and Watchpoint Messages (WPM). Each GTM sub-module generates two watchpoints which can be routed internally to the GTMDI and generate watchpoint triggers or routed to the message formatter and generate watchpoint messages. The selection between watchpoint triggers and messages is implemented per sub-module. Messages and watchpoint triggers can also be generated at the same time based on the same event within a sub-module, thus a TIM channel transition can generate a watchpoint trigger and a watchpoint message. The watchpoint triggers may be sent to the Sequence Processing Unit (SPU) outside the GTMDI if enabled by appropriate control register bits for each sub-module, such as Timer Input Module (TIM), Timer Output Module (TOM) and ARU-connected Timer Output Module (ATOM). The watchpoint messages, if enabled, are sent to the NAR through the Nexus Client interface.

Figure 1879. Watchpoint triggers and watchpoint messages

The SPU provides external control of the watchpoint messages generated by the GTMDI thus controlling the bandwidth over the Nexus Client interface. This functionality is implemented through Start/Stop control signals from the SPU. These signals are connected to the sub-module register bit that enables the message transmission implementing a dual control over these registers, either by JTAG interface programming or by SPU Start/Stop signals. See [Section 76.5, Functional description](#) for more details about register control and general architecture.

76.2.1 Features

The GTMDI block implements the following features:

- Full duplex pin interface for medium and high visibility throughput
 - 2 $\overline{\text{EVTO}}$ (Event Out) for GTM real time signal monitoring
 - 1 $\overline{\text{EVTI}}$ (Event In)
 - IEEE 1149.1 (JTAG) Test Access Port (TAP)
 - 4 pins (TDI, TDO, TMS, and TCK)
 - Reset input $\overline{\text{TRST}}$ driven by either the Nexus Port Controller or an external pin
- GTM Development Support
 - Read/Write registers in debug mode from JTAG port
 - Ability to enter debug mode at reset negation or during normal execution

Note: Enter debug out-of-reset is provided through the SoC system level debug control signal. In order to allow this functionality the GDE and SDBE control bits in the GTMDI_DC register should be set.

- Halt and Watchpoint Configuration
- MCS Data Trace Messaging (DTM) and Watchpoint Messaging (WPM) allows the development tool to trace reads and writes to selected MCS RAM address ranges
 - Two data trace windows for each MCS core with programmable address ranges and access attributes are provided. Data trace windowing reduces the requirement on the Aurora port bandwidth by constraining the number of trace locations.
 - Fetch trace capability controlled by two programmable Watchpoints.
 - Private messages are used to indicate special MCS core cases not covered by public messages. Two MCS cores can be debugged at the same time.

Note: Enabling two MCS cores at the same time for data trace can exceed the capacity of the NAR Client interface throughput thus information can be lost.

- DPLL Data Trace Messaging and Watchpoint Trace Messaging allows the development tool to trace reads and writes to selected DPLL RAM addresses and selected data value.
- ARU Data Trace Messaging and Watchpoint Trace Messaging allows the development tool to trace selected ARU channels.
- Watchpoint Messaging (WPM)
- Trigger Control
 - The GTMDI provides selection of trigger signals that generate debug actions at system level such as Halt GTM itself or cores in the same device.
 - Trace enable signals are provided to control the start/stop of trace messages for each one of the GTM Nexus message sources, such as Timer Input Module (TIM), Timer Output Module (TOM), ARU-connected Timer Output Module (ATOM), etc.
- GTMDI clock operation
 - The module is able to operate in any frequency ratio considering GTMDI and JTAG frequency. The GTMDI operates from the same clock source as the GTM IP module.

76.2.2 Modes of operation

The GTMDI block is placed in reset when the Nexus reset signal is asserted. The JTAG registers controlled by the TCK clock are also put into the reset state if the TAP controller is in the TEST-LOGIC-RESET state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the TEST-LOGIC-RESET state regardless of the initial TAP controller state. Asserting the Nexus reset signal results in asynchronous entry into the reset state not only of the TCK controlled registers but all registers in the GTMDI. The GTMDI is unaffected by other sources of reset. While in reset, the following actions occur:

- The TAP controller is forced into the TEST-LOGIC-RESET state
- The auxiliary output port pins are negated
- The auxiliary output port enable outputs are negated
- The TDI, TMS, and TCK TAP inputs are ignored (The TMS and TCK signal are ignored only while the Nexus reset signal is asserted.)
- Registers default back to their reset values

Note: The GTMDI is not reset by the system reset signal. It is reset during device Power On reset or by a dedicated Nexus reset thus preserving internal registers state and programming during system reset.

Debug Mode can be controlled by on-chip logic through the system debug signal. The level on this signal defines if the GTM module is in debug mode, meaning that it is in Halt state and accepts write and read accesses to internal registers that do not modify the state of those registers. If asserted, the GTM enters Halt state. If negated, the GTM debug mode is controlled by other sources, internal to the GTMDI. The GTM may enter debug out of reset by asserting the system debug signal while the device is being reset. By detecting this condition, the GTMDI puts the GTM into the Halt state. The GDE and SDBE bits described in [Figure 1881](#) must be set during reset allowing the GTM to enter debug state.

76.2.3 DATA port

GTMDI messages are sent through the Message Data Bus. The Message Data Bus has a fixed width of 32 bits which defines one BEAT of data. There are three BEATS per NAR clock thus 96 bits are transmitted in parallel.

76.3 External signal description

The GTMDI pinout provides interface for the transmission of messages and for accessing Nexus registers. The GTMDI pin definition is outlined in [Table 1744](#).

Table 1744. GTMDI signal properties

Name	Port	Function	Reset State
EVTI	Auxiliary	Event In pin	—
$\overline{\text{EVTO}}[1:0]$	Auxiliary	Event Out pin	[11]
TCK	TAP	Test Clock Input	—
TDI	TAP	Test Data Input	—
TDO	TAP	Test Data Output	0
TMS	TAP	Test Mode Select Input	—
$\overline{\text{TRST}}$	TAP	Test Reset Input	—

Each of the signals listed in [Table 1744](#) is described in more detail in the following sections.

76.3.1 Event in ($\overline{\text{EVTI}}$)

Event In ($\overline{\text{EVTI}}$) is used to generate a Halt if enabled by the corresponding control bit. $\overline{\text{EVTI}}$ is an edge-sensitive signal. It is synchronized at the GTMDI input and a falling edge is detected.

76.3.2 Event out $\overline{\text{EVTO}}[1:0]$

Event Out ($\overline{\text{EVTO}}$) are two outputs from GTMDI for development tools with exact timing for a two watchpoints or Halt occurrence. $\overline{\text{EVTO}}$ is asserted for one system clock cycle when Halt or watchpoints are monitored. When internal GTM signals are monitored, such as TIM filtered signals or TOM/ATOM outputs, the $\overline{\text{EVTO}}$ represent the exact signal shape with a certain delay. In this monitoring mode the signal is not inverted through the $\overline{\text{EVTO}}$ output. The real time monitoring mode is intended for oscilloscope type of monitoring thus allowing the user to evaluate the actual shape of the signals. The source selection for the $\overline{\text{EVTO}}$ is centralized in the Development Control register GTMDI_DC.

76.3.3 Test clock input (TCK)

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the JTAG port.

76.3.4 Test data input (TDI)

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

76.3.5 Test data output (TDO)

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is actively driven in the SHIFT-IR and SHIFT-DR states of the JTAG state machine. TDO changes on the falling edge of TCK and is sampled on the rising edge of TCK.

76.3.6 Test Mode Select (TMS)

Test Mode Select (TMS) is an input pin used to sequence the JTAG state machine. TMS is sampled on the rising edge of TCK.

76.4 Register definition

This section provides a detailed description of all GTMDI registers accessible to the development tool. Individual bit-level descriptions and reset states of each register are included. [Table 1745](#) shows the GTMDI registers and index values. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 1745. GTMDI registers

Register	Index	Read/write
Device Identity (DID)	0	R
Reserved	1–4	—
GTMDI Development Control (GTMDI_DC)	5	R/W

76.4.1 Register descriptions

This section consists of GTMDI register descriptions. The registers are shown in [Table 1745](#). The MCS cores selected for debugging are named MCSA and MCSB thus two MCS cores can be debugged at the same time. See registers GTMDI_MCSA_DC and GTMDI_MCSB_DC which specify the real number of the MCS associated with MCSA and MCSB.

76.4.1.1 Device identity register (DID)

The DID register contains the unique identification information as shown in [Figure 1880](#).

Register index: 0

Figure 1880. Device identity register (DID)

[Table 1746](#) describes the device identification register functions.

Table 1746. DID field descriptions

Field	Description
31–28 PRN	Part Revision Number. Contains the revision number of the part.
27–22 DC	Design Center. Indicates the design center.
21–12 PIN	Part Identification Number. Contains the part number of the device. Value is 0x3E3.
11–1 MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID.
0 IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

76.4.1.2 GTMDI development control register (GTMDI_DC)

The GTMDI_DC register controls various trace and debug features of the GTM modules as described in [Figure 1881](#).

Register index: 5

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 1881. GTMDI development control register (GTMDI_DC)

[Table 1747](#) describes the GTMDI_DC register functions.

Table 1747. GTMDI_DC field descriptions

Field	Description
31 GDE	Global Debug Enable. This control bit disables all debug features of the GTMDI module including ability to put GTM IP in Halt state, modify EVTO output, send messages to the DATA bus and set triggers to the SPU module. Before changing the GTMDI configuration it is recommended to clear GDE bit to prevent spurious behavior of the module outputs. See Figure 1926 for details about debug enable logic. 0 GTMDI Global debug is disabled 1 GTMDI Global debug is enabled
27–24 EOS0	EVTO0 Output Selection. This signal is dedicated to sel 1 which is the selection 1 from the indicated GTM modules. See the control registers for each module for a description of this selection. For TIM, TOM and ATOM selections the input filtered signal or output channel signal are used instead of the triggers. 0000 No event on output EVTO0 remains at one 0001 Halt Indication, If EVTO0 is zero indicates that GTM is halted 0010 TIM, Map EVTO0 from TIM channel filter output using ssel 1 selection control 0011 TOM, Map EVTO0 from TOM channel output using ssel1 selection control 0100 ATOM, Map EVTO0 from ATOM channel output using ssel 1 selection control 0101 SPEA, Map EVTO0 from SPEA, controlled by TSS1 described in Figure 1889 0110 SPEB, Map EVTO0 from SPEB, controlled by TSS1 described in Figure 1891 0111 ARU CH0, Map EVTO0 from ARU CH0 1000 DPLL, Map EVTO0 from DPLL according to TSEL1 in Figure 1893 1001 MCSA, Map EVTO0 from MCSA MCSA_sel selection control 1010 MCSB, Map EVTO0 from MCSB MCSB_sel selection control 1011 TBU0 Watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU0_WPC1 register 1100 TBU1 watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU1_WPC1 register 1101 TBU2 watchpoint 1, Watchpoint controlled by TSS1 in GTMDI_TBU2_WPC1 register 1110 Reserved 1111 Reserved
19–16 EOS1	EVTO1 Output Selection. This signal is dedicated to sel 2 which is the selection 2 from the indicated GTM modules. See the control registers for each module for a description of this selection. For TIM, TOM and ATOM selections the input filtered signal or output channel signal are used instead of the triggers. 0000 No event on output EVTO1 remains at one 0001 Halt Indication, If EVTO1 is zero indicates that GTM is halted 0010 TIM, Map EVTO1 from TIM channel filter output using ssel 1 selection control 0011 TOM, Map EVTO1 from TOM channel output using ssel1 selection control 0100 ATOM, Map EVTO1 from ATOM channel output using ssel 1 selection control 0101 SPEA, Map EVTO1 from SPEA, controlled by TSS2 described in Figure 1889 0110 SPEB, Map EVTO1 from SPEB, controlled by TSS2 described in Figure 1891 assert_spe1_dir_evto 0111 ARU CH1, Map EVTO1 from ARU CH1 1000 DPLL, Map EVTO1 from DPLL according to TSEL2A/B in Figure 1893 1001 MCSA, Map EVTO1 from MCSA MCSA_sel selection control 1010 MCSB, Map EVTO1 from MCSB MCSB_sel selection control 1011 TBU0 Watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU0_WPC1 register 1100 TBU1 watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU1_WPC1 register 1101 TBU2 watchpoint 2, Watchpoint controlled by TSS2 in GTMDI_TBU2_WPC1 register 1110 Reserved 1111 Reserved

Table 1747. GTMDI_DC field descriptions (continued)

Field	Description
8 CHR	Clear Halt Request. Writing this bit to one clears halt requests., which means GTM resumes normal operation out of halt state. The status bits of the GTMDI_DS register are cleared. This bit is self-cleared thus read always as zero. 0 No action 1 Clear halt requests
6 EIDR	EVTI Debug Request enable. The EIDR bit enables EVTI input to request the GTM to enter Halt state. After the GTM enters Halt state due to a pulse in EVTI signal, the EIDR bit state is not meaningful, thus it may be cleared and the GTM continues in Halt state. See Figure 1926 for details about debug enable logic. 0 Disable EVTI to control GTM to enter Halt state 1 Enable EVTI to control GTM to enter Halt state
4 DBE	Debug Enable. DBE enables debug mode thus allowing the GTM to enter debug mode which means halt regular operation. The debug events controlled by this register are the ones generated internally to the GTMDI, excluding ipg_debug and EVTI which have their dedicated enable control. See Figure 1926 for details about debug enable logic. 0 Debug mode disabled 1 Debug mode enabled
3 DBR	Debug Request. Mechanism to allow development tool to request modules to enter debug mode directly. See Figure 1926 for details about debug enable logic. 0 Does not modify GTM IP debug state 1 Request GTM IP to enter debug mode
2 SDBE	System Debug Enable. The SDBE bit enables the GTM to enter halt state if system level debug enable signal is asserted. This bit allows the debug controller to select specific sub-groups of cores or modules to halt, while others continue to operate. GDE bit must also be set to allow GTM to halt. See Figure 1926 for details about debug enable logic. 0 GTM does not enter halt state due to system debug enable signal assertion 1 GTM is enabled to enter halt state due to system debug enable signal assertion
0 TSFT	Timestamp Force Transmission. Forces the transmission of the Timestamp value along with the Nexus message data for all messages transmitted by the GTMDI Client module. When Timestamp inclusion is not forced into the client message, its inclusion depends upon the NAR settings. 0 Does not force transmission of Timestamp value 1 Forces transmission of Timestamp along with Nexus message

76.4.1.3 GTMDI development status register (GTMDI_DS)

The GTMDI_DS register described in [Figure 1882](#) shows the status of various conditions that impact GTM development support. All status bits are dynamic and do not require clearing. Debug Status Event is queued due to a change in the Halt or Stop modes and a Debug Status Message is generated as soon as there is an opportunity in the NAR interface. If any status bit changes before the Status message is sent, this change is reflected in the message. The GTMDI_DS register dynamically tracks the debug condition status even when several of them are simultaneously set.

Register index: 6

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 1882. GTMDI development status register (GTMDI_DS)

Table 1748 describes the GTMDI_DS register functions.

Note: The HS1 and HS2 bit fields are cleared as soon as the GTM resumes normal operation which is controlled by the CHR bit in the GTMDI_DC register. One exception is HS1[0] that indicates system debug request, which is not cleared by CHR. This bit is cleared when system debug request is negated.

Table 1748. GTMDI_DS field descriptions

Field	Description
31 HLT	Halt Indication. The HLT bit indicates if the GTM IP is in Halt state, ready to receive debug accesses. 0 GTM is running 1 GTM is in Halt state
28–16 HS1	Halt Status1. The HS1 field shows which source generated the halt condition. More than one source can generate the halt condition at the same time. This register is only meaningful if the GTM is halted. Its content indicates the halt sources that occurred immediately when the halt mode is entered. 0000000000000 No Trigger generated 1xxxxxxxxx TIM x1xxxxxxxxx TOM xx1xxxxxxxxx ATOM xxx1xxxxxxxxx SPEA xxxx1xxxxxxxxx SPEB xxxxx1xxxxxxx ARU xxxxxx1xxxxxx DPLL xxxxxxx1xxxxx MCSA xxxxxxx1xxxxx MCSB xxxxxxx1xxx TBU0 Watchpoint 1 xxxxxxx1xx TBU1 Watchpoint 1 xxxxxxx1x TBU2 Watchpoint 1 xxxxxxx1 External through system debug enable signal

Table 1748. GTMDI_DS field descriptions (continued)

Field	Description
15 STP	Stop Status. Indicates if the GTM is in stop mode with no active clocks. Besides the system level stop mode mechanism, the GTM may independently be programmed for STOP mode by setting the Module Disable Control bit. Thus, the STP field indicates if the GTM is in stop mode no matter if due to the system stop mode assertion or due to the MDIS bit in the GTM module control register. 0 GTM not stopped 1 GTM is stopped in low power mode
12–0 HS2	Halt Status². Similarly to HS1 this field indicates the source for the halt condition selection 2. See Figure 1927 for reference about source selection 1 and 2. The HS2 field shows which source generated the halt condition 2. More than one source can generate the halt condition at the same time. This register is only meaningful if the GTM is halted. Its content indicates the halt condition source that occurred when the halt mode is entered. 00000000000000No Trigger generated 1xxxxxxxxxxx TIM x1xxxxxxxxxxx TOM xx1xxxxxxxxxxx ATOM xxx1xxxxxxxxxxx SPEA xxxx1xxxxxxxxxxx SPEB xxxxx1xxxxxxx ARU xxxxxx1xxxxxxx DPLL xxxxxxx1xxxxxxx MCSA xxxxxxx1xxxxxxx MCSB xxxxxxx1xxx TBU0 Watchpoint 2 xxxxxxx1xx TBU1 Watchpoint 2 xxxxxxx1x TBU2 Watchpoint 2 xxxxxxx1 EVTI

76.4.1.4 TIM watchpoint control register 1 (GTMDI_TIM_WPC1)

The GTMDI_TIM_WPC1 register shown in [Figure 1883](#) controls the Watchpoint Triggers WPT issued by TIM channels. These triggers are used by the GTM internal modules in order to control GTM Halt mode entering and also at SoC level. See [Figure 1927](#) which describes the use of this register.

Note: *Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG. The SEN1 and SEN2 control bits from the GTMDI_TIM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.*

Table 1749 describes the GTMDI_TIM_WPC1 register functions.

Table 1749. GTMDI_TIM_WPC1 field descriptions

Field	Description
29–28 TSS1	TIM Channel Slope Selection 1. The TSS1 field selects the slope for the TIM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
26–24 SSEL1	TIM sub-module Source Selection 1. Selects which TIM sub-module is the source for watchpoint generation. 000 TIM0 001 TIM1 010 TIM2 011 TIM3 100 Reserved 101 Reserved 110 Reserved 111 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the selected TIM Channel is used to halt the GTM module. If this bit is set and an event occurs on the selected TIM Channel filter output, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected TIM Filter output to generate a Watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

Table 1749. GTMDI_TIM_WPC1 field descriptions (continued)

Field	Description
18–16 CHSEL1	TIM channel selection 1. Selects which channel within a selected TIM sub-module generates watchpoints. The selection is actually on the TIM channel input filter. 000 TIM CH0 001 TIM CH1 010 TIM CH2 011 TIM CH3 100 TIM CH4 101 TIM CH5 110 TIM CH6 111 TIM CH7
13–12 TSS2	TIM Channel Slope Selection 2. The TSS2 field selects the slope for the TIM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
10–8 SSEL2	TIM sub-module Source Selection 2. Selects which TIM sub-module is the source for watchpoint generation. 000 TIM0 001 TIM1 010 TIM2 011 TIM3 100 Reserved 101 Reserved 110 Reserved 111 Reserved
7 HEN2	Halt Enable 2. The HEN1 Halt Enable 2 bit controls if the selected TIM Channel is used to halt the GTM module. If this bit is set and an event occurs on the selected TIM Channel filter output, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC1 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected TIM Filter output to generate a Watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
2–0 CHSEL2	TIM channel selection 2. Selects which channel within a selected TIM sub-module generates watchpoints. The selection is actually on the TIM channel input filter. 000 TIM CH0 001 TIM CH1 010 TIM CH2 011 TIM CH3 100 TIM CH4 101 TIM CH5 110 TIM CH6 111 TIM CH7

76.4.1.5 TIM watchpoint control register 2 (GTMDI_TIM_WPC2)

The GTMDI_TIM_WPC2 register shown in [Figure 1884](#) controls the Watchpoint Triggers WPT issued by TIM channels. These watchpoint triggers are used to control GTM Halt state entering, watchpoint messages and control external logic to the GTMDI. See [Figure 1927](#) for details of the logic that uses the bits in this register.

Figure 1884. TIM watchpoint control 2 register (GTMDI_TIM_WPC2)

[Table 1750](#) describes the GTMDI_TIM_WPC2 register functions.

Note: The *SHARED_WPT* and *SHARED_WPT_ST* signals mentioned in [Table 1750](#) and in other tables in this document, refer to the GTMDI top level connections. They correspond to Watchpoint trigger outputs of GTMDI and Stop/Start input signals respectively.

Table 1750. GTMDI_TIM_WPC2 field descriptions

Field	Description
30–28 WTSEL1	Watchpoint Trigger Output Selection 1. The WTSEL1[2:0] bit field selects among 8 available output Watchpoint triggers which one is connected to the selected TIM Channel. Other modules can select the same WTSEL1 value, in this case the result watchpoint signal implements an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21–20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a Watchpoint external trigger is issued. This enable refers to the output selected by the WTSEL1 field. 0 Disable Watchpoint Trigger Generation 1 Enable Watchpoint Trigger Generation

Table 1750. GTMDI_TIM_WPC2 field descriptions (continued)

Field	Description
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enables the selected TIM channel to consider the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_TIM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs
14–12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL1[2:0] bit field selects among 8 available output Watchpoint triggers which one is connected to the selected TIM Channel. Other modules can select the same watchpoint trigger, in this case the result signal implements an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5–4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used to control the watchpoint trace messages for the selected TIM channel. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a Watchpoint external trigger is issued by the selected TIM channel. This enable refers to the output selected by the WTSEL2 field. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enables the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_TIM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

76.4.1.6 TOM watchpoint control register 1 (GTMDI_TOM_WPC1)

The GTMDI_TOM_WPC1 register shown in [Figure 1885](#) controls the Watchpoint Triggers issued by TOM channels. These Watchpoint triggers are used to control the GTM requests to enter Halt, issue watchpoint messages and also by logic external to the GTMDI at SoC level.

Note: *Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_TOM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.*

Field	Description
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a Watchpoint external trigger is issued by the selected TOM channel. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enables the Start/Stop inputs of the GTMDI to control Watchpoint trace messages generated by the TOM selected channel. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_TOM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

76.4.1.8 ATOM watchpoint control 1 register (GTMDI_ATOM_WPC1)

The GTMDI_ATOM_WPC1 register shown in [Figure 1887](#) controls the Watchpoint Triggers issued by ATOM channels. These watchpoint triggers are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note: Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_ATOM_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

[Table 1753](#) describes the GTMDI_ATOM_WPC1 register functions.

Table 1753. GTMDI_ATOM_WPC1 field descriptions

Field	Description
29–28 TSS1	ATOM Channel Slope Selection 1. The TSS1 field selects the slope for the ATOM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
27–24 SSEL1	ATOM sub-module Source Selection 1. Selects which ATOM sub-module is the source for watchpoint generation. 0000 ATOM0 0001 ATOM1 0010 ATOM2 0011 ATOM3 0100 ATOM4 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the selected ATOM Channel is used to halt the GTM module. If this bit is set and an event occurs on the selected ATOM Channel filter output, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected ATOM Channel output to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
18–16 CHSEL1	ATOM channel selection 1. Selects which channel in an ATOM module generates watchpoints. 000 ATOM CH0 001 ATOM CH1 010 ATOM CH2 011 ATOM CH3 100 ATOM CH4 101 ATOM CH5 110 ATOM CH6 111 ATOM CH7
13–12 TSS2	ATOM Channel Slope Selection 2. The TSS2 field selects the slope for the ATOM selected channel. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved

Table 1753. GTMDI_ATOM_WPC1 field descriptions (continued)

Field	Description
11–8 SSEL2	ATOM sub-module Source Selection 2. Selects which ATOM module is the source for watchpoint generation. 0000 ATOM0 0001 ATOM1 0010 ATOM2 0011 ATOM3 0100 ATOM4 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the ATOM selected channel is enabled to HALT the GTM module. If this bit is set and an event occurs on the ATOM selected channel, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on the selected ATOM Channel output to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
2–0 CHSEL2	ATOM channel selection 2. The CHSEL2[2:0] field selects a channel within the TOM selected sub-module to generate watchpoints. 000 ATOM CH0 001 ATOM CH1 010 ATOM CH2 011 ATOM CH3 100 ATOM CH4 101 ATOM CH5 110 ATOM CH6 111 ATOM CH7

76.4.1.9 ATOM watchpoint control 2 register (GTMDI_ATOM_WPC2)

The GTMDI_ATOM_WPC2 register shown in [Figure 1887](#) controls the Watchpoint Triggers issued by ATOM channels. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

Table 1754 describes the GTMDI_ATOM_WPC2 register functions.

Table 1754. GTMDI_ATOM_WPC2 field descriptions

Field	Description
30–28 WTSEL1	Watchpoint Trigger Output Selection 1. The WTSEL1[2:0] bit field selects among 8 available output Watchpoint triggers which one is connected to the selected ATOM Channel. Other modules can select the same WTSEL1 value, in this case the result watchpoint signal implements an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21–20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a Watchpoint external trigger is issued by the ATOM Channel output selected by WTSEL1. 0 Disable Trigger Generation 1 Enable Trigger Generation
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enables the selected ATOM channel to consider the Start/Stop inputs for watchpoint trace messages control. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_ATOM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

Table 1754. GTMDI_ATOM_WPC2 field descriptions (continued)

Field	Description
14–12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available Watchpoint trigger outputs which one is connected to the ATOM selected channel. Other modules can selected the same WTSEL2 value, in this case the result signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5–4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used for the watchpoint message control. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a Watchpoint external trigger is issued by the selected ATOM channel. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enables the Start/Stop inputs of the GTMDI to control Watchpoint trace messages generated by the ATOM selected channel. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_ATOM_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

76.4.1.10 SPEA watchpoint control 1 register 1 (GTMDI_SPEA_WPC1)

The GTMDI_SPEA_WPC1 register shown in [Figure 1889](#) controls the Watchpoint Triggers issued by SPEA channels. These triggers are used for GTM to enter Halt state, generate watchpoint messages and to control logic outside of the GTMDI module, such as SPU interface.

Note: *Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_SEP0_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.*

[Table 1759](#) describes the GTMDI_DPLL_WPC1 register functions.

Table 1759. GTMDI_DPLL_WPC1 field descriptions

Field	Description
25–24 TSEL1	Watchpoint Selection 1. The TSEL1[1:0] field selects if a watchpoint trigger is issued based on TASI or SASI events. 00 Watchpoint on TASI event 01 Watchpoint on SASI event 10 Reserved 11 Reserved
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid transitions on DPLL SASI or TASI to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
21–20 TSS1	TASI/SASI Slope Selection. The TSS1 field selects the slope for TASI or SASI depending on TSEL1 selection. The selected slope is monitored by watchpoints. 00 Any transition (both) 01 Transition from 0 to 1 (positive slope) 10 Transition from 1 to zero (negative slope) 11 Reserved
17 HEN1	The HEN1 Halt Enable 1 bit controls if the DPLL SASI or TASI selected signal is enabled to HALT the GTM module. If this bit is set and an event occurs on the DPLL selected signal, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
13–12 TSEL2B	Watchpoint Selection 2B. The TSEL2B field selects the RAM access type to match on 00 Watchpoint is issued on any access (read or write) 01 Watchpoint is issued based on write accesses 10 Watchpoint is issued based on read accesses 11 Reserved
9–8 TSEL2A	Watchpoint Selection 2A. The TSEL2A field selects if a watchpoint is issued based on the RAM1a, RAM1bc or RAM2 access. 00 Watchpoint is issued based on RAM1a access 01 Watchpoint is issued based on RAM1b access 10 Watchpoint is issued based on RAM2 access 11 Reserved

Table 1759. GTMDI_DPLL_WPC1 field descriptions (continued)

Field	Description
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 controls the watchpoint message sent through the Message Data bus. If this bit is set it enables selected accesses on DPLL RAMs to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
1 HEN2	Halt Enable 2. The HEN Halt Enable bit controls if watchpoint from TSEL2 selection is enabled to HALT the GTM module. If this bit is set and an event occurs on an DPLL selected RAM, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM

76.4.1.15 DPLL watchpoint control 2 register (GTMDI_DPLL_WPC2)

The GTMDI_DPLL_WPC2 register shown in [Figure 1894](#) controls the Watchpoint Triggers issued by DPLL. These triggers are used for GTM to enter Halt state and by GTMDI external logic at SoC level. This register also controls the Watchpoint Trace messages WPM.

[Table 1760](#) describes the GTMDI_DPLL_WPC2 register functions.

Table 1760. GTMDI_DPLL_WPC2 field descriptions

Field	Description
30–28 WTSEL1	Watchpoint Trigger Output Selection 1. The WTSEL1[2:0] field selects among 8 available watchpoint triggers which one is connected to the DPLL SASI or TASI signal. Other modules can select this same WTSEL1 value, in this case the result trigger signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21–20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages related to DPLL SASI or TASI signals. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a watchpoint external trigger is issued by the DPLL TASI or SASI selected event. 0 Disable External Watchpoint Trigger Generation 1 Enable External Watchpoint Trigger Generation
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enable the DPLL TASI or SASI selected event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_DPLL_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs
14–12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available watchpoint triggers which one is connected to the DPLL RAM access signal. Other modules can select this same WTSEL2 value, in this case the result trigger signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5–4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used by the watchpoint trace messages related to DPLL RAM access events for RAM1A, RAM1B and RAM2. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]

Table 1760. GTMDI_DPLL_WPC2 field descriptions (continued)

Field	Description
1 TEN2	Watchpoint Trigger Enable 2. The TEN2 field controls if a watchpoint external trigger is issued by the DPLL RAM selected access. 0 Disable External Watchpoint Trigger Generation 1 Enable External Watchpoint Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enable the DPLL RAM selected access event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_DPLL_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

76.4.1.16 DPLL watchpoint control 3 register (GTMDI_DPLL_WPC3)

The GTMDI_DPLL_WPC3 register shown in [Figure 1895](#) defines the data value observed in the selected DPLL RAM access. A match to this value causes a Watchpoint.

Register index: 43

[Table 1761](#) describes the GTMDI_DPLL_WPC3 register functions.

Table 1761. GTMDI_DPLL_WPC3 field descriptions

Field	Description
28 DMASK	Data Mask. The DMASK field is a mask for the data comparator. If set, the data read or written to the memory should not be considered for watchpoint generation. 0 RAM_DATA should be compared with data from RAM access 1 RAM_DATA is masked and should not be compared
23–0 RAM_DATA	Data value. The RAM_DATA[23:0] field defines the data value that is compared against the data accessed from the selected DPLL RAM.

76.4.1.17 DPLL watchpoint control 4 register (GTMDI_DPLL_WPC4)

The GTMDI_DPLL_WPC4 register shown in [Figure 1896](#) defines the RAM address mask for the DPLL selected RAM address comparison.

Register index: 44

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

[Table 1762](#) describes the GTMDI_DPLL_WPC4 register functions.

Table 1762. GTMDI_DPLL_WPC4 field descriptions

Field	Description
11–0 RAM_ADDR_MASK	RAM Address mask. The RAM_ADDR_MASK[11:0] field is a mask applied bit by bit to the RAM_ADDR defined in the GTMDI_DPLL_WPC5 register. If mask is 1, the corresponding RAM_ADDR bit is not valid for comparison, thus it always returns a match when compared to the selected RAM address.

76.4.1.18 DPLL watchpoint control 5 register (GTMDI_DPLL_WPC5)

The GTMDI_DPLL_WPC5 register shown in [Figure 1897](#) defines the address value that is monitored during DPLL selected RAM access. Once this address value matches with the DPLL RAM address a Watchpoint is issued.

Register index: 45

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Figure 1897. DPLL watchpoint control 5 register (GTMDI_DPLL_WPC5)

[Table 1763](#) describes the GTMDI_DPLL_WPC5 register functions.

Table 1763. GTMDI_DPLL_WPC5 field descriptions

Field	Description
11–0 RAM_ADDR	RAM Address Compare. The RAM_ADDR[11:0] field defines the address value that is compared against the address for write and read DPLL RAM accesses. Before the comparison is executed the RAM_ADDR_MASK should be considered thus masking corresponding bits. A masked bit is always considered a match. <i>Note: DPLL module has three RAM modules with different address widths. The address value in the RAM_ADDR field and the RAM address should be right aligned in order to be compared.</i>

76.4.1.19 DPLL data trace control register (GTMDI_DPLL_DTC)

The GTMDI_DPLL_DTC register shown in [Figure 1898](#) controls data trace message transmission.

Register index: 46

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 1898. DPLL data trace control register (GTMDI_DPLL_DTC)

Note: Start/Stop signals inputs to the GTMDI can overwrite the state of the DMC control bit thus controlling the Data Trace messages behavior. In case of JTAG modifies the DMC bit and Start/Stop signals occur at the same time also modifying the same bit, Start/Stop signals have precedence over JTAG writes. The SEN control bit from the GTMDI_DPLL_DTC register need to be set in order to allow external Start/Stop signals to control the DMC bit.

[Table 1764](#) describes the GTMDI_DPLL_DTC register functions.

Table 1764. GTMDI_DPLL_DTC field descriptions

Field	Description
13–12 RWC	Read/Write Control. This bit controls DPLL data trace message transmission. 00 Transmits only memory reads 01 Transmits only memory writes 10 Transmits all memory accesses 11 Reserved
9–8 RAMSEL	RAM Module Selection. This field selects a DPLL memory module for data tracing. 00 RAM1a selected for data tracing 01 RAM1b selected for data tracing 10 RAM2 selected for data tracing 11 Reserved

Table 1764. GTMDI_DPLL_DTC field descriptions (continued)

Field	Description
6 DMC	Data Trace Message Control. This bit is written by JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Data Trace Messages disabled 1 Data Trace Messages enabled
5–4 STSEL	Start/Stop input signal selection 1. Selects the Start/Stop input that is used to control the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
0 SEN	Start/Stop Enable. The SEN bit field enables the DPLL data trace message generator to consider the Start/Stop inputs for data trace message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DMC Data Trace Message Control bit in this register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

76.4.1.20 ARU watchpoint control 1 register (GTMDI_ARU_WPC1)

The GTMDI_ARU_WPC1 register shown in [Figure 1899](#) controls the Watchpoint Triggers issued by ARU Debugging Channels. These watchpoint triggers are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note: Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_ARU_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Figure 1899. ARU watchpoint control 1 register (GTMDI_ARU_WPC1)

[Table 1765](#) describes the GTMDI_ARU_WPC1 register functions.

Table 1765. GTMDI_ARU_WPC1 field descriptions

Field	Description
28 TSS1	ARU Debugging Channel 0 Data Activity Selection 1. The TSS1 bit selects the type of data activity to monitor on ARU Debugging Channel 0. 0 Any Data (do not compare data). Watchpoint generation is based on a valid data indication on ARU Debugging Channel 0 1 Compare data with expected value
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the ARU Debugging Channel 0 is enabled to HALT the GTM module. If this bit is set and an event occurs on the ARU Debugging Channel 0, a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid matches on the ARU Debugging Channel 0 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
12 TSS2	ARU Debugging Channel 1 Data Activity Selection. The TSS2 bit selects the type of data activity to monitor on the ARU Debugging Channel 1. 0 Any Data (do not compare data). Watchpoint generation is based on a valid data indication on ARU Debugging Channel Monitor 1 1 Compare data with expected value
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the ARU debugging Channel 1 is enabled to HALT the GTM module. If this bit is set and an event occurs on the ARU Debugging Channel 1, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables match on the ARU Debugging Channel 1 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

76.4.1.21 ARU watchpoint control 2 register (GTMDI_ARU_WPC2)

The GTMDI_ARU_WPC2 register shown in [Figure 1899](#) controls the Watchpoint Triggers issued by ARU Debugging Channels. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

Table 1770. GTMDI_ARU_DATA1L field descriptions

Field	Description
28–0 DATA1L	Watchpoint DATA1L. This field is compared against the low word of the ARU Debugging Channel 1.

76.4.1.26 ARU data trace control register (GTMDI_ARU_DTC)

The GTMDI_ARU_DTC register shown in [Figure 1905](#) controls the ARU data trace message transmission. The GTM Module selects two ARU addresses to be monitored, using the ARU Debugging Channels 0 and 1. The data trace for these two channels is controlled by DMC1/2 bits in this register. Once enabled, messages are generated as soon as a valid data is identified in one of the ARU Debugging Channels, 0 or 1.

Note: *Start/Stop signals inputs to the GTMDI can overwrite the state of the DMC1 and DMC2 control bits thus controlling the Data Trace messages behavior. In case of JTAG modifies the DMC1 or DMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits need to be set in order to allow external Start/Stop signals to control the DMC1/2 bits.*

Register index: 56

Figure 1905. ARU data trace control register (GTMDI_ARU_DTC)

Table 1771 describes the GTMDI_ARU_DTC register functions.

Table 1771. GTMDI_ARU_DTC field descriptions

Field	Description
21–20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used by the ARU Debugging Channel 0 data trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 DMC1	Data Trace Message Control. This bit controls ARU data trace messages transmission for ARU Debugging Channel 0. This bit is written by the JTAG interface but can also be controlled at SoC level by dedicated Start/Stop signals, inputs to GTMDI. 0 Data Trace Messages disabled 1 Data Trace Messages enabled
16 SEN1	Start/Stop Enable 1. The SEN 1 bit field enables the ARU data trace message generator for ARU Debugging Channel 0 to consider the Start/Stop inputs for data trace message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DMC1 Data Trace Message Control bit in this register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs
5–4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used by the ARU Debugging Channel 1 data trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]

Table 1771. GTMDI_ARU_DTC field descriptions (continued)

Field	Description
1 DMC2	Data Trace Message Control. This bit controls ARU data trace message transmission for ARU Debugging Channel 1. This bit is written by the JTAG interface but can also be controlled at SoC level by dedicated Start/Stop signals, inputs to GTMDI. 0 Data Trace Messages disabled 1 Data Trace Messages enabled
0 SEN2	The SEN2 bit field enables the ARU data trace message generator for ARU Debugging Channel 1 to consider the Start/Stop inputs for data trace message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to DMC2 Data Trace Message Control bit in this register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

76.4.1.27 MCSA/B development control register (GTMDI_MCSA_DC and GTMDI_MCSB_DC)

The GTMDI_MCSA_DC and GTMDI_MCSB_DC registers shown in [Figure 1906](#) control various trace and debug features.

Note: Since MCSA and MCSB have a common sets of registers they are described together to avoiding duplication of similar information.

Register index: MCSA–60 / MCSB–77

[Table 1772](#) describes the GTMDI_MCSA_DC and GTMDI_MCSB_DC register functions.

Table 1772. GTMDI_MCSA_DC and GTMDI_MCSB_DC field descriptions

Field	Description
11–8 MCSA/B_SEL	MCSA/B Selection field. The MCSA/B_SEL[3:0] selection field selects which one of the MCS cores in the GTM module are assigned as MCSA/B. 0000 MCS0 0001 MCS1 0010 MCS2 0011 MCS3 0100 Reserved 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001 Reserved 1010 Reserved 1011 Reserved 1100 Reserved 1101 Reserved 1110 Reserved 1111 Reserved

76.4.1.28 MCSA/B watchpoint control register (GTMDI_MCSA_WPC and GTMDI_MCSB_WPC)

The MCSA/B Watchpoint Control Registers shown in [Figure 1907](#) are used to configure MCSA/B watchpoints. These registers can be configured for halt/watchpoint based on instruction fetch, data read or data write, with address and data masking options.

Note: Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC control bit thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC bit and Start/Stop signals occur at the same time also modifying the same bit, Start/Stop signals have precedence over JTAG writes. The SEN control bit needs to be asserted in order to allow external Start/Stop signals to control the WMC bit.

The watchpoint channel selection is made through the GTMDI_MCSA_CE and GTMDI_MCSB_CE by the WPCE field.

Register index: MCSA–62 / MCSB–79

Figure 1907. MCSA/B watchpoint control register (GTMDI_MCSA_WPC and GTMDI_MCSB_WPC)

[Table 1773](#) describes the GTMDI_MCSA_WPC and GTMDI_MCSB_WPC register functions.

Table 1773. GTMDI_MCSA_WPC and GTMDI_MCSB_WPC field descriptions

Field	Description
25–24 HACH	Halt/Watchpoint on Active Channel. The HACH field selects which type of MCS RAM access generates a watchpoint or halt. Combining this field with HWO gives GTMDI the capability of monitoring channel activity as well as accesses to specific addresses or data. 00 Match on Instruction Fetch 01 Match on Data Read 10 Match on Data Write 11 Match on Data Read or Write
22 WMC	Watchpoint Message Control. The WMC Watchpoint Message Control bit controls the watchpoint message sent through the Message Data bus. If this bit is asserted it enables MCSA/B Watchpoints to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
19–16 HME	Halt/Watchpoint Data Mask Enable. The HME field selects which data bytes are used for hardware halt/watchpoint generation when comparing to HWD register. This register field is only meaningful if HWO bit field is [x1], otherwise the data comparison is disabled independent of HME value. 0000 All bytes of data compared xxx1 Least significant byte of data masked out xx1x Second least significant byte of data masked out x1xx Second most significant byte of data masked out 1xxx Most significant byte of data masked out
15–14 HWO	Halt/Watchpoint Operand. The HWO field selects if address and/or data matching is done. Registers WPA and WPD are used for address and data comparison, respectively. If address is not compared WPA is not use. If data is not compared then WPD is not used. 00 Comparison Disabled for address or data x1 Compare data with HWD field 1x Compare address with HWA field
8 EOC	$\overline{\text{EVT0}}$ Control. The EOC bit controls the indication on the $\overline{\text{EVT0}}$ output. See Figure 1910 , Figure 1911 , Figure 1912 and Figure 1913 for definition about watchpoint 1 and 2. 0 Indicates Watchpoint 2 occurrence 1 Indicates Watchpoint 1 occurrence
7 HEN	Halt Enable. The HEN Halt Enable bit controls if the MCSA/B Watchpoint is enabled to HALT the GTM IP module. If this bit is set and watchpoint occurs on the MCSA/B a Halt signal is generated to the GTM IP which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
5–4 STSEL	Start/Stop input signal selection. Selects the Start/Stop input that is used to control the watchpoint messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]

Table 1773. GTMDI_MCSA_WPC and GTMDI_MCSB_WPC field descriptions (continued)

Field	Description
1 TEN	Watchpoint Trigger Enable. The TEN field controls if a external trigger is issued by the MCSA/B when a watchpoint occurs. 0 Disables Trigger Generation 1 Enables Trigger Generation
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA/B Watchpoint message to consider the Start/Stop inputs for watchpoint message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC Watchpoint Trace Message Control bit. 0 Disables trace control from Start/Stop inputs 1 Enables trace control from Start/Stop inputs

76.4.1.29 MCSA/B program fetch trace control register (GTMDI_MCSA_PTC and GTMDI_MCSB_PTC)

The GTMDI_MCSA_PTC and GTMDI_MCSB_PTC registers shown in [Figure 1908](#) allow program fetch traces to be enabled and/or disabled on the occurrence of a watchpoint. If the same watchpoint is programmed to enable and disable a trace, the occurrence of the watchpoint toggles the current value of the trace flags. If one watchpoint occurs to enable trace and a different watchpoint occurs to disable trace at the same time the current value of the trace flags also toggle.

Register index: MCSA-63 / MCSB-80

[Table 1774](#) describes the GTMDI_MCSA_PTC and GTMDI_MCSB_PTC register functions.

Table 1774. GTMDI_MCSA_PTC and GTMDI_MCSB_PTC field descriptions

Field	Description
13–12 PFTS	Program Fetch Trace Start. This bit field allows Program fetch trace to be enabled at a watchpoint occurrence. See Figure 1910 , Figure 1911 , Figure 1912 and Figure 1913 for definition about watchpoint 1 and 2. 00 No watchpoint selected (do not start Program Fetch Trace) 01 Program Fetch Trace enabled on MCSA/B Program Watchpoint 1 occurrence 10 Program Fetch Trace enabled on MCSA/B Program Watchpoint 2 occurrence 11 Reserved
9–8 PFTE	Program Fetch Trace End. This bit field allows program trace to be disabled at a watchpoint occurrence. 00 No watchpoint selected 01 Program Fetch Trace disabled on MCSA/B Program Watchpoint 1 occurrence 10 Program Fetch Trace disabled on MCSA/B Program Watchpoint 2 occurrence 11 Reserved
6 FTC	Fetch Trace Control. This bit controls the Fetch Trace message sent through the Message Data bus. If this bit is asserted it enables MCSA/B Fetch access to generate a trace message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI 0 Fetch Messages disabled 1 Fetch Messages enabled
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA/B Fetch message to consider the Start/Stop inputs for message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the FTC Fetch Trace Message Control bit. 0 Disable fetch trace control from Start/Stop inputs 1 Enable fetch trace control from Start/Stop inputs

76.4.1.30 MCSA/B data trace control register (GTMDI_MCSA_DTC and GTMDI_MCSB_DTC)

The GTMDI_MCSA_DTC and GTMDI_MCSB_DTC registers shown in [Figure 1909](#) control which address ranges are enabled for data trace, and if reads and/or writes are traced in that range.

Register index: MCSA–64 / MCSB–81

[Table 1775](#) describes the GTMDI_MCSA_DTC and GTMDI_MCSB_DTC register functions.

Table 1775. GTMDI_MCSA_DTC and GTMDI_MCSB_DTC field descriptions

Field	Description
17 RC0	Range Control 0. Controls the range on data trace window 0. The window 0 is defined by DTAR1 register. See Figure 1915 . 0 Trace addresses outside (exclusive) of data trace window 0 1 Trace address inside (inclusive) of data trace window 0
16 RC1	Range Control 1. Controls the range on data trace window 1. The window 1 is defined by DTAR2 register. See Figure 1916 . 0 Trace addresses outside (exclusive) of data trace window 1 1 Trace address inside (inclusive) of data trace window 1
13–12 RWT0	MCSA/B Read/Write Trace Control 0. RWT0 controls whether data trace messages are generated for MCSA/B RAM read or write accesses. 00 No MCSA/B data trace messages generated for data trace window 0 01 Enable MCSA/B data read trace for MCS window 0 10 Enable MCSA/B data write trace for MCS window 0 11 Enable MCSA/B data read and write trace for data trace window 0
9–8 RWT1	MCSA/B Read/Write Trace Control 1. RWT1 controls whether data trace messages are generated for MCSA/B accesses inside MCS data trace window, and if so, whether reads, writes, or both generate the data trace messages. 00 No MCSA/B data trace messages generated for data trace window 1 01 Enable MCSA/B data read trace for MCS window 1 10 Enable MCSA/B data write trace for MCS window 1 11 Enable MCSA/B data read and write trace for data trace window 1
6 DTC	Data Trace Control. This bit controls the Data Trace message sent through the Message Data bus. If this bit is asserted it enables MCSA/B Data access to generate a data trace message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI 0 Data Messages disabled 1 Data Messages enabled
5–4 DTS	Data Trace Start. This bit field allows data trace to be enabled at a watchpoint occurrence. 00 No watchpoint selected 01 Data Trace enabled on MCSA/B Watchpoint 1 occurrence 10 Data Trace enabled on MCSA/B Watchpoint 2 occurrence 11 Reserved
1–0 DTE	Data Trace End. This bit field allows data trace to be disabled at a watchpoint occurrence. 00 No watchpoint selected 01 Data Trace disabled on MCSA/B Watchpoint 1 occurrence 10 Data Trace disabled on MCSA/B Watchpoint 2 occurrence 11 Reserved
0 SEN	Start/Stop Enable. The SEN bit field enables the MCSA/B Data message to consider the Start/Stop inputs for message transmission. If this bit is cleared, the messages are controlled only by JTAG writes to the DTC Data Trace Message Control bit. 0 Disable data trace control from Start/Stop inputs 1 Enable data trace control from Start/Stop inputs

76.4.1.31 MCSA/B watchpoint address 1 register (GTMDI_MCSA_WPA1 and GTMDI_MCSB_WPA1)

The MCSA/B Watchpoint Address Registers 1 shown in [Figure 1910](#) are used to configure the MCSA/B halt/watchpoint hardware. They are used for data and instruction fetch accesses.

Register index: MCSA–65 / MCSB–82

Figure 1910. MCSA/B watchpoint address 1 register (GTMDI_MCSA_WPA1 and GTMDI_MCSB_WPA1)

Note: The HWA field represents word addresses relative to the MCS address map, not the CPU address map. This applies to GTMDI_MCSA_WPA1, GTMDI_MCSB_WPA1, GTMDI_MCSA_WPA2 and GTMDI_MCSB_WPA2 registers.

[Table 1776](#) describes the GTMDI_MCSA_WPA1 and GTMDI_MCSB_WPA1 register functions.

Table 1776. GTMDI_MCSA_WPA1 and GTMDI_MCSB_WPA1 field descriptions

Field	Description
29–16 HWAM	Halt/Watchpoint Address Mask. The HWAM field is used to select which address bits are compared for halt and watchpoint generation. Address match = (HWA&HWAM) == (Address & HWAM);
13–0 HWA	Halt/Watchpoint Address. The HWA field is used for comparison with instruction or data addresses. The HWA field represents a word address.

76.4.1.32 MCSA/B watchpoint address 2 register (GTMDI_MCSA_WPA2 and GTMDI_MCSB_WPA2)

The MCSA/B Watchpoint Address 2 Registers shown in [Figure 1911](#) are used to configure the MCSA/B halt/watchpoint hardware. They are used for data and instruction fetch accesses.

Register index: MCSA–66 / MCSB–83

Figure 1911. MCSA/B watchpoint address 2 register (GTMDI_MCSA_WPA2 and GTMDI_MCSB_WPA2)

[Table 1777](#) describes the GTMDI_MCSA_WPA2 and GTMDI_MCSB_WPA2 register functions.

Table 1777. GTMDI_MCSA_WPA2 and GTMDI_MCSB_WPA2 field descriptions

Field	Description
29–16 HWAM	Halt/Watchpoint Address Mask. The HWAM field is used to select which address bits are compared for halt and watchpoint generation. Address match = (HWA&HWAM) == (Address & HWAM);
13–0 HWA	Halt/Watchpoint Address. The HWA field is used for comparison with instruction or data addresses. The HWA field represents a word address.

76.4.1.33 MCSA/B watchpoint data 1 register (GTMDI_MCSA_WPD1 and GTMDI_MCSB_WPD1)

The MCSA/B Halt/Watchpoint Data 1 Registers shown in [Figure 1912](#) are used to configure the MCSA/B halt/watchpoint hardware. They are used for data accesses selection only.

Register index: MCSA–67 / MCSB–84

Figure 1912. MCSA/B watchpoint data 1 register (GTMDI_MCSA_WPD1 and GTMDI_MCSB_WPD1)

[Table 1778](#) describes the GTMDI_MCSA_WPD1 and GTMDI_MCSB_WPD1 register functions.

Table 1778. GTMDI_MCSA_WPD1 and GTMDI_MCSB_WPD1 field descriptions

Field	Description
31–0 HWD	Halt/Watchpoint Data. The HWD field is used to compare data operands in a RAM read or write access. Depending upon the size of the access, only certain bits of HWD are compared against the RAM data. If the operation size is 8-bits, the 8 most significant bits of HWD are compared against the RAM data. If the operation size is 24-bits, the 24 least significant bits of HWD are compared against the RAM data. If the operation size is 32-bits, all bits from HWD are compared against the RAM data.

76.4.1.34 MCSA/B watchpoint data 2 register (GTMDI_MCSA_WPD2 and GTMDI_MCSB_WPD2)

The MCSA/B Watchpoint Data 2 Registers shown in [Figure 1913](#) are used to configure the MCSA/B halt/watchpoint hardware. They are used for data accesses selection only.

Register index: MCSA–68 / MCSB–85

Field	Description
31–0 HWD	Halt/Watchpoint Data. The HWD field is used to compare data operands in a RAM read or write access. Depending upon the size of the access, only certain bits of HWD are compared against the RAM data. If the operation size is 8-bits, the 8 most significant bits of HWD are compared against the RAM data. If the operation size is 24-bits, the 24 least significant bits of HWD are compared against the RAM data. If the operation size is 32-bits, all bits from HWD are compared against the RAM data.

76.4.1.35 MCSA/B channel enable register (GTMDI_MCSA_CE and GTMDI_MCSB_CE)

The GTMDI_MCSA_CE and GTMDI_MCSB_CE registers shown in [Figure 1914](#) enable the monitoring for 8 MCSA/B channels independently.

Register index: MCSA–69 / MCSB–86

Figure 1914. MCSA/B channel enable register (GTMDI_MCSA_CE and GTMDI_MCSB_CE)

Table 1780 describes the GTMDI_MCSA_CE and GTMDI_MCSB_CE register functions.

Table 1780. GTMDI_MCSA_CE and GTMDI_MCSB_CE field descriptions

Field	Description
7–0 CFTE	MCSA/B Channel Fetch Trace Enable. The CFTE[7:0] is an one hot bit field which defines the channel or channels to be monitored for fetch traces. If enabled, the corresponding channel Fetches are monitored by Fetch Trace messages. Start and Stop message controls are controlled by the FTC bit in the GTMDI_MCSA/B_PTC registers (Section 76.4.1.29, MCSA/B program fetch trace control register (GTMDI_MCSA_PTC and GTMDI_MCSB_PTC)). 00000000No channel selected for trace xxxxxxx1Channel [0] selected xxxxxx1xChannel [1] selected xxxxx1xxChannel [2] selected xxxx1xxxChannel [3] selected xxx1xxxxChannel [4] selected xx1xxxxxChannel [5] selected x1xxxxxxChannel [6] selected 1xxxxxxxChannel [7] selected 11111111All Channels selected

Table 1780. GTMDI_MCSA_CE and GTMDI_MCSB_CE field descriptions (continued)

Field	Description
7–0 CDTE	MCSA/B Channel Data Trace Enable. The CDTE[7:0] is an one hot bit field which defines the channel or channels to be monitored for data trace messages. If enabled, the corresponding channel Data Accesses are monitored by Data Trace messages. Start and Stop message are controlled by the DTC bit in the GTMDI_MCSA/B_DTC registers (Section 76.4.1.30, MCSA/B data trace control register (GTMDI_MCSA_DTC and GTMDI_MCSB_DTC)) and by the Data trace window. 00000000 No channel selected for trace xxxxxxx1 Channel [0] selected xxxxxx1x Channel [1] selected xxxxx1xx Channel [2] selected xxxx1xxx Channel [3] selected xxx1xxxx Channel [4] selected xx1xxxxx Channel [5] selected x1xxxxxx Channel [6] selected 1xxxxxxx Channel [7] selected 11111111 All Channels selected
7–0 WPCE	MCSA/B Channel Enable. The WPCE[7:0] is a one hot bit field which defines the channel or channels to be monitored for watchpoint, data and fetch traces. The messages controlled by this bit must be also enabled and disabled according to occurrence of Watchpoints and Address Ranges. 00000000 No channel selected for trace xxxxxxx1 Channel [0] selected xxxxxx1x Channel [1] selected xxxxx1xx Channel [2] selected xxxx1xxx Channel [3] selected xxx1xxxx Channel [4] selected xx1xxxxx Channel [5] selected x1xxxxxx Channel [6] selected 1xxxxxxx Channel [7] selected 11111111 All Channels selected

76.4.1.36 MCSA/B data trace address range 1 register (GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1)

The GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1 registers shown in [Figure 1915](#) define a data trace address range. The address range is used by the MCSA/B and enables the range for reads and/or writes access to data only. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 0.

Figure 1915. Data trace address range 1 register (GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1)

Register index: MCSA-71 / MCSB-88

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
RESET:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: The DTSA and DTEA fields represent word addresses relative to the MCS address map, not the CPU address.

[Table 1781](#) describes the GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1 register functions.

Table 1781. GTMDI_MCSA_DTAR1 and GTMDI_MCSB_DTAR1 field descriptions

Field	Description
29-18 DTSA	Data Trace Start Address. The DTSA field is the start address for MCSA/B data trace window.
13-2 DTEA	Data Trace End Address. The DTEA field is the end address for MCSA/B data trace window.

76.4.1.37 MCSA/B data trace address range 2 register (GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR2)

The GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR2 registers shown in [Figure 1916](#) define a data trace address range. The address range is used by the MCSA/B and enables the range for reads and/or writes access to data only. If the start address value is greater than the end address value, all accesses are considered to have the address value outside to the data trace window 1.

Register index: MCSA-72 / MCSB-89

Figure 1916. MCSA data trace address range 2 register (GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR2)

Note: DTSA and DTEA fields represent word addresses which are included in the address range.

[Table 1782](#) describes the GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR12 register functions.

Table 1782. GTMDI_MCSA_DTAR2 and GTMDI_MCSB_DTAR2 field descriptions

Field	Description
29–18 DTSA	Data Trace Start Address. The DTSA field is the start address for MCSA/B data trace window.
13–2 DTEA	Data Trace End Address. The DTEA field is the end address for MCSA/B data trace window.

76.4.1.38 TBU0 watchpoint control 1 register (GTMDI_TBU0_WPC1)

The GTMDI_TBU0_WPC1 register shown in [Figure 1917](#) controls the Watchpoint issued by TBU0 GTM Time Base Units (TBU). These watchpoints are used to control the requests for GTM to enter Halt state, issue watchpoint messages and also to control logic external to the GTMDI at SoC level such as in the SPU interface.

Note: Start/Stop signals inputs to the GTMDI can overwrite the state of the WMC1 and WMC2 control bits thus controlling the Watchpoint messages behavior. In case of JTAG modifies the WMC1 or WMC2 bits and Start/Stop signals occur at the same time also modifying the same bits, Start/Stop signals have precedence over JTAG writes. The SEN1 and SEN2 control bits from the GTMDI_TBU0_WPC2 register need to be set in order to allow external Start/Stop signals to control the WMC1/2 bits.

Register index: 94

Figure 1917. TBU0 watchpoint control 1 register (GTMDI_TBU0_WPC1)

[Table 1783](#) describes the GTMDI_TBU0_WPC1 register functions.

Table 1783. GTMDI_TBU0_WPC1 field descriptions

Field	Description
30–28 TSS1	TBU0 Watchpoint 1 Compare Selection. The TSS1[2:0] field controls the type of comparison used for TBU0 watchpoint generation. 000 TBU0 24-bit update (do not compare data) 001 TBU 27-bit update (do not compare data) 010 Compare TBU0 value in 24-bit mode with expected data⁽¹⁾ 011 Compare TBU0 value in 27-bit mode with expected data 100 Reserved 101 Reserved 110 Reserved 111 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the TBU0 event is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU0 a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid matches or increment on selected TBU0 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
14–12 TSS2	TBU0 Watchpoint 2 Compare Selection 2. The TSS2[2:0] field controls the type of comparison used for TBU0 watchpoint generation. 000 TBU0 24-bit update (do not compare data) 001 TBU 27-bit update (do not compare data) 010 Compare TBU0 value in 24-bit mode with expected data¹ 011 Compare TBU0 value in 27-bit mode with expected data 100 Reserved 101 Reserved 110 Reserved 111 Reserved
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the TBU0 valid event, which is a match or increment, is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU0, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables match or increment on TBU0 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

1. Only bits from 26 to 3 from register GTMDI_TBU0_DATA are used for comparison

76.4.1.39 TBU0 watchpoint control 2 register (GTMDI_TBU0_WPC2)

The GTMDI_TBU0_WPC2 shown in [Figure 1918](#) register controls the Watchpoint Triggers issued by TBU0. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

Register index: 95

Figure 1918. TBU0 watchpoint control 2 register (GTMDI_TBU0_WPC2)

[Table 1784](#) describes the GTMDI_TBU0_WPC2 register functions.

Table 1784. GTMDI_TBU0_WPC2 field descriptions

Field	Description
30–28 WTSEL1	Watchpoint Trigger Selection 1. The WTSEL1[2:0] field selects among 8 available watchpoint triggers which one is connected to the TBU0 selected event, match or increment. Other modules can selected the same WTSEL1 value, in this case the result selection is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
21–20 STSEL1	Start/Stop input signal selection 1. Selects the Start/Stop input that is used by the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
17 TEN1	Watchpoint Trigger Enable 1. The TEN1 field controls if a watchpoint external trigger is issued by the TBU0 selected event, match or increment. 0 Disable Trigger Generation 1 Enable Trigger Generation
16 SEN1	Start/Stop Enable 1. The SEN1 bit field enables the TBU0 selected event to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC1 field in the GTMDI_TBU0_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

Table 1784. GTMDI_TBU0_WPC2 field descriptions (continued)

Field	Description
14–12 WTSEL2	Watchpoint Trigger Output Selection 2. The WTSEL2[2:0] field selects among 8 available watchpoint triggers which one is connected to the TBU0 selected event. Other modules can selected the same WTSEL2 value, in this case the result signal is an OR of all selected sources. 000 SHARED_WPT[0] 001 SHARED_WPT[1] 010 SHARED_WPT[2] 011 SHARED_WPT[3] 100 SHARED_WPT[4] 101 SHARED_WPT[5] 110 SHARED_WPT[6] 111 SHARED_WPT[7]
5–4 STSEL2	Start/Stop input signal selection 2. Selects the Start/Stop input that is used the watchpoint trace messages. These signals are actually a pair of signals. 00 SHARED_WPT_ST[0] 01 SHARED_WPT_ST[1] 10 SHARED_WPT_ST[2] 11 SHARED_WPT_ST[3]
1 TEN2	Watchpoint Trigger Enable 2. The TEN1 field controls if a watchpoint external trigger is issued by the TBU0 selected event. 0 Disable Trigger Generation 1 Enable Trigger Generation
0 SEN2	Start/Stop Enable 2. The SEN2 bit field enable the TBU0 selected event, match or increment to consider the Start/Stop inputs for watchpoint trace message generation. If this bit is cleared, the messages are controlled only by JTAG writes to the WMC2 field in the GTMDI_TBU0_WPC1 register. 0 Disable trace control from Start/Stop inputs 1 Enable trace control from Start/Stop inputs

76.4.1.40 TBU0 watchpoint DATA register (GTMDI_TBU0_DATA)

The TBU0 Watchpoint DATA shown in [Figure 1919](#) is used for watchpoints generation for matching with the TBU0 value.

Figure 1923. TBU2 watchpoint control 1 register (GTMDI_TBU2_WPC1)

[Table 1789](#) describes the GTMDI_TBU2_WPC1 register functions.

Table 1789. GTMDI_TBU2_WPC1 field descriptions

Field	Description
29–28 TSS1	TBU2 Watchpoint 2 Compare Selection. The TSS1[1:0] field controls the type of comparison used for TBU2 watchpoint generation. 00 TBU2 update (do not compare data) 01 Compare TBU2 value with expected data 10 Reserved 11 Reserved
23 HEN1	Halt Enable 1. The HEN1 Halt Enable 1 bit controls if the TBU2 event is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU2 a Halt signal is generated to the GTM which enters debug state. 0 Disables Halt GTM 1 Enables Halt GTM
22 WMC1	Watchpoint Message Control 1. The WMC1 Watchpoint Message Control 1 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables valid matches or increment on selected TBU2 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled
13–12 TSS2	TBU2 Watchpoint 2 Compare Selection 2. The TSS2[1:0] field controls the type of comparison used for TBU2 watchpoint generation. 00 TBU2 update (do not compare data) 01 Compare TBU2 value with expected data 10 Reserved 11 Reserved

Table 1789. GTMDI_TBU2_WPC1 field descriptions (continued)

Field	Description
7 HEN2	Halt Enable 2. The HEN2 Halt Enable 2 bit controls if the TBU2 valid event, which is a match or increment, is enabled to HALT the GTM module. If this bit is set and an event occurs on the TBU2, a Halt signal is generated to the GTM which enters Halt state. 0 Disables Halt GTM 1 Enables Halt GTM
6 WMC2	Watchpoint Message Control 2. The WMC2 Watchpoint Message Control 2 bit controls the watchpoint message sent through the Message Data bus. If this bit is set it enables match or increment on TBU2 to generate a watchpoint message. This bit is written by the JTAG interface but can also be controlled at SoC level with dedicated Start/Stop signals inputs to GTMDI. 0 Watchpoint Messages disabled 1 Watchpoint Messages enabled

76.4.1.45 TBU2 watchpoint control 2 register (GTMDI_TBU2_WPC2)

The GTMDI_TBU2_WPC2 register shown in [Figure 1924](#) controls the Watchpoint Triggers issued by TBU2. These triggers are used for GTM to enter Halt state, generate watchpoint messages and control logic external to GTMDI, such as in the SPU interface.

Register index: 109

Field	Description
23–0 TBU2_DATA	TBU2 Watchpoint DATA. The field TBU2_DATA[23:0] is used to compare against the TBU2 data.

76.4.2 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in [Table 1745](#). Unimplemented registers should not be accessed.

76.5 Functional description

This section describes in detail the main functionality of the GTMDI module.

76.5.1 Debug enable logic

In order to enable the GTM to enter Halt state, which is the module debug state, there are some registers that need to be set. The sources that can put GTM in halt state are events from TIM, TOM, ATOM, MCS and several other internal GTM modules that are selected and controlled by the GTMDI_DC register bits shown in [Figure 1881](#). The system debug request external signal is also a source of halts, as well as direct JTAG write to control register. [Figure 1926](#) describes the logic behind the Halt signal generated by GTMDI. See [Figure 1881](#) for a description of the register bits mentioned in [Figure 1926](#).

Figure 1926. GTM Halt signal enable logic

76.5.2 TIM-TOM-ATOM selection and control logic

The TIM sub-modules can be selected to generate signals that control the watchpoint messages, Halt GTM and watchpoint outputs from the GTMDI module. [Figure 1927](#) describes the TIM selection logic for generation of watchpoint messages, GTM halt and external watchpoint triggers. This logic is duplicated thus allowing independent selection of two TIM filtered inputs. [Figure 1927](#) also shows the register bits that control the selection process. Watchpoint Logic 1 and Watchpoint Logic 2 are two implementations for the same logic.

Figure 1927. TIM selection logic

Note: *Figure 1927* shows four instances of the TIM sub-module which corresponds to the GTM103 IP configuration. Different configurations may have different number of TIM sub-modules, thus SSEL1/2 signals have to be able to select different number of TIM sub-modules.

The selection logic for TOM and ATOM sub-modules is similar to the TIM logic. The register names are also kept the same for easy correlation of functionality.

76.5.3 GTMDI reset configuration

76.5.3.1 Enabling GTMDI class 1 operation

The GTMDI Class 1 features are always enabled after exiting the JTAG TEST-LOGIC-RESET state. But they are disabled while the JTAG is in this state. Thus, allowing low power mode. The registers are always reset while in the JTAG TEST-LOGIC-RESET state.

76.5.3.2 Enabling GTMDI class 3 operation

After exiting JTAG TEST-LOGIC-RESET state, the GTMDI classes 1 and 3 are enabled, otherwise the GTMDI class 3 features are disabled, entering in the Disable-Port Mode, thus no trace output is provided, and auxiliary port output pins are disabled.

76.5.4 Message Data Bus —interface with NAR module

76.5.4.1 Output messages

[Table 1792](#) describes the messages that the GTMDI can transmit on the Message Data Bus.

Table 1792. GTMDI Nexus trace message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Debug Status Message	6	6	fixed	TCODE	Value = 0
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	32	32	fixed	STATUS	Value of the Development Status register GTMDI_DS, see Table 1793
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message	6	6	fixed	TCODE	Value = 8
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	4	4	fixed	ETYPE	Always 0 for GTMDI
	15	15	fixed	ECODE	Error Code, see Table 1794
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
MCS Data Trace, Data Write with Sync Message	6	6	fixed	TCODE	Value = 56
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1=MCSB)
	3	3	fixed	CHN	MCS Channel number
	14	14	fixed	ADDR	Full address of the memory location written
	32	32	fixed	DATA	Data value written
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp

Table 1792. GTMDI Nexus trace message formats (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
MCS Data Trace, Data Read with Sync Message	6	6	fixed	TCODE	Value = 57
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1=MCSB)
	3	3	fixed	CHN	MCS Channel number
	14	14	fixed	ADDR	Full address of the memory location read
	32	32	fixed	DATA	Data value read
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message ⁽¹⁾	6	6	fixed	TCODE	Value = 15
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	15	15	fixed	WPHIT	Number indicating watchpoint source (binary coded), see Table 1795 , Table 1796 and Table 1797
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Fetch Trace	6	6	fixed	TCODE	Value = 58
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1= MCSB)
	3	3	fixed	CHN	MCS Channel number
	6	6	fixed	FSCNT ⁽²⁾	Fetch Sequential Counter. Value 0 indicates there is no relationship between the last fetch trace message and the current message. The counter rolls back to one when a non sequential address is fetched. The counter increments every time a sequential address is fetched. When counter reaches 63 a message is sent and the counter rolls back to one. If an ERROR message is sent the counter rolls back to zero.
	14	14	fixed	FADDR	First element address of the next fetch sequence
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
Fetch Trace End (fetch trace was turned off, no faddr field is sent)	6	6	fixed	TCODE	Value = 59
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	MCSN	MCS number (0 = MCSA; 1= MCSB)
	3	3	fixed	CHN	MCS Channel number
	6	6	fixed	FSCNT	The message is sent with the current value in the FSCNT counter and the counter rolls back to zero after the message is sent.
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp

Table 1792. GTMDI Nexus trace message formats (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
ARU Data Trace	6	6	fixed	TCODE	Value = 60
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	1	1	fixed	CHN	ARU Debugging Channel number (0/1)
	58	58	fixed	DATA	Data value read {ARU_DATAH, ARU_DATA_L}
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp
DPLL Data Trace, Data Read/Write	6	6	fixed	TCODE	Value = 61
	4	4	fixed	SRC	GTMDI source ID. Value = 0x7
	24	24	fixed	DATA	Data value read/written
	12	12	fixed	ADDR	Full address of the memory location written
	1	1	fixed	RW	Read 1, Write 0
	0	30	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Watchpoint Hit Message conforms to the IEEE-ISTO 5001-2003 standard, however, other messages conform to the IEEE-ISTO 5001-2011 standard.
2. FSCNT is the sequential instruction fetch counter that indicates the number of sequential instruction fetches executed by the MCS core for a channel. See [Section 76.5.9.2, Fetch trace state machine](#) for more information.

1	TBU0 Watchpoint 2
2	TBU1 Watchpoint 1
3	TBU1 Watchpoint 2
4	TBU2 Watchpoint 1
5	TBU2 Watchpoint 2
11:6	Reserved

76.5.4.1.1 Temporal ordering of transmitted messages

All messages are sent out in the sequence their related event actually occurred. The GTM interface with the GTMDI provides the GTM signals to be monitored and captured. At the occurrence of any event that would cause a message, a snapshot of all information needed by the message formatter to generate a message is queued. Doing so, several events from either MCS, TIM, ATOM, ARU, etc., can be queued at the same time.

76.5.4.1.2 Interleaved messages

Two MCS cores, TIM channels and other sources can be enabled for trace. The GTMDI formats and queues all messages in the order they are generated. Since there can be message inversion among sources during the send process, if enabled by the TSFT bit in [Figure 1881](#) or by the NAR, the messages are sent along with a timestamp. This timestamp is globally synchronized among all Nexus clients at SoC level.

76.5.5 IEEE 1149.1 (JTAG) input port

The GTMDI block uses the IEEE 1149.1 TAP for accessing registers. This port is shared among all TAP controllers on the SoC. This sharing is controlled by the value in the instruction register and client select control register. The GTMDI implements a Nexus controller state machine that transitions based on the state of the IEEE 1149.1 state

machine shown in [Figure 1929](#). The Nexus controller state machine, shown in [Figure 1930](#), is defined by the IEEE-ISTO 5001-2002 standard.

The instructions implemented by the GTMDI TAP controller are listed in [Table 1799](#). If any other instruction is received it is treated as a BYPASS.

Table 1799. Implemented instructions

Instruction name	Private/ public	Opcode	Description
NEXUS-ENABLE	Public	4b0000	Activate Nexus controller state machine to read and write GTMDI registers
BYPASS	Public	4b1111	Implements a single shift register stage providing a minimum serial length between TDI and TDO

Data is shifted between TDI and TDO starting with the least significant bit, as illustrated in [Figure 1928](#). This applies for the instruction register and all Nexus tool-mapped registers.

Figure 1928. Shifting data into register

76.5.5.1 Enabling the GTMDI TAP controller

Assertion of the $\overline{\text{TRST}}$ input resets all TAP controllers on the SoC. The controllers are loaded with the BYPASS instruction upon exit of the TEST-LOGIC-RESET JTAG controller state. Loading the NEXUS-ENABLE instruction grants access to Nexus debug. GTMDI acts as BYPASS by loading any other instruction. The TDO bit is driven with the value of the instruction register while in SHIFT-IR state.

Figure 1929. IEEE 1149.1 16-State finite state machine

NOTE: The value shown adjacent to each state transition in this figure represents the value of the TMS bit at the time of a rising edge of TCK.

76.5.5.2 Loading NEXUS-ENABLE instruction

Access to the GTMDI registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. The current instruction value is loaded into the IEEE 1149.1 shifter in the CAPTURE-IR state. The instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in [Figure 1930](#), transitions to the REG_SELECT state. [Table 1800](#) illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Figure 1930. Nexus controller state machine

Table 1800. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 State	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1 controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1 shifter is ready. Shift in all but the last bit of the NEXUS_ENABLE instruction
4 TCKs				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	NEXUS-ENABLE ready to be read

76.5.5.3 Selecting an IEEE 1149.1 register

When the NEXUS-ENABLE instruction is loaded in the GTMDI TAP controller instruction register, the input port allows development tool access to all GTMDI registers. Each register has a 7-bit address index. Some clients have registers with the same index as registers in other clients. Therefore, to access the registers of a particular client, the Client Select Control register must be set for that client.

All register access is performed via the SELECT-DR-SCAN path. The Nexus state machine defaults to the register select state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in [Figure 1931](#). The read/write control bit is set to 1 for writes and 0 for reads. The current value of the Controller Command Input is captured into the IEEE 1149.1 shifter during the CAPTURE-DR state while the Nexus controller state machine is in the REG_SELECT state.

Figure 1931. IEEE 1149.1 controller command input

MSB		LSB
7-bit register index		R/W

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the current register value is loaded into the IEEE 1149.1 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

[Table 1801](#) illustrates a sequence which writes a 32-bit value to a register.

Table 1801. Writing to a register

Clock	TMS	IEEE 1149.1 State	Nexus state	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1 controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 6 bits of register index shifted in
7 TCKs				
12	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
13	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
14	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
15	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
16	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
48	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI
49	1	UPDATE-DR	DATA_ACCESS	Value written to register
50	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register

76.5.6 Nexus Class 1 development support

The GTMDI contains a number of hardware hooks that aid in the development of software for the GTM MCS cores. This features described in this section are compliant with the following Nexus Class 1 features:

- Enter a debug mode at reset negation
- Enter a debug mode during normal execution
- Set halts or watchpoints

Refer to [Section 76.6, Initialization/application information](#) for how the following functions provide these features.

76.5.7 Debug status

The GTMDI module provides the Debug Status via the NAR SoC level modules.

76.5.7.1 Messaging

The GTMDI block provides debug status messaging using IEEE-ISTO 5001-2002 standard-defined public messages. If the message queue is full and a new message has to be sent, this message is lost and an ERROR message is queued instead, indicating the loss of trace messages. The debug status message format is shown in [Figure 1932](#).

Figure 1932. Debug status message format

76.5.7.2 Error messages

A debug status overrun error event is queued if a debug status event occurs while the Event Queue is full and is not able to store snapshots. The error message is stored to the event queue indicating a message was lost. The error message is sent as soon as the client is enabled for transmission. The error message format is shown in [Figure 1933](#).

Figure 1933. Debug status error message format

Note: The timestamp value in an Error Message does not contain valid information.

76.5.8 Data trace

MCS cores, ARU and DPLL perform loads and stores to RAM memory modules. The GTMDI block gathers information about these accesses and generate trace messages if enabled.

76.5.8.1 MCS data write message

The MCS data write message contains the data write value and the address of the RAM target location. The data write message format is shown in [Figure 1934](#).

Figure 1934. Data write message format

6 bits	K bits	1 bit	3 bits	14 bits	32 bits
TCODE (56)	SRC	MCSN	CHN	ADDR	DATA

Length = 56+K bits

76.5.8.2 MCS data read message

The MCS data read message contains the data read value and the address of the RAM target location. The data read message format is shown in [Figure 1935](#).

Figure 1935. Data read message format

6 bits	K bits	1 bit	3 bits	14 bits	32 bits
TCODE (57)	SRC	MCSN	CHN	ADDR	DATA

Length = 56+K bits

76.5.8.3 MCS data trace operation

Data tracing is performed by snooping a dedicated MCS/Nexus interface for RAM read and write cycles. Data trace functions are enabled by setting the appropriate fields in the following registers:

- MCSx Development Control (GTMDI_MCSx_DC) Register
- MCSx Data Trace Control (GTMDI_MCSx_DTC) Register
- MCSx Data Trace Address Range (GTMDI_MCSx_DTAR) Register

For details on register configuration, refer to [Section 76.4.1, Register descriptions](#). The MCSx data tracing have independent Data Trace Address Range registers which allows more flexibility. An Error condition may occur in case of Queue full event. Data trace flow is depicted in [Figure 1936](#).

Figure 1936. GTMDI generic data trace flow diagram

76.5.8.3.1 MCS data trace windowing

Data trace windowing is provided so that the development tool can decrease the auxiliary port usage by limiting the accesses that are traced. Data trace windowing is achieved via the address range defined by the DTSA and the DTEA fields of the DTAR register. RAM accesses are traced if their address fall in any of these ranges and the specific range is enabled in the data trace control register. Data read and/or data write trace may be enabled via the Read/Write Trace Control fields in the data trace control registers.

Data trace ranges are 32-bit aligned. This alignment is done by making the two least significant bits of the DTSA and DTEA fields read only. Since the two least significant bits of DTSA and DTEA are read only and default to different values, DTSA can never be equal to DTEA. [Figure 1937](#) shows the relationship between the DTSA and DTEA fields.

Figure 1937. Data trace address range options

Programmed Value	Range Selected
DTSA ≤ DTEA	[DTSA: DTEA]
DTSA > DTEA	All addresses are out of range ⁽¹⁾

1. Since all addresses are considered to be out of range, a Data Trace Event may be recognized if the DTC register is programmed so that addresses out of range are queued.

Note: Before sending through the NAR interface, the MCS, DPLL or ARU Data Trace message is buffered. Due to bandwidth constraints in the NAR interface and in the data trace buffering, this data trace message can be lost when superseded by another data trace message from the same source. In this case an error message is sent. See [Table 1792](#) for more details about GTMDI NAR messages.

76.5.8.4 DPLL data trace

DPLL Data Trace is a straight forward implementation in which the trace is enabled using the DMC bit in the [Figure 1898](#). It is possible to select individual DPLL RAM modules such as RAM1a, RAM1b or RAM2 for tracing using the RAMSEL bit in the same register. Only one memory module is selected for tracing at a given time. Start/Stop inputs from the SPU module can be used to control the DPLL Data Trace messages as well as JTAG interface. This is achieved by controlling the DMC bit which can be done from SPU or JTAG interface. See [Table 1764](#) for more details about the bits that should be used in this process.

76.5.8.5 ARU data trace

The GTM module selects two ARU addresses to be monitored, using the ARU Debugging Channels 0 and 1, see the GTM documentation for details on how to program these channels. The data trace for these two channels is controlled by DMC1/2 bits in the GTMDI_ARU_DTC, see [Section 76.4.1.26, ARU data trace control register \(GTMDI_ARU_DTC\)](#). Once enabled, messages are generated as soon as a valid data is identified in one of the ARU Debugging Channels, 0 or 1.

76.5.9 Fetch trace

Fetch trace tries to record all instruction fetch accesses done by an MCS channel. Fetch trace is handled independently for each MCS channel, therefore what happens to a certain channel does not affect other channels since all channels run independently. Even error conditions are handled independently for each channel.

Fetch trace can be enabled/disabled by two ways:

- By watchpoint hit, if the watchpoint is configured to do so
- Directly by register

When a fetch access hits a watchpoint and the last enables fetch trace (having it disabled before the watchpoint hit), that access is ignored by the fetch trace logic.

76.5.9.1 Enabling MCS program fetch trace

Program fetch trace for the MCS is enabled on a channel by channel basis. This selective enabling allows the debug tool to control the bandwidth for the transmitted messages. The program fetch trace is enabled through a JTAG register, see [Figure 1908](#). Since the registers

may be changed in the middle of a program execution, program fetch trace may be enabled or disabled during program execution as well.

76.5.9.2 Fetch trace state machine

The fetch trace state machine is composed basically by three states: *start*, *running* and *end*. When the fetch trace is enabled, fetch state machine goes to the *start* state. [Figure 1938](#) describes the fetch trace machine state diagram.

Figure 1938. Fetch trace state machine state diagram

76.5.9.2.1 Fetch trace start state

In this state, the fetch trace logic waits for a fetch access to occur. When a fetch access occurs, the fetch trace logic tries to insert (into the corresponding MCS trace buffer) a fetch trace message with FSCNT=0 and the FADDR field equal to the fetch access address. It is possible that the corresponding MCS trace message buffer is full when fetch trace logic tries to insert the message. In this case, the fetch trace logic ignores the current fetch access, does not generate any error, and tries again when another fetch access occurs.

After inserting a message into the buffer, the fetch trace state machine goes to the *running* state.

It is also possible that the fetch trace is disabled before a message is inserted into the MCS trace buffer. In this case state machine goes to the *end* state

76.5.9.2.2 Fetch trace running state

When the fetch trace state machine enters in the *running state* a counter, called CNT, is initialized to 1 and starts counting the number of sequential instruction fetch accesses.

When a fetch access with address ADDR is detected, the fetch trace logic tests if ADDR is equal to the previous fetch address, ADDR_PRV, +1 ($ADDR = ADDR_PRV + 1$). If so, no message is buffered for transmission and CNT increments by 1 ($CNT = CNT + 1$). Otherwise, if ADDR is not a sequential address, a fetch trace message is generated with the FSCNT field equals to the CNT counter value ($FSCNT = CNT$) and FADDR equals to the current address ADDR. The CNT counter is then initialized to 1.

At the moment the previous message is generated, the corresponding MCS fetch trace buffer may or may not be full. If the buffer is not full, the message is inserted into the buffer and the fetch trace state machine continues in the *running* state, otherwise a fetch trace error message is generated for the corresponding MCS and the fetch trace state machine goes to the *start* state.

Note: The MCS is a multi-thread core which executes eight threads, also called channels, in fixed time-slots of one system clock for each thread. Fetch trace is a per channel resource. Thus if more than one channel is selected for trace, each one generates its corresponding fetch trace message. There is one independent fetch state machine and CNT counter for each selected channel.

76.5.9.2.3 Fetch trace end state

In this state, the fetch trace logic ignores all fetch accesses and waits for the corresponding MCS trace buffer to be not full. When this happens, a fetch trace end message is inserted into the buffer with FSCNT equal to CNT (FSCNT = CNT). The CNT value is always reset to 0 when previous state was *start* state.

If the buffer is always full, the fetch trace logic does not exit *end* state until a reset occurs.

Note: A Fetch trace end message is sent when a system reset is detected in the GTM module. There are no further indications about the GTM reset condition.

76.5.10 Watchpoint trace

The GTMDI module provides watchpoint messaging via the auxiliary port, as defined by the IEEE-ISTO 5001-2002 standard.

76.5.10.1 Messaging

The GTMDI block provides watchpoint messaging using IEEE-ISTO 5001-2002 standard-defined public messages. When a watchpoint occurs, a watchpoint event is sent to the Event Queue. If the watchpoint condition occurs while the Event Queue is full, an error message is generated. The watchpoint message format is shown in [Figure 1939](#).

Figure 1939. Watchpoint hit message format

6 bits	K bits	15 bits
TCODE (15)	SRC	WPHIT
Length = 21+Kbits		

The values for the WPHIT packet are described in [Table 1795](#), [Table 1796](#) and [Table 1797](#). Notice that WPHIT is never 0 because the message is only generated when a watchpoint has occurred.

76.6 Initialization/application information

76.6.1 Accessing GTMDI tool-mapped registers

To initialize the JTAG port for register accesses, the following sequence is required:

1. Enable the Nexus TAP controller
2. Retrieve Device ID if needed
3. Load the Nexus TAP controller with the NEXUS-ENABLE instruction

To write control data to GTMDI tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and set the write bit to select register with a pass through the SELECT-DR-SCAN path in the JTAG state machine
2. Write the register value with a pass through the SELECT-DR-SCAN path. The prior value of this register is shifted out during the write

To read status and control data from GTMDI tool-mapped registers, the following sequence is required:

1. Write the 7-bit register index and clear write bit to select register with a pass through SELECT-DR-SCAN path
2. Read the register value with a pass through the SELECT-DR-SCAN path. Data shifted in is ignored

See [Section 76.5.5, IEEE 1149.1 \(JTAG\) input port](#) for more detail.

77 Nexus Crossbar Multi-Master Client (NXMC)

77.1 Introduction

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for devices without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard. The IEEE-ISTO 5001 standard defines an extensible auxiliary port which is used in conjunction with the JTAG port.

Many bus masters such as DMA, Ethernet and FlexRay start accesses to internal address locations via the system bus. The NXMC module monitors the system bus and provides real-time trace information to debug or development tools. This also provides the capability of sending user defined messages for the peripherals attached to it.

77.1.1 Features

The NXMC module is compliant with the IEEE-ISTO 5001-2011 standard. The following features are implemented:

- Data trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to (selected) internal memory resources.
- Multi-master tracing capability for multiple master accesses
- [BLG_NXMC_0001][Covers: ADD16.091]HSM master(s) filtering from the tracing function based on external control[end]
- Watchpoint messaging based on internal/external triggers, via the auxiliary pins
- Watchpoint trigger events out based on internal/external triggers
- Watchpoint trigger enable of data trace messaging
- Peripheral interface for data message transfers based on In Circuit Trace Message (ICTM) format
- Start or stop of Tracing (Data Trace, Watchpoint Trace) based on external triggers.
- Optional timestamping of the messages based on timer value and controls received at the interface
- Nexus Auxiliary port for higher data throughput
 - One $\overline{\text{EVTO}}$ (Watchpoint Event) pin
 - One $\overline{\text{EVTI}}$ (Event In) pin
- Registers for data trace, watchpoint generation, and watchpoint trigger
- All features controllable and configurable via the JTAG port

77.2 External signal description

This section details information regarding the standard ports and protocol. The NXMC pin interface provides the function of transmitting messages from the messages queues to NAR. It is also responsible for handshaking with the message queues.

The NXMC module implements the following signals:

- One $\overline{\text{EVTI}}$
- One $\overline{\text{EVTO}}$

These pins are described in [Table 1803](#).

All NXMC input functionality is controlled through the JTAG port in compliance with IEEE 1149.1 (see [Section 77.5.1, IEEE 1149.1 \(JTAG\) Test Access Port](#) for details). A separate JTAG TAP controller is instantiated within the NXMC. [Table 1802](#) describes the JTAG pins.

Table 1802. JTAG pins for NXMC

JTAG port	Input/output	Description
TDO	O	The Test Data Output (TDO) pin is the serial output for test instructions and data. TDO is three-stateable and is actively driven in the shift-IR and shift-DR controller states. TDO changes on the falling edge of TCK.
TDI	I	The Test Data Input (TDI) pin receives serial test instruction and data. TDI is sampled on the rising edge of TCK and has an internal pull-up resistor.
TMS	I	The Test Mode Select (TMS) input pin is used to sequence the JTAG test controllers' state machine. TMS is sampled on the rising edge of TCK and has an internal pull-up resistor.
TCK	I	The Test Clock (TCK) input pin is used to synchronize the test logic, and control register access through the JTAG port.
TRST	I	The Test Reset ($\overline{\text{TRST}}$) input pin is used to asynchronously initialize the JTAG controller. The $\overline{\text{TRST}}$ pin has an internal pull-down resistor.

Table 1803. NXMC auxiliary pins

Auxiliary port	Input/output	Description
EVTO	O	Event Out ($\overline{\text{EVTO}}$) is an output which, when asserted, indicates one of two events has occurred based on the EOC bits in the DC Register: – one of the internal or external watchpoints has occurred and $\text{EOC} = 2'b00$ – system-level debug mode was entered (ipg_debug) and $\text{EOC} = 2'b01$ $\overline{\text{EVTO}}$ is held asserted for one cycle.
EVTI	I	Event In ($\overline{\text{EVTI}}$) is an input which initiates synchronization messages. If the Nexus module is enabled at reset, (see Section 77.5.2, Enabling NXMC operation), assertion initiates data trace synchronization messages (provided data trace is enabled).

77.3 Supported messages and TCODEs

The NXMC pins allow for flexible transfer operations via public messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2011 standard defines a set of public messages. The NXMC block supports the public TCODEs listed in [Table 1804](#). The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Table 1804. Supported public TCODEs

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Write Message	6	6	TCODE	fixed	TCODE number = 58
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 1805)
	1	32	U-ADDR	variable	Unique portion of the data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Read Message	6	6	TCODE	fixed	TCODE number = 59
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 1805)
	1	32	U-ADDR	variable	Unique portion of the data read address
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	ETYPE	fixed	Error type (See Table 1806)
	14	14	ECODE	fixed	Error code (See Table 1807)
	1	26	TSTAMP	variable	Timestamp (Optional)
Data Trace - Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 60
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 1805)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 1804. Supported public TCODEs (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
Data Trace - Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 61
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access
	3	3	DSZ	fixed	Data size (See Table 1805)
	1	32	F-ADDR	variable	Full access address (leading zero (0) truncated)
	8	64	DATA	fixed	Data read value (size fixed based on DSZ field)
	1	26	TSTAMP	variable	Timestamp (Optional)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	1	8	WPHIT	variable	Watchpoint source(s) number (See Table 1819)
	1	26	TSTAMP	variable	Timestamp (Optional)
Peripheral Message (In circuit Trace Message: ICTM)	6	6	TCODE	fixed	TCODE number = 34
	4	4	SRC	fixed	Source processor identifier (multiple Nexus configuration)
	6	6	CKSRC	fixed	Peripheral source identifier
	1	44	CKDATA	variable	Peripheral data
	1	26	TSTAMP	variable	Timestamp (Optional)

Table 1805. Data trace size (DSZ) encodings (TCODE = 5,6,13,14)

DSZ	Transfer size
001	8-bit
010	16-bit
011	32-bit
100	64-bit
000, 101-111	Reserved

Table 1806. Error Type (ETYPE) encodings (applicable to all error messages)

ETYPE	Description
0000	Queue overrun caused message (one or more) to be lost
0001	Contention with higher priority message caused message(s) to be lost
0010	Reserved
0011	Reserved

Table 1806. Error Type (ETYPE) encodings (applicable to all error messages) (continued)

ETYPE	Description
0100	Reserved
0101	Invalid access opcode (Nexus register unimplemented)
0110–1111	Reserved

Table 1807. Error Code (ECODE) encodings (applicable based on error source)

ECODE		Description ⁽¹⁾
13 to 8	7 to 0	
Source (SRC)		
000000	XXXXXXX1	Watchpoint Message(s) lost
000000	XXXXXX1X	Data Trace Message(s) lost
000000	XXXXX1XX	Reserved
000000	XXXX1XXX	Reserved
000000	XXX1XXXX	Reserved

CKSRCn	1XXXXXXX	Reserved

1. The SRC field values are described in the device-specific chapter that describes how the modules are configured.

77.4 Register description

This section describes the NXMC register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. See [Section 77.5.1, IEEE 1149.1 \(JTAG\) Test Access Port](#) for details. The complete list of registers is shown in [Table 1808](#).

Table 1808. NXMC registers

Nexus register	Nexus access opcode	Read/ write	Read address	Write address
Development Control 1 (DC1)	\$2	R/W	\$04	\$05
Development Control 2 (DC2)	\$3	R/W	\$06	\$07
Watchpoint Trigger (WT)	\$B	R/W	\$16	\$17
Data Trace Control (DTC)	\$D	R/W	\$1A	\$1B

Breakpoint/Watchpoint Control Register2 (BWC2)	\$17	R/W	\$2E	\$2F
Breakpoint/Watchpoint Address Register1 (BWA1)	\$1E	R/W	\$3C	\$3D
Breakpoint/Watchpoint Address Register2 (BWA2)	\$1F	R/W	\$3E	\$3F

77.4.1 Register descriptions

Detailed register definitions for the current NXMC implementation are described in the following sections.

77.4.1.1 Development control register 1 (DC1)

The Development Control Registers control the basic development features of the NXMC module. [Figure 1940](#) shows the format of the DC1.

Figure 1940. Development control register 1 (DC1)

The DC1 is described in [Table 1809](#).

Table 1809. DC1 register field description

Field	Description
31:29	Reserved for future functionality (read as 0)
28:27 EOC	EVTO Control. 00 EVTO upon occurrence of watchpoint (internal or external) 01 EVTO upon entry into system-level Debug Mode 1x Reserved
26:25	Reserved for future functionality (read as 0)

Table 1809. DC1 register field description (continued)

Field	Description
24 WEN	Watchpoint Trace Enable. 0 Watchpoint Messaging disabled 1 Watchpoint Messaging enabled
22:5	Reserved for future functionality (read as 0)
4:3 EIC	$\overline{\text{EVTI}}$ Control. 00 $\overline{\text{EVTI}}$ for synchronization (Data Trace) 01 Reserved 10 $\overline{\text{EVTI}}$ disabled 11 Reserved
2:0 TM	Trace Mode. 000 No Trace 1xx Reserved x1x Data Trace enabled xx1 Reserved

77.4.1.2 Development control register 2 (DC2)

The Development Control Registers control the basic development features of the NXMC module. [Figure 1941](#) shows the format of the DC2.

Figure 1941. Development control register 2 (DC2)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

1. The EOC bits in DC1 must be programmed to trigger EVTO on watchpoint occurrence for the EWC bits to have any effect.

2. The peripheral details are described in the device-specific chapter that describes how the modules are configured.

77.4.1.3 Watchpoint trigger register (WT)

The Watchpoint Trigger Register allows the watchpoints defined either internally to the NXMC module or by an external module to trigger actions. These watchpoints can control data trace enable and disable. The WT bits can be used to produce an address related window for triggering trace messages. [Figure 1942](#) shows the format of the WT register.

Figure 1942. Watchpoint trigger register (WT)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

19:0	Reserved for future functionality (read as 0)

1. The WT bits only enable data trace if the TM bits in the Development Control Register (DC) have not already been set to enable data trace.

77.4.1.4 Data trace control register (DTC)

The Data Trace Control Register controls whether DTM messages are restricted to reads, writes or both for a user programmable address range. There are two data trace channels controlled by the DTC for the NXMC module. [Figure 1943](#) shows the format of the DTC register.

Figure 1943. Data trace control (DTC) register

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

6 RC2	Range Control 2. 0 Condition trace on address within range (endpoints inclusive) 1 Condition trace on address outside of range (endpoints exclusive)
5:0	Reserved for future functionality

1. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

77.4.1.5 Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

The Data Trace Start Address Registers define the start addresses for each trace channel. [Figure 1944](#) shows the format of the DTSA1 and DTSA2 registers.

Figure 1944. Data trace start address registers 1 and 2 (DTSA1 and DTSA2)

77.4.1.6 Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

The Data Trace End Address Registers define the end addresses for each Trace channel. [Figure 1945](#) shows the format of the DTEA1 and DTEA2 registers.

Figure 1945. Data trace end address registers 1 and 2 (DTEA1 and DTEA2)

[Table 1813](#) illustrates the range that are selected for data trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1813. Data trace address range options

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	0	DTSA -> <- DTEA

Table 1813. Data trace address range options (continued)

Programmed values	Range control bit value	Range selected
DTSA ≤ DTEA	1	<- DTSA DTEA ->
DTSA > DTEA	N/A	Invalid range—no trace

Note: DTSA must be less than (or equal to) DTEA in order to guarantee correct data write/read traces.

When the range control bit is 0 (internal range), accesses to DTSA and DTEA addresses are traced. When the range control bit is 1 (external range), accesses to DTSA and DTEA are not traced.

77.4.1.7 Breakpoint/watchpoint control register 1 (BWC1)

Breakpoint/watchpoint control register 1 controls the attributes for generation of NXMC watchpoint#1. [Figure 1946](#) shows the format of the BWC1 register.

Figure 1946. Breakpoint/watchpoint control register 1

77.4.1.9 Breakpoint/watchpoint address registers 1 and 2 (BWA1 and BWA2)

The Breakpoint/Watchpoint Address Registers are compared with system bus addresses in order to generate internal watchpoints. [Figure 1948](#) shows the format of the BWA1 and BWA2 registers.

Figure 1948. Breakpoint /watchpoint address registers 1 and 2

77.4.1.10 Unimplemented registers

Unimplemented registers are those with client select and index value combinations other than those listed in [Table 1808](#). For unimplemented registers, the NXMC module drives TDO to zero during the SHIFT-DR state. It also transmits an error message with the invalid access opcode encoding (ETYPE = 0101).

77.5 Programming considerations (RESET)

If NXMC register configuration is to occur during system reset (as opposed to debug mode), all NXMC configuration should be completed between the negation of $\overline{\text{TRST}}$ and system reset de-assertion, after the JTAG ID register has been read by the tool.

77.5.1 IEEE 1149.1 (JTAG) Test Access Port

The NXMC module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The NXMC module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in [Section 77.5.4, NXMC register access via JTAG](#).

77.5.2 Enabling NXMC operation

The Nexus module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The Nexus module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The Nexus module is also disabled if a Power-on-Reset (POR) event occurs.

If the NXMC module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

77.5.3 Enabling NXMC TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the NXMC TAP is accessed, this information helps the development tool obtain

information about the Nexus module it is accessing, such as version, sequence, feature set, etc.

77.5.4 NXMC register access via JTAG

Access to Nexus register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in [Table 1808](#).

Reading/writing of a Nexus register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the Nexus register to be accessed by providing an index (see [Table 1808](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown in [Figure 1949](#) and [Table 1816](#).

Figure 1949. JTAG DR for Nexus register access

Table 1816. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in Table 1808
Read/Write (R/W)	0Read 1Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
 - a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
 - b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

77.6 Functional description

77.6.1 Data trace

This section describes the data trace mechanism supported by the NXMC module. Data trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the IEEE-ISTO 5001-2011 standard.

77.6.1.1 Data trace messaging (DTM)

NXMC data trace messaging is accomplished by snooping the system bus and storing the information for qualifying accesses (based on enabled features and matching target addresses). The NXMC module traces all data access that meet the selected range and attributes.

77.6.1.2 DTM message formats

The NXMC block supports five types of DTM messages:

- Data write
- Data read
- Data write synchronization
- Data read synchronization
- Error messages

77.6.1.2.1 Data write and data read messages

The data write and data read messages contain the data write/read value and the address of the write/read access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encodings to either 8, 16, 32, 64. The TSTAMP field is 26 bits. Data write message and data read message information is messaged out in the format shown in [Figure 1950](#). The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Figure 1950. DTM message format for DATA width = 64 bits

8/16/32/64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	U-ADDR	DSZ	MASTER	SRC	TCODE (111010 or 111011)

TSTAMP is another optional field which is inserted based on the controls received from the NAR, see [Section 77.6.4, Timestamping feature](#).

77.6.1.2.2 Data trace with non-contiguous byte strobes asserted

The v6 extensions to AMBA 2.0 allow system bus transfers with bytes non-asserted byte strobes in between asserted byte strobes. The NXMC does not support transfers with non-contiguous byte strobes asserted. In such a condition, the invalid bytes in the DATA packet are driven to the value of 0xFF.

77.6.1.2.3 DTM overflow error messages

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards incoming messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a data trace message attempts to enter the queue while it is being emptied, the error message incorporates the data trace only error encoding (ECODE = 00000000000010). If a watchpoint also attempts to be queued while the FIFO is being emptied, then the error message incorporates error encoding (ECODE = 00000000000011).

Error information is messaged out in the format shown in [Figure 1951](#). The SRC field values are described in the device-specific chapter that describes how the modules are configured.

Figure 1951. DTM error message format (fixed length = 48 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

77.6.1.2.4 Data trace synchronization messages

A data trace write/read with synchronization message is messaged via the auxiliary port (provided data trace is enabled) for the following conditions (see [Table 1817](#)):

- Initial data trace message upon exit from system reset or whenever data trace is enabled is a synchronization message.
- Upon returning from a low power state, the first data trace message is a synchronization message.
- Upon returning from debug mode, the first data trace message is a synchronization message.
- After occurrence of queue overrun (can be caused by any trace message), the first data trace message is a synchronization message.
- After the periodic data trace counter has expired indicating 255 without-sync data trace messages have occurred since the last with-sync message occurred.
- Upon assertion of the event in (EVTI) pin, the first data trace message is a synchronization message if the EIC bits of the DC Register have enabled this feature.
- Upon data trace write/read after the previous DTM Message was lost due to a collision while entering the FIFO between the DTM message and any of the following: error message, or watchpoint message or peripheral message. This is a very rare occurrence and possible only in case of continuous burst on the system bus as well as watchpoint events which is unrealistic.

Data trace synchronization messages provide the full address (without leading zeros) and ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write/read with synchronization messages is shown in [Figure 1952](#). The SRC and MASTER field values are described in the device-specific chapter that describes how the modules are configured.

Figure 1952. Data write/read with synchronization message format

8-64 bits	1–32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100 or 111101)

Exception conditions that result in data trace synchronization are summarized in [Table 1817](#).

Table 1817. Data trace exception summary

Exception condition	Exception handling
System Reset Negation	At the negation of JTAG reset ($\overline{\text{TRST}}$), queue pointers, counters, state machines, and registers within the NXMC module are reset. If data trace is enabled, the first data trace message is a data write/read with synchronization message.
Data Trace Enabled	The first data trace message (after data trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a low power mode or debug mode the next data trace message is converted to a data write/read with synchronization message.
Queue Overrun	An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue is a data write/read with synchronization message.
Periodic Data Trace Synchronization	A forced synchronization occurs periodically after 255 data trace messages have been queued. A data write/read with synchronization message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, an $\overline{\text{EVTI}}$ assertion initiates a data write/read with synchronization message upon the next data write/read (if data trace is enabled and the EIC bits of the DC Register have enabled this feature).
Collision Priority	All messages have the following priority: Error > WPM > ICTM > DTM. Although a very rare occurrence, during simultaneous burst lower priority messages can be lost due to burst of high priority messages. Proper error messages are generated and in case of DTM lost a subsequent read/write queues a data write/read with synchronization message.

77.6.1.3 DTM operation

77.6.1.3.1 Enabling data trace messaging

Data trace messaging can be enabled in one of three ways:

- Setting the TM field of the DC Register via JTAG to enable data trace (DC[1]).
- Using the DTS field of the WT Register to enable data trace on watchpoint hits (either watchpoints configured within the NXMC module or external watchpoint inputs controlled by the device).
- By toggling the external start control, which in turn sets the TM field of the DC register to enable data trace. (The TM bit clears and hence the data tracing stops on the toggle of external stop control. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: When enabling the DTM, either via JTAG or external start/stop control, it is important to make sure that all the other controls (i.e. DTC, DTSA/E1/2 and WT register fields) are correctly configured to ensure correct DTM functionality.

77.6.1.4 DTM queueing

The NXMC implements a programmable depth queue for queuing all messages. Messages that enter the queue are transmitted via the auxiliary pins in the order in which they are queued.

Note: If multiple trace messages need to be queued at the same time, watchpoint messages have the highest priority ($WPM > ICTM > DTM$).

77.6.1.5 Relative addressing

The relative address feature is compliant with IEEE-ISTO 5001-2011 and is designed to reduce the number of bits transmitted for addresses of data trace messages. The address transmitted is relative to the address of the previous data trace message. It is generated by XORing the new address with the previous address, and then using only the results up to the most significant 1 in the result. To recreate this address, an XOR of the (most-significant 0-padded) message address with the previously decoded address gives the current address.

For example, if the previous address ($A1$) = 0x0003FC01, the new address ($A2$) = 0x0003F365 as shown in [Figure 1953](#).

Figure 1953. Relative addressing example

77.6.1.6 Data trace windowing

Data write/read messages are enabled via the RWT1(2) field in the Data Trace Control Register (DTC) for each DTM channel. Data trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC1(2) field in the DTC. All system bus DMA initiated read/write accesses which fall inside or outside these address ranges, as programmed, are candidates to be traced.

77.6.1.7 System bus cycle special cases

The system bus cycle special cases are shown in [Table 1818](#).

Table 1818. System Bus cycle special cases

Special case	Action
System bus cycle with data error	Data trace message discarded
System bus cycle completed without error	Cycle captured and transmitted
System bus cycle is an instruction fetch	Cycle ignored

77.6.1.8 System bus multi-master tracing

DTM tracing can be done either for all the masters or for a single master (indicated by the MID field of the DTC register) based on the DTC register MME field. In case of single master, the correct value needs to be configured in the MID register before enabling the data trace operation.

The MASTER field of the DTM message (see figure in [Section 77.6.1.2.1, Data write and data read messages](#) for an example) indicates the system bus master for which the trace has been generated. For each masters (0 to 15) there is a parameter associated (MSID0-15) for indicating its actual ID, which finally gets inserted in the MASTER field. The MASTER field values are described in the device-specific chapter that describes how the modules are configured.

77.6.1.9 HSM master filtering

[BLG_NXMC_0004][Covers: ADD16.091]For security reasons certain HSM masters need to be disabled or filtered from data tracing operations.[end]

77.6.2 Watchpoint support

The NXMC module provides watchpoint messaging via the auxiliary pins, as defined by IEEE-ISTO 5001-2011. Watchpoint messages can be generated by either using the NXMC defined internal watchpoints or by externally defined watchpoint signals.

77.6.2.1 Watchpoint messaging

Enabling watchpoint messaging is accomplished by setting the WEN bit in the DC Register. This bit is set either via JTAG write 1 access or external start indication, and cleared via JTAG write 0 access or external start indication. In case of conflict between JTAG write and external start/stop control, JTAG write takes precedence.

Note: In case of enabling the watchpoint messaging, either via JTAG or external start/stop control, it is important to make sure that all the other Watch Point Message (WPM) controls (i.e. BWC1/2, BWA1/2 register fields) are configured with the correct values in order to ensure correct WPM operation.

Watchpoint setting is supported through two methods:

- Internal watchpoints—Using the BWC1(2) registers, two independently controlled internal watchpoints can be initialized. When a system bus access address matches on BWA1(2), a watchpoint message is transmitted. The system bus multi-master or single master controls applies here too as explained for DTM (in [Section 77.6.1.8, System bus multi-master tracing](#)).
- External watchpoints—The NXMC module supports two external watchpoint inputs. The optional logic to generate these watchpoint signals is implemented at the device level. The watchpoints are described in the device-specific chapter that describes how

the modules are configured. If either of these signals asserts (i.e, on 0-to-1 transition), a watchpoint message is transmitted.

The Nexus module provides watchpoint messaging using the IEEE-ISTO 5001 defined TCODE. When any of the four possible watchpoint sources asserts, a message is sent to the queue to be messaged out. This message indicates the watchpoint number as shown in [Figure 1954](#) and [Table 1819](#).

Figure 1954. Watchpoint message format (fixed length = 18 bits)

8 bits	4 bits	6 bits
WPHIT (RRRRXXXX)	SRC	TCODE (001111)

Table 1819. Watchpoint source description

Watchpoint source (8-bits)	Watchpoint description
RRRRXXX1 ⁽¹⁾	External Watchpoint #1(device defined)
RRRRXX1X	External Watchpoint #2 (device defined)
RRRRX1XX	Internal Watchpoint #1 (BWA1 match)
RRRR1XXX	Internal Watchpoint #2 (BWA2 match)

1. R = reserved for future use (insert 0s).

77.6.2.2 Watchpoint error message

An error message occurs when a new message cannot be queued due to the message queue being full. The FIFO discards messages until it has completely emptied the queue. Once emptied, an error message is queued. The error encoding indicates which type(s) of messages attempted to be queued while the FIFO was being emptied.

If only a watchpoint message attempts to enter the queue while it is being emptied, the error message incorporates the watchpoint only error encoding (ECODE = 00000000000001). If a data trace message also attempts to enter the queue while it is being emptied, the error message incorporates error encoding (00000000000011). Error information is messaged out in the format shown in [Figure 1955](#).

Figure 1955. Error message format (fixed length = 28 bits)

14 bits	4 bits	4 bits	6 bits
ECODE	ETYPE	SRC	TCODE (001000)

77.6.3 Peripheral interface

The NXMC provides an asynchronous interface to peripherals for sending data messages. The NXMC can back pressure or delay the data transfer using a data accept signal. A round-robin scheme is followed between the peripherals for forwarding received data to the queue; therefore, each peripheral has an equal priority and hence bandwidth for data transfers.

To enable messaging from peripherals there are controls present in the DC2 register for individual peripherals: DC2[PME0]. There are no message generated and hence data accepted from a peripheral unless the corresponding enable bit is set to 1.

Figure 1956. Peripheral DATA bus fields

Another input port is present which indicates data loss inside the peripheral itself due to over-run, the module in turn generates error message to communicate such events to the debugger.

77.6.3.1 Peripheral data message format (ICTM)

The message formats for the peripheral data messages (formatted as ICTM) is shown in [Figure 1957](#). The SRC field values are described in the device-specific chapter that describes how the modules are configured. The CKSRC field is received from the MSB 6 bits of the individual peripheral data bus, and CKDATA is a variable field and contains 44 LSBits received on the databus of the peripheral interface.

Figure 1957. Peripheral message format (max length = 60 bits, min length = 17 bits)

77.6.3.2 Peripheral error message format

The error messages are generated based data over-run indication from a peripheral. Error information is messaged out in the format shown in [Figure 1958](#).

Figure 1958. Error message format (fixed length = 28 bits)

The SRC field values are described in the device-specific chapter that describes how the modules are configured. ETYPE and ECODE encoding are listed in [Table 1806](#) and [Table 1807](#).

77.6.4 Timestamping feature

This feature allows a timestamp packet to be appended to all messages, based on the timer value and controls received externally from the NAR. If enabled, this packet is added as the last field to all the outgoing messages. The TSTAMP packet width is 26 bits.

The TSTAMP packet is appended at the end of a message during message formatting, before transfer. [Figure 1959](#) shows an example of ICTM message with a TSTAMP field.

Figure 1959. Message with TSTAMP field example

26 bits	1–44 bits	6 bits	4 bits	6 bits
TSTAMP	CKDATAn	CKSRCn	SRC	TCODE (100010)

The enable or disable indication should remain static for the complete debug session. Dynamically enabling or disabling of the timestamping is not allowed during running debug tracing. The following steps allow seamless enabling/disabling of the timestamping:

- 1. All tracing (DTM/WPM/ICTM) must be disabled
- 2. Wait for the internal queues to be emptied (no further request is asserted at the auxiliary interface)
- 3. Change the timestamp enable indication to assert/deassert
- 4. Enable the required tracing controls (via TM, PME0 etc. control bits)

78 Cyclic Redundancy Check (CRC) Unit

78.1 Introduction

The Cyclic Redundancy Check (CRC) computing unit is dedicated to the computation of CRC, off-loading this work from the CPU. Each context has a separate CRC computation engine in order to allow the concurrent computation of the CRC of multiple data streams. The CRC computation is performed at speed without wait-state insertion. Bit-swap and bit-inversion operations can be applied on the final CRC signature. Each context can be configured with one of three hard-wired polynomials, normally used for most of the standard communication protocols. The data stream supports multiple data width (byte/halfword/word) formats.

78.2 Main features

- 1 context(s) for the concurrent CRC computation
- Separate CRC engine for each context
- Zero-wait states during the CRC computation (pipeline scheme)
- 3 hard-wired polynomials (CRC-8, CRC-32 Ethernet, and CRC-16-CCITT)
- Support for byte, halfword, or word width of the input data stream

78.2.1 Standard features

- Peripheral bus interface
- CRC-8 VDA CAN
- CRC-16-CCITT
- CRC-32 Ethernet

78.3 Block diagram

The top level diagram of the CRC module is given in [Figure 1960](#). Refer to the chip configuration chapter for number of contexts in this module.

Figure 1960. CRC top level diagram

78.4 Signal description

The CRC module does not generate any external signals.

78.4.1 Peripheral bus interface

The peripheral bus interface is a slave bus used for configuration and data streaming (CRC computation) purposes via CPU or DMA. The following bus operations (contiguous byte enables) are supported:

- Word (32 bits) data write/read operations to any registers
- Low and high halfword (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- Byte (8 bits, data[31:24], data[23:16], data[15:8], or data[7:0]) data write/read operations to any registers

Any other operation (free byte enables or other operations) must be avoided.

The CRC module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/halfword/word (free byte enables or other operations) on each register

The registers of the CRC module are accessible (read/write) in each access mode: user, supervisor, and test.

The following summarizes bus operation performance:

- Zero wait states (single bus cycle) for each write/read operation to the CRC_CFG and CRC_INP registers
- Zero wait states (single bus cycle) for each write operation to the CRC_CSTAT register
- Double wait states (3 bus cycles) for each read operation to the CRC_CSTAT or CRC_OUTP registers immediately following (next clock cycle) a write operation to the CRC_CSTAT, CRC_INP, or CRC_CFG registers belonging to the same context; in all the other cases, no wait states are inserted

78.5 Memory map and registers

This section describes, in address-order, all the CRC registers.

78.5.1 Register description

[Table 1820](#) shows the memory map for the CRC registers.

Table 1820. CRC unit memory map⁽¹⁾

Offset from CRCU_BASE	Register	Register classification ⁽²⁾	Location
000h + (N-1)*10h	CRC Configuration Register (CRC_CFG)	Saf-Lat	on page 3423
004h + (N-1)*10h	CRC Input Register (CRC_INP)	Saf-Relv	on page 3424

Table 1820. CRC unit memory map⁽¹⁾ (continued)

Offset from CRCU_BASE	Register	Register classification ⁽²⁾	Location

W											SWAP_BYTEWISE	SWAP_BITWISE	POLYG		SWAP	INV
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	f(N) (1)	0	0

1. Reset value is a function of N. When N%2 = 0, reset value = 1. When N%2 = 1, reset value = 0.

Table 1821. CRC_CFG field descriptions

Field	Description
SWAP_BYTEWISE	SWAP_BYTEWISE 0 No swap 1 Byte wise (MSB ↔ LSB bytes) swap performed on CRC_INP input data internally for CRC-32 polynomial calculations. <i>Note: INV and SWAP bits are set to '1' for CRC-32 polynomial calculations.</i>
SWAP_BITWISE	SWAP_BITWISE 0 No swap 1 Bit wise (MSB ↔ LSB) bits swap performed on CRC_INP input data internally for CRC-16 polynomial calculations.

Table 1821. CRC_CFG field descriptions (continued)

Field	Description
POLYG	Polynomial selection 00 CRC-CCITT polynomial 01 CRC-32 polynomial 10 CRC-8 polynomial 11 Reserved This bit can be read and written by software. <i>Note: This bit can be written only during the configuration phase.</i>
SWAP	SWAP selection 0 No swap selection applied on the CRC_OUTP content 1 Swap selection (MSB → LSB, LSB → MSB) applied on the CRC_OUTP content. In case of CRC-CCITT polynomial, the swap operation is applied on the 16 LSB bits. This bit can be read and written by software. <i>Note: This bit can be written only during the configuration phase.</i>
INV	INV selection 0 No inversion selection applied on the CRC_OUTP content. 1 Inversion selection (bit x bit) applied on the CRC_OUTP content. In case of CRC-CCITT polynomial the inversion operation is applied on the 16 LSB bits. This bit can be read and written by software. <i>Note: This bit can be written only during the configuration phase.</i>

78.5.1.2 CRC Input Register (CRC_INP)

Figure 1962. CRC Input Register (CRC_INP)

Table 1822. CRC_INP field descriptions

Field	Description
INP	Input data for the CRC computation The INP register can be written at byte, halfword (high and low), or word in any sequence. In case of halfword write operation, the bytes must be contiguous. Only the bits written are fed to the CRC engine. This register can be read and written by software.

78.5.1.3 CRC Current Status Register (CRC_CSTAT)

Figure 1963. CRC Current Status Register (CRC_CSTAT)

Table 1823. CRC_CSTAT field descriptions

Field	Description
CSTAT	Status of the CRC signature The CSTAT register includes the current status of the CRC signature. No bit swap and inversion are applied to this register. In the case of the CRC-CCITT polynomial, only the16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. The CSTAT register can be written at byte, halfword, or word. This register can be read and written by software. <i>Note: This register can be written only during the configuration phase.</i>

78.5.1.4 CRC Output Register (CRC_OUTP)

Figure 1964. CRC Output Register (CRC_OUTP)

Table 1824. CRC_OUTP field descriptions

Field	Description
OUTP	Final CRC signature The OUTP register includes the final signature corresponding to the CRC_CSTAT register value eventually swapped and inverted. In the case of the CRC-CCITT polynomial, only the 16 LSB bits are significative. The 16 MSB bits are tied at 0b during the computation. In the case of the CRC-8 polynomial, only the 8 LSB bits are significative. The 24 MSB bits are tied at 0b during the computation. This register can be read by software.

78.6 Functional description

The CRC module supports the CRC computation for each context. Each context has its own complete set of registers, including the CRC engine. The data flow of each context can be interleaved. The data stream can be structured as a sequence of bytes, halfwords, or words. The input data sequence is provided, eventually mixing the data formats (byte, halfword, and word), writing to the input data register (CRC_INP).

The data stream is generally executed by n concurrent DMA data transfers (mem2mem) where n is less than or equal to the number of contexts.

- The standard generator polynomials are given in [Equation 88](#), [Equation 89](#), and [Equation 90](#) for the CRC computation of each context. Two separate registers are available: CRC_INP for writing data and CRC_CSTAT for retrieving the (accumulated up to now) CRC.

Equation 88 CRC8 VDA CAN:

$$x^8 + x^4 + x^3 + x^2 + 1$$

Equation 89 CRC-CCITT (x.25 protocol):

$$x^{16} + x^{12} + x^5 + 1$$

Equation 90 CRC-32 (Ethernet protocol):

$$x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$$

Figure 1965. CRC-CCITT engine concept scheme

The initial seed value of the CRC can be programmed by initializing the CRC_CSTAT register. The concept scheme (serial data loading) of the CRC engine is given in [Figure 1965](#) for the CRC-CCITT. The design implementation executes the CRC computation in a single clock cycle (parallel data loading). A pipeline scheme has been adopted to decouple the peripheral bus interface from the CRC engine in order to allow the computation of the CRC at speed (zero wait states).

If the CRC signature is used for encapsulation in the data frame of a communication protocol (for example, SPI, etc.), a bit swap (MSB → LSB, LSB → MSB) and/or bit inversion of the final CRC signature can be applied (CRC_OUTP register) before transmitting the CRC.

Use of the CRC module is summarized in the flow chart given in [Figure 1966](#).

Figure 1966. CRC computation flow

78.7 Use cases

The number of contexts depends on the application. The overall number of contexts for the CRC peripheral depends on the number of peripherals that concurrently require intervention by the CRC module. Two main use cases are considered:

- Calculation of the CRC of the configuration registers during the process safety time
- Calculation of the CRC on the incoming/outcoming frames for the communication protocols (not protected with CRC by definition of the protocol itself) used as a safety-relevant peripheral

The signature of the configuration registers is computed correctly only if these registers do not contain any status bit.

Assuming that the DMA engine has n channels (greater than or equal to the number of contexts) configurable for the following types of data transfer — mem2mem, periph2mem, mem2periph — then this sequence, as shown in [Figure 1967](#), is applied to manage the transmission data flow:

1. DMA/CRC module configuration (context x , channel x) by CPU
2. Payload transfer from the MEM to the CRC module (CRC_INP register) after MSB → LSB change (input mirroring) to calculate the CRC signature (phase1) by DMA (mem2mem data transfer, channel x)
3. CRC signature copy from the CRC module (CRC_OUTP register) to the MEM (phase 2) by CPU
4. Data block (payload + CRC) transfer from the MEM to the PERIPH module (for example, SPI Tx FIFO) (phase 3) by DMA (mem2periph data transfer, channel x)

Figure 1967. DMA-CRC transmission sequence

79 Memory Error Management Unit (MEMU)

79.1 Introduction

The MEMU is responsible for collection and reporting of error events associated with ECC (Error Correction Code) logic used on SRAM, Peripheral System RAM and flash memory. When any of the following events occur the MEMU receives an error signal which causes an event to be recorded and corresponding error flags to be set and reported to FCCU (Fault Collection and Control Unit).

- Correctable Error: It comprises the following:
 - Single Bit error in the data part that is detected via ECC for a System RAM or Peripheral RAM or flash memory.
 - Single Bit error in the data part that is detected via MBIST on any RAM.
- Uncorrectable Error: It comprises the following:
 - Multiple bit error that is detected via ECC for a Peripheral SRAM, System RAM or flash memory.
 - Multiple bit error that is detected via MBIST on any SRAM. Based on MBIST implementation, the MBIST might report several correctable errors in the same word instead of an uncorrectable one. It is the task of the software after MBIST to aggregate these reports and detect the uncorrectable error.
 - Addressing errors and unused data bit errors detected by ECC logic.

The MEMU system connections are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

When multiple errors are indicated from various sources at same instant, an Overflow can be indicated by the MEMU to the FCCU. Overflow can also be indicated if the reporting table entries are full and a new unique error is reported by the system.

MEMU processes the errors based on whether they are correctable or uncorrectable (from either ECC or MBIST logic), independent of the source generating these errors.

The MEMU has three instances of the basic reporting block; one each for System RAM ECC and MBIST, Peripheral SRAM ECC or flash memory ECC.

Each instance has two reporting tables—Correctable errors are reported in one table while the uncorrectable are reported in the other.

See [Section 79.4, Design overview](#) for the reporting block details.

79.2 Features

The MEMU has the following features:

- Supports up to 128 error sources per Reporting Block (System RAM ECC and MBIST, Peripheral SRAM ECC or flash memory ECC): The number of error sources are chip-

specific; see the Device Configuration chapter that describes how modules are configured and connected.

- Support for error reporting from the following category of error sources (both for ECC and MBIST):
 - System RAM
 - Peripheral SRAM
 - Flash memory
- Unique reported errors are logged into the module's reporting table which is accessible to CPU via memory mapped CPU register programming interface.
- MEMU handles overflow during error assertion and reports status accordingly.
- Unique errors are stored in correctable and non correctable section of the reporting table and corresponding indication is generated to the FCCU.
- CPU can program the known errors into the reporting table to avoid their re-reporting by MEMU.
- CPU can clear the reporting table errors.
- The reporting table for uncorrectable errors supports only 1 entry.

79.3 Block diagram

Figure 1968. MEMU block diagram

79.4 Design overview

The MEMU block has three instantiations of the basic reporting block along with a common CPU interface for the user software to access the storage block.

The MEMU should be enabled on power on reset. The user software can write known error addresses into the reporting table to prevent reporting of those error addresses to FCCU should they later be accessed in operation. All writes into the reporting table by the CPU that assert the Valid Bit (of the respective reporting table entry) will be indicated as a new error detected and will be reported to the FCCU. This feature can also be used as self-checking option of the MEMU and the MEMU-FCCU connection.

The MEMU design does not limit any particular sequence or errors. See [Section 79.7.3, Handling overflows \(Multiple error reporting\)](#) for details on overflow behaviors.

The basic algorithm flow/architecture for error reporting in the MEMU is summarized below:

1. Synchronizer block

For asynchronous inputs, a FIFO-based structure (per asynchronous channel) is implemented. All the error inputs (correctable error reported, uncorrectable error reported, error address and bad bits) are concatenated and stored in the FIFO. While storing the entry in the FIFO, a duplicity check is performed with the previously stored entry (the entry which was stored in the last cycle). If both the entries are duplicate the new entry is deleted and the pointers are rolled back to the old value, otherwise the new entry is stored. Whenever there is an overflow (FULL condition) in the Asynchronous FIFO, it is denoted by setting the Error Buffer Overflow or the EBO flag to the FCCU and the corresponding bit in the Concurrent Overflow Register is set.

For synchronous inputs, inputs are sampled whenever the corresponding clock synchronizing signal is asserted for a particular channel.

2. Error Processing block

This block is used to process the incoming errors coming from the device.

- Error Sequencer is used for sequencing the errors so that these are processed one per clock. In case of more than one errors detected by the sequencer logic, one is sent for the processing (error comparison block), the other is stored in the error buffer and the rest are marked as overflows in the Concurrent overflow register.
- All the sequences of incoming errors are supported. However, in case of multiple errors being asserted in back to back clock cycles, MEMU will process the errors being forwarded by the sequencer logic and register the rest of the errors as Concurrent Overflows in the Concurrent Overflow Register.
- While storing the error in the error buffer, uniqueness is determined by comparing the error address, correctable or uncorrectable error type and the bad bit (depending on ECC or MBIST logic) of the incoming error with the one stored in buffer. If the error buffer is full, and the incoming error to be stored in the error buffer is not yet in the error table, Error Buffer Overflow (EBO) is registered and the corresponding bit in the Concurrent Overflow Register is set., else the incoming error is dropped.
- While doing the error buffer uniqueness check, the type of error i.e Correctable Error (CE) or Uncorrectable Error (UCE) is also compared, hence even if the Error Address and the Bad bit fields (Depending on whether the incoming error is generated from ECC or MBIST logic) of the incoming error matches with the error buffer, if the type of errors (CE and UCE) differ they are treated as unique
- Determine the type and uniqueness of errors in the error comparison block and store them in the correct reporting table (correctable or uncorrectable)
- Generate signals to assert the necessary flags. Be aware that it takes several MEMU clock cycles (≤ 5 unless the error gets temporarily stored in the error

buffer due to a collision) for an error report to cause a signal to be sent to the FCCU.

3. Reporting table

This is a pre-defined table in the MEMU to store the details for the device. For the reporting table if the entry is unique it is stored in the reporting table. If the entry is not unique it is not stored and discarded.

The MEMU asserts proper flags when error is stored in the reporting table or an overflow is asserted. Flags are also asserted when the software writes the VLD bit to the reporting table.

The CPU can clear the flags signalling errors or overflows to the FCCU directly by writing 1 at the corresponding valid bit of the status register (i.e. [Section 79.6.2.4, System RAM correctable error reporting table status register \(SYS_RAM_CERR_STS_n\)](#) or [Section 79.6.2.6, System RAM uncorrectable error reporting table status register \(SYS_RAM_UNCERR_STS\)](#)). The clearing of flags is totally independent from the status of VLD bits in the reporting table.

The reporting table sizes are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

4. Register block

The CPU register programming interface comprises of memory mapped registers necessary for the CPU to access the reporting table and other control and status registers for the modules. Flags to FCCU will be asserted on write by CPU to the valid bit or by MEMU itself if a unique error is stored. However, in the situation when both MEMU and the CPU are accessing the same Register location, a wait cycle will be signalled to the CPU and the CPU command will be completed in the next clock cycle.

The software, in principle, is not supposed to write VLD to 1 if it is already 1.

The CPU register interface provides the decoding of the peripheral signals to allow access to the reporting table and other registers in module.

Figure 1969. MEMU error buffer uniqueness check flow chart

Figure 1970. MEMU reporting table uniqueness check flow chart

79.5 External signal description

MEMU has no external signals.

79.6 Memory map and register definition

79.6.1 Memory map

The memory map comprises 32-bit aligned registers that can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved address locations will generate a transfer error. Read data from reserved locations will also generate a transfer error and the read data bus will return all 0's.

Note: The module does not check for correctness of the programmed values in registers. Software must ensure that the correct values are being written.

The Control, Error Flag and Debug registers are common for all MEMU error reporting blocks. The correctable error status, correctable error address, uncorrectable error status, uncorrectable error address and concurrent error overflow registers are replicated for each MEMU instance.

Note: The actual availability, number of registers and number of reported errors in the reporting table are chip-specific; see the Device Configuration chapter that describes how modules are configured and connected.

Table 1825. MEMU memory map

Offset or address	Register	Access	Reset value	Section/ page

17–31	Reserved

79.6.2.2 Error flag register (ERR_FLAG)

Bits in the ERR_FLG register indicate:

- A new entry in an error reporting table has been made (indicated by PR_CE, PR_UCE, F_CE, F_UCE, SR_CE, and SR_UCE)
- An overflow condition has been encountered when attempting to make a new entry in an error reporting table (indicated by SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO)
- An overflow condition has been encountered in the internal error processing buffer of a MEMU reporting block.

Individual flags can be cleared by writing a '1'. This also resets the corresponding error indication to FCCU. Flags will not automatically reset if entries are removed from the reporting table. They have to be explicitly cleared by SW.

Bits SR_UCO, SR_CEO, F_UCO, F_CEO, PR_UCO, and PR_CEO are asserted when an overflow in the uncorrectable error reporting table is detected.

Table 1827. ERR_FLAG field descriptions

Field	Description
0–10	Reserved
11 PR_CE	Peripheral RAM ECC Correctable Error detect flag. Indicates that a new and unique Peripheral RAM ECC correctable error is detected. Asserted when a new entry is inserted into the correctable error reporting table (either by CPU or module) 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
12 PR_UCE	Peripheral RAM ECC Uncorrectable Error Detect flag. Asserted when a new Peripheral RAM ECC uncorrectable error was detected or a new entry is inserted into the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
13 PR_CEO	Peripheral RAM ECC Correctable error Overflow flag. Asserted when the Peripheral RAM ECC correctable error reporting table is full and a new entry is attempted to be made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
14 PR_UCO	Peripheral RAM ECC Uncorrectable error Overflow flag. Asserted when the Peripheral RAM ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.

Table 1827. ERR_FLAG field descriptions (continued)

Field	Description
15 PR_EBO	Peripheral RAM ECC Error buffer Overflow flag. Asserted when the internal error processing buffer of Peripheral RAM ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
16–18	Reserved
19 F_CE	Flash ECC Correctable Error Detect flag. Indicates that a new and unique Flash ECC correctable error was detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.
20 F_UCE	Flash ECC Uncorrectable Error Detect flag. Asserted when: – a new Flash ECC uncorrectable error was detected. – a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
21 F_CEO	Flash ECC Correctable Error Overflow flag. Asserted when the Flash ECC correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
22 F_UCO	Flash ECC Uncorrectable Error Overflow flag. Asserted when the Flash ECC uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
23 F_EBO	Flash ECC Error buffer Overflow. Flag Asserted when the internal error processing buffer of Flash ECC MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for MEMU to process them all. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.
24–26	Reserved
27 SR_CE	System RAM ECC and MBIST Correctable Error detect flag. Indicates that a new and unique System RAM ECC and MBIST correctable error is detected. Asserted when a new entry to the correctable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in correctable error reporting table is made.

Table 1827. ERR_FLAG field descriptions (continued)

Field	Description
28 SR_UCE	System RAM ECC and MBIST Uncorrectable Error Detect flag. Asserted when: – a new System RAM ECC and MBIST uncorrectable error is detected. – a new entry to the uncorrectable error reporting table is done (either by CPU or module) 0 No new and unique error detected. 1 New entry in uncorrectable error reporting table is made.
29 SR_CEO	System RAM ECC and MBIST Correctable error Overflow flag. Asserted when the System RAM ECC and MBIST correctable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the correctable error reporting table detected.
30 SR_UCO	System RAM ECC and MBIST Uncorrectable error Overflow flag. Asserted when the System RAM ECC and MBIST uncorrectable error reporting table is full and a new entry is made to this table. 0 No Overflow. 1 Overflow in the uncorrectable error reporting table detected.
31 SR_EBO	System RAM ECC and MBIST Error buffer Overflow. Flag asserted when the internal error processing buffer of System RAM ECC and MBIST MEMU reporting block has overflowed. This can happen when too many errors are reported in a short interval of time for processing by MEMU. The channel(s) from which error reports were dropped due to the overflow are indicated in the XXXXX_OFLW registers. This field will also be set to 1 if the input ASYNC FIFOs overflow. 0 No Overflow. 1 Overflow in the internal error processing buffer detected.

Table 1843. FLASH_OFLWn field descriptions

Field	Description
0–31 OFLW	Overflow Bit. Each bit corresponds to an error source and is asserted when any of the conditions mentioned in Section 79.7.3, Handling overflows (Multiple error reporting) , occurs.

79.7 Functional description

79.7.1 Initializing MEMU

MEMU is always enabled and can be configured by user software for known errors which the system/application has collected over a period of time. The MEMU logic will not update the reporting table corresponding to the programmed values which have the VLD bit SET.

The user software can write into the reporting table and must make VLD bit = '1' for the programmed entry to be valid. Any write by the CPU that asserts the VLD bit will cause a corresponding flag to FCCU.

The software can program the table with known error addresses by setting the valid bit and storing the corresponding error address. The sequence of programming to prevent a collision of reporting table entries written by the HW and the SW is as follows

- 1) Check that the VLD bit is not set,
- 2) Write an invalid address/bad bit information,
- 3) Set VLD bit,
- 4) Check that the address still has an invalid value,
- 5) Write address/bad bit information to desired address.

If the FCCU is programmed to cause an IRQ on new MEMU table entries, steps 3 to 5 should be executed with interrupts disabled to prevent any error handling SW to read the invalid address written in step 2). Note that in the case the software is in between the 3rd and the 6th step, and the MEMU writes an error with the same address that Software wants to program, both the errors will be stored in the reporting table (i.e. duplicate entries).

79.7.2 Reading the reporting table

The software at any time can read the reporting table via the software programming interface. It should read the entries with the valid bit set and take necessary action. To invalidate any entry, the valid bit must be cleared. Reading an entry which does not have the VLD bit set will return invalid data.

		Address [A:0]	Bad Bit [B:0]	Valid
Correctable	1			
	2			
	3			
	4			
	5			
	6			
				
				
	N			
	1			
Uncorrectable		(B+1) {1'b1}		
Flags				
Overflow Source Bits [C:0]				
		Address - The address associated with the table entry.		
		Bad Bit - (As needed) a binary encoding of the single bit that is in error.		
		Valid - A user clearable bit that indicates that the row is valid		
		Flags - Indications of important events that occurred.		
		Overflow Source Bits - A one hot encoding of the Source channel or channels that resulted in the overflow event.		

Figure 1989. Generic representation of the reporting table of one MEMU reporting block

79.7.3 Handling overflows (Multiple error reporting)

When a bit in the overflow registers (either error buffer or reporting table though the overflow registers are same) is asserted it can indicate the occurrence of one of the following conditions:

- a) Error buffer overflow–More than two memories reporting an error at the same instant or the input ASYNC FIFOs reach the FULL level (overflow)
- More than 2 errors detected at same time. This would lead to overflow in the error buffer. MEMU can process only one error at a time while storing the other in the error buffer. So this would be indicated as an overflow.The uniqueness check in the input buffer does not “guarantee” that an ECC-supervised memory with only one error will not be marked as overflow source. If that one error occurs together

with two (or more) additional errors at the same cycle it can get flagged as an overflow.

- b) Correctable/Uncorrectable Error Overflow—Overflow in correctable and uncorrectable reporting table occurs only when a unique entry is to be stored but the tables are already full (all entries have valid bit set).
 - AN ECC error which matches the address of an MBIST error is dropped (same as if it matched the address of an ECC error). In case, where a MBIST error comes with ECC error already in the table, both the address and bad bits are compared to determine uniqueness.
- c) The Overflows will be stored in the bit-wise order i.e., if the error bit 31 reports an error, the bit 31 of the overflow register will be set to '1'.

80 Indirect Memory Access (IMA)

80.1 Introduction

Indirect Memory Access (IMA) refers to the activity of accessing any chip memory for the purpose of reading and/or modifying data, including ECC check bits. This capability is useful for test activities, e.g., verifying ECC functionality.

The SPC57EM80xx MCU provides two mechanisms for IMA:

- The built-in CPU End2End ECC test capability provides a path for accessing data and ECC check bits from some SRAM arrays
- An IMA controller module provides registers for selecting, reading, and writing memory data.

Note: Not all SRAM data and ECC bits are accessible. See the Device Configuration chapter for details.

80.2 Accessing memory via CPU End2End ECC test

The processor cores can access all bits (including ECC check bits) in SRAM arrays that support E2E ECC with the exceptions of addresses that are blocked by MPU configuration.

Note: All memory accesses by the processor cores are filtered through the MPU. There are no back doors to blocked memory addresses.

SRAM is selected by absolute memory address with check bit data in a special register. The register used depends on which memory is being accessed—I-cache/D-cache, or other memory.

Since all CPU memory accesses are arbitrated by the crossbar (XBAR), there is no need to halt normal memory access in software.

Memory is accessed via processor core registers. The register(s) used depends on the memory being accessed. This is described in the following sections.

80.2.1 Accessing I-cache and D-cache memory via processor core

For I-cache and D-cache memory, the SRAM location is selected by cache way, set and word with data and check bits in registers provided specifically for reading and writing cache tag bits and ECC check bits. There are two Device Control Registers (DCRs) provided for cache access:

- Cache Debug Access Control Register (CDACNTL)
- Cache Debug Access Data Register (CDADATA)

These registers are summarized in the following sections.

80.2.1.1 Cache Debug Access Control register (CDACNTL)

The Cache Debug Access Control Register (CDACNTL) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

Figure 1990. Cache Debug Access Control Register (CDACNTL)

T/D	0			CWAY	0		CSET						WORD			PARITY CHECK BITS								0			CACHE	R/W	GO		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

The CDACNTL bits are described in [Table 1844](#).

Table 1844. CDACNTL field descriptions

Bits	Name	Description
0	T/D	Tag / Data: 0 Data array selected 1 Tag array selected
1–2	—	Reserved - read as zeros
3	CWAY	Cache Way. Specifies the cache way to be selected
4–5	—	Reserved - read as zeros
6–12	CSET	Cache Set. Specifies the cache set to be selected. Only valid set numbers for the selected cache are supported, otherwise results are undefined.
13–15	WORD	Word (Used for data array access only, I or D-cache) Specifies one of eight words of selected set
16–23	PARITY CHECK BITS	Parity check bits (I or D-cache) D-cache Data array, I-cache Data Array: parity check bits for data. Tag Array: parity check bits for tag.
24–27	—	Reserved - read as zeros
28	CACHE	Cache Select. Specifies the cache to be selected. 0 Selects the data cache for the operation. 1 Selects the instruction cache for the operation.
29	R/W	Read / Write: 0 Selects write operation. Write the data in the CDADATA register to the location specified by this CDACNTL register. 1 Selects read operation. Read the cache memory location specified by this CDACNTL register and store the resulting data in the CDADATA register and store the parity bits in this CDACNTL register.
30–31	GO	GO command bits 00 Inactive or complete (no action taken) hardware sets GO=00 when an operation is complete 01 Read or write cache memory location specified by this CDACNTL register. 1x Reserved

80.2.1.2 Cache Debug Access Data Register (CDADATA)

The Cache Debug Access Data Register (CDADATA) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to I-cache and D-cache memory.

Figure 1991. Cache Debug Access Data Register (CDADATA)

The CDADATA bits are described in [Table 1845](#).

Table 1845. CDADATA field descriptions

Bits	Name	Description
0–31	TAG	TAG Array Access Data - when accessing the tag array of the I-cache: 0–19Tag compare bits 20–22Reserved 23Valid bit 24R bit 25SO bit 26–28Reserved 29–31Lockout bits. These three bits should have the same value, 1-Locked out, 0- not locked out. TAG Array Access Data - when accessing the tag array of the D-cache: 0–20Tag compare bits 21–22Reserved 23Valid bit 24R bit 25SO bit 26SW bit 27UW bit 28Reserved 29–31Lockout bits. These three bits should have the same value, 1-Locked out, 0- not locked out.
	DATA	DATA Array Access Data (Bytes 0:3 of the selected word) - when accessing the data array of either cache: 0–7 byte 0 8–15 byte 1 16–23byte 2 24–31byte 3

80.2.2 Accessing non I-cache or D-cache memory via processor core

The e2eECC Error Control/Status Register 0 (E2EECSR0) is provided specifically for reading and writing E2E ECC check bits. This register is described in the following section.

80.2.2.1 e2eECC Error Control/Status Register 0 (E2EECSR0)

The e2eECC Error Control/Status Register 0 (E2EECSR0) is a 32-bit privileged register (available only in supervisor and debug modes) that provides access to E2E ECC data. It is shown in the following figure.

Figure 1992. e2eECC Error Control/Status Register 0 (E2EECSR0)

0				RCHKBIT								0				WRC	INVC	0				WCHKBIT/CHKINVT									
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

The E2EECSR0 bits are described in [Table 1846](#).

Table 1846. CDACNTL field descriptions

Bits	Name	Description
0–3	—	Reserved - read as zeros
4–11	RCHKBIT	Read Checkbits. This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the data BIU. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation, assuming interrupts are masked.
12–15	—	Reserved - read as zeros
16–17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) with the values in the WCHKBIT control field. Software must clear this field before re-writing to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10, by driving the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved <i>Note: Checkbit substitution has priority over Error injection</i>
18–19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before re-writing to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved <i>Note: Checkbit substitution has priority over Error injection</i>
20–23	—	Reserved - read as zeros
24–31	WCHKBIT/CHKINVT	Write Checkbits / Checkbit Invert Mask. This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out when error injection occurs.

80.3 Accessing memory via the IMA module

The Indirect Memory Access (IMA) module provides an alternative way to access on-chip memory without going through standard peripheral or system RAM interfaces to check the data or change the data.

This alternative path can be used for diagnostic purposes. For example, for SRAM arrays that do not support E2E ECC, the IMA block provides a way to write corrupted ECC values so that the ECC error decoding logic can be checked.

Please note the following restrictions on memory access via IMA:

- ECC must be disabled prior to IMA write access. If ECC is enabled and a write access is attempted to ECC-bits, the write access is blocked and an error signal is forwarded to the FCCU and the corresponding error flag is set. Read access is always allowed.
- The IMA must be unlocked for reads

The order of precedence for access to a memory is shown below. Once the IMA has been granted access, no other accesses are allowed until the IMA select line to the selected memory is negated by the IMA.

Note: Once the IMA has selected a RAM, it expects no other accesses from any other master until deselected by the IMA.

The IMA module signals the FCCU when it is reading or writing to a memory address. This enables the FCCU to assess whether the access is intentional or spurious. For an intentional access the respective FCCU error input needs to be disabled, otherwise it should be enabled.

80.3.1 Features

The IMA module includes the following features:

- Able to read all bits in all RAM arrays connected to the IMA, once the IMA is unlocked for reads
- Enables reading and manipulation of ECC check bits.
- During an IMA SRAM access, other accesses are affected as follows:
 - Reads return random data.
 - Writes have no effect.
- Any IMA access to memory are indicated in the Fault Collection and Control Unit (FCCU).
- IMA accesses to memory do not bypass any SRAM repair which may have occurred during production test of the device.
- IMA accesses to memory use a physical address, not a logical address, and thus memory addresses used by the IMA are not memory mapped.

80.3.2 Block diagram

The following figure shows the structure and function of the IMA module. The Register Control Block contains the memory-mapped registers accessible by software. The Safety Block prevents spurious activation of the IMA module. It ensures the IMA does not access RAM unless the system needs it to.

Figure 1993. IMA block diagram

80.3.3 IMA Module Memory Map and Registers

This section provides details of the IMA memory map. [end] It also provides detailed descriptions for each of the registers in that map.

The Indirect Memory Access unit's memory map allows for the CPU to access RAM's on the chip to write test data so that single-bit ECCs and multi-bit ECC logic can be tested.

Table 1847. IMA Memory Map

Offset or Address	Register	Access	Reset Value	Section/Page
0000_0000	IMA Control Register (IMA_CTRL)	R/W ⁽¹⁾	0x0000_0000	80.3.3.1/3464
0000_0004	IMA Enable Access Register (IMA_ENABLE)	R/W	0x0000_0000	80.3.3.2/3465

0000_0010	IMA Write Unlock Register (IMA_WRITE_UNLOCK)	R/W	0x0000_0000	80.3.3.5/3468
0000_0014	IMA Read Unlock Register (IMA_READ_UNLOCK)	R/W	0x0000_0000	80.3.3.6/3469
0000_002C	IMA RAM Write Data Register 4 (IMA_WRITE_DATA_4)	R/W	0x0000_0000	80.3.3.7/3470
0000_0030	IMA RAM Write Data Register 3 (IMA_WRITE_DATA_3)	R/W	0x0000_0000	80.3.3.7/3470
0000_0034	IMA RAM Write Data Register 2 (IMA_WRITE_DATA_2)	R/W	0x0000_0000	80.3.3.7/3470
0000_0038	IMA RAM Write Data Register 1 (IMA_WRITE_DATA_1)	R/W	0x0000_0000	80.3.3.7/3470
0000_003C	IMA RAM Write Data Register 0 (IMA_WRITE_DATA_0)	R/W	0x0000_0000	80.3.3.7/3470
0000_004C	IMA RAM Read Data Register 4 (IMA_READ_DATA_4)	R	0x0000_0000	80.3.3.8/3471
0000_0050	IMA RAM Read Data Register 3 (IMA_READ_DATA_3)	R	0x0000_0000	80.3.3.8/3471
0000_0054	IMA RAM Read Data Register 2 (IMA_READ_DATA_2)	R	0x0000_0000	80.3.3.8/3471
0000_0058	IMA RAM Read Data Register 1 (IMA_READ_DATA_1)	R	0x0000_0000	80.3.3.8/3471
0000_005C	IMA RAM Read Data Register 0 (IMA_READ_DATA_0)	R	0x0000_0000	80.3.3.8/3471

1. Note that R/W registers may contain some read-only or write-only bits.

80.3.3.1 IMA Control Register (IMA_CTRL)

The IMA CTRL register controls read/write accesses. Since the IMA may interfere with proper read/write access of RAMs, a locking scheme is implemented to prevent accidental activation of the IMA. Using this scheme, the IMA read/write accesses can be locked when desired.

Figure 1994. IMA Control Register (IMA_CTRL)

Offset 0x00												Access: User read/write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 1848. IMA_CTRL field descriptions

Field	Description
0–30 Reserved	
31 READ	IMA Read. This bit controls whether the IMA will perform a read or write 0 The IMA access will be a write. 1 The IMA access will be a read.

80.3.3.2 IMA Enable Access Register (IMA_ENABLE)

The Enable Access Register is a single-bit register that starts an IMA access. The bit automatically clears itself after two clocks thus providing an enable pulse.

Note: *Back to back writes to the enable bit is not valid. It will still generate a two clock enable pulse and will be considered as a single access initiation.*

Figure 1995. IMA Enable Access Register (IMA_ENABLE)

Offset 0x04 Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1

Table 1850. IMA_STATUS field descriptions

Field	Description
0–22 Reserved	
23 WRITE_LOCK	The ability of the IMA to do write accesses. The WRITE_LOCK bit shows the current status of the lock on IMA write accesses. If set, the IMA does not write to the memories. If cleared, the IMA is allowed to do writes to the memories. 0 Write accesses from the IMA to memories are allowed 1 Write accesses from the IMA to memories are not allowed. Any memory writes from the IMA are ignored.
24–30 Reserved	
31 READ_LOCK	The ability of the IMA to do read accesses. The READ_LOCK bit shows the current status of the lock on IMA read accesses. If set, the IMA does not do reads from the memories. If cleared, the IMA is allowed to do reads from the memories. 0 Read accesses from the IMA to memories are allowed. 1 Read accesses from the IMA to memories are not allowed. Any memory reads from the IMA are ignored.

80.3.3.4 IMA RAM Select Register (IMA_SLCT)

The IMA RAM Select register provides a method of selecting which RAM memory block will be accessed. This method is used because RAM is to be accessed in a non-functional way, i.e., accessing all bits including the ECC, and accessing on RAM word boundaries instead of byte or 32-bit word boundary.

Note: Only one RAM can be selected at a time. Each SoC has a different encoding for the RAMs. See the Device Configuration chapter for details.

Figure 1997. IMA RAM SELECT Register (IMA_SLCT)

Offset 0x0C												Access: User read/write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	ROW_SLCT												
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	ARRAY_SLCT					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1851. IMA_SLCT field descriptions

Field	Description
0–2 Reserved	
2–15 ROW_SLCT	The ROW_SLCT value specifies the row of the current RAM array under test to be selected. Hence the largest RAM which the IMA can access is an 8 KB word RAM.
16–25 Reserved	
26–31 ARRAY_SLCT	The ARRAY_SLCT specifies the RAM array to be tested. Up to 64 RAM instances can be supported.

80.3.3.5 IMA Write Unlock Register (IMA_WRITE_UNLOCK)

The Unlock register is a safety feature to ensure that the IMA does not access RAMs unless the system needs for it to access the memories. The unlock register has to be written with two unique values for the IMA to unlock. The WRITE_LOCK bit in the IMA_STATUS register indicates whether the IMA is unlocked for writes.

Figure 1998. IMA Write Unlock Register (IMA_WRITE_UNLOCK)

Offset 0x10				Access: User read/write															
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31			
R	READ_KEY																		
W																			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1853. IMA_READ_UNLOCK field descriptions

Field	Description
0–31 READ_KEY	Key to unlock the IMA Read Access to RAMs. – 0xF06AB5BC is the first key that has to be written to start the unlock process. – 0x14081B56 is the second key that has to be written to unlock the IMA.

80.3.3.7 IMA RAM Write Data Register n (IMA_WRITE_DATA_n)

The IMA_WRITE_DATA_n registers hold the data values to be written to the RAM. The number of active data bits depends on the number of IOs for the RAM selected. Upper unused write data bits are ignored during the RAM access. With IMA_CTRL[READ] set to 0, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a write access.

Figure 2000. IMA RAM Write Data Register n (IMA_WRITE_DATA_n)

Table 1854. IMA_WRITE_DATA_n field descriptions

Field	Description
0–31 WRITEn	Contains data to be written to RAM. – WRITE_DATA_4[WRITE_4] contains write data bits[159:128] – WRITE_DATA_3[WRITE_3] contains write data bits[127:96] – WRITE_DATA_2[WRITE_2] contains write data bits[95:64] – WRITE_DATA_1[WRITE_1] contains write data bits[32:63] – WRITE_DATA_0[WRITE_0] contains write data bits[31:0]

80.3.3.8 IMA RAM Read Data Register n (IMA_READ_DATA_n)

The IMA_READ_DATA_n registers hold the data values read from the RAM. The number of active data bits depends on the number of IOs for the RAM selected. Upper unused READ DATA bits are updated to zeroes during the RAM access. With IMA_CTRL[READ] set to 1, by writing a 1 to the IMA_ENABLE[EN] bit, the IMA will begin a read access. Performing a read operation on IMA_READ_DATA_n registers causes data from RAM to be latched into these registers and presented to the CPU on the next clock.

Figure 2001. IMA READ_DATA_n Register (IMA_READ_DATA_n)

Table 1855. IMA_READ_DATA_n field descriptions

Field	Description
0–31 WRITEn	Contains data to be written to RAM. – READ_DATA_4[READ_4] contains read data bits[159:128] – READ_DATA_3[READ_3] contains read data bits[127:96] – READ_DATA_2[READ_2] contains read data bits[95:64] – READ_DATA_1[READ_1] contains read data bits[32:63] – READ_DATA_0[READ_0] contains read data bits[31:0]

80.3.4 IMA module functional description

This section describes the operation of the IMA, beginning with the unlocking of reads and writes, the software initialization, then the software interface for generating single-bit ECC errors, generating multiple-bit ECC errors, and a software supported memory BIST.

80.3.4.1 Initialization sequence

This section describes which registers are reset due to hardware reset and what locations the user must initialize prior to doing an access by the IMA.

80.3.4.2 Hardware controlled initialization

In the IMA, registers and control logic are reset by hardware (system reset). A system reset deasserts output signals and resets general configuration bits.

80.3.4.3 User initialization (prior to asserting IMA_ENABLE[EN])

The user needs to initialize portions of the SoC prior to setting the IMA_ENABLE[EN] bit. The exact values depend on the particular application. Please consult the specific chapter's memory map to see how to turn off that peripheral so that accesses are not happening at the same time as the IMA. Without the peripheral shut down, there is a small chance that the IMA and the peripheral can interfere with each other in accessing the RAM.

80.3.4.3.1 Shut down the peripheral

The IMA can cause problems with the system or the peripheral if both the IMA and the other system components are accessing the RAM during normal operation.

To shut down the peripheral, please read the peripheral's documentation. The documentation will describe how to put the peripheral into a quiet state so that it will not access the RAM during the IMA access. If the other functional path is running at the same time, the data for the other peripheral will be corrupted and unknown.

80.3.4.3.2 Unlocking reads

The IMA will not allow a read to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the READ_KEY register to unlock writes. To unlock the read feature, the system will have to do the following:

1. Write 0xF06AB5BC to READ_KEY
2. Write 0x14081B56 to READ_KEY

The IMA has two features to make the READ_KEY lock in the following instance:

- Writing an incorrect key to READ_KEY

80.3.4.3.3 Unlocking writes

(The IMA will not allow a write to any memory unless it has been unlocked. This is a safety feature so that it will take two unique writes to the WRITE_KEY register to unlock writes. To unlock the write feature, the system will have to do the following:

1. Write 0x04A43F95 to WRITE_KEY
2. Write 0xE4A9EBF7 to WRITE_KEY

The IMA has a feature to make the WRITE_KEY lock in the following two instances:

1. Writing an incorrect key to WRITE_KEY
2. Not setting the IMA_ENABLE[bit] for 16,384 system clocks.

80.3.4.4 IMA lock

The IMA module also allows for read/write access locking via an input pin. If this input is asserted, both read/write accesses via IMA are locked. This locking scheme overrides the above KEY based locking scheme. Hence it provides additional safety over the KEY based locking method. However, usage of this feature is entirely SOC specific.

80.3.4.5 IMA access

There are two differences between a read access and a write access. The first difference is that the IMA_STATUS[WRITE_LOCK] bit has to be cleared for writes and the IMA_STATUS[READ_LOCK] has to be cleared for reads. The second difference is that the IMA_CTRL[READ] has to be set for reads and IMA_CTRL[WRITE] has to be cleared for writes.

The following sections show the different accesses that are available depending on the options.

80.3.4.5.1 Read access

Read Accesses are expected to follow the sequence below

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Set the READ bit in the IMA_CTRL register
4. Set the EN bit in the IMA_ENABLE register to initiate read access. The EN bit will self-clear after two clocks.
5. Software must wait an appropriate number of clocks depending on the speed of the SRAM for the access to complete.
6. Read data from READ_DATA registers. This causes data from RAM to be latched into the IMA and returned to the CPU on the next clock.

80.3.4.5.2 Write access

Write Accesses are expected to follow the sequence below

1. Unlock Read Access by performing appropriate consecutive writes to READ_UNLOCK register.
2. Based on the address to be accessed, write the ARRAY_SLCT and ROW_SLCT fields in the IMA_SLCT register.
3. Write the Write Data in WRITE_DATA registers.
4. Clear the READ bit in the IMA_CTRL register
5. Set the EN bit in the IMA_ENABLE register to initiate write access. The EN bit will self-clear after two clocks.
6. Software must wait an appropriate number of clocks for the IMA write to occur, depending on the speed of the SRAM being written.

80.3.5 Application information

Warning: The IMA will inhibit correct operation of the underlying peripherals. The application software is responsible for ensuring there is not a resource conflict.

The primary function of the IMA module is to provide a means for the system to program invalid ECC bits and see that the appropriate peripheral is able to detect the error. For a

single-bit error, the peripheral should be able to correct the error. For a multiple-bit error, the peripheral should report an error.

81 Fault Collection and Control Unit (FCCU)

81.1 Introduction

The Fault Collection and Control Unit (FCCU) offers a hardware channel to collect errors and to place the device into a safety state when a failure in the device is detected. No CPU intervention is requested for collection and control operation.

The FCCU offers a systematic approach to fault detection and control. The distinctive features of the module are:

- Redundant collection of hardware checker (e.g. RCCU) results
- Redundant collection of error information from safety relevant modules on the device
- Collection of test results
- Configurable and graded fault control
- Internal reactions (independently configurable for each RF):
 - No reset reaction
 - IRQ
 - Short functional reset
 - Long functional reset
 - NMI
- External reaction (failure is reported to the outside world via one or more output pins)
- Watchdog timer for the reconfiguration phase
- The FCCU's configuration is lockable in two ways:
 - Permanently locked until next reset or transiently locked until a specific key is written. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (ie., other than 0XBC). Key to lock the FCCU permanently is 0XFF, written in the FCCU_TRANS_LOCK register.
- One of the failure indication pins is high to indicate operational (OK) state (in bi-stable operation mode). The above is not true in case the failure indication protocol is configured to be a toggling protocol i.e. dual rail and time switching.
- After power-on the error out pins have high impedance. FCCU goes to operational state only on software request.
- In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_{min} , even if SW tries to release it before (for the case of error pin configured in Bi-stable mode only). $T_{min} = 250 \mu s + \Delta T$, with ΔT parameter being configurable by SW up to 10 ms.
- The overall error detection, processing and indication time is less than 10 ms.
- The actual maximum time is 5 safe (IRCOSC) clock cycles.

Two classes of fault are identified based on the criticality and the related reactions. Internal (short or long functional reset request pulse, interrupt request) and external (EOUT signaling) reactions are statically defined or programmable based on the fault criticality. The default configuration can be modified only in a specific FCCU state for application/test/debugging purposes.

81.1.1 Acronyms and abbreviations

Table 1856. Acronyms and abbreviations

Term	Description
UF	Unrecoverable fault
CPU	Central processing unit
EOUT	Error out
FOSU	FCCU output supervision unit
FSM	Finite state machine
INTC	Interrupt controller
intf	Interface
IRQ	Interrupt request
MC	MC_CGM, MC_ME, MC_PCU, and MC_RGM modules
RF	Recoverable fault
NMI	Non-maskable interrupts
NVM	Nonvolatile memory
RCC	Redundancy control checkers
RCCU	Redundancy control checker unit
SoC	System-on-chip
STCU	Self-test control unit
SW	Software
WKPU	Wake-up unit

81.2 Main features

- 1 to 128 recoverable faults management
- HW or SW fault recovery management
- Fault detection collection
- Fault injection (fake faults; see the implementation-specific details)
- External reaction (fault state): EOUT signaling. Failure indication via the pin(s) is controlled by the FCCU.
- Internal (SoC) reactions (alarm state): interrupt request
- Internal (SoC) reactions (fault state): long functional reset request pulse, short functional reset request pulse, NMI
- Bi-Stable, Dual-Rail and Time Switching output protocols on EOUT
- Watchdog timer for the reconfiguration phase
- Configuration lock

81.2.1 Standard features

- IPS (slave bus signals) bus interface

81.3 Block diagram

The top-level diagram of the FCCU module is given in [Figure 2002](#).

Figure 2002. FCCU block diagram

The FCCU module includes the submodules listed in [Table 1857 \(FCCU submodules\)](#).

Table 1857. FCCU submodules

Submodule	Description
REG intf	Includes the register file, the IPS bus interface, the IRQ interface and the parity block (PB) for the configuration registers
HNSHK blocks (master and slave blocks)	Includes the FSMs to support the handshake between the REG if and the FSM unit due to the usage of 2 asynchronous clocks (IPS system clock and RC oscillator clock)
FSM unit	Implements the main functions of the FCCU. The FSM also includes the: – Watchdog timer (WDG) – Alarm timer (ALRT)
FAULT intf	Implements the interface for the fault conditioning and management
EOUTx units	Implement the output stage to manage the EOUT interfaces

81.4 Signal description

81.4.1 Pinout

The FCCU generates two external signals, EOUT[0] and EOUT[1]. These are described in [Section 81.5.9, EOUT interface](#).

For the availability of these signals on a chip, see the device configuration chapter.

81.4.2 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus operations (contiguous byte enables) are supported:

- word (32 bits) data write/read operations to any registers
- low and high half-words (16 bits, data[31:16] or data[15:0]) data write/read operations to any registers
- byte (8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data write/read operations to any registers
- any other operation (free byte enables or other operations) must be avoided.

The FCCU module generates a transfer error in the following cases:

- any write/read access executed outside the address space of the peripheral.
- any write/read operation different from byte/hword/word (free byte enables or other operations) on each register.
- any write access to the configuration registers not executed in CONFIG state
- any write access to the Transient and permanent Lock Register in any mode other than supervisor access mode

The registers of the FCCU module are accessible (read/write) in each access mode: user, supervisor or test.

81.5 Functional description

81.5.1 Definitions

In general, the following definitions are applicable for the fault management:

- HW recoverable fault: the fault indication is an edge-triggered and level-sensitive signal that remains asserted until the fault cause is asserted. That is, if 0 on the fault signal indicates fault, then the status flags are valid until the fault line is '0'. The status is automatically cleared when the fault signal goes to 1. Typically the fault signal is latched in an external module at the FCCU. The FCCU state transitions are consequently executed on the state changes of the input fault signal. No SW intervention in the FCCU is required to recover the fault condition.
- SW recoverable fault: the fault indication is a signal asserted without a defined time duration. The fault signal is latched in the FCCU. The fault recovery is executed following a SW recovery procedure (status/flag register clearing).

HW recoverable is an option to exclude the handling of error source/s by FCCU management SW, in case it is known that the error is recoverable by itself when the error condition gets corrected.

The following types of reset are applicable:

- Destructive reset: any type of reset related to a power failure condition that implies a complete system re-initialization
- Long functional reset: implies the Flash and digital circuitry (most of it except FCCU, STCU) initialization
- Short functional reset: implies the digital circuitry (most of it except FCCU, STCU) initialization.

81.5.2 FSM description

The FCCU module functionality is depicted by the FSM diagram given in [Figure 2003](#).

Basically four states are identified with the following meaning:

- **CONFIG:** The configuration state is used only to modify the default configuration of the FCCU. A sub-set of the FCCU registers, dedicated to define the FCCU configuration (global configuration, reactions to fault, time-out, recoverable fault masking) can be accessed in write mode only in the CONFIG state.
The CONFIG state is accessible only in NORMAL state and if the configuration is not locked. The permanent configuration lock can be disabled by a reset of the FCCU, the transient lock register is unlocked by writing BCh into it. FCCU gets transiently locked again if an invalid key is written into FCCU_TRANS_LOCK register (ie., other than 0XBC). Key to lock the FCCU permanently is 0XFF, written in the FCCU_TRANS_LOCK register. After reset lifts, the state shall be transiently locked (permanent lock → is unlocked and transient lock → is locked).
The CONFIG to NORMAL state transition can be executed by SW or automatically following a time-out condition of the watchdog. In case the timeout information and the SW request to mode change to NORMAL appears at the same time, watchdog timeout had the priority and hence the Configuration registers (those that are writeable only in CONFIG mode) are reset to their default values. The movement to NORMAL is made. The incoming faults, occurring during the configuration phase (CONFIG state) are anyway latched in order to process them when the FCCU is moved into the NORMAL state, according to the new configuration.
- **NORMAL:** This is the FCCU's operating state when no faults are occurring. It is also the default state on the reset exit. Following one of the following events:
 - unmasked recoverable faults with the time-out disabled → the FCCU moves to the FAULT state
 - unmasked recoverable faults with the time-out enabled → the FCCU moves to the ALARM state
 - masked recoverable faults → the FCCU stays in NORMAL state
- **ALARM:** the FCCU moves into the ALARM state when a unmasked recoverable fault occurs and the time-out is enabled. The transition to the ALARM state goes along with an interrupt (irq_alarm), if enabled. By definition, this fault may be recovered within a programmable time-out period, before it generates a transition to the FAULT state. The time-out is re-initialized if the FCCU state moves to the NORMAL state. The time-out restarts following the recovery from the FAULT state.
- **FAULT:** the FCCU moves into the FAULT state when one of the following condition occurs:
 - time-out related to a recoverable fault when the FCCU is in the ALARM state
 - unmasked recoverable faults with the time-out disabled

The transition from NORMAL/ALARM state goes along with the generation of:

- NMI interrupt (optional)
- EOUT signaling (optional)
- SW option: Soft reaction (Short functional reset request pulse if configured)
- SW option: Hard reaction (Long functional reset request pulse if configured)

Non Maskable Interrupt (NMI) is routed only to the Safety Core.

Figure 2003. FCCU state diagram

81.5.3 Reset interface

The FCCU has two input resets, as described in [Table 1858](#) and two output resets related to the FAULT state. In FAULT state, each fault can be programmed to generate a soft or hard reaction request pulse.

In [Table 1859](#) for each type of fault reaction (hard, soft or self-checking), the respective output reset (rst_lfunc_b, rst_sfunc_b) is activated. In [Table 1860](#) for each type of reset source (external reset, POR, STCU, FCCU failure, short functional, long functional), the respective FCCU input reset state is described.

The MC unit is responsible to generate the corresponding input reset as described in [Table 1859](#) and [Table 1860](#). [Table 1859](#) and [Table 1860](#) describe a typical reset strategy at system level. [Table 1861](#) summarizes the MC actions corresponding to each reset generated by FCCU.

Table 1858. Input reset

Input reset	Description
ipg_hard_asynch_rst_clk_b	Global reset of the FCCU (synchronous to the system clock)
ipg_hard_asynch_rst_clk_safe_b	Global reset of the FCCU (synchronous to the IRCOSC)

Table 1859. Reset reactions

FAULT reaction	Active reset	ipg_hard_asynch_rst_*_b
Hard	rst_lfunc_b	disabled
Soft	rst_sfunc_b	disabled

[Table 1860](#) shows the Reset sources.

Table 1860. Reset sources

Reset source	ipg_hard_asynch_rst_*_b
External reset	enabled
POR	enabled
STCU	enabled
FCCU failure	application dependent
Functional reset	disabled

Table 1861. MC actions

Active reset	MC action
rst_lfunc_b	Long functional reset (FLASH + digital modules excluded FCCU, STCU)
rst_sfunc_b	Short functional reset (digital modules excluded FCCU, STCU)

In reset state the FCCU is not able to collect any RF. The FCCU reset phase (POR, external reset, STCU, destructive reset, FCCU failure) must guarantee the assertion of the FCCU input resets at least for 2 IRCOSC clock periods.

81.5.4 Fault priority scheme and nesting

The FAULT state has a higher priority than the ALARM state in case of concurrent fault events (and recoverable) that occur in the NORMAL state.

The ALARM to FAULT state transition occurs if a recoverable fault (unmasked and with time-out disabled) is asserted in the ALARM state.

The ALARM to NORMAL state transition occurs only if all the recoverable faults (including the faults that have been collected after the entry in the ALARM state) have been cleared (SW or HW recovery) otherwise the FCCU will remain in the ALARM state.

The FAULT to NORMAL state transition occurs only if all the recoverable faults (including the faults that have been collected after the entry in the FAULT/ALARM state) have been

cleared (SW or HW recovery) otherwise the FCCU will return in the ALARM state (if any recoverable fault is still pending and the time-out is not elapsed).

In general, no fault nesting is supported except for the recoverable faults that causes a ALARM to FAULT state transition. In this case the NCT timer is stopped until the FAULT state is recovered.

81.5.5 Fault recovery

The following timing diagrams describe the main use cases of the FCCU in terms of fault events and related recovery.

A typical sequence related to a recoverable FAULT management (ALARM state), see [Figure 2004](#) and [Figure 2005](#), is as follows:

- recoverable fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
 - alarm interrupt request (if configured)
 - time-out running
- system state: RUN
- alarm interrupt management: FAULT recovery (by SW)—FCCU state transition ALARM → NORMAL

Figure 2004. Recoverable FAULT (ALARM state) recovery (a)

Figure 2005. Recoverable FAULT (ALARM state) recovery (b)

A typical sequence related to a recoverable FAULT management (ALARM → FAULT state), see [Figure 2006](#), is as follows:

- recoverable fault assertion
- FCCU state transition (automatic): NORMAL → ALARM
 - alarm interrupt request (if enabled)
 - time-out running
- FCCU state transition (following the time-out trigger): ALARM → FAULT — xNMI assertion (if enabled)
- system state transition: RUN → SAFE
- NMI interrupt management (if enabled)
 - FAULT recovery (by SW): FCCU state transition FAULT → NORMAL
 - system state transition: SAFE → RUN

Figure 2006. Recoverable FAULT (ALARM -> FAULT state) recovery

81.5.6 NMI interface

BLG The NMI signal internally generated by FCCU is masked when:

- FCCU asynchronous reset
- MC's current mode (`mc_state[3:0]`) = RESET

and unmasked when a SW change request of the MC state is triggered (`sw_mode_change_req` = 1).

81.5.7 FAULT interface

The basic functionality of the fault interface is to provide a simple programmable edge sensitive interface (active high or low) to signal a fault condition to the FCCU module.

To support a fault injection mechanism, in order to generate fake faults directly in the FAULT root, an additional and optional signal is available. It is an active high signal and is asserted for a single clock cycle synchronously at the system clock. The behavior is given in [Figure 2007](#). The fault injection is executed by a write operation in the FCCU_RFF register. The reaction following a fake recoverable fault can be masked. The fault injection mechanism is optional; see the implementation-specific details.

To support a fault clearing mechanism, in order to clear a fault latched directly in the FAULT root, an additional and optional signal (`fccu_rf_clr`) is available. This active-high signal is asserted for a single clock cycle synchronously at the system clock. The behavior is given in [Figure 2008](#). The fault clearing is executed when the SW "clears" the status (flag) bits of the

FCCU_RF_Sx. The fault clearing mechanism is optional and its support must be specified at system level.

Figure 2007. FAULT injection

Figure 2008. FAULT clearing

81.5.8 STCU interface

The STCU interface includes:

- a set of signals resulting from the self-checking procedure connected externally at these FCCU faults:
 - recoverable

The STCU fault signals are processed by the FCCU when the SOC is rebooted following the self-testing procedure. The STCU includes also a status register that stores the self-testing results (flags).
- a mask (`fccu_eout_msk[1:0]`) that inhibits the EOUT dummy signaling until the STCU self-checking procedure has been completed.

During the self testing procedure, depending on the STCU results, three cases are applicable:

- STCU completes the self testing procedure successfully. The SOC reboots and the FCCU is responsible to provide a reaction.
- STCU completes the self testing procedure with low severity failures. The FCCU is responsible to provide the proper reactions according to the fault occurred.
- STCU completes the self testing procedure with serious failures. The FCCU or other critical parts of the SoC could not be able to provide the proper reaction. STCU should keep permanently the SoC in RESET state. This feature is optionally programmable inside the STCU.

Figure 2009. STCU-FCCU (case a)

Figure 2010. STCU-FCCU (case b)

Figure 2011. STCU-FCCU (case c)

81.5.9 EOUT interface

The FCCU provides up to two bidirectional signals (EOUT interface) as a failure indication to the external world (see table “FCCU failure inputs” in the “Functional safety” chapter for details). These signals need to be mapped to appropriate pins for external visibility. Since SIUL2 does not control the pad buffer enable during Alternate function, FCCU provides a mechanism to drive the pad in OD (Open Drain) mode where the pad is driven Hi-Z only when FCCU drives logic ‘1’ else it drives logic ‘0’ (when FCCU drives logic ‘0’). The selection

to OD is done by OD bit in FCCU_CFG register. Different protocols for the EOUT interface are supported, selecting the FCCU_CFG.FOM register field:

- Dual rail protocol
- Time switching protocol
- Bi-stable protocol
- Test mode

The signal polarity can be programmed by setting the PS fields in the FCCU_CFG register. For example, for PS = 0, fcc_eout[0] = 0 and fcc_eout[1] = 1 in FAULT state for bi-stable and for PS = 1, it is inverted. All the diagrams and tables are related to the default configuration selection: switching mode (FCCU_CFG.SM = 0b). In case of inverted polarity (FCCU_CFG.PS = 1b) all the values on the EOUT output pins are inverted.

Two modes can be programmed to define the EOUT protocol transitions in dual-rail or time-switching mode:

- slow switching mode: no EOUT frequency violation during the FCCU state transition (NORMAL to ERROR or viceversa and CONFIG to NORMAL). The EOUT protocol transition occurs after a max delay equal to the duration of the semi-period of the EOUT frequency.
- fast switching mode: The EOUT protocol transition (NORMAL to ERROR or viceversa and CONFIG to NORMAL) occurs immediately. A pulse with the minimum duration corresponding to 16 MHz/1024 (IRCOSC clock) period can occurs in fast switching mode. It implies a frequency violation of the EOUT protocol.

The EOUT frequency is generated by dividing IRCOSC clock by a fixed factor of 2^{18} . With an IRCOSC clock of 16 MHz, this drives a signal of 61 Hz on EOUT.

The external monitor of the EOUT protocol should oversample the EOUT signals in order to synchronize periodically the external clock (used by the monitor) and the IRCOSC clock detecting the edge transition of the EOUT protocol in dual-rail or time-switching mode.

In case of a failure event or on software request for Error pin indication, the pin(s) are set to faulty state for a minimum time T_min, even if SW tries to release it before. If SW configures the error pins to OK(1) and if a fault comes trying to drive the pin to NOK(0), then priority is given to the fault indication and error pins indicate NOK ie. an incoming fault is not masked when SW has set the error pin to high. During the T_min by a non-SW fault, the FCCU FSM moves independently of this pin state (low) and as soon as the timer expires, the pin behavior is dictated by the state in which the FSM finds itself in and it is not possible to set the pins to OK by SW moving FCCU to CONFIG state, as long as this timer is running. No SW intervention is needed to bring the pin from the low state. The SW can bring the pin back to OK state by clearing the faults and waiting for the T_min to expire, after which the FCCU automatically enters NORMAL state and the error pin indicates OK.

In case another failure event happens within T_min after a first one, the T_min counter is restarted.

Resets (except the power on reset and software bit FCCU_RST in RGM_PRST5 should not influence the state of the failure indication ie pins.

Note: The transition from error to config state is not possible but is shown to display the behavior in all four states — reset, normal, error, and config.

Table 1862. FCCU error pin behavior on STATE transitions⁽¹⁾

Fault signaling state	Transition from NORMAL to FAULT state			NORMAL+CONFIG states			Transition from NORMAL to ALARM state		
	with Fault disabled enabled						with Fault disabled enabled		
	Internal Error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad	Internal error pin	Error pin enable	Error pad
Disabled	NA OK	NA 1	NA OK	OK	1	OK	NA OK	NA 1	NA OK
Enabled	NA NOK	NA 1	NA NOK	OK	1	OK	NA OK	NA 1	NA OK

1. Table valid only after SW has written fccu_set_after_reset bit to 1.

Note: FCCU remains in NORMAL state when fault is disabled hence, “NA” (Not Applicable) appears in the above table.

81.5.9.1 Dual-rail protocol

Dual-rail encoding is an alternate method for encoding bits. In contrast with classical encoding, where each signal carries a single-bit value, dual-rail encoded circuits use two wires to carry each bit. The encoding scheme is given in [Table 1863](#) and the related timing diagram is given in [Figure 2012](#) and [Figure 2013](#).

Table 1863. Dual-rail encoding

Logical state	Dual-rail encoding (output pins fccu_eout[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	00	toggling
faulty	11	
reset	Hi impedance	no toggling
configuration	same as NORMAL	toggling

As long as FCCU is in NORMAL or ALARM state, output will show “non-faulty” signal. Output pins #0, #1 will toggle between 01 and 10 with a given frequency of 61 Hz.

In the RESET phase the output pins are set as “high impedance”.

Note: [Figure 2012](#) and [Figure 2013](#) are formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.

Figure 2012. Dual-rail protocol (slow switching mode)

Figure 2013. Dual-rail protocol (fast switching mode)

81.5.9.2 Time-switching protocol

The encoding scheme is given in [Table 1864](#) and the related timing diagram is given in [Figure 2014](#).

Table 1864. Time-switching encoding

Logical state	Time-switching encoding (output pins fccu_eout[1:0])	Note
non-faulty	10	toggling
non-faulty	01	
faulty	10	no toggling
reset	high-Z	no toggling
configuration	same as NORMAL	toggling

As long as FCCU is in NORMAL or ALARM state, outputs will show “non-faulty” signal. Output pins #0, #1 will toggle between 01 and 10 with frequency of 61 Hz.

In the FAULT state, the output pin fccu_eout[0] is set as low.

In Time Switching mode the second output (fccu_eout[1]) is the inverted signal of first output (fccu_eout[0]).

In the RESET phase the output pins are set as “high impedance”.

Note: *Figure 2014 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.*

Figure 2014. Time-switching protocol

81.5.9.3 Bi-stable protocol

The encoding scheme is given in [Table 1865](#) and the related timing diagram is given in [Figure 2015](#).

Table 1865. Bi-stable encoding

Logical state	Bi-stable encoding (output pins fccu_eout[1:0])	Note
non-faulty	01	no toggling
faulty	10	no toggling
reset	high-Z	no toggling
configuration	same as NORMAL	no toggling

In the FAULT state, the faulty logical state is indicated. In NORMAL or ALARM state, “no-faulty” state is indicated. In Bi-stable mode the second output (fccu_eout[1]) is the inverted signal of first output (fccu_eout[0]).

In the RESET phase the output pins are set as “high impedance”.

Note: *Figure 2015 is formatted to display the behavior in all four phases (reset, normal, error, and config), not to imply transitions between one phase to another. In particular, transition from error phase to config phase is not possible.*

Figure 2015. Bi-stable protocol

81.6 Register description

The FCCU registers are listed in [Table 1866](#). Any address offset not explicitly mentioned in [Table 1866](#) is reserved.

All the registers accessible in write mode only in CONFIG state (last column of the [Table 1866](#)) are referred as configuration registers. These configuration registers return to the default value after configuration watchdog timer expires. These are the registers protected by FCCU_TRANS_LOCK and FCCU_PERMNT_LOCK registers. The configuration register setting has effect only when the FCCU state exits from the CONFIG state.

For each possible RF failure source a different reaction shall be configurable through the use of NMI, IRQ, long/short reset selection registers as well as no reaction by disabling the former registers. It is not possible for a single event upset to switch off all reactions on failures as implementation is per fault source (but it will be possible to switch them all off by SW if intended). Failures themselves are not able to disable all reactions and indications.

The FCCU is not reset by short or long functional resets.

Table 1866. FCCU register set

Address offset	Register	Access (1)	Register classification (2)	Location
000h	FCCU Control Register (FCCU_CTRL)	R/W always	Saf-Lat	on page 3496
004h	FCCU CTRL Key Register (FCCU_CTRLK)	W always	Saf-Relv	on page 3498
008h	FCCU Configuration Register (FCCU_CFG)	R always; W in CONFIG state only	Saf-Lat	on page 3498
01Ch	FCCU RF Configuration Register 0 (FCCU_RF_CFG0)	R always; W in CONFIG state only	Saf-Lat	on page 3500
020h	FCCU RF Configuration Register 1 (FCCU_RF_CFG1)		Saf-Lat	
024h	FCCU RF Configuration Register 2 (FCCU_RF_CFG2)		Saf-Lat

81.6.1 FCCU Control Register (FCCU_CTRL)

The FCCU_CTRL register allows to execute the following operations:

- moving the FCCU state from the NORMAL state into the CONFIG state
- moving the FCCU state from the CONFIG state into the NORMAL state
- reading or to clear the RF status register
- reading the FCCU FSM status register
- reading or to clear the FCCU freeze registers
- reading the ALARM timer
- reading the Watchdog timer
- configure the glitch filter present on location given by FILTER_POSITION parameter

Some critical operations requires a key as defined in the FCCU_CTRLK register.

Figure 2017. FCCU Control Register (FCCU_CTRL)

Table 1867. FCCU_CTRL field descriptions

Field	Description
FILTER_BYPASS	Filter bypass 0: glitch filter not bypassed 1: glitch filter bypassed
FILTER_WIDTH	Filter width 00: filters glitches up to 50 μ s 01: filters glitches up to 75 μ s 10,11: filters glitches up to 100 μ s for 20 MHz IRC clock
DEBUG	Debug mode entry 0: Normal operation 1: Put FCCU into debug mode When ipg_debug signal is asserted and this bit is set, FCCU moves into debug state and FCCU's FSM remains in the same state.

Table 1867. FCCU_CTRL field descriptions (continued)

Field	Description
OPS	Operation status 00: Idle 01: In progress 10: Aborted 11: Successful This bit can be read and cleared (via OP15 operation) by the software.
OPR	<i>Operation run</i> 00000: No operation [OP0] 00001: Set the FCCU into the CONFIG state [OP1] 00010: Set the FCCU into the NORMAL state [OP2] 00011: Read the FCCU state (see the FCCU_STAT register) [OP3] 00100: Read the FCCU frozen status flags (see the N2AF_STATUS register) [OP4] 00101: Read the FCCU frozen status flags (see the A2FF_STATUS register) [OP5] 00110: Read the FCCU frozen status flags (see the N2FF_STATUS register) [OP6] 00111: Read the FCCU frozen status flags (see the F2AF_STATUS register) [OP7] 01000: Read the FCCU frozen status flags (see the FCCU_SCFS register) [OP8] 01001: Reserved 01010: Read the RF status register (see the FCCU_RF_S register) [OP10] 01011: Reserved 01100: RF status clear operation in progress (see the FCCU_RF_S register) [OP12] 01101: Clear the freeze status registers (see the freeze registers) [OP13] 01110: CONFIG to NORMAL FCCU state (configuration timeout) in progress [OP14] 01111: Clear the operation status (OPS=Idle) [OP15] 10000: Reserved 10001: Read the ALARM timer (see the FCCU_XTMR register) [OP17] 10010: RESERVED 10011: Read the CFG timer (see the FCCU_XTMR register) [OP19] 10100: Read the Error Pin low counter value (see Section 81.6.21, FCCU XTMR Register (FCCU_XTMR)) [OP20] 10101–11111: Reserved The SW application must not modify the OPR field (any write operation will be ignored) until the completion of the operation. Once the operation has been completed, the operation status (OPS) is set and the OPR field is automatically cleared (OPR = 000). The opcode OP11, OP12 must not be programmed. The OPR field is automatically set to OP11 or OP12 when the FCCU_RF_S registers are cleared by a write-clear operation into the related register. The opcode OP14 must not be programmed. The OPR field is automatically set to OP14 when the timeout occurs (FCCU_CFG_TO) during the configuration procedure => the FCCU state is automatically forced in NORMAL mode setting the default configuration. In this phase any write operation to the FCCU configuration registers is inhibited. The reserved operations (OP21 -OP30) are forbidden. In case of execution, they return an ABORT response without any side effect. The ABORT response occurs in the following cases: – wrong access (missing or wrong key) to the FCCU_RF_S register (clear operation OP12) – wrong access (missing or wrong key) to the FCCU_CTRL register (OP1, OP2 operation) – OP1 (CONFIG command) execution when FCCU state != NORMAL or configuration locked – OP21-OP30 (RESERVED operations) execution

81.6.2 FCCU CTRL Key Register (FCCU_CTRLK)

The FCCU_CTRLK register implements the key access for the operations OP1, OP2 according to the following sequence:

1. Write the key into the FCCU_CTRLK register.
2. Write the FCCU_CTRL register (operations OP1 or OP2).

Note: *There should not be any other operation in between the above steps.*

The FCCU_CTRLK register is not readable, a 0000_0000h value is always returned in case of read operation. The key must be written by a word (32 bits) data write operation.

Figure 2018. FCCU CTRL Key Register (FCCU_CTRLK)

Table 1868. FCCU_CTRLK field descriptions

Field	Description
CTRLK	Control register key = 913756AFh: Key for the operation OP1 = 825A132Bh: Key for the operation OP2

81.6.3 FCCU Configuration Register (FCCU_CFG)

The FCCU_CFG register defines the global configuration for the FCCU module.

This register is writable only in the CONFIG state.

1. Writable only in the CONFIG state.

Table 1869. FCCU_CFG field descriptions

Field	Description
FCCU_SET_AFTER_RESET	This bit controls the enable of the o/p error pin after reset lifts 0: FCCU's Error indication stops functioning and error pins are in HI-Z state. 1: write to start FCCU functioning. After power-on the error out pins shall be in high impedance. They will go to normal state only on software request ie. this bit is set to '1'. It is SW's responsibility to write this bit to 1 else the error pin stays in High-Z state after reset lifts and FCCU is not functioning.
FCCU_SET_CLEAR	Error pin state can be controlled by these bits 01: Error Pin goes in Faulty state. 11 write: Error Pin goes OK state (write not possible when FCCU already in the T min timer phase (entered into a fault or by SW writing fccu_set_clear bit field to 01)). 00, 10: FCCU acts independent of above SW control. These bits clear(0) and set(1) the error pin. Higher priority is of the FCCU_SET_AFTER_RESET bit's capability to lead the error pins to Hi-Z. Switch to software configuration (01, 11) comes into effect when FCCU FSM leaves CONFIG state. After this is in effect, software maintains priority over FCCU FSM. The switch back to FSM control is again done by writing into these fields with 00 or 10 by going to CONFIG state.

Table 1869. FCCU_CFG field descriptions (continued)

Field	Description
OD	Open Drain Mechanism to select between Push-pull and Open drain(OD) mode for the error indicating pin(s) 0: push-pull 1: OD
SM	<i>Switching mode</i> 0: EOUT protocol (dual-rail, time-switching) slow switching mode. 1: EOUT protocol (dual-rail, time-switching) fast switching mode. SM has no effect on the bi-stable protocol.
PS	<i>Polarity selection</i> 0: fcc_eout[1] active high, fcc_eout[0] active low 1: fcc_eout[1] active low, fcc_eout[0] active high This bit can be read and written by the software. Active state here means a state indicating FAULT and applicable when pins are non-toggling in Error phase.
FOM	<i>Fault Output Mode selection</i> 000: Dual-Rail (default state) [fccu_eout[1:0]= outputs] 001: Time Switching [fccu_eout[1:0]= output to be used] 010: Bi-Stable 011: Reserved 100: Reserved 101: Test0 (controlled by FCCU_EOUT register) [fccu_eout[0]= input, fccu_eout[1]= output] 110: Test1 (controlled by FCCU_EOUT register) [fccu_eout[0]= output, fccu_eout[1]= output] 111: Test2 (controlled by FCCU_EOUT register) [fccu_eout[0]= output, fccu_eout[1]= input] <i>Note: In Testx mode, a simple double-stage resynchronization stage is used to resynchronize the EOUT input/outputs on the system/IRCOSC clock.</i>

81.6.4 FCCU RF Configuration Registers (FCCU_RF_CFG[0:3])

The FCCU_RF_CFGx registers contain the configuration of each recoverable fault in terms of fault recovery management. The configuration depends on the type of signaling of a fault event. HW recoverable faults should be configured only if a previous latching stage captures and hold the physical fault otherwise the fault can be lost. All the other faults should be configured as SW fault.

These registers are writable only in the CONFIG state.

81.6.5 FCCU RFS Configuration Registers (FCCU_RFS_CFG[0:7])

The FCCU_RFS_CFGx registers contain the configuration of each recoverable fault in terms of fault reaction (short or long functional reset request pulse) when it is the root cause for the FAULT state transition.

These registers are writable only in the CONFIG state.

81.6.6 FCCU RF Status Register (FCCU_RF_S[0:3])

The FCCU_RF_Sx register contains the latched fault indication collected from the recoverable fault sources. Faults are latched also in the CONFIG state and independently from the enabling or reactions programmed for the RF.

No reactions are executed until the FCCU moves in the NORMAL state.

FCCU reacts and moves from the NORMAL state into the ALARM state only if the respective enable bit for a fault is set in the FCCU_RF_Ex register and the respective enable bit for the time-out is set in the FCCU_TOEx register.

FCCU reacts and moves from the NORMAL or ALARM state into the FAULT state if the respective enable bit for a fault is set in the FCCU_RF_Ex register and the respective enable bit for the time-out is disabled in the FCCU_TOEx register.

FCCU reacts and moves from the ALARM state into the FAULT state if the time-out (FCCU_TO register) is elapsed before to recovery the fault.

The time-out is stopped only when the FCCU returns in the NORMAL state.

The FCCU_RF_Sx register is encoded respectively into the N2FF_STATUS or A2FF_STATUS register to freeze the entry condition in the FAULT state. The status bits of the FCCU_RF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the proper key into the FCCU_RFK register.
2. Clear the status (flag) bit RFSx => the opcode OP12 is automatically set into the FCCU_CTRL.OPR field.
3. Wait for the completion of the operation (FCCU_CTRL.OPS field).
4. Read the FCCU_RF_Sx register in order to verify the effective deletion and in case of failure to repeat the sequence.

As result of the above sequence, in addition the FAULT interface provides support to clear the external fake FAULT root (see [Section 81.5.7, FAULT interface](#)).

Note: *There should not be any other operation in between the above steps.*

The FCCU moves from the FAULT or ALARM state into the NORMAL state if all the source faults that caused the transition into the FAULT state have been removed (HW recoverable fault) or cleared via SW (SW recoverable fault). In case of nested faults that are not all recovered, the FCCU will remain in the FAULT or ALARM state.

The SW application executes the FCCU_RF_Sx read operation by the following sequence:

1. Set the OP10 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU_RF_Sx register.

In case of reconfiguration of the FCCU (CONFIG state), before to return in NORMAL state the pending status bits into the FCCU_RF_Sx must be cleared in order to avoid a false transition in ALARM/FAULT state.

The following errors are ignored:

- to write a wrong key into the FCCU_RFK register
- to attempt to clear a HW recoverable error

81.6.7 FCCU RF Key Register (FCCU_RFK)

The FCCU_RFK register implements the key access to clear the status flags of the FCCU_RF_Sx register.

The status bits of the FCCU_RF_Sx register, configured as SW recoverable faults, can be cleared by the following locked sequence:

1. Write the key into the FCCU_RFK register.
2. Clear the status (flag) bit RFSx.

The key must be written for each FCCU_RF_Sx clear operation.

Note: There should not be any other operation in between the above steps.

The FCCU_RFK register is not readable; a 0000_0000h value is always returned in case of read operation.

Figure 2023. FCCU RF Key Register (FCCU_RFK)

Table 1876. FCCU_RFK field descriptions

Field	Description
RFK	recoverable fault key = AB34_98FEh

81.6.8 FCCU RF Enable Registers (FCCU_RF_E[0:3])

The FCCU_RF_Ex registers enable the fault sources to allow a transition from the NORMAL into the FAULT or ALARM state. In case of fault masking, the respective status bit into the FCCU_RF_Sx register is anyway set (for debugging purposes), only the reaction is masked.

These registers are writable only in the CONFIG state.

81.6.9 FCCU RF Timeout Enable Registers (FCCU_RF_TOE[0:3])

The FCCU_RF_TOEx registers enable a transition from the NORMAL state into the ALARM state if the respective recoverable fault is enabled (RFE_x and RFTOEx are set). In case the respective time-out is disabled (RFTOEx is cleared) and the recoverable fault is enabled (RFE_x is set) the FCCU moves into the FAULT state if the related recoverable fault is asserted. The timer (preset with the time-out value defined by FCCU_TO register) is started when the FCCU moves into the ALARM state. If the fault is not recovered within the time-out the FCCU moves from the ALARM state to the FAULT state.

These registers are writable only in the CONFIG state.

81.6.10 FCCU RF Time-out Register (FCCU_RF_TO)

The FCCU_RF_TO register defines the preset value of the timer for the recovery of the recoverable faults (enabled). Once FCCU enters in ALARM state, following the assertion of a recoverable fault enabled (RFEx and RFTOEx are set), the timer starts the count down.

If the fault is not recovered within the time-out the FCCU moves from the ALARM state to the FAULT state.

This register is writable only in the CONFIG state.

Figure 2026. FCCU RF Time-out Register (FCCU_RF_TO)

Table 1881. FCCU_RF_TO field descriptions

Field	Description
TO	<i>Recoverable fault timeout</i> $\text{Timeout} = (\text{TO}) \times T_{\text{RC16MHz}}$

81.6.11 FCCU CFG Timeout Register (FCCU_CFG_TO)

The FCCU_CFG_TO register defines the preset value of the watchdog timer for the recovery from the CONFIG state. Once FCCU enters in CONFIG state, following a SW request (OP1 opcode), the watchdog timer is initialized and starts the countdown if the reset is not asserted.

If the configuration is not completed within the time-out, the FCCU moves automatically from the CONFIG state to the NORMAL state and the default values for the configuration register is restored. The watchdog time-out is clocked with the RC oscillator clock (16 MHz). The default time-out value is 4.096 ms. Longer activation of CONFIG state can lead to resets if a failure is indicated during the time the FCCU is in CONFIG state due to FOSU.

The FCCU_CFG_TO register is writable in any state excluded the CONFIG state as follows the execution of the OP1 opcode (NORMAL to CONFIG state) and until the completion of the OP2 opcode (CONFIG to NORMAL state).

In case of watchdog time-out the FCCU_CFG_TO register is not accessible until the OP14 operation (CONFIG to NORMAL) has been completed.

TO	Configuration time-out $\text{Timeout} = T_{\text{RC16MHz}} \times 2^{(\text{TO} + 10)}$ 000: Time-out = 64 μs ... 111: Time-out = 8.192 ms

81.6.12 FCCU IO Control Register (FCCU_EINOUT)

The FCCU_EINOUT register allows the following operations typically in NORMAL state:

- to control the fccu_eout[1] output level when the FCCU is configured in “Test1” or “Test0” fault output mode (FCCU_CFG.FOM)
- to control the fccu_eout[0] output level when the FCCU is configured in “Test1” or “Test2” fault output mode (FCCU_CFG.FOM)
- to observe the fccu_ein[1:0] inputs level

Table 1883 shows Bi-stable encoding.

Table 1883. Bi-stable encoding

Mode = FCCU_CFG.FOM	FCCU_EOUT[0]	FCCU_EOUT[1]
Test1	output	output
Test2	output	input
Test0	input	output

Note: Due to the resynchronization stage of the EOUT interface, there is a latency of a few IRCOSC clock cycles following a write/read operation of the FCCU_EINOUT register.

1. fccu.fccu_ein[x] depends on the PAD configuration, i.e., internal pull-up enabled as default or pull-down and therefore EINx bit is 1 or 0 upon reset.

Table 1884. FCCU_EINOUT field descriptions

Field	Description
EIN1	EIN1: Error input 1 0: when fccu_ein[1] = 0 1: when fccu_ein[1] = 1 The EIN1 captures the respective fccu_ein[1] input signal.
EIN0	Error input 0 0: when fccu_ein[0] = 0 1: when fccu_ein[0] = 1 The EIN0 captures the fccu_ein[0] input signal.
EOUT1	Error out 1 (significant only if the FCCU_CFG.FOM = Test1 or Test0 => fccu_eout[1] configured in output mode) 0: force fccu_eout[1] = 0 1: force fccu_eout[1] = 1 The EOUT1 set/clear the respective fccu_eout[1] output signal if FCCU_CFG.FOM = 110 or 101, otherwise it is a "don't-care" value.
EOUT0	Error out 0 (significant only if the FCCU_CFG.FOM = Test1 or Test2 => fccu_eout[0] configured in output mode) 0: force fccu_eout[0] = 0 1: force fccu_eout[0] = 1 The EOUT0 set/clear the respective fccu_eout[0] output signal if FCCU_CFG.FOM = 110 or 111, otherwise it is a "don't care" value.

81.6.13 FCCU Status Register (FCCU_STAT)

The FCCU_STAT register includes the FCCU status for debugging/test purposes. The FCCU finite state machine (FSM) operates by the RC oscillator clock (ipg_clk_safe) asynchronous with the system clock (ipg_clk). The FCCU status read operation requires a

safe mechanism operated by a HW/SW synchronization sequence. The SW application executes a FCCU status read operation by the following sequence:

1. Set the OP3 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the FCCU status (FCCU_STAT register).

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Table 1885. FCCU_STAT field descriptions

Field	Description
ESTAT	Current Error Pin Status. SW can write this bit with a different value. The new value is valid for 1 clock cycle, thereafter it returns to indicate the actual value being driven from FCCU. For example in non-faulty states, this bit reads 0 and can be set for one cycle to 1. Similarly in faulty state, this bit reads 1 and sw can write it to 0 and after one cycle the bit reads 1 again. 0: System is OPERATIONAL (OK). 1: System is in FAULT state. This state is taken from the FCCU Eout logic (ie., as late as possible).
PhysicErrorPin	PhysicErrorPin : Physical Error Pin's state. PhysicErrorPin[0] corresponds to error pin 0 and PhysicErrorPin[1] corresponds to error pin 1. For each of these, the bit values have the following meanings: 0: Error Pin is at logical 0 1: Error Pin is at logical 1 During Fault state, a static or toggling value is observed based on selected protocol.
STATUS	FCCU Status 000: NORMAL state 001: CONFIG state 010: ALARM state 011: FAULT state Other: UNKNOWN state

81.6.14 FCCU NA Freeze Status Register (N2AF_STATUS)

The N2AF_STATUS register contains a unique code to identify the “recoverable” source (fccu_rf[x]) that caused the state transition from the NORMAL state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the N2AF_STATUS read operation by the following sequence:

1. Set the OP4 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2AF_STATUS register

The SW application executes the N2AF_STATUS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

81.6.15 FCCU AF Freeze Status Register (A2FF_STATUS)

The A2FF_STATUS register contains a unique code to identify the time-out trigger (recoverable fault) that caused the state transition from the ALARM state to the FAULT state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the A2FF_STATUS read operation by the following sequence:

1. Set the OP5 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the A2FF_STATUS register.

The SW application executes the FCCU_AFFS clear operation by the following sequence:

1. Set the OP13 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).

All the freeze registers are cleared by this operation.

81.6.17 FCCU FA Freeze Status Register (F2A_STATUS)

The F2AF_STATUS register contains a unique code to identify the "recoverable fault" source (fccu_rf[x]) that caused the state transition from the FAULT state to the ALARM state. In case of multiple fault conditions the fault source cannot be identified. This register is for test/debug purposes.

The SW application executes the F2AF_STATUS read operation by the following sequence:

1. Set the OP7 operation into the FCCU_CTRL.OPR field.
2. Wait for the completion of the operation (FCCU_CTRL.OPS field).
3. Read the N2FF_STATUS register.

The SW application executes the F2AF_STATUS clear operation by the following sequence:

1.

Set the OP13 operation into the FCCU_CTRL.OPR field.
2.

Wait for the completion of the operation (FCCU_CTRL.OPS field). (All the freeze registers are cleared by this operation.)

81.6.18 FCCU RF Fake Register (FCCU_RFF)

The FCCU_RFF register contains a unique code to set a “recoverable fault” in mutually exclusive mode by the external FAULT interface signal setting. It allows the SW emulation of the recoverable faults, by the injection of the fault directly in the FAULT root, in order to verify the entire path and reaction. The fault injection mechanism is optional and requires a proper management as described in [Section 81.5.7, FAULT interface](#). The reaction following a fake recoverable fault can be masked. The FCCU_RFF is a write-only register with a set of codes corresponding to each recoverable fault injection.

81.6.19 FCCU IRQ Status Register (FCCU_IRQ_STAT)

The FCCU_IRQ_STAT register defines the FCCU interrupt status register related to the following events:

- Configuration time-out error
- Alarm interrupt
- NMI interrupt

The external interrupt line “irq_misc” is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

The NMI and ALARM interrupts are asserted and cleared according to the FCCU state. The status bits of the FCCU_IRQ_STAT trace the status of the related interrupt lines.

81.6.20 FCCU IRQ Enable Register (FCCU_IRQ_EN)

The FCCU_IRQ_EN register defines the FCCU interrupt enable register related to the following events:

Configuration time-out error

The external interrupt line “irq_misc” is asserted if any interrupt status bit of the FCCU_IRQ_STAT is set and the respective enable bit of the FCCU_IRQ_EN register is also set.

This register is writable only in the CONFIG state.

81.6.21 FCCU XTMR Register (FCCU_XTMR)

The FCCU_XTMR register contains the read values of the Alarm or Watchdog Timer or EOUT pin low counter. These timers are clocked on the IRCOSC clock.

ETMR is the EOUT pin in logic 0 counter. After EOUT has been set to low (by SW or by a real fault), it goes high at the end of the T_min period from the last fault trigger.

The SW application executes the timer read operation by the following sequence:

- Set any of the following operations into the FCCU_CTRL.OPR field:
 - OP17
 - OP19
- OP20 Wait for the completion of the operation (FCCU_CTRL.OPS field)
- Read the FCCU_XTMR register

[Table 1893](#) shows Timer state/value.

Table 1893. Timer state/value

TIMER	CONFIG state	NORMAL state	ALARM state	FAULT state
ALARM	00000000h	Initial value	Running	Idle/End of count
CFG	Running	0001FFFFh	0001FFFFh	0001FFFFh
ETMR	00000000h	00000000h	00000000h	Running

Field	Description
XTMR	Alarm/Watchdog/Safe request timer The current timer value is measured in IRCOSC clock cycles. These bits can be read by the software.

81.6.22 FCCU MCS Register (FCCU_MCS)

The FCCU_MCS register contains a queue of the last four states of the MC. MCS0 is the latest one, while MCS3 is the oldest one. In addition a qualifier indicates if the FCCU is in the FAULT state when the MC state has been captured. The MC state is synchronous to the system clock and provided by a different module while the FCCU state is synchronous to the IRCOSC, therefore some uncertainty must be considered regarding the FAULT state indication.

Figure 2038. FCCU MCS Register (FCCU_MCS)

Table 1895. FCCU_MCS field descriptions

Field	Description
VLx	Valid It indicates that the correspondent MCSx and FSx fields are valid. 0: MCSx, FSx fields are not significative 1: MCSx, FSx fields are significative
FSx	Fault status It indicates that the correspondent MCSx field has been captured when the FCCU is in FAULT state. 0: MCSx field captured in any state different from the FAULT state 1: MCSx field captured in FAULT state
MCSx	MCSx: <i>State of MC modules</i> The MCSx is the state of MC modules. MCS0 = latest state MCS3 = oldest state On any MC state change the previous MC states are shifted (MCS3 = MCS2, MCS2= MCS1, MCS1= MCS0) and the latest one is captured in MCS0. For a definition of these states, see the description of the MC modules in the chip reference manual.

81.6.23 FCCU Transient Register (FCCU_TRANS_LOCK)

The FCCU_TRANS register is used for unlocking configuration by writing BCh. This register is available only in supervisor mode. This register is write only.

Figure 2039. FCCU Transient Register (FCCU_TRANS_LOCK)

81.8 FCCU Output Supervision Unit (FOSU)

The FOSU provides a supervision of the primary error notification path by analyzing FCCU behavior for correctness. It waits for any reaction of the FCCU in a fixed time window after an error arrives.

The intention of the FOSU is to provide a secondary error reaction path in most cases the FCCU fails but not to needlessly propagate an error which is already handled by the FCCU into a full chip reset. Only a failed primary error reaction (i.e., FCCU's failure) is a reason for the secondary reaction to take over (and generate a destructive reset request).

There is a 'do nothing' input coming from the FCCU that indicates that the FCCU is programmed for no reaction. It is a "static" input in the sense that it is not changing after configuration. The FOSU masks the incoming faults with the 'do nothing' control from the FCCU, meaning that a fault is not captured by the FOSU if the 'do nothing' signal is asserted. The active edge of an incoming fault that has not been masked is captured by the FOSU. There is no minimum pulse width requirement on the fault indication other than what is required by the technology, which is the same as that of the FCCU.

The FOSU contains a timer with a duration of FOSU_COUNT, driven by the IRCOSC. The timer is initialized and started on a captured fault for which the FCCU is programmed to show a reaction. While the timer is running, any subsequent captured fault will neither restart nor reinitialize the timer. The timer is stopped when the FCCU shows any of the following reactions (the FCCU does not check whether the reaction is the configured one):

- Reset
- IRQ
- Error out triggered (by FCCU or by SW)

When the timer is stopped, the fault capture logic is cleared in order to ensure that the timer is not restarted due to faults still 'stuck' in the capture logic. The timer will then be restarted by the next new failure indication. When the timer expires, the FOSU's failure indicator output is asserted. The FOSU's failure indicator output is connected to one of the MC_RGM's 'destructive' reset inputs, so its assertion will cause a reset sequence to be initiated starting at PHASE0. The FOSU module is reset with the same reset as is used by the FCCU (ipg_hard_asynch_rst_clk_safe_b), which is asserted on power-on, 'destructive', and long external resets. When this reset is asserted, the FOSU's capture logic is cleared, its timer is kept stopped and in a non-expired state, and its failure indicator output is deasserted.

Figure 2045. FOSU connections to the FCCU and MC_RGM

It is important to remember that there will be no FCCU reaction to an error while the FCCU is in the CONFIG state. For this reason, the FCCU should not be kept in CONFIG for longer than the FOSU_COUNT duration. Otherwise, there is a risk that an incoming error report causing the FOSU to mistakenly see the FCCU as having failed, and then reset the MCU.

81.9 Use cases and limitations

81.9.1 Misconfigurations

The following configurations are appropriate:

1. If at least one reaction to fault is enabled by default then the corresponding fault should also be enabled by default.
2. Enable a fault but disabling all reactions is not a meaningful configuration from safety point of view.
3. Disable the fault and also its reactions. Applicable when a specific fault line is not of interest in a specific application scenario.
Example: FCCU goes into ALARM state due to a failure, but the IRQ is disabled for that failure.
4. Software reset is optional.
5. If the user programs the FCCU for a higher timeout value than what is hardcoded for FOSU, then FCCU reacts later than what FOSU would be expecting and as a result, FOSU will generate destructive reset request on its timeout.

81.9.2 Recommendations to configure FCCU

1. After Power on reset, where both system and FCCU get reset, following steps could be followed to configure FCCU:
 - a) Check and clear any pending fault status
 - b) Verify FCCU is in NORMAL state, else repeat step(a) above
 - c) Configure FCCU
2. After functional reset of the system, arising out of reset request from FCCU or other sources, the following steps could be followed to reconfigure FCCU:
 - a) If active, wait for the Error out T_{min} to expire
 - b) Check and clear fault status
 - c) Error pin moves to “non faulty” state, once fault status is cleared and T_{min} expires
 - d) Reset FCCU by register bit in RGM. All FCCU registers and Error pin initialize to default state
 - e) Read and verify default value in FCCU_NCF_Ex to ascertain reset of FCCU
 - f) Check and clear any new pending fault status until FCCU is in NORMAL state
 - g) Reconfigure FCCU

Note: Software reset of FCCU by RGM_PRST5.FCCU_RST bit is optional since FCCU registers are not initialized during functional reset. RGM_PRST5.FCCU_RST has the same effect on FCCU as power on reset. If the bit is activated, it can change the state of the error pin, if the current state of the pin is different from default.

82 Self-Test Control Unit (STCU2)

82.1 Introduction

Self-Test Control Unit (STCU2) is a comprehensive programmable hardware module that controls the self-test sequence applied both during the Off-Line and/or On-Line conditions. It is able to manage by hardware the device's Logic Built-In Self Test (LBIST) and the SRAM/ROM Built-In Self Test (MBIST) blocks. The STCU2 includes the SSCM DCF bus to load the Self-test parameters (L/MBIST scheduling activity, LBIST setup, Unrecoverable/Recoverable faults management, CRC and MISR expected values, PLL management, and so on) from flash memory during the Off-Line Self-Test phase. This interface is able only to write the configuration parameters and start the Self-Test execution once after the STCU2 global reset has been applied. The register access by software is granted by an IPS interface with the purpose to check the results of the Off-Line Self-Test but also to load/check the execution of the On-Line Self-Test.

The STCU2 includes:

- A CRC block that can be optionally enabled to monitor the internal critical signals during the Self-Test run to increase the STCU2's Self-Checking capability
- A programmable Watchdog timer (WDG) to check the Self-Test operations (both LBIST than MBIST) have been completed within the assigned time slot or the STCU2 RUN or BYPASS bits have been programmed before Watchdog time-out
- The PLL direct control during the Off-Line Self-Test sequence
- Two interrupt lines enabled only during the On-Line Self-Test to simplify the software handling of Self-Test execution end
- Two sets of result registers to collect the L/MBIST result during Off/On-Line Self-Test separately

To increase the security capability of this module, a different Security Key sequence is also required during Off/On-Line Self-Test in order to unlock the write access to the STCU2 registers. The STCU2 also implements two power-saving mechanisms to switch off:

- The global STCU2 clock after Self-Test sequence is completed
- The register ITF clock when the WDG time-out is detected after a Double Security Key sequence is applied during the application run (available only when IPS write access is enabled otherwise the clock is off).

82.2 Main features

- Double registers interface (SSCM DCF with priority over IPS)
- SSCM DCF write one time register interface
- IPS read and write (depends on SSCM enable parameters and STCU_CFG.WRP bit) register interface
- Programmable scheduler for LBIST/MBIST execution
- LBIST concurrent/sequential execution
- MBIST concurrent/sequential execution
- Programmable LBIST delayed concurrent start
- 32-bit CRC for STCU2 Self-Checking capability (enabled by STCU_CFG.CRCEN bit)
- On-Line hardware and software Self-Test sequence abort capability
- Programmable Internal clock prescaler to reduce Internal and M/LBIST TCK clocks
- Programmable PLL direct control during Off-Line Self-test sequence
- PLL Lock signal monitoring during Off-On/Line Self Test
- L/MBIST dedicated On-Line interrupt source generation
- Programmable WDG Timer for Self-Check M/LBIST Time Execution
- Hard Coded WDG time-out to flag off-line initialization errors
- Hard Coded WDG time-out to Auto-lock STCU2 write access after Double-Key sequence
- LBIST and SRAM/ROM MBIST Off-Line status flags
- STCU2 internal errors Off-Line status flag
- LBIST and SRAM/ROM MBIST On-Line status flags
- STCU2 internal errors On-Line Status flag
- On-Line hardware and software abort status flag
- LBIST and SRAM/ROM MBIST Off-On/Line programmable failure severity (UF/RF)
- STCU2 internal errors Off-On/Line programmable failure severity (UF/RF)
- STCU2 errors (UF/RF) lines for FCCU signaling
- Redundant UF/RF generation logic to improve safety
- FCCU UF/RF faults injection mechanism
- CRCE register access to perform redundant check by software
- LBIST MISRE registers access to perform redundant check by software
- Self-Test Bypass capability
- Global write register's protection mechanism based on Double Security Key
- STCU2 Global Auto Power-saving when Self-Test is completed, bypass mode is selected or WDT time-out is detected
- STCU2 ITF/WDG clock wake-up mechanism when software application writes Double Security Key sequence (available when STCU_CFG.WRP bit is active)
- STCU2 ITF/WDG Auto Power-saving when Hard Coded WDG time-out is detected after software application writes Double Security Key sequence (available when STCU_CFG.WRP bit is active)

82.3 Block diagram

The top level diagram of the STCU2 module is given in [Figure 2046](#).

Figure 2046. STCU2 block diagram

The STCU2 module includes the following sub-modules:

- **Reg interface:** This module includes the registers, the security key logic, the IPS and SSCM DCF bus interface
- **CRC:** This module is the core of the Self-Checking architecture of the STCU2. It samples a set of selected internal signals when STCU2 is running.
- **Fault interface:** This module collects the error conditions related to L/MBIST execution and STCU2 internal failures and, depending on the UF/RF configuration of each one of them, sets the global STCU2 UF or RF flag. It also manages the UF/RF fault lines and the Set/Clear injection mechanism provided by the FCCU. To improve the intrinsic safety of this critical logic, the generation logic is duplicated.
- **Clock Block:** This module manages the internal and the L/MBIST TCK clock prescaler, the internal Clock Gating Power Saving and the wake-up clock feature.
- **WDG FSM:** This module includes two different Watchdogs. The first one is Hard Coded and is used to Auto Lock the STCU2 access forcing a reset condition on the Double Security Key registers while the second one has a double functionality. After a reset event initializes the STCU2, it is used as Hard Coded Watchdog time-out while during

L/MBIST run it is used as programmable Watchdog timer to check the L/MBIST have been completed in the assigned to L/MBIST time slot.

- **STCU2 Master FSM:** This module includes the main FSM of the STCU2 used to coordinate and schedule all the operations performed during the Self-Test Sequence.
- **STCU2 Load Shifter FSM:** This module includes the common shifter register and the related state machine used to program the L/MBIST registers and read back the data to be checked at the end of each Test operation.
- **LBIST interface:** This module includes the interface between the device's LBIST engines and the STCU2 controllers.
- **MBIST interface:** This module includes the interface between the MBIST controller and STCU2 controllers.

82.3.1 IPS bus interface

The IPS bus interface is a slave bus used for configuration purposes via CPU. The following bus read operations (contiguous byte enables) are supported:

- Word (32 bits) data read operations to any registers
- Low and high half-words (16 bits, data[31:16] or data[15:0]) data read operations to any registers
- Byte(8 bits, data[31:24] or data[23:16] or data[15:8] or data[7:0]) data read operations to any registers
- Any other operation (free byte enables or other operations) has to be avoided.

The same operations are also supported in write mode only in the following scenario:

- The Self-Test sequence parameters are loaded before Off-Line Self-test is executed
- The IPS access on some specific register (see [Section 82.5, Register description](#)) is allowed by software only when the bit STCU_CFG.WRP is cleared
- In all the other conditions the write operations are not supported and all the STCU2 registers can be only read. Only exceptions are the following rw bits: STCU_CFG.WRP, STCU_ERR_STAT.UFSF and STCU_ERR_STAT.RFSF. See related register description for additional details

The STCU2 module generates a transfer error in the following cases:

- Any write/read access to the register addresses not mapped on the peripheral but included in the address space of the peripheral
- Any write/read operation different from byte/hword/word (free byte enables or other operations) on each register
- Any write operation on Double Security Key register applying a wrong sequence of keys (the two write operations cannot be interleaved with other access to STCU2 registers)
- Any write operation performed on a register when the Double Security keys have not been applied
- Any write operation performed on registers when the STCU_CFG.WRP bit is set and the access is performed through software (IPS interface)
- Any write operation performed through software (IPS interface) on row registers
- Any write operation performed off-line on registers in which writing operation is allowed only in the On-Line Self-Test phase when STCU_CFG[WRP] = 1
- Any write operation performed on Read Only registers

The registers of the STCU2 module are accessible (read/write) in each access mode: user, supervisor or test.

In case there are write operations on bits marked as reserved, the transfer error is not generated.

For more details about the registers protection features, see [Section 82.5, Register description](#).

82.4 Functional description

82.4.1 FSM description

The module has three state machines that work together: Master State Machine, Loader/Shifter State Machine, and the Watchdog State Machine. Basically the Master State Machine is the core unit of the STCU2 module. It coordinates all the Self Test operations and the other State Machines. The Loader/Shifter State Machine is used to program the MBIST and the LBIST parameters and to retrieve the related results depending on the parameters stored into the STCU2 registers and under the control of the Master State Machine. The Watchdog State Machine evaluates all the schedule time for MBIST and LBIST and the time-out in case of wrong STCU2 programming.

82.4.2 Reset management

The asynchronous reset line initializes the STCU2 module status forcing the Off-Line Self-Test condition and cleaning up all the registers and state machine of the module.

The reset signals generated by the STCU2 module at the end of the Self-Test execution phase depends on the Self-Test conditions and on the content of the STCU_LBRMSW register as reported in the following.

82.4.2.1 Off-Line reset generation

At the end of the Off-Line Self-Test execution the STCU2 raises the global functional reset.

82.4.2.2 On-Line reset generation (only MBIST)

The On-Line execution of the MBIST does not generate any reset from STCU2 at the end of the execution. This is because the software application has to manage all the possible consequences related to the write operations performed by the MBIST execution other than prevent any read/write operation during the Self-Test execution. If necessary, the software must also restore the memory content (only for RAMs) at the end of the Self-Test execution.

82.4.2.3 On-Line Reset generation (LBIST enabled)

The On-Line execution of the LBIST generates at the end of the execution two possible types of reset depending on the status of the STCU_LBRMSW register. See [Section 82.5.17, STCU2 On-Line LBIST Reset Management \(STCU_LBRMSW\)](#).

In case all the selected LBIST do not require the global functional reset, only the LBISTed partitions are cleaned up applying a pulse on the dedicated reset line while when at least one of the selected LBIST requires the global functional reset, then the global functional reset will be raised at the end of the On-Line Self-Test execution.

Note: In case there is an ABORT condition detected by STCU2 during the On-Line Self-Test execution, independently of the value of the STCU_LBRMSW register, only the related reset line is pulsed to prevent any potential dangerous system level operations.

82.4.3 LBIST and MBIST scheduling

The STCU2 module has been designed to be very flexible allowing to program the parallel/serial execution of the MBIST or LBIST depending on the power/timing/coverage constraints. The limitation in the programming flexibility is described in [Section 82.7.4, Design implementation information](#).

The mechanism used to provide this flexibility is a linked list where the starting pointer is the bitfield STCU_CFG.PTR. The first LBIST is mapped on 00h, the second on 01h, and so on. The first MBIST is mapped at the address 10h, the second on 11h and so on. The additional pointers are in the bitfield STCU_LB_CTRL[X].PTR for LBIST[X] (where X is the selected LBIST) and STCU_MB_CTRL[Y].PTR for MBIST (where Y is the selected MBIST) and have to be filled depending on the selected sequence of run. The additional bitfield STCU_LB_CTRL.CSM and STCU_MB_CTRL.CSM provide the flexibility to run concurrently or sequentially the chosen set of the LBIST or MBIST or to close the linked list setting the NIL pointer. For more details, see [Section 82.5.34, STCU2 LBIST Control Register \(STCU_LB_CTRL\)](#) and [Section 82.5.46, STCU2 MBIST Control Register \(STCU_MB_CTRL\)](#).

82.4.4 ABORT management

The STCU2 module provides two mechanisms to perform the On-Line Self-Test execution abort. When the abort is detected in both cases, the On-Line Self-Test operation stops running and the status of the currently running MBIST or LBIST is saved into the related registers to provide intermediate results that might be useful in case of debug or in case of concurrent run. In case of LBIST run, see [Section 82.4.2, Reset management](#), for more details about reset specific management when abort is detected. The following sections describe the differences between these two modalities.

82.4.4.1 Hardware ABORT management

The STCU2 enters in this abort condition as a consequence of a Functional reset that requires to stop the Self-Test execution.

When hardware abort is detected the bit ABORTHW of the STCU_ERR_STAT register is set. This flag allows the software to diagnose what has happened during the On-Line Self-Test execution run.

82.4.4.2 Software ABORT management

The STCU2 enters in the abort condition because the software set the bit RUNSW_ABORT in the STCU_RUNSW register. In order to allow the software to understand when STCU2 has completed the abort sequence, this bit will be maintained active until the abort sequence is completed. At that time the STCU2 will clear this bit as described in [Section 82.5.3, STCU2 Run Software Register \(STCU_RUNSW\)](#).

When software abort is raised the bit ABORTSW of the STCU_ERR_STAT register is set. Even if the abort condition is forced by software operation, this flag allows to diagnose what has happened during the On-Line Self-Test execution run.

82.4.5 PLL interface

The STCU2 module is able to directly control the PLL during the Off-Line Self-Test operations depending on the status of the STCU_RUN[MBPLEN] and STCU_RUN[LBPLEN] as described in [Section 82.5.3, STCU2 Run Software Register \(STCU_RUNSW\)](#).

When STCU_RUN[RUN] is set to start the Off-Line Self-test operations, the STCU2 takes control of the PLL and changes the PLL clock configurations parameters according to the values programmed into the STCU_PLL_CFG register.

When the STCU_RUN[MBPLEN] is active and the MBIST is currently selected, the STCU2 waits for the PLL lock. As soon as the lock happens, the STCU forces the clock to switch to the PLL output clock. This allows the MBIST to proceed at the PLL output frequency. At the end of the MBIST run the clock source is reverted to the original one. Same behavior will be applied when STCU_RUN[LBPLEN] is active and LBIST is currently selected.

82.4.6 Interrupt interface

There are two interrupt sources:

- One triggered by MBIST (enabled by programming STCU_RUNSW[MBIE] = 1)
- One triggered by LBIST (enabled by programming STCU_RUNSW[LBIE] = 1)

As described in [Section 82.5.3, STCU2 Run Software Register \(STCU_RUNSW\)](#), register description, the interrupts are generated at the end of any concurrent run. This means that in case of multiple sequential run in the same session, the number of interrupts generated is equivalent to the number of the sequential session providing in such a way a fine granularity with respect the completed run.

The bits LBIFLG and MBIFLG in the [STCU2 Interrupt Flag Register \(STCU_INT_FLG\)](#) register flag these interrupt conditions and allow the clearing of interrupt requests. These two interrupt bits have to be cleared writing the related bit to 1 to enable the next interrupt request.

82.4.7 FCCU interface

The FCCU interface is the hardware flag mechanism towards the system, to indicate the occurrence of an Unrecoverable and/or a Recoverable failure during the Self Test sequence.

To diagnose physical defects on the two fault signals, a fault injection mechanism is also provided. In this case, the FCCU interface allows the user application to check the integrity of the UF and RF connection lines between the STCU2 and the FCCU. Refer to the description of FCCU fault injection mechanism to understand how the UF/RF set/clear mechanism works.

82.4.8 Watchdogs

The STCU2 implements three different watchdog ensure that operations are finished in time.

82.4.8.1 Initialization sequence

The STCU2 has two initialization operating modes: program the Self-Test sequence and run it (Safety mode) or bypass completely the Self-Test sequence setting the bit

STCU_CFG.BYP. In case there are faults during the initialization phase preventing the selection of one of these two operating modes, a hard-coded Watchdog time-out flags the wrong behavior. See [Section 82.5.7, STCU2 Watchdog Register Granularity \(STCU_WDG\)](#), for more details.

82.4.8.2 LBIST and MBIST scheduling

The LBIST and MBIST execution time has to be configured as described in [Section 82.5.7, STCU2 Watchdog Register Granularity \(STCU_WDG\)](#), to account for the overall execution time of the Self-Test sequence. In case the selected LBISTs or MBISTs are not yet completed during the Off-line Self-Test assigned time, the current LBISTs or MBISTs execution is interrupted and a failure is flagged into STCU_ERR_STAT.WDTO and STCU_MBEL/M/H or STCU_LBE registers while in case of On-Line Self-Test into STCU_ERR_STAT.WDTOSW and STCU_MBELSW/MSW/HSW or STCU_LBESW.

In case of multiple sequential run in the same On-Line/Off-Line session and the time-out happens in the middle of a sequential run, the next sequential run will be skipped and the execution ends with the current updated status of the registers reported above.

In all the cases, the STCU2 reset generation is managed in one of the modes described in [Section 82.4.2, Reset management](#).

82.4.8.3 Write access time-out

The access on the STCU2 registers during the Self Test configuration phase (both On-Line/Off-Line) is protected by a key mechanism to prevent any unwanted access, as described in the STCU_SKC register description. In addition to this safety feature, there is a hardware Watchdog that, after 1024 STCU2 clock cycles, lock the access requiring to apply again the STCU_SKC keys.

This feature is particularly useful in case STCU_CFG[WRP] = 0 during the software Self Test configuration since in this case the software application might enable the write access to the STCU2 registers.

82.4.9 CRC

The CRC block is used to increase the intrinsic coverage of the STCU2 module and implements a 32-bit ethernet protocol polynomial to evaluate the signature of the most important and critical internal signals. This feature is by default switched off but it can be turned on setting the bit STCU_CFG.CRCEN. Once this bit is set the expected signature has to be programmed into the STCU_CRCE register; at the end of the Self-Test execution the STCU2 update the content of the STCU_CRCR register with the evaluated signature and compare this value with the expected one previously programmed into STCU_CRCE. In case of mismatches a UF/RF condition is flagged depending on the fault mapping selected into the STCU_ERR_FM register.

82.4.10 SSCM interface

The SSCM interface is used to program the STCU2's configuration parameters without the CPU intervention after a reset trigger event initializes the STCU2. This bus interface has the priority over the IPS.

82.5 Register description

The STCU2 registers are listed in [Table 1906](#).

Table 1906. STCU2 register set

Address offset	Register Name	Location
0000h	STCU2 Run Register (STCU_RUN)	on page 3542
0004h	STCU2 Run Software Register (STCU_RUNSW)	on page 3543
0008h	STCU2 SK Code Register (STCU_SKC)	on page 3544

82.5.1 Register description conventions

The register information is presented in:

- Register figures
- Field-description tables
- Associated text

The register figures show the field structure using the conventions in [Figure 2047](#).

Figure 2047. Register figure conventions

The numbering of register bits and fields is as follows:

- Register bit numbers, shown at the top of each figure, use the bit ordering (0, 1, 2, ..., 31).
- Multi-bitfields within a register use the bit ordering (... , 2, 1, 0).

82.5.2 STCU2 Run Register (STCU_RUN)

The STCU_RUN register defines the RUN bit to start the off-line self testing procedure as long as some configuration bits required ONLY during this Self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Figure 2048. STCU2 Run Register (STCU_RUN)

Table 1907. STCU_RUN field descriptions

Field	Description
BYP	Bypass mode 0: Off-Line Self-Test is active. In case the RUN bit into the STCU_RUN register is not set before the Hard-Coded WDG Time-out, the WDTO error is generated into the STCU_ERR_STAT register. 1: Off-Line Self-Test is completely bypassed and the access to STCU2 is locked until the STCU_SCK register is written according to the request access mode.
MBPLEN	Off-Line MBIST with PLL Enabled 0: Off-Line MBIST is executed without using the on-chip PLL. 1: Off-Line MBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU_PLL_CFG register.

Table 1907. STCU_RUN field descriptions (continued)

Field	Description
LBPLEN	Off-Line LBIST with PLL Enabled 0: Off-Line LBIST is executed without using the on-chip PLL. 1: Off-Line LBIST is executed enabling the on-chip PLL control interface selecting the parameters defined into STCU_PLL_CFG register.
RUN	RUN: RUN 0: Idle 1: Off-Line Self testing procedure is running The RUN bit is automatically cleared by the STCU2 when the off-line self testing procedure has been completed.

82.5.3 STCU2 Run Software Register (STCU_RUNSW)

The STCU_RUNSW register defines the RUN bit to start the on-line self testing procedure as long as some configuration bits required ONLY during this Self-test phase.

The R/W fields in this register are readable at any time. However, you can write to these fields only when both of the following conditions are true:

- STCU_CFG[WRP] = 0
- On-line Self-Test phase is active. The On-Line condition starts when the Off-Line is over. In this condition, system is alive and the SW can program the STCU

Figure 2049. STCU2 Run Software Register (STCU_RUNSW)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1908. STCU_RUNSW field descriptions

Field	Description
MBIE	MBIST Interrupt Enable 0: Interrupt is not generated at the end of the software MBIST execution phase of the selected Memories. 1: At the end of the software MBIST execution phase of the concurrent selected memories the STCU2 forces an interrupt request to notify MBISTs of that concurrent selected memories are over. In case there is a sequence of concurrent run in the same Self-Test run, the interrupt request is generated at the end of each concurrent run provided that the software will clear the STCU_INT_FLG[MBIFG] bit in between.
LBIE	LBIST Interrupt Enable 0: Interrupt is not generated at the end of the software LBIST execution phase of the selected LBIST. 1: At the end of the software LBIST execution phase of the concurrent selected LBIST the STCU2 forces an interrupt request to notify LBIST of the concurrent selected partitions are over. In case there is a sequence of concurrent run in the same Self-Test run, the interrupt request is generated at the end of each concurrent run provided that the software will clear the STCU_INT_FLG.LBIFG bit in between.
MBSWPLEN	On-Line MBIST with PLL Enabled 0: On-Line MBIST is executed without using the on-chip PLL. 1: On-Line MBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
LBSWPLEN	On-Line LBIST with PLL Enabled 0: On-Line LBIST is executed without using the on-chip PLL. 1: On-Line LBIST is executed using the PLL configuration provided by software. STCU2 does not take the PLL control but monitors the PLL lock signal to check if PLL is working correctly.
RUNSW_ABORT	Software abort of the self-test currently running This bit is automatically cleared by the STCU2 when the software self-test abort sequence has been completed. 0: On-line self-test abort is not requested. 1: On-line self-test abort is requested.
RUNSW	RUNSW 0: Idle 1: On-line self testing procedure is running The RUNSW bit is automatically cleared by the STCU2 when the on-line self testing procedure has been completed.

82.5.4 STCU2 SK Code Register (STCU_SKC)

The STCU_SKC register implements the security key code mechanism needed to access in write mode to the other STCU2 registers. In order to unlock the STCU2 access after:

- The STCU2 asynchronous reset
- The end of the STCU2 run

the software (IPS bus) or the SSCM interfaces have to apply the following sequence:

- write the key1 into the STCU_SKC register
- write the key2 into the STCU_SKC register

Depending on the off/on-line test step, the two keys will be different. Byte write operation is not allowed since the full key has to be recognized as one unit.

It has to be noticed that after the Self-Test sequence has been completed or the Bypass feature has been enabled (setting the bit BYP into the STCU_CFG), the SSCM interface is no more available.

In case of invalid access or sequence (Key1/2 have to be applied consecutively), a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

In case the STCU2 register access last more cycles than the one defined into the Hard-coded WDG time-out, the STCU2 write access is locked and the WDG and Register ITF clocks are switched off. Also in this case, in order to enable again the write access to the STCU2 and the WDG and Register ITF clocks, it is required to apply again the sequence.

In case it is required to extend the STCU2 register access cycles before the Hard-coded WDG time-out expires, only the Key2 has to be applied. The effect of this write operation is to re-initialize the WDG time-out counter. In such a condition, Key1 has not to be applied otherwise a transfer error on the IPS or SSCM bus is asserted depending on the selected source. The STCU2 write access is locked and to unlock the access the sequence has to be applied again.

The STCU_SKC register is not readable. The value 00000000h is always returned in case of read operation.

	STCU2 security key code for on-line Test = 753F924Eh: Key1 to unlock the write access the STCU2 = 8AC06DB1h: Key2 to unlock the write access the STCU2

82.5.5 STCU2 Configuration Register (STCU_CFG)

The STCU_CFG register includes the global configuration of the STCU2 and can be updated both in the Off/On-Line Test steps.

The access to this register is described in [Figure 2051](#). It further depends on the state of the WRP bit as follows:

- When WRP = 0: The register can be written during the on-line Self-Test case without restrictions
- When WRP = 1:
 - The only bit that can be written without any restriction is WRP.
 - In case there are software operations that write all the register's bits, a transfer error is raised only if the value of the selected byte written differs from the current status of the register. This functionality has been implemented to prevent potential compilation behavior that might invalidate this single bit clean capability.

Figure 2051. STCU2 Configuration Register (STCU_CFG)

1. You can always read this field. In the off-line Self-Test phase, you can always write to this field. In the on-line Self-Test phase, you can write to this field only when WRP = 0.

Table 1910. STCU_CFG field descriptions

Field	Description
PTR	LBIST or MBIST pointer PTR defines the logical pointer to the first LBIST or MBIST to be scheduled when the self testing procedure is enabled. PTR is the entry pointer to a linked list of BIST descriptors. If PTR = 0 then the LBIST0 is initially scheduled. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1): pointer to MBIST 7Fh: pointer to NIL. No BIST execution.
LB_DELAY	Delay LBIST run LB_DELAY defines the delay between the LBIST starts when more than a single LBIST is selected of being executed concurrently with the purpose of smoothing the power consumption transient. The allowed delay time are the following: 00h: No delay 01h: 1 × 16 STCU2 Core clock cycles 02h: 2 × 16 STCU2 Core clock cycles 03h: 3 × 16 STCU2 Core clock cycles ... FDh: 253 × 16 STCU2 Core clock cycles FEh: 254 × 16 STCU2 Core clock cycles FFh: 255 × 16 STCU2 Core clock cycles Note that in case the Frequency of the STCU2 core clock is 16 MHz, the delay parameters is expressed in μs.
WRP	Write Protection 0: Specific STCU2 registers can be written through IPS bus interface after Off-Line Self-Test sequence has been completed 1: Specific STCU2 registers cannot be written though IPS also after Off-Line Self-Test sequence has been completed preventing in such a way any user application write operation
CRCEN	CRCEN: <i>CRC Enable comparison</i> 0: The CRC comparison is not performed and the STCU_ERR_STAT.CRCS[SW] and STCU_ERR_STAT.UF/RF global flags are not updated in case of mismatches between STCU2.CRCE and STCU2.CRCR values 1: The CRC comparison is performed and the status is updated into the related flags of the STCU_ERR_STAT register
PMOSEN	MBIST PMOS Test Enable 0: MBIST PMOS Test is not enabled 1: MBIST PMOS Test is enabled

Table 1910. STCU_CFG field descriptions (continued)

Field	Description
MBU	<i>MBIST MBU Test Enabled</i> 0: MBIST Full algo or reduced one without PMOS test (PMOSEN set to 0) is applied. 1: MBIST simplified Multi Bit Upset algo is used to check the RAM. In case a ROM is selected, the applied algo will be Standard one without PMOS Test. <i>This bit overwrite the PMOSEN feature.</i>
CLK_CFG	Logic, Memory Bist and STCU2 core CLK <i>Clock configuration</i> CLK_CFG defines the ratio between the sys_clk and the TCK used to program both the LBIST and the MBIST and the STCU2 core clock. The punch-out mechanism is used to generate the derived clocks. The allowed configurations are the following: 000: sys_clk 001: sys_clk/2 010: sys_clk/3 ... 101: sys_clk/6 110: sys_clk/7 111: sys_clk/8

82.5.6 STCU2 PLL Configuration Register (STCU_PLL_CFG)

The STCU_PLL_CFG register defines the parameters used to program the PLL only when the Off-line L/MBIST are performed and STCU_RUN[MBPLEN] = 1 or STCU_RUN[LBPLEN] = 1.

In the On-line condition, these bits are not effective. It is also possible to set the PLL during active On-line mode to prevent any potential functionality issue.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Figure 2052. STCU2 PLL Configuration Register (STCU_PLL_CFG)

Offset: 0010h

Table 1911. STCU_PLL_CFG field descriptions

Field	Description
PLLODF	PLL Output Division Factor The value of this field drives the Output Division factor of the PLL embedded into the device. Refers to the PLL specifications to define the exact mapping between the PLLODF value and the related PLL's Output Division factor.
PLLIDF	PLL Input Division Factor The value of this field drives the Input Division factor of the PLL embedded into the device. Refers to the PLL specifications to define the exact mapping between the PLLIDF value and the related PLL's Input Division factor.
PLLLDF	PLL Loop Division Factor The value of this field drives the Loop Division factor of the PLL embedded into the device. Refers to the PLL specifications to define the exact mapping between the PLLLDF value and the related PLL's Loop Division factor.

82.5.7 STCU2 Watchdog Register Granularity (STCU_WDG)

The STCU_WDG register defines the time budget of LBIST and MBIST execution providing a protection mechanism in case of dead-lock or end-less conditions during the Self-Test procedure. When the Off-line Self-Test sequence is not run and the BYP bit of the STCU_CFG register is not set, the bits 15...0 defines the time-out before the bit WDTO of the STCU_ERR register is set and the STCU2 core clock is switched off.

In case Off/On-line Self Test sequence is run, it defines the time-out of the execution run.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

Figure 2053. STCU2 Watchdog Register Granularity (STCU_WDG)

Table 1912. STCU_WDG field descriptions

Field	Description
WDGEOC	Watchdog End of Count Timer This value has to be set in order to define the time budget related to the Off/On-Line Self Test execution and check that everything is correctly working within this slot of time. The allowed delay time are the following: 0000 0000h: 1 × 16 STCU2 Core clock cycles 0000 0001h: 2 × 16 STCU2 Core clock cycles 0000 0002h: 3 × 16 STCU2 Core clock cycles ... FFFF FFFDh: 4294967294 × 16 STCU2 Core clock cycles FFFF FFFEh: 4294967295 × 16 STCU2 Core clock cycles FFFF FFFFh: 4294967296 × 16 STCU2 Core clock cycles

82.5.8 STCU2 Interrupt Flag Register (STCU_INT_FLG)

The STCU_INT_FLG register includes the MBIST and LBIST interrupt pending bits. These bits are effective only during the On-Line Self-Test phase and are managed only when the related control bit into the STCU_RUNSW register (MBIE and LBIE) are enabled.

Figure 2054. STCU2 Interrupt Flag Register (STCU_INT_FLG)

Table 1913. STCU_INT_FLG field descriptions

Field	Description
MBIFLG	<i>MBIST Interrupt Flag</i> 0: No interrupt is pending 1: An interrupt, highlighting that the On-Line execution of the concurrent scheduled MBIST is completed, is pending. Write 1 to clear the bit.
LBIFLG	<i>LBIST Interrupt Flag</i> 0: No interrupt is pending 1: An interrupt, highlighting that the On-Line execution of the concurrent scheduled LBIST is completed, is pending. Write 1 to clear the bit.

82.5.9 STCU2 CRC Expected Status Register (STCU_CRCE)

The STCU_CRCE register includes the expected signature of the CRC-32 (ethernet protocol). The CRC-32 bit engine is initialized at STCU_CRCE_RES and computes the CRC signature of the STCU2's critical signals and when STCU_CFG[CRCE] = 1, it is able to provide the Self-Check capability of the STCU2 managing the CRCS[SW] bits of the STCU_ERR_STAT register. The polynomial CRC used to evaluate the status of this register is the following:

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$$

Equation 91 CRC-32 (ethernet protocol)

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

Figure 2055. STCU2 CRC Expected Status Register (STCU_CRCE)

Offset: 001Ch

Access: User read/write

Table 1914. STCU_CRCE field descriptions

Field	Description
CRCE	CRC expected signature

82.5.10 STCU2 CRC Read Status Register (STCU_CRCR)

The STCU_CRCR register reports the value obtained at the end of the Off/On-line Self-Test sequence. It might be used for diagnoses and also as additional check with respect to the CRCS[SW] bit of the STCU_ERR_STAT register.

The content of this register is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Figure 2056. STCU2 CRC Read Status Register (STCU_CRCR)

Table 1915. STCU_CRCR field descriptions

Field	Description
CRCR	Read CRC signature

82.5.11 STCU2 Error Register (STCU_ERR_STAT)

The STCU_ERR_STAT register includes the status flags related to the STCU2 internal error conditions occurred during the configuration or the On/Off-Line self testing execution.

The UFSF and RFSF can be set/cleared using the FCCU dedicated channels as described in [Section 82.7.4, Design implementation information](#).

The access to this register is described in [Figure 2057](#) and as follows:

- If you select the byte write capability to write only the UFSF and RFSF, then there is no restriction in writing these bits.
- If your software performs the write operations on other bits besides UFSF/RFSF, then a transfer error is generated only if the value you are writing to the other bits differs from their value currently stored in the register. This functionality has been implemented to

prevent potential compilation behavior that might invalidate the UFSF/RFSF single bit set/clean capability.

1. You can always read this field. The content of this field is initialized to its reset value as soon as STCU_RUNSW[RUNSW] = 1.

Table 1916. STCU_ERR_STAT field descriptions

Field	Description
ABORTHW	<i>On-line hardware abort flag</i> 0: No hardware abort was requested during the On-Life Self-Test sequence 1: A hardware abort was detected during the On-Life Self-Test sequence
ABORTSW	<i>On-line software abort flag</i> 0: No software abort was requested during the On-Life Self-Test sequence 1: A software abort was detected during the On-Life Self-Test sequence
LOCKESW	<i>On-Line LOCK Error</i> 0: In case PLL is enabled, it is correctly locked during the Self-Test sequence 1: When the PLL is enabled, this flag highlight that there has been an unexpected PLL unlock event during the On-Line Self-Test sequence execution. The On-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU_RUNSW.LBSWPLEN is set and/or during the MBIST run when STCU_RUNSW[MBSWPLEN] = 1.
WDTOSW	<i>On-Line Watchdog time-out</i> 0: LBIST and MBIST time slot have been completed within the assigned watchdog time. 1: LBIST and MBIST time slot have not been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished

Table 1916. STCU_ERR_STAT field descriptions (continued)

Field	Description
CRCSSW	<i>On-Line CRC Status</i> This flag is activated ONLY when On-Line Self Test is performed and STCU_CFG.CRCEN is set to 1 otherwise it is always forced to 0 preventing in such a way the generation of the related STCU_ERR_STAT.UFSF/RFSF bits. In both the cases, the content of the STCU_CRCCR register report the current evaluated CRC. 0: Successful CRC comparison or comparison has been masked (STCU_CFG.CRCEN set to 0) 1: Failed CRC comparison
ENGESW	<i>On-Line Engine Error</i> 0: Valid Engine execution 1: Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
INVPSW	<i>On-Line Invalid Pointer</i> 0: Valid linked pointer list 1: Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in the LBIST/MBIST linking (execution generates an infinite loop)
UFSF	Unrecoverable Faults Status Flag This flag report the global status of the UF. 0: No errors that trigger the Unrecoverable Faults condition 1: There are errors that trigger the Unrecoverable Faults condition
RFSF	Recoverable Faults Status Flag 0: No errors that trigger the Recoverable Faults condition 1: There are errors that trigger the Recoverable Faults condition
LOCKE	<i>Off-Line LOCK Error</i> 0: The PLL is correctly locked during the Self-Test sequence 1: When the PLL is enabled, this flag highlight that there has been an unexpected PLL unlock event during the Off-Line Self-Test sequence execution. The On-Line Self-test run is stopped and the status of the current running LBISTs or MBISTs is saved into the related registers. The LOCK signal is monitored during the LBIST run when STCU_RUN[LBPLEN] = 1 and/or during the MBIST run when STCU_RUN[MBPLEN] = 1.
WDTO	<i>Off-Line Watchdog time-out</i> 0: LBIST and MBIST time slot have been completed within the assigned watchdog time. 1: LBIST and MBIST time slot haven't been completed within the assigned watchdog time or there are internal mismatches among End of Execution signals. The conditions that flag the failures are the following: – The STCU_RUN[RUN] bit or the STCU_CFG[BYP] bit are not set before the Watchdog reach the End of Count – MBIST BEND status flags that at least one of the selected MBIST run is not finished – lbist_done of the selected LBIST flags the LBIST run is/are not finished

Table 1916. STCU_ERR_STAT field descriptions (continued)

Field	Description
CRCS	<i>Off-Line CRC status</i> This flag is activated ONLY when Off-Line Self Test is performed STCU_CFG[CRCEEN] is set to 1 otherwise it is always forced to 0 preventing in such a way the generation of the related STCU_ERR_STAT.UFSF/RFSF bits. In both the cases, the content of the STCU_CRCCR register report the current evaluated CRC. 0: Successful CRC comparison or comparison has been masked (STCU_CFG[CRCEEN] programmed to 0) 1: Failed CRC comparison
ENGE	<i>Off-Line Engine Error</i> 0: Valid Engine execution 1: Invalid Engine execution. The following conditions set this bit: – STCU2 state machines (Watchdog, Master and Loader/Shifter) selects an unused code – Serial pass/fail status of the selected MBIST and the global BBAD flag are not aligned – Serial bend status of the selected MBIST and the global BEND flag are not aligned
INVP	<i>Off-Line Invalid pointer</i> 0: Valid linked pointer list 1: Invalid linked pointer list. The following conditions set this bit: – Initial LBIST or MBIST pointer is out of range – LBIST is selected when MBIST is concurrently running or vice versa – Error in the LBIST/MBIST linking (execution generates an infinite loop)

82.5.12 STCU2 Error FM Register (STCU_ERR_FM)

The STCU_ERR_FM register defines the fault mapping of the STCU2 faults described into the register STCU_ERR_STAT in terms of Unrecoverable or Recoverable Fault. All sources of internal faults can be routed to UF and RF.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

82.5.17 STCU2 On-Line LBIST Reset Management (STCU_LBRMSW)

The STCU_LBRMSW register defines the On-Line reset mapping for each LBIST. Global or specific functional reset can be programmed depending on the On-Line Self-Test requirements and top level integration architecture.

The size of the register depends on the number of LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

Figure 2063. STCU2 On-Line LBIST Reset Management (STCU_LBRMSW)

82.5.18 STCU2 LBIST Unrecoverable FM Register (STCU_LBUFM)

The STCU_LBUFM register defines the fault mapping of each LBIST in terms of Unrecoverable or Recoverable Fault.

The size of the register depends on the number of LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

82.5.34 STCU2 LBIST Control Register (STCU_LB_CTRL)

The STCU_LB_CTRL register defines the control setting of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

Figure 2080. STCU2 LBIST Control Register (STCU_LB_CTRL)

Offset: 0100h + (NLBIST – 1) × 40h

Access: User read/write

**Table 1939. STCU_LB_CTRL field descriptions**

Field	Description
CSM	<i>Concurrent/sequential mode</i> 0 Sequential mode 1 Concurrent mode
PTR	<i>Next LBIST or MBIST pointer</i> PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it's scheduled sequentially to the completion of the current LBIST execution. In case of NIL pointer the CSM bit has to be set Sequential (0) to define this is the end of the list. The self testing procedure is stopped when the current LBIST has been completed. 0h to (NLBIST -1): pointer to LBIST 10h to (10h + MBIST -1b): pointer to MBIST 7Fh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the STCU_ERR register.
PRPGEN	<i>Enable PRPG Loading</i> 0: Default LBIST value of the PRPG is used during LBIST run 1: LBIST PRPG value is initialized with the STCU_LB_PRPGL/H
SHS	<i>Shift speed</i> SHS defines the shift speed 000: Shift at full rate (bist_clk) 001: Shift at 1/2 rate (bist_clk) 010: Shift at 1/3 rate (bist_clk) 011: Shift at 1/4 rate (bist_clk) 100: Shift at 1/5 rate (bist_clk) 101: Shift at 1/6rate (bist_clk) 110: Shift at 1/7rate (bist_clk) 111: Shift at 1/8 rate (bist_clk)

Table 1939. STCU_LB_CTRL field descriptions (continued)

Field	Description
SCEN_OFF	<i>Scan enable OFF</i> SCEN_OFF defines the number of clock cycles OFF following the falling transition on the SCEN 0000: 0 delay cycles 0001: 1 delay cycles ... 1111: 15 delay cycles
SCEN_ON	<i>Scan enable ON</i> SCEN_ON defines the number of clock cycles OFF following the rising transition on the SCEN 0000: 0 delay cycles 0001: 1 delay cycles ... 1111: 15 delay cycles
PFT	<i>Past Flush Test</i> The LBIST controller, by default apply 32 Flush Test patterns. This bit allows to skip/apply the Flush test pattern sequence. 0: Apply Flush Test Patterns 1: Skip Flush Test Patterns
CWS	<i>Capture window size</i> CWS defines the capture window size. 000: illegal 001: controller waits 1 shift cycle for capture to finish 010: controller waits 2 shift cycles for capture to finish ... 111: controller waits 7 shift cycles for capture to finish

82.5.35 STCU2 LBIST PC Stop Register (STCU_LB_PCS)

The STCU_LB_PCS register defines the pattern counter stop of each LBIST controller.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

Figure 2081. STCU2 LBIST PC Stop Register (STCU_LB_PCS)

Table 1940. STCU_LB_PCS field descriptions

Field	Description
PCS	<i>Pattern counter stop</i> PCS defines the pattern counter stop value.

82.5.36 STCU2 LBIST PRPG Low Register (STCU_LB_PRPGL)

The STCU_LB_PRPGL register defines the LSB part (31..0) of the PRPG start value of the LBIST controller.

The size of the register depends on the number of PRPG bits of the related LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

82.5.38 STCU2 Off-Line LBIST MISR Expected Low Register (STCU_LB_MISREL)

The STCU_LB_MISREL register defines the LSB part (31..0) of the Expected MISR of the Off-Line LBIST controller.

The size of the register depends on the number of MISR bits of the related LBIST.

The R/W fields in this register are readable at any time. However, you can write to these fields only when Off-line Self-Test phase is still active.

Figure 2084. STCU2 Off-Line LBIST MISR Expected Low Register (STCU_LB_MISREL)

Table 1943. STCU_LB_MISREL field descriptions

Table 1945. STCU_LB_MISRRL field descriptions

Field	Description
MISRRLx	<i>Off-Line MISR Read Low Bits</i> This field is equivalent to the Low Bits (31..0) of the MISR obtained at the end of the Off-Line LBIST execution

82.5.41 STCU2 Off-Line LBIST MISR Read High Register (STCU_LB_MISRRLH)

The STCU_LB_MISRRLH register report the MSB part (63..32) of the MISR obtained at the end of each Off-Line LBIST controller execution.

The size of the register depends on the number of MISR bits of the related LBIST.

Table 1946. STCU_LB_MISRRH field descriptions

Field	Description
MISRRx	Off-Line MISR Read High Bits This field is equivalent to the High Bits (63..32) of the MISR obtained at the end of the Off-Line LBIST execution

82.5.42 STCU2 On-Line LBIST MISR Expected Low Register (STCU_LB_MISRELSW)

The STCU_LB_MISRELSW register defines the LSB part (31..0) of the Expected MISR of the On-Line LBIST controller.

The size of the register depends on the number of MISR bits of the related LBIST.

The R/W fields in this register are readable at any time. You can write to these fields when either of the following conditions is true:

- Off-line Self-Test phase is active
- On-line Self-Test phase is active and STCU_CFG[WRP] = 0

Figure 2088. STCU2 On-Line LBIST MISR Expected Low Register (STCU_LB_MISRELSW)

Table 1951. STCU_MB_CTRL field descriptions

Field	Description
CSM	<i>Concurrent/sequential mode</i> 0: Sequential mode 1: Concurrent mode
PTR	<i>Next LBIST or MBIST pointer</i> PTR defines the logical pointer to the next LBIST or MBIST to be scheduled. The next LBIST or MBIST is scheduled concurrently to the current one if the CSM bit is set to 1, otherwise it's scheduled sequentially to the completion of the current MBIST execution. In case of NIL pointer the CSM bit has to be set Sequential (0) to define this is the end of the list. The self testing procedure is stopped when the current MBIST has been completed. 0h to (LBIST -1): pointer to LBIST 10h to (10h + MBIST -1b): pointer to MBIST 7Fh: pointer to NIL. No BIST execution. others: invalid pointer => an error is set into the STCU_ERR register.

82.6 Register map

In the following is reported the STCU2 register map in case a full implementation is performed. In case a small number of LBIST or MBIST are implemented the following considerations have to be taken into account:

- the size of the STCU_LBS, STCU_LBSSW, STCU_LBE, STCU_LBESW, STCU_LBRMSW, STCU_LBUFM depends on the number of LBIST;
- the size of STCU_MBSL, STCU_MBSLSW, STCU_MBEL, STCU_MBELSW, STCU_MBUFML depends on the number of BISTed RAMs/ROMs;
- the size of STCU_MBSM, STCU_MBSMSW, STCU_MBEM, STCU_MBEMSW, STCU_MBUFMM depends on the number of BISTed RAMs/ROMs only when the related value is greater than 32, otherwise these registers are not implemented;
- the size of the STCU_MBSH, STCU_MBSHSW, STCU_MBEH, STCU_MBEHSW, STCU_MBUFMH depends on the number of BISTed RAMs/ROMs only when the related value is greater than 64, otherwise these registers are not implemented;
- the number of STCU_LB_CTRL, STCU_LB_PCS, STCU_LB_PRPGL, STCU_LB_PRPGH, STCU_LB_MISREL, STCU_LB_MISRELSW, STCU_LB_MISREH, STCU_LB_MISREHSW, STCU_LB_MISRRL, STCU_LB_MISRRLSW, STCU_LB_MISRRLH and STCU_LB_MISRRLHSW depends on the number of LBIST;
- the size of each STCU_LB_MISREL, STCU_LB_MISRELSW and STCU_LB_MISRRL, STCU_LB_MISRRLSW depends on the number of MISR bits of the related LBIST;
- the size of each STCU_LB_MISREH, STCU_LB_MISREHSW, and STCU_LB_MISRRLH, STCU_LB_MISRRLHSW, depends on the number of MISR bits of the related LBIST only when the related value is greater than 32 otherwise the registers are not implemented;
- the size of STCU_LB_PRPGL and STCU_LB_PRPGH depends on the number of PRPG bits of the related LBIST.
- the number of STCU_MB_CTRL depends on the number of BISTed RAMs/ROMs.

82.7 Use cases and limitations

The STCU2 module is designed to give high flexibility during the on/off-line test. In the following are reported the programming operations that have to be performed to correctly use the functionality of this module considering the three typical usage cases:

- the Off-line Self Test Sequence after a reset trigger event
- the bypass mode of the Self Test Sequence after a reset trigger event
- the On-line Self-test Sequence

82.7.1 Off-Line Self-Test Sequence

This is the typical mode of using the STCU2 module after reset trigger event is applied to STCU2. The SSCM DCF bus is used to retrieve the STCU2 schedule and L/MBIST execution parameters stored into the NVM memory. The target is to cover the amount of physical defect into the digital logic and into the System RAMs/ROMs according to the System specifications. The sequence is the following:

- Unlock the Off-Line STCU2 access writing the Key1/Key2 sequence into the STCU_SKC register
- Program the LBIST fault reaction conditions (UF/RF) setting the STCU_LBUFM register
- Program the MBIST fault reaction conditions (UF/RF) setting, depending on the number of memories, the STCU_MBUFML/M/H registers
- Program the STCU2 internal fault reaction conditions (UF/RF) setting the STCU_ERR_FM register
- Program the STCU_LB_CTRL, STCU_LB_PCS, STCU_MISREL/H registers of each LBIST to be executed. Optionally, also the STCU_LB_PRPGL/H can be programmed in order to load a specific seed.
- Program the STCU_MB_CTRL registers of each NMCUT to be executed
- Program the STCU_WDG register to define the time budget assigned for the L/MBIST execution
- Program the STCU_CFG register in order to define: the core and L/MBIST TCK clock prescaling factor setting the CLK_CFG bits; the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase; the PMOSEN or CHKBRD in order to define the

algorithm to be used during MBIST run, the CRCREN bit to enable the self-checking feature and finally set the pointer to the first LBIST/NMCUT to be executed.

- In case the internal CRC comparison has been enabled, program the CRCE value expected at the end of the off-line Self Test sequence into the STCU_CRCE register
- In case the PLL usage has been enabled, program the STCU_PLL_CFG value in order to set the required system frequency
- Program the RUN bit into the STCU_RUN register to enable the Off-Line Self-Test execution and the L/MBPLEN bits to enable the PLL during L/MBIST execution according to STCU_PLL_CFG register content
- Start the Off-Line Self-Test and, depending on PLL management and L/MBIST execution order, .
- Wait the WDGE0C run time execution specified into the STCU_WDG register.
- The STCU2 switch-off the core clock at the end of the Self-Test run and release the PLL control in case this feature has been enabled.
- The STCU2 reset the STCU_RUN[RUN] bit and the device exit from boot sequence. In case there are failures, the STCU2 flag these failures toward the FCCU rising one/both the *stcu_ncf* and *stcu_cf* lines.
- The software application read the STCU_LBS flag register to check the failed LBIST when UF or RF conditions is/are detected.
- The software application read the STCU_LBE flag register to check the LBIST still on-going when UF or RF is/are detected.
- The software application read the STCU_MBSL/M/H flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected.
- The software application read the STCU_MBEL/M/H flag registers, depending on the number of memories, to check the RAMs/ROMs Memory BIST still on-going when UF or RF is/are detected.
- The software application read the bit INV, ENGE, CRCS, WDTO, LOCKE of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected.
- In case the CRCEN bit has been enabled, the software application read the CRCE and CRCR registers to check the coherence with the bit CRCS of the STCU_ERR register.
- The software application read for each device's LBIST, the STCU_LBMISREL/H and STCU_LBIST_MISRRL/H registers to check the coherence with the STCU_LBS bits.

Note: :The software application read operations on the STCU2 CRC and LBIST MISR registers after off-line self Test execution has been successfully performed are just an additional safety layer to be added to improve the already implemented Auto Self-Test feature included into STCU2.

82.7.2 On-Line Self-Test Sequence

This is the typical mode of using the STCU2 module during the application run. The IPS interface is used to program the STCU2 registers and to schedule the L/MBIST execution. Since the On-Line L/MBIST operations clean-up the content of the related Digital Logic

(LBIST) or RAM (MBIST) the activation of this mode has to be done carefully. The suggested sequence is the following:

- Unlock the On-Line STCU2 access writing the Key1/Key2 sequence into the STCU_SKC register
- Check and/or clean-up the bit WRP into the STCU_CFG register to open the IPS access on the STCU2 On-Line Self-Test registers
- The LBIST, MBIST and STCU2 internal fault reaction should have been already programmed during the Off-Line Self-Test sequence and so they should not be programmed again. However, in case they have not been programmed or there is the need of changing them for any reason, they can be overwritten setting respectively the registers: STCU_LBUFM, STCU_MBUFML/M/H and STCU_ERR_FM.
- Program the Reset management during on-Line LBIST execution setting the STCU_LBRMSW register
- The STCU_LB_CTRL, STCU_LB_PCS should have been already programmed during Off-Line Self-test sequence and so they should not be programmed again. However, in case they have not been programmed or there is the need of changing them for any reason, they can be overwritten. The registers STCU_LB_MISRELSW/HSW have to be programmed according to the expected signature.
- Overwrite/Program the STCU_MB_CTRL registers of each NMCUT to be executed
- Overwrite/Program the STCU_WDG register to define the time budget assigned for the L/MBIST execution
- Overwrite/Program the STCU_CFG register in order to define: the core and L/MBIST TCK clock prescaling factor setting the CLK_CFG bits; the LB_DELAY field to delay the LBIST start when many LBIST are run concurrently to mitigate the potential transient power issue during the start-up phase; the PMOSEN or CHKBRD in order to define the algorithm to be used during MBIST run, the CRCREN bit to enable the self-checking feature and finally set the pointer to the first LBIST/NMCUT to be executed.
- In case the internal CRC comparison has been enabled, overwrite/program the CRCE value expected at the end of the on-line Self Test sequence into the STCU_CRCE register
- Program the RUNSW bit into the STCU_RUNSW register to enable the On-Line Self-Test execution, the L/MBIE to enable the Interrupt requests, and the L/MBSWPLEN bits to enable the PLL lock signal monitor during L/MBIST execution.
- Start the On-Line Self-Test and depending on PLL management and L/MBIST execution order.
- Wait the WDGEOC run time execution specified into the STCU_WDG register
- In case the L/MBIE have been enabled, an interrupt is generated at the end of all the L/MBIST execution. The software application has to manage these interrupt signals and clean-up the related flag (L/MBIFLG) into the STCU_INT_FLG register.
- The STCU2 switch-off the core clock at the end of the Self-Test run
- The functional reset activated is managed by the STCU_LBRMSW.
- In case, at least one of the selected LBIST enables the Global functional reset, the STCU2 requests a functional reset which restarts the system while, when all the

selected LBIST enables its own dedicated functional reset, only these local reset lines are applied and only the related LBIST partitions are cleaned-up.

- The STCU2 resets the STCU_RUNSW[RUNSW] bit. In both the reset cases and in case of error/s, the STCU2 flags the failure toward the FCCU rising one/both of the *stcu_ncf* and *stcu_cf* lines.
- The software application read the STCU_LBSSW flag register to check the failed LBIST when UF or RF conditions is/are detected
- The software application read the STCU_LBESW flag register to check the LBIST still on-going when UF or RF is/are detected
- The software application read the STCU_MBSLSW/MSW/HSW flag registers, depending on the number of memories, to check the failed RAMs/ROMs Memory BIST when UF or RF is/are detected
- The software application read the STCU_MBELSW/MSW/HSW flag registers, depending on the number of memories, to check the RAMs/ROMs Memory BIST still on-going when UF or RF is/are detected
- The software application read the bit INVPSW, ENGESW, CRCSSW, WDTOSW, LOCKESW of the STCU_ERR_STAT register to check whether there has been an internal STCU2 engine/parameters failure when UF or RF is/are detected
- In case the CRCEN bit has been enabled, the software application read the CRCE and CRCE registers to check the coherence with the bit CRCSSW of the STCU_ERR register
- The software application read for each device's LBIST, the STCU_LBMISRELSW/HSW and STCU_LBIST_MISRRLSW/HSW registers to check the coherence with the STCU_LBS bits

Note: The software application read operations on the STCU2 CRC and LBIST MISR registers after on-line self-test execution has been successfully performed are just an additional safety layer to be added to improve the already implemented Auto Self-Test feature included in the STCU2.

82.7.3 Bypass USER Mode

In this case, the USER application parameters stored in FLASH and read by SSCM are written in order to skip the Self-Test procedure after a reset trigger event is applied. It might be useful in case the device is not configured for Safety application. The sequence is the following:

1. Unlock the STCU2 access writing the Off-Line Key1/Key2 sequence into the STCU_SKC register
2. Set the BYP bit in the STCU_RUN register

After BYP bit is set, the core clock is switched off, the Self-Test sequence is not applied and the system can wake up and start the user application.

82.7.4 Design implementation information

The following list reports the limitations related to the current implementation:

- Every NMCUT MBIST or LBIST can be run one time during the On/Off-line Self-test procedure.
- It is not possible to run LBIST and MBIST concurrently.
- Since during the On-Line Self-Test the software has the full control of the system while applications are running, the STCU2 is not allowed to take the control of the PLL but can just monitor the lock signal to flag wrong unlock events.

82.8 Open issues

No open issues.

83 Register Protection (REG_PROT)

83.1 Introduction

83.1.1 Overview

The Register Protection (REG_PROT) module offers a mechanism to protect defined memory-mapped address locations in a module under protection from being written. The address locations that can be protected are module-specific.

Note: Please see the device configuration chapter of the device reference manual for details of the protected registers and bytes.

The protection module is located between the module under protection and the AIPS. This is shown in [Figure 2093](#).

Figure 2093. REG_PROT Block Diagram

83.1.2 Features

The Register Protection includes these distinctive features:

- Restrict write accesses for the module under protection to supervisor mode only
- Lock registers for first 6 KB of memory-mapped address space
- Write to address mirror automatically sets corresponding lock bit
- Once configured lock bits can be protected from changes

Also, hard lock bit protection can only be cleared by a system reset once set

83.1.3 Modes of operation

The Register Protection module is operable when the module under protection is operable.

83.2 External signal description

There are no external signals.

83.3 Memory map and register definition

This section provides a detailed description of the memory map of a module using the REG_PROT. The original 16 KB module memory space is divided into five areas as shown in [Figure 2094](#).

Figure 2094. REG_PROT Memory Diagram

- Area 1 is 6 KB and holds the normal functional module registers and is transparent for all read/write operations.
- Area 2 is 2 KB starting at offset 0x1800 is a reserved area, which shall not be accessed.
- Area 3 is 6 KB, starting at offset 0x2000 and is a mirror of area 1. A read/write access to an offset 0x2000+X will read/write the register at offset X. However a write access to offset 0x2000+X will additionally set the optional Soft Lock Bits for this offset X in the same cycle as the register at offset X is written. This provides for an atomic write and lock operation. Not all registers in area 1 need to have protection defined by associated

Soft Lock Bits. For unprotected registers at offset Y, accesses to offset 0x2000+Y will be identical to accesses at offset Y.

- Area 4 is 1.5 KB and holds the Soft Lock Bits, one bit per byte in area 1. The four Soft Lock Bits associated with one module register word are arranged at byte boundaries in the memory map. The Soft Lock Bit registers can be directly written using a bit mask.
- Area 5 is 512 bytes large and holds the configuration bits of the protection mode. There is one configuration hard lock bit per module that prevents all further modifications to the Soft Lock Bits and can only be cleared by a system reset once set. The other bits, if set, will allow user access to the protected module.

If any locked byte is accessed with a write transaction, a transfer error will be issued to the system and the write transaction will not be executed. This is true even if not all accessed bytes are locked.

Accessing unimplemented 32-Bit registers in Areas 4 and 5 will result in a transfer error.

83.3.1 Memory map

[Figure 1953](#) shows the memory map for a module which is protected via a REG_PROT module.

Table 1953. REG_PROT Memory Map

Offset	Use	Location
0x0000	Module Register 0 (MR0)	on page 3601
0x0001	Module Register 1 (MR1)	on page 3601
0x0002	Module Register 2 (MR2)	on page 3601
0x0003 - 0x17FF	Module Register 3 (MR3) - Module Register 6143(MR6143)	on page 3601
0x1800 - 0x1FFF	Reserved	
0x2000	Module Register 0 (MR0) + Set Soft Lock Bit 0 (LMR0)	on page 3601
0x2001	Module Register 1 (MR1) + Set Soft Lock Bit 1 (LMR1)	on page 3601
0x2002 - 0x37FF	Module Register 2 (MR2) + Set Soft Lock Bit 2 (LMR2) - Module Register 6143 (MR6143) + Set Soft Lock Bit 6143 (LMR6143)	on page 3601

0x3801	Soft Lock Bit Register 1 (SLBR1): Soft Lock Bits 4-7	on page 3601
0x3802 - 0x3DFF	Soft Lock Bit Register 2 (SLBR2): Soft Lock Bits 8-11 - Soft Lock Bit Register 1535 (SLBR1535): Soft Lock Bits 6140-6143	on page 3601
0x3E00 - 0x3FFB	Reserved	
0x3FFC	Global Configuration Register (GCR)	on page 3603

Note: *Reserved registers in area #1 will be handled as specified in the protected module's documentation.*

83.3.2 Register descriptions

This section describes in address order all the REG_PROT registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Figure 2095. Key to Register Fields

83.3.2.1 Module Registers (MR0-6143)

This is the lower 6 KB module memory space which holds all the functional registers of the module that is protected by the REG_PROT module.

83.3.2.2 Module Register and Set Soft Lock Bit (LMR0-6143)

This is memory area #3 that provides mirrored access to the MR0-6143 registers with the side effect of setting Soft Lock Bits in case of a write access to a MR that is defined as protectable by the locking mechanism. Each MR is protectable by one associated bit in a SLBR n .SLB m , according to the mapping described in [Table 1954](#).

83.3.2.3 Soft Lock Bit Register (SLBR0-1535)

These registers hold the Soft Lock Bits for the protected registers in memory area #1.

Figure 2096. Soft Lock Bit Register (SLBR n)

Address 0x3800-0x3DFF					Access: Read always Supervisor write			
	0	1	2	3	4	5	6	7
R	0	0	0	0	SLB0	SLB1	SLB2	SLB3
W	WE0	WE1	WE2	WE3				
Reset	0	0	0	0	0	0	0	0

Table 1954. SLBR n field descriptions

Field	Description
0 WE0	Write Enable Bits for Soft Lock Bits (SLB): WE0 enables writing to SLB0 1 Value is written to SLB 0 SLB is not modified
1 WE1	Write Enable Bits for Soft Lock Bits (SLB): WE1 enables writing to SLB1 1 Value is written to SLB 0 SLB is not modified

Table 1954. SLBR_n field descriptions (continued)

Field	Description
2 WE2	Write Enable Bits for Soft Lock Bits (SLB): WE2 enables writing to SLB2 1 Value is written to SLB 0 SLB is not modified
3 WE3	Write Enable Bits for Soft Lock Bits (SLB): WE3 enables writing to SLB3 1 Value is written to SLB 0 SLB is not modified
4 SLB0	Soft Lock Bits for one MR _n register: SLB0 can block accesses to MR[_n * 4 + 0] 1 Associated MR _n byte is locked against write accesses 0 Associated MR _n byte is unprotected and writeable
5 SLB1	Soft Lock Bits for one MR _n register: SLB1 can block accesses to MR[_n * 4 + 1] 1 Associated MR _n byte is locked against write accesses 0 Associated MR _n byte is unprotected and writeable
6 SLB2	Soft Lock Bits for one MR _n register: SLB2 can block accesses to MR[_n * 4 + 2] 1 Associated MR _n byte is locked against write accesses 0 Associated MR _n byte is unprotected and writeable
7 SLB3	Soft Lock Bits for one MR _n register: SLB3 can block accesses to MR[_n * 4 + 3] 1 Associated MR _n byte is locked against write accesses 0 Associated MR _n byte is unprotected and writeable

Table 1955 gives some examples how SLBR_n.SLB and MR_n go together:

Table 1955. Soft Lock Bits vs. Protected Address

Soft Lock Bit	Protected address
SLBR0.SLB0	MR0
SLBR0.SLB1	MR1
SLBR0.SLB2	MR2
SLBR0.SLB3	MR3
SLBR1.SLB0	MR4
SLBR1.SLB1	MR5
SLBR1.SLB2	MR6
SLBR1.SLB3	MR7
SLBR2.SLB0	MR8
...	...

83.3.2.4 Global Configuration Register (GCR)

This register controls the configuration of the locking of the SLB's and the level of user access allowed to the protected registers.

Figure 2097. Global Configuration Register (GCR)

Offset 0x3FFC																Access: Read Always Supervisor write															
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0															

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1956. GCR field descriptions

Field	Description
HLB	Hard Lock Bit. This register can not be cleared once it is set by software. It can only be cleared by a system reset. 1 All SLB bits are write protected and can not be modified 0 All SLB bits are accessible and can be modified.
UAA	User Access Allowed. 1 The registers in the module under protection can be accessed in the mode defined for the module registers without any additional restrictions. 0 The registers in the module under protection can only be written in supervisor mode. All write accesses in non-supervisor mode are not executed and a transfer error is issued. This access restriction is in addition to any access restrictions imposed by the protected IP module.

Note: The GCR.UAA bit has no effect on the allowed access modes for the registers in the REG_PROT module.

83.4 Functional description

83.4.1 General

This module provides a generic register (address) write-protection mechanism. The protection size can be:

- 32-bit (address == multiples of 4)
- 16-bit (address == multiples of 2)
- 8-bit (address == multiples of 1)

Which addresses are protected and the protection size depend on the SoC and/or module..

For all addresses that are protected there are $SLBRn.SLBm$ bits that specify whether the address is locked. When an address is locked it can only be read but not written in any mode (supervisor/normal). If an address is unprotected the corresponding $SLBRn.SLBm$ bit is always 0b0 no matter what software is writing to.

83.4.2 Change lock settings

To change the setting whether an address is locked or unlocked the corresponding $SLBRn.SLBm$ bit needs to be changed. This can be done using the following methods:

- Modify the $SLBRn.SLBm$ directly by writing to area #4
- Set the $SLBRn.SLBm$ bit(s) by writing to the mirror module space (area #3)

Both methods are explained in the following sections.

83.4.2.1 Change lock settings directly via Area #4

In memory area #4 the lock bits are located. They can be modified by writing to them. Each $SLBRn.SLBm$ bit has a mask bit $SLBRn.WEm$ which protects it from being modified. This masking makes clear-modify-write operations unnecessary.

Figure 2098 shows two modification examples. In the left example there is a write access to the $SLBRn$ register specifying a mask value which allows modification of all $SLBRn.SLBm$ bits. The example on the right specifies a mask which only allows modification of the bits $SLBRn.SLB[3:1]$.

Figure 2098. Change lock settings directly via Area #4

Figure 2098 showed four registers that can be protected 8-bit wise. In *Figure 2099* registers with 16-bit protection and in *Figure 2100* registers with 32-bit protection are shown:

Figure 2099. Change lock settings for 16-bit protected addresses

On the right side of [Figure 2099](#) it is shown that the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[1] also. This is done as the address reflected by SLBRn.SLB[0] is protected 16-bit wise. Note that in this case the write enable SLBRn.WE[0] must be set while SLBRn.WE[1] does not matter. As the enable bits SLBRn.WE[3:2] are cleared the lock bits SLBRn.SLB[3:2] remain unchanged.

In the example on the left side of [Figure 2099](#) the data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] and the data written to SLBRn.SLB[2] is mirrored to SLBRn.SLB[3] as for both registers the write enables are set.

In [Figure 2100](#) a 32-bit wise protected register is shown. When SLBRn.WE[0] is set the data written to SLBRn.SLB[0] is automatically written to SLBRn.SLB[3:1] also. Otherwise SLBRn.SLB[3:0] remains unchanged.

**Figure 2100. Change lock settings for 32-bit protected addresses**

In [Figure 2101](#) an example is shown which has a mixed protection size configuration:

**Figure 2101. Change lock settings for mixed protection**

The data written to SLBRn.SLB[0] is mirrored to SLBRn.SLB[1] as the corresponding register is 16-bit protected. The data written to SLBRn.SLB[2] is blocked as the corresponding register is unprotected. The data written to SLBRn.SLB[3] is written to SLBRn.SLB[3].

83.4.2.2 Enable locking via mirror module space (Area #3)

It is possible to enable locking for a register after writing to it. To do so the mirrored module address space must be used. [Figure 2102](#) shows one example:

Figure 2102. Enable Locking Via Mirror Module Space (Area #3)

When writing to address 0x0008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits remain unchanged (left part of [Figure 2099](#)).

When writing to address 0x2008 the registers MR9 and MR8 in the protected module are updated. The corresponding lock bits SLBR2.SLB[1:0] are set while the lock bits SLBR2.SLB[3:2] remain unchanged (right part of [Figure 2099](#)).

[Figure 2103](#) shows an example where some addresses are protected and some are not:

Figure 2103. Enable locking for protected and unprotected addresses

In the example in [Figure 2103](#) addresses 0x0C and 0x0D are unprotected. Therefore their corresponding lock bits SLBR3.SLB[1:0] are always 0b0 (shown in bold). When doing a 32-bit write access to address 0x200C only lock bits SLBR3.SLB[3:2] are set while bits SLBR3.SLB[1:0] stay 0b0.

Note: Lock bits can only be set via writes to the mirror module space. Reads from the mirror module space will not change the lock bits.

83.4.2.3 Write protection for locking bits

Changing the locking bits through any of the procedures mentioned in [Section 83.4.2.1, Change lock settings directly via Area #4](#) and [Section 83.4.2.2, Enable locking via mirror module space \(Area #3\)](#) is only possible as long as the bit GCR.HLB is cleared. Once this bit is set the locking bits can no longer be modified until there was a system reset.

83.4.3 Access errors

The protection module generates transfer errors under several circumstances. For the area definition refer to [Figure 2094](#)

1. If accessing area #1 or area #3, the protection module will pass on any access error from the underlying Module under Protection.
2. If user mode is not allowed, user writes to all areas will assert a transfer error and the writes will be blocked.
3. If accessing the reserved area #2, a transfer error will be asserted.
4. If accessing unimplemented 32-bit registers in area #4 and area #5 a transfer error will be asserted.
5. If writing to a register in area #1 and area #3 with Soft Lock Bit set for any of the affected bytes a transfer error is asserted and the write will be blocked. Also the complete write operation to non-protected bytes in this word is ignored.
6. If writing to a Soft Lock Register in area #4 with the Hard Lock Bit being set a transfer error is asserted.
7. Any write operation in any access mode to area #3 while Hard Lock Bit GCR.HLB is set

83.5 Initialization/application information

83.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (See [Section 83.3.2, Register descriptions](#)). In summary, after reset, locking for all MR_n registers is disabled. The registers can be accessed in Supervisor Mode only.

83.5.2 Writing C code using the register protection scheme

There is a set of macros provided as part of the device specific header file, which defines the memory map, the peripheral registers, and the fields of these registers. These macros are intended to make working with the register protection scheme easier for the developers of device driver software and/or other application code. This section describes these macros and how to use them.

A first macro is made available to perform a write to the mirrored module register space (Area 3). As described in this document, this results in concurrently setting the corresponding soft lock bit, while writing to the module register. There are three flavors of this macro, to account for the different size of the related module register `<thereg>` (the value of `<size>` is either 8, 16, or 32 bit):

```
WRITE_WITH_LOCK<size>(<thereg>, <newvalue>)
```

This macro writes the value `<newvalue>` into the register `<thereg>` assuming a register size of `<size>`. The parameter `<thereg>` must be the name of a register using the notation in the device specific header file.

A second set of macros is made available to work with the soft lock bits provided by the register protection scheme. The value of these bits associated with a particular module register `<thereg>` can be retrieved, set, and cleared. The macros provided for this purpose are:

```
GET_SOFTLOCK(<thereg>, <dest>)
SET_SOFTLOCK<size>(<thereg>)
CLR_SOFTLOCK<size>(<thereg>)
```

The macro `GET_SOFTLOCK` retrieves the value of the soft lock bit register associated with the given register `<thereg>` and stores it in the variable `<dest>`; which is always an eight bit

value. The other two macros (SET_SOFTLOCK, CLR_SOFTLOCK) set or clear the softlock bits associated with the given register <thereg>; assuming this register has a size of 8, 16, or 32 bit as indicated by the macro name. For all three macros, the parameter <thereg> must be the name of a register using the notation in the device specific header file.

Three more macros are made available to modify bits in the Global Configuration Register (GCR) of the protection gasket for the corresponding block. In contrast to the earlier ones, these macros receive the base address of the corresponding block (usually named <block_name>_BASEADDRESS) as a parameter.

SET_HARDLOCK(base)

Sets the Hard Lock Bit HLB in the GCR register associated with the module identified by the given base address <base>.

USER_ACCESS_FORBIDDEN(base)

Clears the User Access Allowed Bit UAA in the GCR register associated with the module identified by the given base address <base>. When cleared, this bit denies any write access to the protected module in user mode and generates a transfer error in case of an attempt to write a protected register.

USER_ACCESS_ALLOWED(base)

Sets the User Access Allowed Bit UAA in the GCR register associated with the module identified by the given base address <base>. When set, this bit permits write accesses to the protected module in user mode when the corresponding register are not additionally protected by other means.

Finally, two more macros are provided to permit direct access to the registers in the register protection gasket using the same semantic as other register definitions in the device specific header file:

LOCK_SLB(thereg)

provides the content of the soft lock bit register associated with the register <thereg>; the parameter <thereg> must be the name of the corresponding module register using the notation in the device specific header file.

LOCK_GCR(base)

provides the content of the Global Configuration Register GCR for the block identified by its base address <base>; the parameter <base> must be the base address of the corresponding block.

84 Password and Device Security Module (PASS)

84.1 Introduction

84.1.1 Overview

The Password and device security (PASS) module shown in [Figure 2104](#), receives password challenges and determines their validity. It also maintains the device security and access states.

Figure 2104. PASS module block diagram

84.1.2 Features

The PASS includes these distinctive features:

- Life cycle status
- Password comparison
- JTAG password comparison
- Production Disable control

84.1.3 Modes of operation

The PASS operates identically in all system modes.

84.2 External signal description

The PASS has 1 external pin that is used for Production Disable control.

84.3 Memory map/register definition

This section provides a detailed description of all memory-mapped registers and DCF clients in the PASS.

Where a DCF client is listed, the reset value of that register maybe automatically preloaded during reset based on the data stored in DCF Records in flash UTEST region.

[Table 1957](#) shows the memory map for the PASS. Note that all addresses are offsets; the absolute address for registers may be calculated by adding the specified offset to the base address of the PASS. The address of the DCF client is local to the PASS module and must be qualified with the appropriate Chip Select (CS[14:0]) for the PASS module as defined in the DCF Record Section of the Reference Manual

Table 1957. Module memory map

Offset	Register	Access	Reset Value	DCF Client Address (ADDR[14:0])	Section/Page

1. Reset value depends on life cycle status

2. Reset value depends on password group lock state

Note: Non-implemented registers generate bus aborts, if enabled by the SOC.

84.3.1 Register descriptions

The following registers are available in the PASS. Those bits that are shaded out are reserved for future use. To optimize future compatibility, these bits should only be written with '0'. They will always read back '0'.

84.3.1.1 Life Cycle Status register (LCSTAT)

The Life Cycle Status Register reflects the production status and censorship status of the device. It's possible to mature the device (move the device life cycle forward), but never to make the device younger (move the life cycle to an earlier state).

The reset value for the LCSTAT register LIFE field is defined by a DCF client that is automatically pre-loaded during reset from data in flash UTEST region. The DCF client is 0xFF by default and configured such that bits can only be written from '1' to '0'. Subsequent DCF records can move the LIFE field through the Life Cycle states.

Figure 2105. Life Cycle Status register (LCSTAT)

Note: 'X' means the reset value is coming from a DCF client

Offset 0x0000

Access: Read

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

PASS_LCSTAT register functions are as shown in [Table 1958](#).

Table 1958. LCSTAT register field descriptions

Field	Description
0 CNS	This field indicates the System Censoring Status. The bit can be set (or cleared) via DCF Record in UTest Flash. See section Section 84.5.4, "Censoring/uncensoring the device" . 1 Device is censored 0 Device is uncensored
1 JUN	This field indicates whether the device has been temporarily uncensored. Successful transmission of the JTAG password sets this bit to 1, otherwise it is 0. Unsuccessful transmission clears this bit.
2–23	Reserved
24–31 LIFE	This field shows the value of the life cycle DCF Record. The field can not be written directly, but is determined by the Life cycle records which have been written into the UTest Flash. 1111_110- Customer Delivery 1111_10-- OEM Production 1111_0--- In Field ---0---- Failure Analysis mode ('-' indicates that the value of the bit is not considered for interpretation of the life cycle.)

The effects of the life cycle on security is described in [Section 84.4.1, Life cycle and security](#).

84.3.1.2 Challenge Selector register (CHSEL)

This register determines which password group is challenged via the Challenge Input Register.

Figure 2106. CHSEL register

Offset 0x0008												Access: Read/Write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

CHSTAT register functions are as shown in [Table 1960](#).

Table 1960. CHSEL register field descriptions

Field	Description
0–27	Reserved
28–31 CMST	ID of the master which has last written the CHSEL register

Only the master shown in this register can access the CINn registers—access by other masters will result in a comparison fail, regardless of the values written.

84.3.1.4 Challenge Input register (CIN_n)

This register is used to provide the Challenge word *n* for a password group as selected by the Challenge Selector Register.

Figure 2108. CIN_n register

CIN register functions are as shown in [Table 1961](#).

Table 1961. CIN register field descriptions

Field	Description
0–31 PW32	32 bits of the 256 bit password challenge. Only 32-bit writes may be used.

After programming the Challenge Selector Register the password challenge needs to be written with eight 32bit writes to CIN0 to CIN7 - in that order. The most significant 32 bits of the password challenge must be written to CIN0. Once CIN7 is written the password will be compared. The write access will only complete once the comparison has been executed.

All accesses to these registers need to be made by the bus master which wrote the CHSEL register previously. If another master writes any of the CIN registers before the original master has written CIN7, the comparison will fail.

84.3.1.5 Censorship

Censorship is a DCF client that is NOT accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the flash UTEST region. The Censorship DCF clients defines if the MCU is censored.

DCF Client Address: 0x00B0 Censorship

Access: DCF Record Write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. This bit is not defined
2. This value is loaded by DCF Record during reset

Table vi

Field	Description
0–15	Reserved
16:31	Censorship If this value is 0x55AA the MCU is NOT censored If this value is anything other than 0x55AA, the MCU is censored

84.3.1.6 Production Disable

Production Disable is a DCF client that is NOT accessible by software. It is automatically pre-loaded during reset with data stored in DCF Record format in the flash UTEST region. The Production disable DCF clients defines two different aspects of the Production Disable feature:- Debug Disable; and Hardware Interlock.

The DCF client implements 2 bits. Their default values are both '0'. The DCF client can only be written once. Writes from subsequent DCF records will be ignored.

For more information on Production disable, see [Section 84.5.6, Production disable](#)

84.3.1.6.1 Debug Disable (DD)

Debug Disable is an optional feature that, once the Lifecycle is >= In Field, overrides all other debug controls, and disables the debug interface. The Debug Disable feature has higher priority than Censorship, JTAG password and PASS_LOCK3[DBL] bit. All Debug access is blocked while Clock Jitter is NOT enabled.

Once Clock Jitter IS enabled, the Debug interface is NOT disabled and can be enabled temporarily or permanently using Censorship or JTAG password or PASS_LOCK3[DBL] bit.

84.3.1.6.2 Hardware Interlock (HI)

Hardware Interlock is an optional feature that, once the Lifecycle is >= In Field, blocks programming of the BAF flash block while an external hardware pin is asserted low. This feature has higher priority than PASS_LOCK0[BAF] bits. While the pin is asserted, no software action anywhere in the MCU can cause the BAF to be programmed.

Once the hardware pin is asserted high, programming of BAF is controlled by PASS_LOCK0[BAF] bits.

Figure 2109. Production Disable DCF client definition

DCF Client Address: 0x00C0 Production Disable

1 HI	Hardware Interlock '0' = BAF flash block programming is controlled by PASS_LOCK0[BAF] bits '1' = BAF flash block is locked for programming while external hardware pin is asserted '0'
2–31	Reserved

84.3.1.7 Clock Jitter Enable

Software accessible one time writable register. This register stores the jitter enable status for Pseudo Random Clock Divider Module (PRCD). The default value of this register is '1'. When this bit is cleared, the PRCD is enabled and the baud rate clock to several serial communications modules will include large amounts of pseudo random clock edge jitter, making the serial communications modules unusable. For details about which serial communications modules are affected, see the clocking section of the Reference Manual.

For more information on Production disable, see [Section 84.5.6, Production disable](#)

When Production disable bit[0] (Gated Debug Enable) is asserted, Chip is in Field and CAN Jitter is not enabled then debug access is blocked.

1–31	Reserved

84.3.1.8 Password Group *n* - Lock 0 Status register (LOCK0_PG*n*)

Each Password Group has one Lock 0 Status register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register will become writable. For additional details of the LOCK bits, refer to the flash memory description.

The LOCK bits will not come into effect before the life cycle is matured to “OEM Production” or older.

Figure 2111. LOCK0_PGn register

1. If no DCF records have been written to change the lock state, the bit will reset to '1'.

LOCK0_PGn register functions are as shown in [Table 1964](#).

Table 1964. LOCK0_PGn register field descriptions

Field	Description
0 TSLOCK	UTest NVM Lock. This bit is used to lock the UTest NVM block from programs (erase protection not needed since UTest NVM is OTP and not erasable).
1 ATSL	Alternate Interface UTest NVM Lock. This bit is used to lock the UTest NVM block from programs on the alternate interface (erase protection not needed since UTest NVM is OTP and not erasable).
2–15 LOWLOCK	Low Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.
16–31 MIDLOCK	Mid Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTest Flash block and copied over during reset. The default value before any DCF record is written, is '1' which indicates a block is locked.

During the life cycle “Customer Delivery”, the user must program a valid password or a DCF record that write this register to unprotect the UTest for each password group to prevent permanent and irreversible locking of flash blocks.

Warning: Failure to program valid passwords or DCF records for all password groups before the life cycle is matured to “OEM Production” will render the part unusable.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible.

However unless the life cycle is older than “OEM Production”, the Flash blocks will always be unlocked, regardless of the values in the password groups.

When Production Disable register bit[1](BAF PLock Hardware Interlock enable) is asserted and lifecycle is infield, then the external signal will be ORed with BAF_plock(low_lock[0]) of LOCK0_PGx

BAF_plock signal can only be deasserted when external BAF PLock is deasserted and correct password is driven to deassert BAF_plock(low_lock[0]) of LOCK0_PGx

84.3.1.9 Password Group *n* - Lock 1 status register (LOCK1_PG*n*)

Each Password Group has one Lock 1 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register will become writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits will not come into effect before the life cycle is matured to “OEM Production” or older.

LOCK1_PG*n* register functions are as shown in [Table 1965](#).

Table 1965. LOCK1_PGn register field descriptions

Field	Description
0–15	Reserved
16–31 HIGHLOCK	High Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: Lock registers can only be accessed with 32-bit operations.

The initial value of the lock bits is set via DCF records stored in UTest Flash block and copied over during reset. The default value before any DCF record is written, is '1' which indicates a block is locked.

During the life cycle 'Customer Delivery', the user must program a valid password or a DCF record that write this register to unprotect the UTEST for each password group to prevent permanent and irreversible locking of flash blocks.

Warning: Failure to program valid passwords or DCF records for all password groups before the life cycle is matured to "OEM Production" will render the part unusable. However, additional DCF Records can be written to UTest to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible.

However unless the life cycle is older than "OEM Production", the Flash blocks will always be unlocked, regardless of the values in the password groups.

84.3.1.10 Password Group *n* - Lock 2 status register (LOCK2_PGn)

Each Password Group has one Lock 2 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked the register will become writable. For additional details of the LOCK bits, refer to the Flash description.

The LOCK bits will not come into effect before the life cycle is matured to "OEM Production" or older.

Figure 2113. LOCK2_PGn register

1. If no DCF records have been written to change the lock state, the bit will reset to '1'.

Note: Lock registers can only be accessed with 32-bit operations.
LOCK2_PGn register functions are as shown in Table 1966.

Table 1966. LOCK2_PGn register field descriptions

Field	Description
0–31 256LCK_L	Lower 256KByte Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

The initial value of the lock bits is set via DCF records stored in UTest Flash block and copied over during reset. The default value before any DCF record is written, is '1' which indicates a block is locked.

During the life cycle 'Customer Delivery', the user must program a valid password or a DCF record that write this register to unprotect the UTest for each password group to prevent permanent and irreversible locking of flash blocks.

Warning:

Failure to program valid passwords or DCF records for all password groups before the life cycle is matured to “OEM Production” will render the part unusable. However, additional DCF Records can be written to UTest to change the initial value of this register.

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible.

However unless the life cycle is older than “OEM Production”, the Flash blocks will always be unlocked, regardless of the values in the password groups.

84.3.1.11 Password Group n - Lock 3 status register (LOCK3_PG n)

Each Password Group has one Lock 3 Status Register. This register shows the current lock state for the Flash blocks. Each time a password group is unlocked, the PGL bit will be cleared and the Lock registers will become writable.

The LOCK bits will not come into effect before the life cycle is matured to “OEM Production” or older.

1. Not all devices include this field. See the device reference manual's chip configuration chapter for details.
2. Reset value depends on life cycle. If life cycle is Customer delivery or earlier, the value will be 0, otherwise 1.
3. If no DCF records have been written to change the lock state, the bit will reset to '1'.

LOCK3_PG n register functions are as shown in [Table 1967](#).

Table 1967. LOCK3_PGn register field descriptions

Field	Description
0 PGL	Password Group Lock This bit may be set in software to lock the password group, when the device is older than Customer Delivery. Before that the value of the bit is always 0. This bit can be cleared by writing a valid password to the Password Challenge Input Registers. 0 Password group registers are unlocked. All four registers in the Password group may be read and written without restriction. 1 Password group registers are locked. Writes to the password group registers have no effect. Read accesses work normally. (If life cycle is Customer Delivery or earlier, this bit has no effect and the registers are always unlocked.)
1 DBL	Debug Interface Lock 0 Debug interface is unlocked. Accessed to all JTAG clients is allowed (Except HSM) 1 Debug interface is locked. Only access to JTAG password challenge register is possible. Access to all other JTAG clients is blocked
2 MO	Master Only 0 All masters can modify the passgroup settings if PGL is cleared 1 Only the Master which unlocked the passgroup can change the passgroup settings
3	Reserved
4-7 MSTR	Master Access Only the Master with this matching master ID can change the passgroup settings. This field is loaded with the ID of the master which unlocked the passgroup once the correct password is provided.
8-10	Reserved
11 RL4	Read Lock Region 4 lock bit. Note that not all devices include this field. Not all devices include this field. See the device reference manual's chip configuration chapter for details. 0Region 4 is not protected 1Region 4 is protected
12 RL3	Read Lock Region 3 lock bit. Note that not all devices include this field. Not all devices include this field. See the device reference manual's chip configuration chapter for details. 0Region 3 is not protected 1Region 3 is protected
13 RL2	Read Lock Region 2 lock bit. Note that not all devices include this field. Not all devices include this field. See the device reference manual's chip configuration chapter for details. 0Region 2 is not protected 1Region 2 is protected
14 RL1	Read Lock Region 1 lock bit. Note that not all devices include this field. Not all devices include this field. See the device reference manual's chip configuration chapter for details. 0Region 1 is not protected 1Region 1 is protected
15 RL0	Read Lock Region 0 lock bit. Note that not all devices include this field. Not all devices include this field. See the device reference manual's chip configuration chapter for details. 0Region 0 is not protected 1Region 0 is protected
16-31 256LCK_U	Upper 256 KB Block Lock. A value of 1 in a bit of the lock register signifies that the corresponding block is locked for program and erase.

Note: *Lock registers can only be accessed with 32-bit operations.*

The initial value of the lock bits is set via DCF records stored in UTest Flash block and copied over during reset. The default value before any DCF record is written, is '1' which indicates a block is locked.

During the life cycle "Customer Delivery", the user must program a valid password or a DCF record that write this register to unprotect the UTest for each password group to prevent permanent and irreversible locking of flash blocks.

Warning: **Failure to program valid passwords or DCF records for all password groups before the life cycle is matured to "OEM Production" will render the part unusable. However, additional DCF Records can be written to UTest to change the initial value of this register.**

Once a password group is unlocked, software can set or clear any of the lock bits in the group, by writing to the registers.

The resulting lock status of a Flash block is determined by the combination of the lock bits of all password groups. If a block is locked in multiple groups, then all lock bits for the block need to be cleared before program and erase is possible.

However unless the life cycle is older than "OEM Production", the Flash blocks will always be unlocked, regardless of the values in the password groups.

Regions will be read protected when write protection and censorship applies and the system is in debug mode. To access the Flash regions, the right passwords need to be provided and the region locks must be cleared.

Once a censored device enters lifecycle "Failure Analysis" read protection is active regardless whether the system is in debug mode or not. Its still possible to unlock Flash regions with the correct passwords, however.

84.4 Functional description

The primary purpose of the PASS is to provide fine-grained access control to the Flash and debugger interface. It utilizes the DCF mechanism, as described in the SSCM section.

84.4.1 Life cycle and security

The security of the device depends on security state and life cycle of the device as described in Table 1968.

Table 1968. Security features mapped to life cycle

Life Cycle	UTest OTP	Passwords Readable	Crypto Keys Readable	Test Mode Access	HSM available	Debug Access
Customer Delivery	yes	yes	no	no	no	yes
OEM Production	yes	no	no	no	depends on settings	depends on settings

Table 1968. Security features mapped to life cycle (continued)

Life Cycle	UTest OTP	Passwords Readable	Crypto Keys Readable	Test Mode Access	HSM available	Debug Access
In the Field	yes	no	no	no	depends on settings	depends on settings
Failure Analysis	yes	no	no	yes	depends on settings	depends on settings

After the life cycle “OEM Production” debugging access can be prevented by censoring the device. (See Flash documentation.).

If the device is censored and HSM is enabled, then debug access can be granted via HSM challenge/response mechanism—see HSM documentation. If the HSM is not enabled on a censored device, then access is possible via JTAG password.

84.5 Initialization/application information

84.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (see [Section 84.3.1, Register descriptions](#)). However many bits will receive their values based on DCF records stored in the UTest flash memory block.

84.5.2 Modifying life cycle (maturing the device)

To modify the life cycle, the DCF mechanism in the UTest Flash needs to be activated if that hasn't been done already. For this the DCF start record has to be written at location 0x400200.

Following that a life cycle record can be appended at the next free location. If only the start record has been written, that location is at 0x400200 + 0x04, if N records have been written already, the location is at 0x400200 + $(N+1)*0x04$.

The value to be written is determined by [Table 1969](#).

Table 1969. Possible life cycle records

Life Cycle	DCF Value	
	CS/ADDR	Data
Customer Delivery	0x0010_00A0	0x*****FC
OEM Production	0x0010_00A0	0x*****F8
In the Field	0x0010_00A0	0x*****F0
Failure Analysis	0x0010_00A0	0x*****E0

Only the lower 8 bits of the data field are relevant, the others are not used by the PASS.

[Table 1970](#) shows how the life cycle is advanced to “OEM Production” if no other DCF records were written previously.

Table 1970. Moving life cycle to “OEM Production”

ADDR offset	Record	Description
0x00	0x05AA_55AF	Start Record
0x04	0x0000_0000	
0x08	0x0000_00F8	Data Record: OEM Production
0x0C	0x0010_00A0	
0x10	0xFFFF_FFFF	Stop Record
0x14	0xFFFF_FFFF	
...	...	

If now the life cycle needs to be advanced to “In the Field”, the UTest content would be modified as shown in [Table 1971](#)

Table 1971. Moving life cycle to *In the Field*

ADDR offset	Record	Description
0x00	0x05AA_55AF	Start Record
0x04	0x0000_0000	
0x08	0x0000_00F8	Data Record: OEM Production
0x0C	0x0010_00A0	
0x10	0x0000_00F0	Data Record: In the Field
0x14	0x0010_00A0	
0x18	0xFFFF_FFFF	Stop Record
0x1C	0xFFFF_FFFF	
...	...	

The PASS module will not accept later DCF records to move the life cycle backwards. It's possible to write the 0x0000_00F0 value first, and afterwards the 0x0000_00F8, however the most mature life cycle will take precedence.

84.5.3 Setting lock bits in a password group

There is no restriction on setting and clearing lock registers in the UTest flash, apart from the available space for DCF records. It's possible to set and clear them multiple times.

Table 1972. CS/ADDR Values for Lock Registers

Register	DCF CS/ADDR
PW Group 0	
Lock0	0x0010_0100
Lock1	0x0010_0104

Table 1972. CS/ADDR Values for Lock Registers (continued)

Register	DCF CS/ADDR
Lock2	0x0010_0108
Lock3	0x0010_010C
PW Group 1	
Lock0	0x0010_0110
Lock1	0x0010_0114
Lock2	0x0010_0118
Lock3	0x0010_011C
PW Group 2	
Lock0	0x0010_0120
Lock1	0x0010_0124
Lock2	0x0010_0128
Lock3	0x0010_012C
PW Group3	
Lock0	0x0010_0130
Lock1	0x0010_0134
Lock2	0x0010_0138
Lock3	0x0010_013C

In order to set the MIDLOCK field in the Lock0 register of password group 1 to the value 0x00FF other fields to 0, the DCF record would have to be added to [Table 1970](#) as shown in [Table 1973](#).

Table 1973. Setting some bits in the MIDLOCK field

ADDR offset	DATA	Description
0x00	0x05AA_55AF	Start Record
0x04	0x0000_0000	
0x08	0x0000_00F8	Data Record: OEM Production
0x0C	0x0010_00A0	
0x10	0x0000_00FF	PW Group 1, Lock0 Set MIDLOCK to 0xFF
0x14	0x0010_0110	
0x18	0xFFFF_FFFF	Stop Record
0x1C	0xFFFF_FFFF	
...	...	

84.5.4 Censoring/uncensoring the device

There is no restriction on setting and clearing the censorship status in the UTest Flash, apart from the available space for DCF records. It's possible to censor and uncensor multiple times.

The Client Select / Address for the Censorship record is 0x0010_00B0. In order to uncensor the device the data field of the record need to be written with 0x----55AA (upper 16 bits are not compared). Any other value would censor the device.

On delivery the device will be uncensored.

84.5.5 Unlocking the debug interface via JTAG

To open the debug interface, the JTAG password challenge register needs to be written by the debugger with the correct JTAG password.

84.5.6 Production disable

84.5.6.1 Overview and rationale

Production Disable is an optional feature that, once enabled, allows the MCU to functional completely normally without any constraints, except the Debug interface is disabled. Once the customer has decided that the Debug Interface should be re-enabled, the process to re-enable it, makes the MCU unusable in a production environment by adding clock jitter to the baud rate clocks of several serial communications modules (normally CAN and FlexRay). This jitter means those serial communications modules will not be able to communicate on the network.

As this Production Disable feature renders the MCU unusable in the application, inadvertent activation would be disastrous. Therefore a feature is included that prevents this Jitter activation unless an external hardware pin is asserted.

84.5.6.2 Enablement

The feature is enabled via 2 bits in the Production Disable DCF client in the PASS module. One bit enables the Debug Interface Disable. The other bit enables the Hardware Interlock pin. See [Section 84.3.1.6, Production Disable](#) for details.

These bits can be written by adding a DCF Record to the DCF record list in flash UTEST. This DCF Client is configured to accept only one write. Subsequent DCF records that write to this DCF client are ignored.

If no DCF Record writes to this client, the default state is both features is disabled. If, for a particular application, there is no intention of every using this feature, it would be good practice to add a DCF Record that writes this client to 0x0000_0000. This is not essential but ensures the feature can not be Enabled accidentally.

84.5.6.3 Activation

The BAF code is always the first code executed out of reset. The BAF code as part of the normal boot sequence, copies the 'Clock Jitter Activation' constant value from a location in the BAF code space, to the Clock Jitter Register in the PASS module (See [Section 84.3.1.7, Clock Jitter Enable](#) for details).

This register is write once. The default value for the Clock Jitter Activation constant in BAF flash is 0xFFFF_FFFF (erased state)

To enable the Clock Jitter feature, the value of the Clock Jitter Activation constant in BAF flash should be programmed to make the most significant bit '0'. After the next reset, the BAF will copy this updated value to the Clock Jitter Register and the feature will be activated.

The BAF flash block is assigned as OTP and it is protected from programming by a bit in the PASS LOCK0 registers; but the BAF flash block can further be protected from programming by an external hardware pin. If the hardware interlock feature is enabled, while this pin is logic '0' the BAF flash block can not be programmed.

84.5.6.4 Truth table

[Table 1974](#) shows the relationship between various input conditions and the state of the Debug Interface & Baud Rate Clock.

Table 1974. Truth Table of Production Disable Feature

Production Disable[Debug Disable]	Clock Jitter Activation Constant	JTAG Password, Censorship, LOCK3[DBL]	Debug Interface State	Baud Rate Clock State
0	Don't Care		Dependent on JTAG Password or Censorship or LOCK3[DBL]	Normal
1	0b1xxxxxx_(24 more x)	Don't Care	Disabled	Normal
1	0b0xxxxxx_(24 more x)		Dependent on JTAG Password or Censorship or LOCK3[DBL]	Jittering

85 Tamper Detection Module (TDM)

85.1 Overview

Note: Unless otherwise noted, any information related to the flash memory makes reference to the FMC flash memory.

The Tamper Detection Module provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. The mechanism does not *prevent* an erase operation on any block within a TDR—it requires a record to be written before the operation can execute. Collectively, the records are referred to as a “diary”. At minimum, the diary serves as an erase counter. Because the diary record content is customer-defined, the diary can also serve as a history.

Up to 6 TDRs can be defined via DCF records.

[Figure 2115](#) shows the block diagram of the TDM and its interface to other system components.

Figure 2115. Tamper Detection Module block diagram

Security information is passed to the TDM by the SSCM module. Among the data are the OTP (One Time Programmable) settings for each of the flash Code sectors, the base address for the diary in the flash and the block assignments for the TDRs. The TDM module in turn provides three dedicated signals:

- Two 128-bit buses to the flash memory
- One 32-bits bus to the SSCM module.

The two flash buses are used to control the flash blocks for erase operation and set them as OTP. OTP means that flash erase of the entire block is disabled and the only words that are

already erased can be programmed. Over-programming is not possible. The PASS module provides the control for erase operation for each flash block as well as for each region of the flash memory, and the PASS settings have priority over the settings of the TDM.

The flash block indicates to the TDM the address of the programmed word. This address is internally decoded and provides a mean to verify whether the block is part of any TDRs. The memory map registers interface provides a mean to the user to read information of the TDM registers.

85.2 Features

The Tamper Detection Module supports these distinctive features:

- Erase Counter (diary) per TDR to record up to 256 write attempts on the flash blocks;
 - The diary is divided into 6 parts (TDRs), each consisting of 256 64-bit records.
 - The diary block should be assigned as OTP region in flash.
 - The diary area can store any type of relevant information.
- Tamper Detection Region Block Assignment
 - Any flash block can be assigned to any TDR and be controlled.
- 32-bit Erase Lock registers for each TDR to the flash memory.
- 32-bit OTP Enable registers to disable the erase operation for an entire flash block
- Override TDR via DCF records
 - It allows block assigned to a TDR to be unlocked for erase even if the TDR is locked for this operation.
- Memory Map Registers Interface for reading via software of specific registers.

85.3 External signal description

There are no external signals driving or being driven by the TDM.

85.4 Memory map and register description

This section provides a detailed description of all registers accessible in the TDM module memory map.

85.4.1 DCF client

[Table 1975](#) gives an overview on the TDM DCF clients implemented.

Table 1975. DCF client address map

DCF Client Address ADDR[16:2]	DCF Client Name	Description	Width
0x0	Diary Base Address ^{(1),(2)}	Stores the base address of the diary being accessed	32
0x1	Tamper Region Override ⁽³⁾	Stores information of which TDR is to be overridden (unlocked for erase)	6

Table 1975. DCF client address map (continued)

DCF Client Address ADDR[16:2]	DCF Client Name	Description	Width
0x8 - (0x8 + 3)	OTPEN[nb] - OTP Enable ⁽³⁾	Stores information of which flash blocks is to be assigned as OTP (One Time Programmable) - nb means one register for each Lock register of the flash memory	32
0x14 - (0x14 + (4 * 6) - 1))	TDR[n]_LOCK[m] Region Assignment ⁽³⁾	Stores information of which flash block is assigned to a TDR. - n specifies a TDR - m specifies the flash blocks as per the LOCK registers of the flash memory.	32

1. DCF client is write-once.
2. DCF client bits can be written from 1-> 0 only.
3. DCF client bits can be written from 0-> 1 only.

85.4.2 Memory Mapped Registers

Table 1976 shows the memory map for the memory mapped registers

Table 1976. TDM IPS registers address map

Offset from TDM_BASE_PP	Register	Access	Width	Reset Value
0x0000_0000	TDR Status Register (TDRSR)	Read	6	0x0000_003F
0x0000_0004	Last Flash Programmed Address Register (LFPAR)	Read	24	0x0000_0000

The convention in Figure 2116 serves as a key for the individual register diagrams.

Always Reads 1	1	Always Reads 0	0	R/W bit	BIT	Read-Only bit	BIT	Write-Only bit	BIT	Write 1 to clear	BIT	Self-clear bit	0	N/A	BIT
----------------	---	----------------	---	---------	-----	---------------	-----	----------------	-----	------------------	-----	----------------	---	-----	-----

Figure 2116. Key for register rield

Note: Reserved bits will be read as 0s. Attempts on writing to reserved bits can generate unpredictable results for DCF clients and transfer errors for memory mapped registers.

85.4.3 DCF client and register descriptions

This section describes in address order all the TDM DCF clients and registers. Details of the register bit and field function follow the register diagrams in bit order.

85.4.3.1 DCF clients

85.4.3.1.1 Diary Base Address (DBA) DCF client

This DCF client holds base address information of the diary. [Figure 2117](#) shows the diagram for this register.

Warning: This DCF client is implemented as Write Once and is writable for 1 to 0 only. After one DCF Record has written to this client, all subsequent writes are ignored.

Figure 2117. Diary Base Address (DBA) DCF client

Table 1977. DBA field descriptions

Field	Description
0–31 DBA	Diary Base Address. This field holds the base address of the diary. This information is then used to verify if the diary being programmed matches any TDR region.

85.4.3.1.2 Tamper Region Override (TO) DCF client

This DCF client holds override information for each TDR. [Figure 2118](#) shows the diagram for this register.

Warning: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored

Figure 2118. Tamper Region Override (TO) DCF client

DCF Client Address: 0x0001

Access: DCF write

Table 1978. TO field descriptions

Field	Description
0–25 Reserved	Reserved
26–31 TOE[5:0]	TDR Override Enable. Each TOE field, where <i>n</i> represents the TDRs, holds information of the Override Enable status for each TDR. 0 Normal operation. Blocks assigned to this TDR can NOT be erased until the diary is written. 1 Diary override. The diary for this TDR can be erased WITHOUT writing to the diary.

85.4.3.1.3 One Time Programmable Enable (OTPEN0) DCF client

This DCF Client holds the OTP information for the Low and Mid blocks of the flash memory. This register mirrors the LOCK0 register of the flash memory. [Figure 2119](#) shows the diagram for this register.

Warning: This DCF client is writable from 0 to 1 only. Attempted writes of bits from 1 to 0 will be ignored
UTEST is always assigned as OTP

Figure 2119. One Time Programmable Enable (OTPEN0) DCF client

DCF Client Address: 0x0008

85.4.3.2 Memory mapped registers

85.4.3.2.1 TDR Status Register (TDRSR)

This register holds information for the status of each TDR. There is one bit in the register for each TDR. The status bit is a combination of the unlock state and the TDR AND the TDR Override bit. The default state of each status bit is '1', meaning that Erase operation for all flash blocks associated to the TDRs is disabled. The status bit for a TDR will be set to '0' (Indicating that Erase operation for all flash blocks associated to the TDR can be Erased), if either a successful programming operation to the TDR diary region has been performed OR the TDR Override bit for that TDR is set.

TDRSR is a read-only register and write shall have no effect, and attempts on doing so will generate a transfer error.

85.5 Functional description

The primary purpose of the TDM is to provide a Tamper Detection mechanism by enabling an Erase Counter (or diary) for regions within the flash. These regions are called Tamper Detection Regions. The following sections cover the entire functionality of this module.

85.5.1 Flash erase counter and tamper detection

A flash region block or part of it is assigned for implementing the diary. The base address for the Diary is determined by a DCF Record.

The diary is divided into 6 parts where each part consists of 256 x 64-bit records, to record until 256 write attempts on the flash blocks assigned to each Tamper Detection Region. For correct operation, the Diary should reside in a flash block that is assigned as OTP.

Each flash block can be assigned to any of the TDRs. Related to each TDR is a group of 4 x 32 bits registers. These registers mirror exactly the LOCK registers bits from the flash module.

Each of the m registers is loaded at boot time by the SSCM, which defines if the associated flash block is Locked for Erase in a particular TDR:

- '1' means the flash block is locked for erase
- '0' means the flash block is not locked for erase

Before performing an erase in one of the blocks locked for erase and associated to a TDR, a program operation has to be performed on the diary part for that TDR. As the diary should be OTP, successive writes are allowed on unprogrammed double words only. This ensure that diary records can only increase and that data recorded in the diary is not modifiable by software.

At the end of a successful double word program operation, the flash module indicates to the TDM the address of the programmed double word. TDM determines whether the programmed data is done within a TDR and unlocks the blocks for erase operation if data are programmed a diary. TDM ensures that this erase operation on unlocked blocks is allowed until the flash indicates a program erase complete interrupt or till next hard reset.

Note: All blocks associated to a TDR where an erase operation is allowed can be erased all together.

TDM has no control of how much data a diary has loaded. It is a responsibility for the user to verify if the diary is full. There is also no restriction to what type of data can be programmed in the diary. If diary is detected to be full, TDM provides a mean to disable the tamper detect mechanism so that erase operations can be performed to a TDR without any diary entry. In this case, the user is required to program the Tamper Region Override Register for the corresponding TDR.

The data programmed in the diary location is flexible, and may include count information or other important customer information.

Software has to check whether the diary is full. Once the diary area for a TDR is full, the software has to program a DCF record for overriding blocking of erase from TDR, disabling tamper detect, so that erases can be done to that TDR without any diary entry

The setting from "override tamper region lock" DCF record (see [Section 85.5.3, Diary](#)) has priority in the settings in the TDRx_LOCK0-3 registers. In other words, if a TDR is unlocked for erase by the override tamper region lock, the TDRx_LOCK n bits have no effect on the TDR that has been overridden, but the tamper detection remains active for all TDRs not having the override bit set.

Moreover, the settings from PASS_LOCKx_PG n registers have priority on TDRx_LOCKs setting. For example, if a block is password-protected for write operations, the TDR lock setting is ignored.

A schematic representation of the diary is depicted in [Figure 2129](#).

Figure 2129. Diary implementation

Note: The settings in the Tamper Region Override Register have priority over the $TDRn_LOCKm$ Registers. The SSCM module also has priority over the settings done in the TDM. For instance, if blocks in a TDR are unlocked for erase operation via TDM, but the same block are programmed to be locked for erase operation in SSCM, the blocks end up being locked for erase operation.

85.5.2 Assigning blocks to Tamper Detect Regions (TDR)

Each TDR is a group of 4 x 32 bit registers. These registers mirror exactly the LOCK registers bits from the flash module. Hence, the block assignment registers are named as $TDRn_LOCKm$ where n is the number of a tamper region, i.e., 0-5.

In these registers:

- '1' means that the corresponding flash block is assigned to this TDR
- '0' means that the corresponding flash block is not assigned to this TDR (Default)

These DCF clients are only writable once during reset and the bit default state is 0. These registers are not visible to software. They can not be read nor written. They can only be initialized by DCF record within UTest block during reset. The value of these registers can be evaluated by reading all the UTest DCF records and searching for records that write these registers.

Note: The DCF clients are used to load the data recorded in the UTest block in device configuration format, loaded previously by the SSCM module, into registers. Consult the DCF Client documentations for further details.

85.5.3 Diary

The diary is a region of the flash memory where records of block erases for each TDR are stored. The format and size of the records are not fixed. The only requirements are that each diary has a maximum size of 2 KB, and the minimum size of any programming operation is 8 bytes. Therefore each diary can hold a maximum of 256 64-bit entries.

A flash region block or part of it must be assigned for implementing the diary. The base address for the diary is determined by a value written in a DCF record. The diary can be placed within any flash block in flash array, and history records in it can be read by any core (also from HSM, if present).

Note: To maintain the security of the TDR, the block where the diary is placed must be assigned as OTP within the OTP registers.

The base address of the diary is implemented using a DCF Client. The DCF client is only writable once during reset and the default bit state is 1.

The DCF clients can not be read nor written by software. They can only be initialized by DCF record from within UTEST block during reset. The value of these registers can be evaluated by reading all the UTEST DCF records and searching for records that write these DCF clients.

85.5.4 Specifying the diary base address

The diary is a region of flash memory where records of block erases for each TDR are stored. The format and size of these records is defined by the customer. The only hardware constraints are that each diary has a maximum size of 2 KB and the minimum size of any programming operation is 8 bytes. Therefore the diary can hold a maximum of 256 x 8 byte entries.

The diary can be placed within any flash block in the flash array. To maintain the security of the TDR, the block where the diary is placed, must be assigned as OTP within the OTP registers, while in customer delivery or OEM production life cycle states.

The base address of the diary is implemented with a 20-bit DCF client that can be initialized by the SSCM during reset. The DCF client is writable once during reset and the default bit state is '0'.

The base address register is not visible to software. It cannot be read nor written. It can only be initialized by DCF record within UTest flash during reset. The value of this register can be evaluated by reading all the UTest flash DCF Records and searching for record that writes this register.

Each TDR is assigned a 2 KB section of the diary. With 6 TDRs, 12 KB of diary space is required.

The diary base address must be at a 4 KB boundary. Therefore the least significant 12 bits of the base address must all be '0' (Hence only 20 bit DCF client is required).

The Base address of the diary is represented by:-

Diary_Base_Address = 0bxxxx_xxxx_xxxx_xxxx_xxxx_0000_0000_0000

The base address of each TDR is shown below:

- TDR0 = Diary_Base_Address + 0b00_0000_0000_0000
- TDR1 = Diary_Base_Address + 0b00_1000_0000_0000
- TDR2 = Diary_Base_Address + 0b01_0000_0000_0000
- TDR3 = Diary_Base_Address + 0b01_1000_0000_0000
- TDR4 = Diary_Base_Address + 0b10_0000_0000_0000
- TDR5 = Diary_Base_Address + 0b10_1000_0000_0000
- End of the diary = Diary_Base_Address + 0b11_0000_0000_0000

85.5.5 Diary Base Address Verification

The status of whether a TDR is locked for erase is maintained by the TDM. This is accomplished by implementing a register with as many bits as the number of TDRs. See [Section 85.4.3.2.1, TDR Status Register \(TDRSR\)](#) for further details about this register.

When the flash memory module has completed a programming operation, the address of the location programmed is output from the flash module. The TDM in turn compares that address to determine if it falls within the range of any TDR diary regions. If it is within any TDR, the corresponding status bit is set to 0 meaning "TDR Erase Enabled".

These status bits are all reset to 1 when the flash module signals an erase complete by asserting the PEC (Program Erase Complete) signal.

The state of the 6 status bits can be read through the TDRSR. See [Section 85.4.3.2.1, "TDR Status Register \(TDRSR\)"](#). The address of the last successful programming operation provided from the flash memory to the TDM can be read through the LFPAR. See [Section 85.4.3.2.2, "Last Flash Programmed Address Register \(LFPAR\)"](#).

85.5.5.0.1 Diary management

Before a block protected by a tamper detect region can be erased, a record must be written to the associated diary. Software must search through the diary to find the end of the records, where the next available diary location that can be written. After a maximum of 256 records are programmed to the diary, a TDR diary is full. Full means that at least 1 bit has been programmed to '0' in each 64-bit double word within the 2 KB diary.

If software determines that a particular TDR diary is full it may override the diary to allow erasing to continue or it may choose to stop further erases and to flag an error.

Diary Override bits are implemented with a DCF client consisting of 6 bits - one for each TDR. See [Table 121](#) for TDM DCF client details.

The Diary Override bits are by default set to '0', which means the diary must be written before an erase can occur. The DCF client can be written many times but the bits can only be written to '1'. Writes to '0' are ignored. In this way, by default, all Tamper Detect Regions are active. The Tamper detect region diaries can be individually overridden by writing a DCF record that sets that corresponding bit to '1'. In this mode, the TDR status bit is permanently set to 0 to allow flash erase.

85.5.6 One Time Programmable (OTP)

85.5.6.1 Overview

Any flash block within the flash array can be assigned, at any time, to be OTP. Once a flash block is assigned OTP, it cannot be changed back.

OTP means that flash erase of the entire block is disabled and that only 64-bit double words that are already erased (i.e., flash content is 0xFFFF_FFFF_FFFF_FFFF) can be programmed. Over-programming is not possible.

Flash blocks are assigned as OTP by writing a DCF record. The block will become OTP after the next reset.

86 Arithmetic Modeling Unit (AMU)

86.1 Introduction

The Arithmetic Modeling Unit (AMU) is a customer arithmetic calculation unit. It is used for designing complex multi-dimensional data models. The AMU incorporates a variant of neural network technology to accomplish calculation tasks. The AMU contains two separate channels, which are timing-independent and register-independent. They both share the same arithmetic logic. Operations are interleaved on a data path containing two multipliers, one accumulator, and one exponential function, besides a number of blocks to feed these arithmetic blocks with data. The interleaving of the channels is such that operations on one channel do not influence the timing on the other channel.

A block diagram of the AMU block is given in [Figure 2130](#). The block consists of a local 32 KB RAM with 64-bit ECC, a hard-wired data path to calculate the AMU function, and DMA channels to do data transfers from flash to the AMU local RAM. The AMU local RAM is also visible over the peripheral bus to the system. The data path is superscalar, in that it contains two multipliers. This allows two multiplications to be done in one cycle for one channel.

Figure 2130. AMU block diagram

86.1.1 Features

- Two independent calculation channels. The two independent channels allow two concurrent processes to use the AMU to do a calculation, with a guarantee in hardware there is no influence between the two processes.
- Two independent DMA channels. The DMA channels are high-bandwidth direct memory access channels, that allow transfer of flash data to local RAM.

86.2 Memory map and register definition

The AMU module provides an IPS programming model mapped to standard 16 KB on-platform peripheral slots. The local AMU RAM is accessible for read and write via the IPS interface and is mapped to four contiguous and properly aligned 16 KB peripheral slots for a maximum RAM size of 64 KB. The programming model can only be referenced in supervisor mode using 32-bit (word) accesses. Attempted references while in user mode, using different access sizes, or to undefined (reserved) addresses generate an IPS error termination. All programming model register reads and writes complete in a single IPS clock cycle.

86.2.1 AMU memory map

The following table shows the memory map for the AMU module.

Table 1989. AMU memory map

1. p9, as defined in the RfQ, does not have a separate register. Its function is handled by v32_n.

86.2.2 Register Descriptions

This section consists of register descriptions in ascending order. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Figure 2131. Key to register fields

86.2.2.1 AMU V Pointer Channel *n* register (VCH_{*n*})

Figure 2132. AMU V Pointer Channel *n* register (VCH_{*n*})

0x10000 VCH0 - V Pointer Channel 0 register

0x10080 VCH1 - V Pointer Channel 1 register

Access: Read/write

Table 1990. VCH n field description

Field	Description
0:15	Reserved.
16:29 P[15:2]	Pointer[15:0] is the byte address in the local RAM. A 32-bit alignment is forced, as the two LSBs are zero.
30 V16	0: V-vector is 32-bit IEEE floating-point format 1: V-vector is 16-bit IEEE floating-point format
31 CADDR	0: Normal addressing mode 1: Circular address mode. Addressing modulo 256 bytes

0x10098 P6CH1 - P6 Channel 1 register

Access: Read/write

Table 1996. P6CH n field description

Field	Description
0:15	Reserved.
16:31 P6[15:0]	Outer loop count limit (unsigned integer). This field remains static once written.

86.2.2.8 AMU Ncrossing Channel n register (NCH n)

Figure 2139. AMU Ncrossing Channel n register (NCH n)

0x1001C NCH0 Ncrossing channel 0 register

Access: Read/write

0x1009C NCH1 Ncrossing channel 1 register

Table 1997. NCH n field description

Field	Description
0:15	Reserved.
16:31 NCRS[15:0]	Ncrossing value (unsigned integer). When properly enabled in STCFG n [VSN], the V calculation is stopped after NCRS iterations of the outer loop. After the calculation is stopped, the p8 outer loop count matches the NCRS value set in this register. The intermediate value contained in the V32 register is consistent with this p8/NCRS value. Additionally, when the STCFG n [NIE] control bit is set, an interrupt is triggered when the outer loop count reaches the specified NCRS value. The interrupt enable/disable control is independent of the STCFG n [VSN] setting.

86.2.2.9 AMU P7 Channel *n* register (P7CH*n*)Figure 2140. AMU P7 Channel *n* register (P7CH*n*)

0x10020 P7CH0 - P7 Channel 0 register

0x100A0 P7CH1 - P7 Channel 1 register

Access: Read/write

Table 1998. P7CH*n* field description

Field	Description
0:26	Reserved.
27:31 P7[4:0]	Inner loop count limit (unsigned integer). This field remains static once written.

86.2.2.10 AMU P4 Channel *n* register (P4CH*n*)
AMU P5 Channel *n* register (P5CH*n*)Figure 2141. AMU P4, P5 Channel *n* register

Table 1999. P4CHn, P5CHn field description

Field	Description
0:31 P4[31:0] P5[31:0]	Parameter P4, P5 values, IEEE 32-bit floating point format. These values remain static once written.

86.2.2.11 AMU Result Channel n register (RESCHn)

Figure 2142. AMU Result Channel n register (RESCHn)

Table 2000. RESCHn field description

Field	Description
0:31 RESULT[31:0]	Result value - IEEE 32-bit floating point notation

86.2.2.12 AMU 32-bit V vector Channel n register (V32_n)

Note: The initial V32 (also known as parameter p9) value must be written before any new calculation is started. The value is not retained, as V32 is updated after each iteration of the outer loop of the calculation.

Figure 2143. 32-bit V Vector Channel n register (V32_n)

Table 2001. V32_n field description

Field	Description
0:31 V32[31:0]	32-bit v-vector, IEEE 32-bit floating point format. When a value is written to the register AMU_v32, the register AMU_v64 is also updated. The conversion from 32-bit IEEE floating point to 64-bit IEEE floating point is done on-the-fly. When a processor writes to the register AMU_v64, this register is not updated. When the calculation engine advances, and increments p8, the new V value is written both to AMU_v64 and AMU_v32.

86.2.2.13 64-bit V Vector Least Significant Bytes Channel *n* register (V64Ln)

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 2006. DCTLCH*n* field description

Field	Description
0 SRT	DMA transfer in progress 0: No action 1: DMA transfer start request
1 STP	Result of last stop action – Read 0: transfer was completed - stop did not have effect 1: transfer was in progress - stop did cancel transfer – Write 0: No action 1: DMA transfer stop request
2 WVS	– Wait if VSRT = 1 – Read 0: DMA operates normally 1: DMA does not move data while VSRT set (AMU Status Configuration Register flag) Set on WVS=1(read mode) Cleared on WVC written 1, or VSRT cleared – Write 0: No action 1: Set WVS
3 WVC	WVS clear 0: No action 1: Clear WVS

Table 2006. DCTLCHn field description (continued)

Field	Description
4 DINT	Done interrupt flag Read Set on completion of DMA transfer Cleared on writing '1' to DIN Write Done Interrupt Clear. 0: No action 1: Clear DINT
5 DIE	Done Interrupt Enable 0: Interrupt disabled 1: Interrupt enabled
6 SKIP	0: normal operation 1: the first $p8 * p7$ halfwords or words (depending on v16 bit setting) are not transferred. However, counters are incremented as if these bytes have been transferred
7 DFA	DMA FIFO 0: Normal operation 1: DMA FIFO active. Needs to be used together with circular addressing on the destination pointer. In this case, the FIFO logic stalls the DMA when an overflow of the circular buffer is imminent.
8:15 AP[15:8]	Averaging period This is a time in increments of 256 clocks.
16:23 MIN[7:0]	Averaged over the av_period, the DMA does not transfer more than one 32-bit packet per this number of clock periods.
24:31 MAX[7:0]	The DMA transfers at least one 32-byte packet per this number of clocks. If less data is transferred, the DMA activates high-priority mode on its private flash interface. The transfer time is averaged over the complete length of the DMA transfer.

86.2.2.19 AMU Status and Configuration register (STCFGn)

This section provides details on the AMU Status and Configuration registers (STCFGn).

Figure 2150. AMU Status and Configuration register (STCFGn)

Table 2007. STCFGn field description

Field	Description
0 USRT	U Calculation Start and Status The U calculation can be initiated by writing this bit to 1. The bit reads as 1 while the U calculation is in progress and reads as 0 after it completes.
1 VSRT	V Calculation Start and Status The V calculation can be initiated by writing this bit to 1. The bit reads as 1 while the V calculation is in progress and reads as 0 after it completes or is stopped.
2 VSTP	V Stop Request and Status – Read 0: Calculation was not underway when VSTP request was made. VSTP did not have effect. 1: Calculation was stopped by VSTP request, result is not final, calculation needs to be restarted. Intermediate V32 values and the P8 loop index are consistent and valid upon stopping a calculation. VSTP is also asserted in response to a properly enabled overflow or Ncrossing stop event. – Write 0: No action 1: Request to stop V calculation

Table 2007. STCFGn field description (continued)

Field	Description
3 WDMA	– Read 0: No delay on start of V-calculation. 1: V-calculation is postponed until DMA done or DMA stop reached. - Set on write to WDMA, cleared on write to WDMAC or DMA completion – Write 0: No action 1: Set WDMA
4 WDMAC	0: No action 1: Clear WDMA
5 VINT	- V Calculation Complete Interrupt. – Read - Set on completion of V calculation. – Write 0: No action 1: Clear V Calculation Complete Interrupt
6 OINT	- Overflow interrupt – Read. - Set on overflow on final result or V.[– Write 0: No action 1: Clear Overflow interrupt
7 EINT	- Error Interrupt. – Read - Set on error detect – Write 0: No Action 1: Clear EINT
8 NINT	- Ncrossing interrupt. – Read - Set when NCRS == (p8-1) and p8 is incremented. The final value of p8 after the interrupt is NCRS. – Write 0: No action 1: Clear Ncrossing Interrupt
21 VIE	- V calculation Interrupt Enable - Controls if VINT is sent to interrupt controller or not. 0: V Calc Interrupt disabled 1: V Calc Interrupt enabled
22 OIE	- Overflow Interrupt Enable 0: Overflow interrupt disabled 1: Overflow interrupt is enabled

Table 2007. STCFGn field description (continued)

Field	Description
23 EIE	Error Interrupt Enable. 0: Error interrupt is disabled 1: Error interrupt is enabled
24 NIE	Ncrossing Interrupt Enable 0: Ncrossing interrupt disabled 1: Ncrossing interrupt enabled
27 EON	Exponential on Negative (Infinity). 0: Generates zero on its output when input value is negative infinity 1: Exponential function generates infinity on its output when input value is negative infinity
28 VOOE	V operand overflow 0: No overflow signalling on V. Only on F 1: Overflow interrupt is triggered on V operand overflow
29 VSO	0: V calculation continues on overflow 1: Vstop automatically triggers on V overflow
30 VSN	0: Ncrossing does not influence Vstop. 1: Vstop automatically triggers on Ncrossing interrupt
15 DFA	DMA FIFO Active. 0: DMA FIFO is not active. Normal operation 1: DMA FIFO is active. Allows start of calculation to be triggered before DMA transfer for V vector completed.
26 ASTOP	DMA Auto Stop 0: DMA stop not triggered 1: DMA stop triggered on any Vstop condition

86.2.2.20 Error Status Register (ESRn/ESRnNC)

This section provides details on the AMU Error Status registers (ESR) and Error Status registers No Clear on read (ESRnNC).

Figure 2151. Error Status Register (ESR)

0x10050 ESR0 error flags, auto clear, channel 0

0x10054 ESR0NC error flags, no clear, channel 0

0x100D0 ESR1 error flags, auto clear, channel 1

0x100D4 ESR1NC error flags, no clear, channel 1

Access: Read only

Table 2008. ESR field description

Field	Description
0 ADER	Address Error. Read or write to unimplemented address of the local RAM.
1 REGCF	Register Conflict Error. While V calculation is in progress for a given channel, one of the following registers associated with the same channel was written: 1. RESCHn (result) 2. V32_n 3. V64M_n 4. V64L_n 5. P8CHn
2 VOV	Overflow on intermediate V32_n value.
3 FOV	Overflow on final result RESCHn.
4:31	Reserved.

Reading ESR0 or ESR0NC returns the channel 0 error status flags. Reading ESR1 or ESR1NC returns the channel 1 error status flags. The channel 0 error status flags are automatically cleared on a read from ESR0, but not on read from ESR0NC. The channel 1 error status flags are automatically cleared on read from ESR1, but not on read from ESR1NC.

86.2.2.21 AMU DMA V Vector Holdoff Count Channel *n* register (DVHCH_{*n*})

Figure 2152. DMA V Vector Holdoff Count Channel *n* register (DVHCH_{*n*})

0x10058 DVHCH0 - DMA V Vector Holdoff Count Channel 0 register

0x100D8 DVHCH1 - DMA V Vector Holdoff Count Channel 1 register

Access: Read/write

Table 2009. DVHCH_{*n*} field description

Field	Description
0:16	Reserved.
18:31 VOFF[14:0]	Vector holdoff count. Value equal to p7*p8 Number of elements of the V-vector the DMA does not transfer if DCTLCH _{<i>n</i>} [SKIP] = 1

86.3 Functional description

The AMU block has two independent channels, called CHANNEL 0 and CHANNEL 1, featuring independent registers. Each of the AMU channels has a calculation engine, and a DMA. The calculation engine supports algorithmic calculations based on the data in the AMU's local RAM, and visible over the peripheral bus. The DMA executes data transfers from the system flash to the AMU local RAM using a private interconnect. The calculation engine has two start bits, STCFG_{*n*}[USRT, VSRT], that each initiate part of a calculation to be performed.

1. When STCFG_{*n*}[USRT] is set, it activates the updating of the U vector:

```
int k ;
double t ;
extern float *U_pointer ;    // register
extern float * p1_pointer ; // register
extern float * p2_pointer ; // register
extern short int p7 ;        // register 5-bit int p7
for(k = 0; k < p7; k=k+1)
{
    *(U_pointer +k) = *(U_pointer+k) * *(p2_pointer+k) -
                      *(p1_pointer+k) * *(p2_pointer+k) ;
}
```

```

t = 0 ;
for(k = 0; k < p7; k=k+1)
{
    t = t - *(U_pointer+k) * *(U_pointer+k) ;
}
result = t;

```

2. When STCFGn[VSRT] is set, it activates the updating of the v32, v64, p8 and result values in the corresponding registers:

```

int k ;
double t ;
extern short int p6 ;      // register
extern short int p8 ;      // register
extern short int p7 ;      // register, 5-bit int p7
extern float *U_pointer ;  // register
extern float *V_pointer ;  // register
                           // if V16 set, V-pointer is pointer to 16-bit
float.
extern float *p3_pointer ; // register
extern float v32 ;         // register
extern double v64 ;        // register
extern float p4 ;          // register
extern float p5 ;          // register
extern float result ;      // register
extern float exp(double t); // exp function takes double argument,
returns float.

while(p8 < p6)
{
    t = result ; // this is the result of the U-vector calculation
    for(k = 0; k < p7; k=k+1)
    {
        t = t + *(V_pointer + p8*p7+k) * *(U_pointer+k) ;
    }
    v64 = v64 + *(p3_pointer+j) * exp(t) ;
    v32 = (float) v64 ;
    p8 = p8 + 1 ;
}
result = v32 * p4 + p5 ;

```

The first part of the calculation is not interruptible, whereas the second part is. There are stop flags controlling the interruption, and there is an external input signal (ipg_debug) that can stall the calculation.

If both calculations need to be done in sequence, it suffices to set both start flags in a single write to the STCFGn register. The hardware ensures the calculations are completed in the proper order.

86.3.1 Register data types

In the pseudo-code given above, some values are taken from registers. Their data types are defined in [Table 2010](#).

Table 2010. Data types in registers

Operand	Type
U_pointer ⁽¹⁾	Pointer to IEEE 32-bit floating-point
p1_pointer	Pointer to IEEE 32-bit floating-point
p2_pointer	Pointer to IEEE 32-bit floating-point
result	IEEE 32-bit floating point
p6	Integer with limited number of bits
p8	Integer with limited number of bits
p7	Integer with limited number of bits
p3_pointer	Pointer to IEEE 32-bit floating-point
v_pointer	Pointer to IEEE 32-bit floating-point or Pointer to IEEE 16-bit floating-point
v32	IEEE 32-bit floating-point
v64	IEEE 64-bit floating-point
p4	IEEE 32-bit floating-point
p5	IEEE 32-bit floating-point

1. All pointers reference the AMU local RAM, and are limited to 16-bits wide as the RAM is maximum 64 KB.

86.3.2 Calculation precision—Deviation from IEEE standard

- All multiplies are done with the precision of their input operands, into an IEEE 64-bit floating point number (double).
- All additions are done with IEEE 64-bit floating-point precision.
- There is an error of one LSB on the 64-bit v64 register when the value is negative.
- Rounding is always to nearest.
- Denorm numbers and NAN are not supported. They are interpreted as zero and infinity respectively.
- Exponential function inputs a 64-bit *t* operand and produces an IEEE 32-bit floating point result. The precision of the result is 23 mantissa bits (including the 'hidden' bit).

86.3.3 DMA

Each channel is equipped with one DMA channel. This allows optimized copying of data from flash and system calibration memories (if applicable) to local RAM. There is a source address, a destination address, and a count register. All three registers are updated while the DMA is running. The DMA terminates when the count decrements to zero.

86.3.4 Advanced features

86.3.4.1 DMA FIFO

There is a coupling mechanism implemented between the Calculation Engine and the DMA, in the form of a data FIFO. This mechanism allows the AMU calculation engine to be started before the DMA transfer for the corresponding V vector completes. To activate the coupling mechanism, set the DCTLCHn[DFA] and STCFGn[DFA] bits. Next start the DMA by setting DCTLCHn[SRT], and without waiting for the DMA transfer to complete^(z), start the AMU calculation engine.

The mechanism stalls the AMU calculation engine when the DMA is lagging, or it stalls the DMA if it gets too far ahead of the AMU calculation engine.

When the DMA FIFO is used, the DMA source pointer initially points to V[0], the first element of the V-vector in flash. The DMA destination pointer defines the base of the V-vector in local RAM. This is the same value as programmed in the AMU V_pointer. The DMA count is set equal to the total size (in bytes) of the V-vector. Its value needs to be $p6 * p7 * 2$ (in case of 16-bit V-vector) or $p6 * p7 * 4$ (in case of 32-bit V-vector).

As such, the DMA is programmed to transfer the V vector values, starting from V[0]. Now, if the AMU calculation engine p8 value is nonzero, the values V[0: (p8 * p7-1)] are transferred, but not used by the calculation engine.

If the DCTLCHn[SKIP] bit is set, the DMA suppresses, that is, skips, the transfer of the not-used V-vector values. When the DMA transfer is started, the AMU calculation engine examines the values of p8, p7 and V16, and skips any part of the DMA transfer that is not needed by the AMU calculation engine^(aa).

The number of skipped elements, which is equal to $p8 * p7$ (bytes), is available in the DMA V Vector Holdoff Count Channel n register.

86.3.4.2 Circular transfer

When DMA FIFO feature is used^(ab), it is possible to activate circular transfer (modulo 256) on the V pointer and on the daddr pointer. This limits the V-space used in local RAM to 256 bytes. It needs to be used on both pointers in conjunction.

86.3.4.3 Flow control

In order to prevent excessive dissipation by the AMU, and in order to prevent excessive flash bandwidth usage, an effective mechanism for flash bandwidth throttling is implemented^(ac). There are three bit fields for this function in the DCTLCHn register: AP[15:8], MIN[7:0] and MAX[7:0]. AP[15:8] defines the averaging period for max bandwidth while MIN[7:0] effectively forces a minimum time between AMU memory requests. The mechanism does not immediately limit bandwidth; it makes sure that averaged over

z. The DMA transfer does not need to be complete. However, it does not harm if the AMU calculation start is delayed (for example, the processor is servicing an interrupt) until the DMA transfer completes.

aa. If DCTLCHn[SKIP] is set, the registers p7, p8 and the field V16 must have valid values when DMA start is issued (DCTLCHn[SRT] = 1).

ab. The DMA FIFO feature can also be used without the circular transfer feature.

ac. The power dissipation limiting feature is implemented on the AMU DMA, as this function is the major contributor to incremental AMU power dissipation due to its read of flash data.

AP[15:8]×256 clocks, no more than one transfer per MIN[7:0] takes place. MAX[7:0] ensures an average transfer rate (averaged over the duration of the transfer) at least equal to this time. High priority escalation is used to meet this time.

System performance is improved when these times are not equal. This is because processor accesses to flash is very irregular. When they are not equal, the AMU DMA uses all available flash bandwidth that the processors are not using, and when the processors have a flash bandwidth peak, the AMU DMA only activates the high-priority mode when the MAX[7:0] time, averaged over the length of the transfer, is not met any more. So, that means, it catches up when the processors are idle, and wait when the processors are busy, and only activates the high priority mode when the average processor flash access rate is very high.

86.3.4.4 DMA WaitVBusy flag (WVS)

In some use cases, the DMA and the calculation engine operate in an interleaved way. This means, first the DMA does a copy of V-vector data from flash to the local RAM, and when this is done, the calculation engine starts based on this data. When the calculation engine is finished, a new DMA transfer can be started.

The hardware has a flag that allows the DMA to be programmed for the next transfer, while the calculation engine is still running. That means it is possible to program the DMA while the calculation engine is still operating on the previous request. As an immediate DMA start would risk overwriting the current V-vector in local RAM with the newly copied V-vector, in this case, the hardware ensures the DMA start is postponed until the calculation engine is ready. This is done by writing the WVS, in read mode, to one when the early start is given. When the calculation engine is done, the flag automatically clears and the calculation engine starts the next calculation. When the flag is written while the calculation engine is idle, it has no effect.

86.4 Programming examples

86.4.1 AMU operation with U, p1, p2, p3, V vector resident in local RAM

Step 1: Write values for the parameters V pointer, U pointer p1, p2, p3, p8, p6, Ncrossing, p7, p4, p5 to the relevant registers. V16 in V pointer register indicates whether V pointer is an array of 16-bit float else the array is of 32-bit float. Set it to one if V pointer is array of 16-bit float. CADDR bit in V pointer register should be written zero.

Step 2: If there is a 32-bit initial value for V, write it to V32 register. If there is a 64-bit initial value for V, write it to V64 register. One of these registers should be written, not both.

Step 3: Write AMU Status and Configuration register for channel 0.

- Program VSRT and USRT bits equal to 1
- Program DFA equal to 0
- Program VSN equal to 1 if calculation needs to stop on Ncrossing. Program to 0 otherwise

Step 4: Wait for completion (either interrupt, or polling of VSRT flag)

86.4.2 AMU operation with p1, p2, p3, U vector in local RAM, and V vector in flash

Step 1: Write values for the parameters U pointer p1, p2, p3, p8, p6, Ncrossing, p7, p4, p5 to the relevant registers.

Step 2: Write the destination address of the V vector in local SRAM to both V pointer register and AMUDMA destination address register. Write also the V16 bit to V vector bit 2 (indicates 16-bit or 32-bit V vector), and write CADDR bit to both registers. Write '0' for the CADDR bit, if there is enough space in RAM to hold the complete V vector, write '1' for the CADDR bit, if there is only 256 bytes of space in the local RAM. If '0' is written for CADDR, a subsequent AMU operation can read the V vector from local SRAM, if '1' is written for CADDR, the V vector needs to be reread from flash every time its needed.

Step 3: If there is a 32-bit initial value for V, write it to V32 register. If there is a 64-bit initial value for V, write it to V64 register. One of these registers should be written, not both.

Step 4: Write the source address of the V vector in flash to AMUDMA source address. This needs to be the address of V[0], even if p8 is nonzero.

Step 5: Write AMUDMA count equal to $p6 \times p7 \times 4$ if V16 = 1 or $p6 \times p7 \times 2$ if V16=0

Step 6: Write AMUDMA control register.

- Write START = 1
- Write DIE = 1 if DMA done interrupt is enabled, zero otherwise.
- Write SKIP = 1 if values V[0] to V[p8-1] need not be copied from flash to SRAM.
- Write DFA = 1
- Write values for the 3 bandwidth control parameters AP, MIN, MAX

Step 7: Write AMU Status and Configuration register. No need to wait for DMA completion.

- Write VSRT and USRT bits = 1.
- Write DFA = 1
- Write VSN = 1(Vstop on Ncross) if calculation needs to stop on Ncrossing. Program to 0 otherwise.
- Write ASTOP = 1

Step 8: Wait for completion. (either interrupt, or polling of Vstart flag.)

86.4.3 AMU resume

Following are steps required for an AMU resume.

Step 1: Restore registers to values after stop. If no intermediate calculation has been done, no need to restore anything.

Step 2: If this was a chained AMU plus DMA transfer, write start bit in AMUDMA control register to 1.

Step 3: Write VSRT bit in AMU Status and Configuration register.

Step 4: Wait for completion.

86.4.4 DMA only operation

Step 1: Write the destination address of the V vector in SRAM to AMUDMA destination address. Write CADDR equal to 0.

Step 2: Write the source address of the V vector in flash to AMUMDA source address.

Step 3: Write AMUDMA count equal to the number of bytes to be transferred.

Step 4: Write AMUDMA control register.

- Write START = 1
- Write DIE = 1 if DMA done interrupt is enabled, zero otherwise.
- Write SKIP= 0
- Write DFA = 0
- Write values for the 3 bandwidth control parameters AP, MIN, MAX

Step 5: Wait for completion (either interrupt, or polling of VSRT flag)

87 Wakeup Unit (WKPU)

87.1 Introduction

87.1.1 Overview

The Wakeup Unit (WKPU) supports one external source that can cause non-maskable interrupts to on-chip cores and wakeup events to the system. This NMI external source can also generate a functional reset event to the MC_RGM. [Figure 2153](#) is a block diagram of the WKPU and its interfaces to other system components.

Figure 2153. WKPU block diagram

87.1.2 Features

The WKPU supports these distinctive features:

- one external NMI source
- one analog glitch filter
- independent interrupt destination for each core (safety core, main core, and IOP):
 - non-maskable interrupt
 - critical interrupt
 - machine check request
- active edge selection control for events to each core and functional reset event to MC_RGM
- configurable wakeup event from low power mode to the MC_ME
- configurable wakeup event to exit from STOP mode to the MC_ME
- WKPU register configuration lock

87.2 External signal description

There is a single, active-edge-selectable, NMI pin (ESR1) on the device that connects to the WKPU block. See “Signal Description” chapter for more detail on the ESR1 pin.

87.3 Memory map and register description

This section provides a detailed description of all registers accessible in the WKPU module.

87.3.1 Memory map

[Table 2011](#) gives an overview of the WKPU registers.

Table 2011. WKPU memory map

Address offset	Register	Size (bits)	Supported access sizes (bits)	Location
0x0000	NMI Status Flag Register (NSR)	32	32/16/8	on page 3678
0x0004	Reserved			
0x0008	NMI Configuration Register (NCR)	32	32/16/8	on page 3680
0x000C – 0x03FFF	Reserved			

Note: *Reserved registers will read as 0, writes will have no effect. If supported and enabled by the SoC, a transfer error will be issued when trying to access completely reserved register space.*

87.3.2 Register descriptions

This section describes in address order all the WKPU registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

87.3.2.1 NMI Status Flag Register (NSR)

This register holds the status flags of the NMI external source pin and reset request. This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register. The status flag is set whenever an NMI or reset request event is detected. The overrun flag is set whenever an NMI or reset request event is detected and the status flag is set (i.e. has not yet been cleared). The reset request overrun is a don't-care since the device will be reset on the first event.

The status flags are set independently of the NDSS/RDSS bits. Therefore, these flags can be set but not generate a non-maskable interrupt or system wakeup if NWRE/RWRE = 0 or if NDSS is set to "no request".

Note: The overrun flag is cleared by writing a '1' to the appropriate overrun bit in the NSR. If the status bit is cleared and the overrun bit is still set, the pending interrupt will not be cleared.

Note: NIF is set when: NMI Destination Source Select is disabled (NDSS = 11) and NMI System Wakeup Request is disabled (NWRE = 0) and an NMI input event is seen (pad4 is toggled).

Also see notes in [Section 87.3.2.2, NMI Configuration Register \(NCR\)](#).

Figure 2154. NMI Status Flag Register (NSR)

Address: 0x0000

Access: User read/write (write 1 to clear)

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

R	NIF[2]	NOVF[2]	0	0	0	0	0	0	RIF	ROVF	0	0	0	0	0	0
W	w1c	w1c							w1c	w1c						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 2012. NSR field descriptions

Field	Description
NIF _[x⁽¹⁾]	NMI Status Flag x This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (NREE[x] or NFEE[x] set), an NMI input event will set NIF[x]. NIF[x] causes an interrupt request based on the NMI destination, as configured by the NDSS bits, and/or a system wakeup request based on the NWRE bit configuration. 1An event as defined by NREE[x] and NFEE[x] has occurred 0 No event has occurred on the pad
NOVF _[x⁽¹⁾]	NMI Overrun Status Flag x This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current NIF[x] value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. NOVF[x] causes an interrupt request based on the NMI destination, as configured by the NDSS bits, and/or a system wakeup request based on the NWRE bit configuration. 1An overrun has occurred on NMI input x 0 No overrun has occurred on NMI input x
RIF	Reset status Flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. If enabled (i.e., if RREE or RFEE is set), RIF status bit is set and will cause a functional reset request to RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short "functional" reset. 1An event as defined by RREE and RFEE has occurred 0No event has occurred on the pad
ROVF	Reset overrun status flag This flag can be cleared only by writing a 1. Writing a 0 has no effect. It will be a copy of the current RIF value whenever a NMI event occurs, thereby indicating to the software that an NMI occurred while the last one was not yet serviced. If enabled (RREE or RFEE set), ROVF can cause a reset request to MC_RGM if RDSS[1:0] of NCR is '00'. This bit is automatically cleared if the ESR1 reset request is configured in the MC_RGM to generate a long or short "functional" reset. 1An overrun has occurred on NMI input 0No overrun has occurred on NMI input

1. Index 'x' designates the core: 0 is the safety core, 1 is the main core, and 2 is the IOP.

87.3.2.2 NMI Configuration Register (NCR)

This register holds the configuration bits for the non-maskable interrupt settings.

Figure 2155. NMI Configuration Register (NCR)

Address: 0x0008

Access: User read/write

	0	1	2	3	4	5	6	7

Table 2013. NCR field descriptions

Field	Description
NLOCK[x ⁽¹⁾]	NMI Configuration Lock Register x Writing a 1 to this bit locks the configuration for the NMI until it is unlocked by a system reset. Writing a 0 has no effect.
NDSS[x ⁽¹⁾]	NMI Destination Source Select x 00 Non-maskable interrupt. A non-maskable interrupt will occur if NIF[x] or NOV[x] is set. 01 Critical interrupt. A critical interrupt will occur if NIF[x] or NOV[x] is set. 10 Machine check request. A machine check request will occur if NIF[x] or NOV[x] is set. 11 No reaction
NWRE[x ⁽¹⁾]	NMI System Wakeup Request Enable x 1 A set NIF[x] bit or set NOV[x] bit causes a system wakeup request 0 System wakeup requests from the corresponding NIF[x] bit are disabled
NREE[x ⁽¹⁾]	NMI Rising-edge Events Enable x 1 Rising-edge event is enabled 0 Rising-edge event is disabled

Table 2013. NCR field descriptions (continued)

Field	Description
NFEE[x ⁽¹⁾]	NMI Falling-edge Events Enable x 1 Falling-edge event is enabled 0 Falling-edge event is disabled
NFE[0]	NMI Filter Enable Enable analog glitch filter on the NMI pad input. 1 Filter is enabled 0 Filter is disabled
RLOCK	Reset Configuration Lock Register Writing a 1 to this bit locks the configuration for the reset until it is unlocked by a system reset. Writing a 0 has no effect.
RDSS	Reset Destination Source Select 00 Reset request to RGM 01 No reaction 10 No reaction 11 No reaction
RWRE	Reset Wakeup Request Enable 1 A set RIF bit or set ROVF bit causes a system wakeup request 0 System wakeup requests from the corresponding RIF bit are disabled
RREE	Reset Rising-edge Events Enable 1 Rising-edge event is enabled 0 Rising-edge event is disabled
RFEE	Reset Falling-edge Events Enable 1 Falling-edge event is enabled 0 Falling-edge event is disabled

1. Index 'x' designates the core: 0 is the safety core, 1 is the main core, and 2 is the IOP.

Note: Writing a '0' to both NREE[x] and NFEE[x] disables the NMI functionality completely (i.e. no system wakeup or interrupt will be generated on any pad activity)!

Note: Writing to the NCR when NIF = 1 or NOV = 1 causes an interrupt to the destination source/system wakeup to be generated independent of an NMI wakeup event.

87.4 Functional description

This section provides a complete functional description of the features of the WKPU.

87.4.1 Non-maskable interrupts

The WKPU allows the external NMI pin (ESR1) to assert the non-maskable interrupts of the cores on the device. These interrupts include non-maskable interrupts, critical interrupts, or machine check requests to any of the cores including the main core, IOP, and safety core. The safety core's non-maskable interrupt line from the WKPU is combined with the FCCU internal NMI interrupt event arising due to fault management logic.

The NMI destination interrupt is controlled by the user through the configuration of the NDSS bits. See [Table 2013](#) for details.

The enabling of rising edge, falling edge, or either edge reaction to the NMI pin is independent for each core, and is controlled by NFEE[2:0] and NREE[2:0] bits in the NCR.

The WKPU supports the capturing of a second event per NMI input before the interrupt is cleared, thus reducing the chance of losing an NMI event.

The NMI supports a status flag and an overrun flag, which are located in the NSR. See [Section 87.3.2.1, NMI Status Flag Register \(NSR\)](#) for more information.

87.4.2 Reset management

The WKPU allows the external NMI pin (ESR1) to assert a non-destructive reset request to the MC_RGM block. The ESR1 reset request can be reconfigured in the MC_RGM to generate a SAFE mode or interrupt request (see [Chapter 57: Reset Generation Module \(MC_RGM\)](#) for details).

The enabling of rising edge, falling edge, or either-edge reaction to the NMI pin is independent for the reset request, and is controlled by the RFEE/RREE bits in the NCR.

Reset request supports a status flag and an overrun flag, which are located in the NSR. See [Section 87.3.2.1, NMI Status Flag Register \(NSR\)](#) for more information.

87.4.3 System wakeup

The WKPU allows the external NMI pin (ESR1) to assert a system wakeup from STOP to the MC_ME block on the device. The system wakeup enable is asserted in the NCR by any of the NWRE/RWRE bits.

87.4.4 Glitch filter

An analog glitch filter is placed between the NMI pin (ESR1) and the WKPU block. The filter is enabled by the NFE[0] bit in the NCR. See the device data sheet for the glitch filter electrical specifications.

87.4.4.1 Edge detect

Each NMI and reset request can be enabled or disabled independently. This can be performed using the single NCR laid out to contain all configuration bits for a given NMI in a single byte (see [Figure 2155](#)). The user can configure interrupts with an active rising edge, an active falling edge, or either edge being active. Disabling both edge events results in no interrupt or reset being propagated from the WKPU block.

The active NMI edge is controlled by the user through the configuration of the NREE and NFEE bits. The active reset request edge is controlled by the RREE and RFEE bits.

Note: After reset, NREE/RREE and NFEE/RFEE are set to '0', therefore the NMI functionality and reset request is disabled after reset and must be enabled explicitly by software.

87.5 Initialization information

This section discusses initialization for the following features:

- glitch filter and pad configuration
- non-maskable interrupt initialization
- reset request

87.5.1 Glitch filter and pad configuration

Glitch filter control and pad configuration should be performed while the NMI is disabled in order to avoid erroneous triggering by glitches caused by the configuration process itself.

Note: When enabling the glitch filter, do not enable the rising-/falling-edge events bits (NREE[x], NFEE[x], RREE, RFEE) in the same register write.

87.5.2 Non-maskable interrupt initialization

When an NMI interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request during pin interrupt initialization the user must do the following:

1. mask interrupts by clearing the NIF[n] and NOV[n] bits in WKPU_NSR
2. clear WKPU_NCR bit NFEE[n] and NREE[n], preferably by writing 0 to all bits in this register
3. enable the analog glitch filter as desired by writing the NFE[0] bit in the WKPU_NCR
4. configure the appropriate SIUL2_MSCR for the desired NMI interrupt pin(s) as follows:
 - clear the ODC bits to disable output
 - set the IBE bit to enable the pin's input buffer
 - if the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits

Note: NMI interrupt pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

5. write appropriate bit values to the WKPU_NCR to configure:
 - NMI source (NDSS[n])
 - wakeup request (NWRE[n])
 - glitch filter (NFE[0])
 - rising/falling edge events enable (NFEE[n] and NREE[n])
 - NMI configuration lock (NLOCK[n])

87.5.3 Reset request

When an NMI reset request pin is first enabled, it is possible to get a false reset request. To prevent a false reset request during pin reset request initialization the user must do the following:

1. mask reset requests by clearing the RIF and ROVF bits in WKPU_NSR
2. clear WKPU_NCR bit RFEE and RREE, preferably by writing 0 to all bits in this register
3. enable the analog glitch filter as desired by writing the NFE[0] bit in the WKPU_NCR
4. configure the appropriate SIUL2_MSCR for the NMI reset request pin(s) as follows:
 - clear the ODC bits to disable output
 - set the IBE bit to enable the pin's input buffer
 - if the internal weak pull-up/pull-down is used, configure the appropriate WPUE and WPDE bits

Note: NMI reset request pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external reset request inputs are desired since false reset requests could be detected (such as from a GPIO configuration).

5. write appropriate bit values to the WKPU_NCR to configure:
 - reset destination source (RDSS)
 - reset wakeup request (RWRE)
 - glitch filter (NFE[0])
 - rising/falling edge events enable (RFEE and RREE)
 - reset configuration lock (RLOCK)

88 GTM103 Integration (GTMINT) Module

88.1 Introduction

This chapter specifies the functionality of the GTMINT module. The GTMINT is integrated IP with timer and debug functions and is comprised of:

- The Bosch GTM-IP_103 timer module (also called GTM-IP)
- The GTMDI debug interface IP
- 12 ECC error correction encoder / decoders for the RAMs required by the timer.

The timer GTM-IP_103 is a very complex block that can be configured to perform several timer functions. The debugger module is the GTMDI IP (GTM Development Interface IP) that is a Nexus based interface that is connected to the chip level NAR and used to monitor the software and hardware activities of GTM-IP. The ECC sub-blocks generate the parity bits on RAM writes and detect errors in the data read from the RAMs.

Note: This chapter does not intend to present details of GTM-IP nor GTMDI. For full information about the timer and the debugger, please refer to the GTMDI subsection in the 'Calibration and Debug' chapter of the SPC57EM80xx Reference Manual and the GTM103 Reference Manual.

88.1.1 Features

The GTMINT module features include:

- GTM-IP timer features
 - Time base generators
 - Advanced data signal / time base router
 - Input signal processors (32 inputs)
 - Simple output signal generators (48 outputs)
 - Microprocessed output signal generators (40 outputs)
 - Digital PLL
 - BLDC support
 - Safety features - GTM is a non-safety relevant module
 - Output compare unit
 - Monitoring unit
 - CPU bus interface clock operates asynchronously to timer section clock allowing CPU low power operation.
- GTMDI debug block features
 - Full duplex pin interface for medium and high visibility throughput
 - Pin interface shared among all Nexus-based development interfaces on the device
 - Auxiliary Output Port
DATA with MDO (Message Data Out) and MSEO (Message Start/End)
2 EVTO (Event Out) pin for GTM real time signal monitoring
 - Auxiliary Input Port
1 EVTI (Event In) pin

- IEEE 1149.1 (JTAG) Test Access Port (TAP)
Support for optional Multi-JTAG TAP Linking Module (TLM)
4 pins (TDI, TDO, TMS, and TCK)
Reset input TRST driven by either the Nexus Port Controller or an external pin
- GTM Development Support
 - Read/Write registers in debug mode from JTAG port
 - Ability to enter debug mode at reset negation or during normal execution
 - Breakpoint and Watchpoint Configuration
 - Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This allows the development tool to trace reads and writes to selected RAM address ranges
Two data trace windows for each MCS core with programmable address ranges and access attributes are provided. Data trace windowing reduces the requirement on the Aurora port bandwidth by constraining the number of trace locations.
Fetch trace capability controlled by two programmable Watchpoints.
Private messages are used to indicate special MCS core cases not covered by public messages. Up to two^(ad) MCS cores can be debugged at the same time.
 - Watchpoint Messaging (WPM)
- Trigger Control
 - The GTMDI provides selection of trigger signals that will generate debug actions at system level such as Halt GTM itself or cores in the same device.
 - Trace enable signals are provided to control the start/stop of trace messages for each one of the GTM Nexus message sources, such as TIM, TOM, ATOM, etc.
- GTMDI Clock operation
 - The module is able to operate in any frequency ratio considering GTMDI and JTAG frequency. The GTMDI should operate in the same clock source as the GTM IP module.
- ECC encoder / decoder for each of 12 RAM interfaces
 - Parity calculation using the whole word and the target memory address value.
 - Detection and correction of single error on the read data value
 - Detection of single bit error on address field but no need for correction
 - Double error detection on data or address field without error correction.
 - ECC report generation for each RAM containing:
 - Address of the error in the register map (see [Section 88.2, "Memory Map and Register Definition"](#))
 - Non-correctable error indication (not correctable data + address ECC detected errors)

ad. Note that by enabling two MCS cores at the same time for data trace can exceed the capacity of the Nexus Aurora Router throughput thus information can be lost.

- Correctable error indication (correctable data error)
- Generation of 151 interrupt requests and or DMA requests.
- Debugger is allowed to read all GTM registers through the peripheral bus even when the timer is running. Read-access of the debugger is possible without destroying or changing the contents of these registers.
- Debugger is allowed to read all GTM addresses read-/writeable from the peripheral bus when GTM is running or halted.

88.1.2 Modes of Operation

88.1.2.1 Normal Mode

The normal mode is the mode in which the GTMINT module is after a reset is applied. In this mode the timer IP is functional and processes input timing signals and generates timed outputs based on the input timing signals or controlled by the internal channels software. The GTMDI development interface is also active.

88.1.2.2 Stop Mode

This mode is set when the global stop input is received or when the bit field MDIS on the GTMMCR register is asserted. In this case all functional clocks are disabled (ipg_clk and ipg_clk_gtm), but the slave bus clock is not disabled. Please, see more details on [Section 88.3.4, Stop Mode Description](#).

88.1.2.3 Debug Mode (or Halt Mode)

The debug mode or GTM-IP halt mode is externally requested through the GTMDI. In this mode, the GTM-IP main clock is requested to stop (ipg_clk_gtm only) and the bus interface clocks remain running to access all registers and memories. It is possible to read the registers not interfering into the logic status, even for FIFOs, by configuring the debug access controls on GTMDI.

88.1.3 Block Diagram

[Figure 2156](#) shows the interconnections in the GTMINT Module.

Figure 2156. GTMINT block diagram

88.2 Memory Map and Register Definition

This section provides a reference table to the GTM-IP sub-module registers. Details of each register are found in the *GTM-IP specification* document. Additional registers from those used in the GTM-IP are described in this section.

88.2.1 Module Memory Map

The GTMINT simplified memory map is shown in [Table 2014](#). Offsets are relative to the GTMINT base address.. See the device memory map for the module base address.

Note: The GTMINT module has only a few registers, detailed in [Section 88.2.2, Register Descriptions](#). The module also acts as an interface to all implemented GTM-103 control registers. For details see the GTM-IP Specification document.

0x00828 + AAi	SPE output control register (SPE[i]_OUT_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0082C + AAi	SPE Interrupt notification register (SPE[i]_IRQ_NOTIFY)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x00830 + AAi	SPE Interrupt enable register (SPE[i]_IRQ_EN)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x00834 + AAi	SPE Interrupt generation by software (SPE[i]_IRQ_FORCINT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x00838 + AAi	IRQ mode configuration register (SPE[i]_IRQ_MODE)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0083C + AAi	SPE Interrupt enable register (SPE[i]_EIRQ_EN)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x00840 + AAi	SPE Interrupt generation by software (SPE[i]_REV_CNT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x00844 + AAi	IRQ mode configuration register (SPE[i]_REV_CMP)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
(0x00848 – 0x0087C) + AAi	Reserved			
0x00900 – 0x009C0	Reserved for SPE2/3			
0x00A00 – 0x00EFC	Reserved			
TIM0 Input Mapping Module (MAP) Registers				
0x00F00	MAP Control register (MAP_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x00F04 – 0x00F3C	Reserved for MAP			
Memory Configuration (MCFG) Configuration Registers				
0x00F40	Memory layout configuration (MCFG_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x00F44 – 0x00FA0	Reserved for MCFG			

Table 2015. GTMINT Module Memory Map (continued)

Offset	Use	Access	Reset value ⁽¹⁾	Location
0x00FA4 – 0x00FFC	Reserved			
Timer Input Module (TIM) Configuration Registers (BBi = i*0x800, n = 0...7, i = 0..3)				
0x01000+n*0x80 + BBi	Channel n general purpose 0 (TIM[i]_CH[n]_GPR0)	R	0x0X00_0000	See GTM Spec. ⁽²⁾
0x01004+n*0x80 + BBi	Channel n general purpose 1 (TIM[i]_CH[n]_GPR1)	R	0x0X00_0000	See GTM Spec. ⁽²⁾
0x01008+n*0x80 + BBi	Channel n SMU counter (TIM[i]_CH[n]_CNT)	R	0x0000_0000	See GTM Spec. ⁽²⁾
0x0100C+n*0x80 + BBi	Channel n SMU counter (TIM[i]_CH[n]_ECNT)	R	0x0000_0000	See GTM Spec. ⁽²⁾
0x01010+n*0x80 + BBi	Channel n SMU shadow counter (TIM[i]_CH[n]_CNTS)	R/W	0x0X00_0000	See GTM Spec. ⁽²⁾
0x01014+n*0x80 + BBi	Channel n TDU control (TIM[i]_CH[n]_TDUC)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x01018+n*0x80 + BBi	Channel n TDU control (TIM[i]_CH[n]_TDUV)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0101C+n*0x80 + BBi	Channel n filter parameter 0 (TIM[i]_CH[n]_FLT_RE)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x01020+n*0x80 + BBi	Channel n filter parameter 1 (TIM[i]_CH[n]_FLT_FE)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x01024+n*0x80 + BBi	Channel n control (TIM[i]_CH[n]_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x01028+n*0x80 + BBi	Channel n control (TIM[i]_CH[n]_ECTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0102C+n*0x80 + BBi	Channel n interrupt notification (TIM[i]_CH[n]_IRQ_NOTIFY)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x01030+n*0x80 + BBi	Channel n interrupt enable (TIM[i]_CH[n]_IRQ_EN)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x01034+n*0x80 + BBi	Channel n software interrupt force (TIM[i]_CH[n]_IRQ_FORCINT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x01038+n*0x80 + BBi	Channel n IRQ mode configuration register (TIM[i]_CH[n]_IRQ_MODE)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0103C+n*0x80 + BBi	Channel n software interrupt force (TIM[i]_CH[n]_EIRQ_EN)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
(0x01040+n*0x80 – 0x01074+n*0x80) + BBi	Reserved for TIM[i]_CH[n]			
0x01078 + BBi	Channel n IRQ mode configuration register (TIM[i]_IN_SRC)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x107C + BBi	TIM Global software reset (TIM[i]_RST)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾

Table 2015. GTMINT Module Memory Map (continued)

Offset	Use	Access	Reset value ⁽¹⁾	Location
(0x01078+n*0x80 – 0x0107C+n*0x80) + BBi	Reserved (n > 0)			
(0x01400 – 0x017FC) + BBi	Reserved			
0x03000 – 0x04400	Reserved for TIM4 to TIM6			
0x04404 – 0x07FFC	Reserved			
Timer Output Module (TOM) Configuration Registers (CCi = i*0x800, i = 0...2, n = 0...15)				
0x08000 + n*0x0040 + CCi	TOM Channel m control register (TOM[i]_CH[n]_CTRL), i = 0...2, n = 0...15	R/W	0x0000_X000	See GTM Spec. ⁽²⁾
0x08004 + n*0x0040 + CCi	TOM Channel n CCU0 compare shadow register (TOM[i]_CH[n]_SR0)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08008 + n*0x0040 + CCi	TOM Channel n CCU1 compare shadow register (TOM[i]_CH[n]_SR1)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0800C + n*0x0040 + CCi	TOM Channel n CCU0 compare register (TOM[i]_CH[n]_CM0)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08010 + n*0x0040 + CCi	TOM Channel n CCU1 compare register (TOM[i]_CH[n]_CM1)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08014 + n*0x0040 + CCi	TOM Channel n CCU0 counter register (TOM[i]_CH[n]_CNO)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08018 + n*0x0040 + CCi	TOM channel n status (TOM[i]_CH[n]_STAT)	R	0x0000_0001	See GTM Spec. ⁽²⁾
0x0801C + n*0x0040 + CCi	TOM channel n interrupt notification register (TOM[i]_CH[n]_IRQ_NOTIFY)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08020 + n*0x0040 + CCi	TOM channel n interrupt enable register (TOM[i]_CH[n]_IRQ_EN)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08024 + n*0x0040 + CCi	TOM channel n software interrupt generation (TOM[i]_CH[n]_IRQ_FORCINT)		0x0000_0000	See GTM Spec. ⁽²⁾
0x08028 + n*0x0040 + CCi	Channel n IRQ mode configuration register (TOM[i]_CH[n]_IRQ_MODE)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0802C + n*0x0040 + CCi	Reserved			
0x08030 + CCi	TGC0 global control reg (TOM[i]_TGC0_GLB_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08034 + CCi	TGC0 action time base register (TOM[i]_TGC0_ACT_TB)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08038 + CCi	TGC0 force update control reg (TOM[i]_TGC0_FUPD_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0803C + CCi	TGC0 internal trigger control (TOM[i]_TGC0_INT_TRIG)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾

Table 2015. GTMINT Module Memory Map (continued)

Offset	Use	Access	Reset value ⁽¹⁾	Location
0x08070 + CCi	TGC0 enable/disable control reg (TOM[i]_TGC0_ENDIS_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08074 + CCi	TGC0 enable/disable status reg (TOM[i]_TGC0_ENDIS_STAT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08078 + CCi	TGC0 output enable control reg (TOM[i]_TGC0_OUTEN_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0807C + CCi	TGC0 output enable status reg (TOM[i]_TGC0_OUTEN_STAT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
x08230 + CCi	TGC1 global control register (TOM[i]_TGC1_GLB_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08234 + CCi	TGC1 action time base register (TOM[i]_TGC1_ACT_TB)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08238 + CCi	TGC1 force update control reg (TOM[i]_TGC1_FUPD_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0823C + CCi	TGC1 internal trigger control (TOM[i]_TGC1_INT_TRIG)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08270 + CCi	TGC1 enable/disable control reg (TOM[i]_TGC1_ENDIS_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08274 + CCi	TGC1 enable/disable status reg (TOM[i]_TGC1_ENDIS_STAT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x08278 + CCi	TGC1 output enable control reg (TOM[i]_TGC1_OUTEN_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0827C + CCi	TGC1 output enable status reg (TOM[i]_TGC1_OUTEN_STAT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
(0x08030 – 0x0803C) + m*0x0040 + CCi	Reserved (m= 2..7, 10..15)			
(0x08400 – 0x087FC) + CCi	Reserved			
0x09800 – 0x0ABFC	Reserved for TOM3 to TOM5			
0x0AC00 – 0x0CFFC	Reserved			
ARU-connected Timer Output Module (ATOM) Registers (DDi = i*0x800, i = 0..4, m = 0..7)				
0x0D000 + m*0x0080 + DDi	ATOM Channel m ARU read address register (ATOM[i]_CH[m]_RDADDR)	R/W	0x01FE_01FE	See GTM Spec. ⁽²⁾
0x0D004 + m*0x0080 + DDi	ATOM Channel m control register (ATOM[i]_CH[m]_CTRL)	R/W	0x0000_X000	See GTM Spec. ⁽²⁾
0x0D008 + m*0x0080 + DDi	ATOM Channel m CCU0 compare shadow register (ATOM[i]_CH[m]_SR0)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0D00C + m*0x0080 + DDi	ATOM Channel m CCU1 compare shadow register (ATOM[i]_CH[m]_SR1)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾

Table 2015. GTMINT Module Memory Map (continued)

Offset	Use	Access	Reset value ⁽¹⁾	Location
0x0D010 + m*0x0080 + DDi	ATOM Channel m CCU0 compare register (ATOM[i]_CH[m]_CM0)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0D014 + m*0x0080 + DDi	ATOM Channel m CCU1 compare register (ATOM[i]_CH[m]_CM1)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0D018 + m*0x0080 + DDi	ATOM Channel m CCU0 counter register (ATOM[i]_CH[m]_CN0)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0D01C + m*0x0080 + DDi	ATOM Channel m status register (ATOM[i]_CH[m]_STAT)	R/W	0x0000_0001	See GTM Spec. ⁽²⁾
0x0D020 + m*0x0080 + DDi	ATOM channel m interrupt notification register (ATOM[i]_CH[m]_IRQ_NOTIFY)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0D024 + m*0x0080 + DDi	ATOM channel m interrupt enable register (ATOM[i]_CH[m]_IRQ_EN)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0D028 + m*0x0080 + DDi	ATOM channel m software interrupt generation (ATOM[i]_CH[m]_IRQ_FORCINT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0D02C + m*0x0080 + DDi	Channel m IRQ mode configuration register (ATOM[i]_CH[m]_IRQ_MODE)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
(0x0D030 – 0x0D03C) + m*0x0080 + DDi	Reserved for ATOM[i]_CH[m]			
0x0D040 + DDi	AGC Global control register (ATOM[i]_AGC_GLB_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x0D044 + DDi	AGC0 Enable/disable control register (ATOM[i]_AGC_ENDIS_CTRL)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾

(0x18438+m*0x40 – 0x1843C+m*0x40) + EEi	Reserved			
(0x18600 – 0x18FFC) + EEi	Reserved for FIFO[i]			
(0x19000 – 0x19FFC) + EEi	FIFO[i] Memory			See GTM Spec. ⁽²⁾
(0x1A000 – 0x1BFFC) + EEi	Reserved			
0x1C000 – 0x1DFFC	Reserved for F2A1, AFD1, FIFO1, and FIFO1 MEM			
0x1E000 – 0x27FFc	Reserved			
Digital PLL Module (DPLL)				
0x28000	Control Register 0 (DPLL_CTRL_0)	R/W	0x003B_BA57	See GTM Spec. ⁽²⁾
0x28004	Control Register 1 (DPLL_CTRL_1)	R/W	0xB000_0000	See GTM Spec. ⁽²⁾
0x28008	Control Register 2 (actions 0–7 enable) (DPLL_CTRL_2)	R/W	x0000_0000	See GTM Spec. ⁽²⁾
0x2800C	Control Register 3 (actions 8–15 enable) (DPLL_CTRL_3)	R/W	x0000_0000	See GTM Spec. ⁽²⁾
0x28010	Control Register 4 (actions 16–24 enable) (DPLL_CTRL_4)	R/W	x0000_0000	See GTM Spec. ⁽²⁾
0x28014	Control Register 5 (actions 16–24 enable) (DPLL_CTRL_5)	R/W	x0000_0000	See GTM Spec. ⁽²⁾
0x28018	ACTION Status Register with connected shadow register (DPLL_ACT_STA)	R/W	x0000_0000	See GTM Spec. ⁽²⁾
0x2801C	Offset and switch old/new address register (DPLL_OSW)	R/W	0x0000_0200	See GTM Spec. ⁽²⁾

Table 2015. GTMINT Module Memory Map (continued)

Offset	Use	Access	Reset value ⁽¹⁾	Location
0x28020	Address offset register for APT in RAM region 2 (DPLL_AOSV_2)	R/W	0x1810_0800	See GTM Spec. ⁽²⁾
0x28024	Actual RAM pointer to RAM regions 2a, b and d (DPLL_APT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28028	Actual RAM pointer to regions 1c1, 1c2 and 1c4 (DPLL_APS)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x2802C	Actual RAM pointer to RAM region 2c (DPLL_APT_2c)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28030	Actual RAM pointer to RAM region 1c3 (DPLL_APS_1c3)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28034	Number of recent TRIGGER events used for calculations (mod 2*(TNU +1-SYN_NT)) (DPLL_NUTC)	R/W	0x0001_2001	See GTM Spec. ⁽²⁾
0x28038	Number of recent STATE events used for calculations (mod 2*(SNU +1-SYN_NS) (DPLL_NUSC)	R/W	0x0000_2081	See GTM Spec. ⁽²⁾
0x2803C	Number of active TRIGGER events to interrupt (DPLL_NTI_CNT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28040	Interrupt notification register (DPLL_IRQ_NOTIFY)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28044	Interrupt enable register (DPLL_IRQ_EN)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28048	Interrupt force register (DPLL_IRQ_FORCINT)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x2804C	Interrupt mode register (DPLL_IRQ_MODE)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28050	Error Interrupt enable register (DPLL_EIRQ_EN)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28054 – 0x280AC	Reserved			
0x280B0	Counter for pulses for TBU_TS1 to be sent in automatic end mode (DPLL_INC_CNT1)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x280B4	Counter for pulses for TBU_TS2 to be sent in automatic end mode when SMC = RMO = 1w (DPLL_INC_CNT2)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x280B8	Old RAM pointer and offset value for TRIGGER (DPLL_APT_SYNC)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x280BC	Old RAM pointer and offset value for STATE (DPLL_APS_SYNC)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x280C0	TBU_TS0 value at last TRIGGER event (DPLL_TBU_TS0_T)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x280C4	TBU_TS0 value at last STATE event (DPLL_TBU_TS0_S)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x280C8	Direct load input value for SUB_INC1 (DPLL_ADD_IN_LD1)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾

Table 2015. GTMINT Module Memory Map (continued)

Offset	Use	Access	Reset value ⁽¹⁾	Location
0x280CC	Direct load input value for SUB_INC2 (DPLL_ADD_IN_LD2)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x280D0 – 0x280F8	Reserved for DPLL			
0x280FC	Status Register (DPLL_STATUS)	R/W	0x0000_0000	See GTM Spec. ⁽²⁾
0x28100 + n*0x0004	9 bit ID information for input signal PMTR_n (8:0), n = 0...23 (DPLL_ID_PMTR_n)	R/W	0x0000_01FE	See GTM Spec. ⁽²⁾
0x28160 – 0x281DC	Reserved for DPLL			
0x281E0	shadow register of DPLL_CTRL_0 (DPLL_CTRL_0_SHADOW_TRIGGER)	R/W	0x0000_0257	See GTM Spec. ⁽²⁾

0x37000 – 0x37FFC	Reserved			
MCS Memories (GGi = i*0x8000, i = 0..3)				
(0x38000 – 0x3BFFC) + GGi	MCS Memory (MCS[i]_MEM)			See GTM Spec. ⁽²⁾
(0x3C000 – 0x3FFFC) + GGi	Reserved			
0x58000 – 0x6BFFC	Reserved for MCS4 / 5 / 6 Memories			
0x6C000 – 0xFFFFC	Reserved			

1. Default value when in reset state.
2. For detailed information see the *GTM-IP Specification* document.
3. Reset value depends on configuration parameters.
4. RAM reserved position for GTM-IP internal use. No error occurs when accessed.

88.2.2 Register Descriptions

This section contains the description of additional registers on the top integration module. Description of GTM-IP registers, or GTMDI registers are found in their respective specification document.

88.2.2.1 GTM Module Configuration Register (GTMMCR)

The GTMMCR contains the control bits to configure the general operation of the GTMINT and GTM-IP Module.

Figure 2157. GTM Module Configuration Register (GTMMCR)

Offset 0x000C0

Access: User read/write

Reset	0	— ⁽¹⁾	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Reset value is SoC dependent.

GTMMCR register functions are as shown in [Table 2016](#).

Table 2016. GTMMCR field descriptions

Field	Description
1 MDIS	MDIS Module Disable. The MDIS bit puts the GTMINT Module in stop/disabled mode. Communication through the slave-bus Interface is ignored in this mode except reads/writes to the GTMMCR register and reads from other integration registers which are allowed. 1 Module disable request 0 Normal Mode
15 AEISREN	AEISREN AEI interface soft-reset control enable. The AEISREN bit enables the soft-reset of the AEI interface that is controlled by AEISRST bit on GTMMAEICR register.. Please, refer to Section 88.3.7, AEI Interface Software Reset Description for more details. 1AEI soft-reset control is enabled 0AEI soft-reset control is disabled
17 STPS	STPS Stop Mode Status. The STPS bit indicates the GTM-IP Module is in stop mode, or by MDIS bit field setting or by stop line request. Please, refer to Section 88.3.4, Stop Mode Description for more details. 1GTM is in Stop Mode 0Normal Mode

88.2.2.2 GTM Interrupts Clear Register (GTMINTCLR)

The GTMINTCLR contains the control bits to clear some specific interrupt request output.

GTMMAEICR register functions are as shown in [Table 2019](#).

Table 2019. GTMMAEICR field descriptions

Field	Description
31 AEISRST	AEISRST AEI interface soft-reset control. The AEISRST bit when set applies a reset on the GTM-IP AEI interface. The set is enabled by the AEISREN bit on GTMMCR register. This is a self clear bit and is always read as 0.. Please, refer to Section 88.3.7, AEI Interface Software Reset Description for more details.

88.3 Functional Description

The following sections describe the GTMINT Module functionality.

The GTMINT Module is designed to accommodate the multipurpose timer (GTM-IP) and the debugger block (GTMDI). The GTM-IP can generate timed signals and also can handle external signals to obtain their timing information. The GTMDI provides several features to help the development of programs to be run on GTM-IP. Please refer to [Figure 2156](#) for the integration architecture.

The GTMINT Module integrates the following internal sub-modules into the SPC57EM80xx platform:

- GTM-IP timer
- GTMDI debug interface
- ECC error correction sub-blocks
- Interface match logic

The following sections describe each one of these sub-modules and their combined operation.

88.3.1 GTM-IP Timer

The Generic Timer Module (GTM) is composed of several submodules of different functionality. These submodules can be combined in a configurable manner to form a complex timer module that serves different application domains and different classes within one application domain. Because of this scalability and configurability the timer is called generic. The scalability and configurability is reached with an architecture philosophy where dedicated hardware submodules are located around a central routing unit called Advanced Routing Unit (ARU). The ARU can connect the submodules in a flexible manner. The connectivity is software programmable and can be configured during runtime.

Nevertheless, the GTM-IP is designed to unload the CPU or a peripheral core from a high interrupt load. Most of the tasks inside the GTM-IP can run (once set up by an external CPU) independent and in parallel to the software. There may be special situations, where the CPU has to take action but the goal of the GTM design was to reduce these situations to a minimum.. In addition, the timer section of GTM-IP runs at a fixed clock frequency (80MHz) to allow real time period counting, but the interface to CPU can work with a frequency variable clock.

88.3.1.1 GTM-IP Timer Architecture

The hardware submodules have dedicated functions, e.g., there are timer input modules where incoming signals can be captured and characterized together with a notion of time. By combination of several submodules through the ARU complex functions can be established. For example, the signals characterized at an input module can be routed to a signal processing unit where an intermediate value about the incoming signal frequency can be calculated.

The modules that help to implement such complex functions are called infrastructural components further on. These components are present in all GTM variants. However, the number of these components may vary from device to device. Other submodules have a more general architecture and can fulfill typical timer functions, e.g., there are PWM generation units. The third class of submodules are those fulfilling a dedicated functionality for a certain application domain, e.g., the DPLL serves engine management applications. A fourth group of submodules is responsible for supporting the implementation of safety functions to fulfill a defined safety level.

Each GTM-IP is build up therefore with submodules coming from those four groups. The application class is defined by the amount of components of those submodules integrated into the implemented GTM-IP.

A list of submodules is given in [Table 2020](#) below.

Table 2020. Submodules of GTM-IP

Item	Submodule	Group
1	Advanced Routing Unit (ARU)	Infrastructural components
2	Broadcast Module (BRC)	
3	First In First Out Module (FIFO)	
4	AEI-to-FIFO Data Interface (AFD)	
5	FIFO-to-ARU Interface (F2A)	
6	Clock Management Unit (CMU)	
7	Time Base Unit (TBU)	
8	Timer Input Module (TIM)	IO Modules
9	Timer Output Module (TOM)	
10	ARU-connected Timer Output Module (ATOM)	
11	Multi Channel Sequencer (MCS)	Signal generation and processing
12	Memory Configuration Module (MCFG)	Infrastructural component for MCS
13	TIM0 Input Mapping Module (MAP)	Dedicated
14	Digital PLL (DPLL)	
15	Sensor Pattern Evaluation Module (SPE)	BLDC support
16	Interrupt Concentrator Module (ICM)	Interrupt services
17	Output Compare Unit (CMP)	Safety features
18	Monitoring Unit (MON)	

For more details, please refer to the *GTM-IP Specification* document.

88.3.2 GTMDI Debug Interface

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including MCS cores, ARU data trace, Input Channel Filters trace, Output Timer channels, DPLL and SPE sub-modules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules in order to implement complex debug features. Trace capability is also provided along with a global time-stamp which allows real time trace for several GTM sub-module events.

The GTMDI implements a Nexus Client standard interface and a JTAG standard Port Controller to provide communication capability with the JTAG and Nexus Aurora router on-chip modules. Please, note that the Nexus standard is only used for the physical interfaces. In order to implement the debug features such as breakpoint and messages required for the GTM debug, the Nexus standard could not be followed.

For detailed architecture and features description, please refer to the GTMDI chapter of this reference manual.

88.3.2.1 Peripheral Slave Bus Read Debug Access

Debugger is able to read all GTM registers, which are visible from the peripheral bus even when the timer is running. Read-access of the debugger is possible without destroying or

changing the contents of these registers. A read debug access using the slave bus has no side effects on the timer. The main example is a read access to the FIFO that does not update the FIFO pointers.

88.3.3 Error Detection on GTM Memories Accesses

The GTM-IP architecture requires 12 RAM units that should be placed on the SoC. Each RAM is connected with separated input and output ports to the GTM-IP for safety purposes.

Memories of this block are equipped with error detection features for safety improvement. The following procedures detect errors on memory accesses:

- Memory write data and its address are considered in the parity bits calculation. These parity bits are stored in that memory address as part of the written data.
- Memory read data and its address are considered in the error detection. The parity bits are part of the data read from the specified memory address.
- Error Correcting Code (ECC), that corrects single errors and detects double errors on each read access

88.3.3.1 ECC Description

The Error Correcting Code (ECC) for GTM RAMs provides guaranteed single bit error correction and double bit error detection (without correction) per accessed word. On write accesses, the parity bits are calculated and appended to the original data bits to be written into the specified memory address. And error detection and correction are performed on read accesses.

Note: In case of error detection (with correction or not), no write operation is done here to fix possible errors in the memory content.

Note: All memories must be initialized with write operations in all addresses because the ECC parity bits need to be stored in each memory address before any read operation.

GTM-IP sub-block does this initialization automatically for all memories, except for FIFO0 RAM. In this case, the user must be careful to execute writes before reads.

[Table 2021](#) presents a summary of GTM memories and the necessary ECCs for single error correction / double error detection.

Table 2021. ECC Characteristics for GTM Memories

Memory	MEM Number of Words	MEM Address Width (bits)	Uncoded Data Width (bits)	ECC (bits)	MEM Data In/Out (Data + ECC) (bits)	Matrix Size (N.o Synd.)
FIFO0 RAM	1024	10	29	7	36	46
DPLL RAM1A	96	7	24	7	31	38
DPLL RAM1B	384	9	24	7	31	40
DPLL RAM2	2048	11	24	7	31	42
MCS0 RAM0	1024	10	32	7	39	49
MCS1 RAM0	1024	10	32	7	39	49
MCS2 RAM0	1024	10	32	7	39	49

Table 2021. ECC Characteristics for GTM Memories

Memory	MEM Number of Words	MEM Address Width (bits)	Uncoded Data Width (bits)	ECC (bits)	MEM Data In/Out (Data + ECC) (bits)	Matrix Size (N.o Synd.)
MCS3 RAM0	1024	10	32	7	39	49
MCS0 RAM1	512	9	32	7	39	48
MCS1 RAM1	512	9	32	7	39	48
MCS2 RAM1	512	9	32	7	39	48
MCS3 RAM1	512	9	32	7	39	48

88.3.3.1.1 Error Correcting Code (ECC) and Syndrome Definition

This ECC is based on the Hsiao code with 7 parity bits for each data word.

[Table 2022](#) shows the definition of the syndrome field for each bit position. Note that the ECC data vector width can be different for each memory, so we consider only the necessary positions for each one, not all the table positions.

Table 2022. 42 bits Word Based Syndrome Definition

SYND[6:0] / Element Value (hex)	Error Result (for SMATRIX)	Matrix Element (for MATRIX)	SYND[6:0] / Element Value (hex)	Error Result (for SMATRIX)	Matrix Element (for MATRIX)
40	error on code bit 6	-	54	error on data bit 23	element 23
20	error on code bit 5	-	15	error on data bit 22	element 22
10	error on code bit 4	-	16	error on data bit 21	element 21
08	error on code bit 3	-	34	error on data bit 20	element 20
04	error on code bit 2	-	25	error on data bit 19	element 19
02	error on code bit 1	-	26	error on data bit 18	element 18
01	error on code bit 0	-	64	error on data bit 17	element 17
4F	error on data ⁽¹⁾ bit 41	element 41	2C	error on data bit 16	element 16
3E	error on data bit 40	element 40	1A	error on data bit 15	element 15
3D	error on data bit 39	element 39	23	error on data bit 14	element 14
3B	error on data bit 38	element 38	2A	error on data bit 13	element 13
37	error on data bit 37	element 37	32	error on data bit 12	element 12
2F	error on data bit 36	element 36	46	error on data bit 11	element 11
1F	error on data bit 35	element 35	4A	error on data bit 10	element 10
70	error on data bit 34	element 34	52	error on data bit 9	element 9
68	error on data bit 33	element 33	62	error on data bit 8	element 8
07	error on data bit 32	element 32	13	error on data bit 7	element 7

Table 2022. 42 bits Word Based Syndrome Definition

SYND[6:0] / Element Value (hex)	Error Result (for SMATRIX)	Matrix Element (for MATRIX)	SYND[6:0] / Element Value (hex)	Error Result (for SMATRIX)	Matrix Element (for MATRIX)
49	error on data bit 31	element 31	29	error on data bit 6	element 6
0D	error on data bit 30	element 30	31	error on data bit 5	element 5
0E	error on data bit 29	element 29	43	error on data bit 4	element 4
38	error on data bit 28	element 28	45	error on data bit 3	element 3
4C	error on data bit 27	element 27	19	error on data bit 2	element 2
1C	error on data bit 26	element 26	51	error on data bit 1	element 1
58	error on data bit 25	element 25	61	error on data bit 0	element 0
0B	error on data bit 24	element 24	-	-	-
-	-	-	-	-	-
00	no error	-	any other ⁽²⁾	non-correctable error	-

1. Actually the data can be data or address bit.
2. For the FIFO0 RAM with 29 data bits and 10 address bits, the valid error positions are from bit 0 to bit 38, only. The syndromes with values for bit 39 to 41 of the table are considered also for non-correctable errors.

88.3.3.2 Error Report Description

Each RAM generates a defined number of information to report an error on an access. Each of them is described below.

- Error Address - this is the mapped address of the RAM as defined in [Section 88.2.1, Module Memory Map](#). This field has only meaning when an error occurs and is flagged by the two error signals below. It is reported on read or write operations.
- Non-correctable Error - this one bit width error indicates that:
 - The ECC detected errors in the read access and it is not possible to correct them because the ECC can only fix single bit error. The error can occur in the RAM read data bus (parity bits + data) or in the address value that the RAM has received.
- Correctable Error - this one bit width error indicates that:
 - The ECC detected and corrected a single bit error on the RAM read data bus (parity bits + data). The parity bits are discarded after the ECC decoder but this error report includes these bits to obtain the performance of the whole RAM data storage sector..

This Error Report remains active for only one RAM clock cycle and should be captured by the external RAM Error Monitor module. These error indications are also available for the GTM-IP timer module that is the block that requests the RAM accesses. Uncorrectable ECC error indication are provided to GTM-IP but the reaction to the error depends on this block itself. Please refer to its specification for more details.

88.3.4 Stop Mode Description

The stop mode is characterized by the stopping of the functional clock and the timer configuration registers clock. Therefore, the timers become stopped and almost all registers access are not allowed. This mode can be requested by two ways:

- By asserting the bit field MDIS in the GTMMCR configuration register.
- By receiving the SoC stop request signal ipg_stop.
 - the minimum waiting time to a new stop request is about 20 bus clock cycles.

However, it is important to note that to confirm the stop request was granted, it is necessary to read the stop status bit field STPS in the GTMMCR register.

88.3.4.1 Stop Mode by MDIS

The stop mode is requested by asserting this bit field with a write operation on the GTMMCR mapped register. The module only requests to stop the clocks when no slave bus accesses are pending in the GTM-IP. When in stop mode:

- The clocks are disabled to feed the whole GTM-IP and peripheral functions like the ECC
- The stop status bit field STPS in GTMMCR register is set.
- Read or write accesses to all mapped registers are not allowed and generates an access error indication, except accesses for the GTMMCR register.
- The slave bus clock is not affected by stop mode.

This stop mode ends by clearing the MDIS bit field.. The STPS stop status bit is automatically cleared after a while (it is considered that the SoC stop request is not set).

88.3.5 Debug / Halt Mode Description

The debug / halt mode is requested via GTMDI and is used to debug the GTM-IP sub-block. In this mode it is required that the core of GTM-IP becomes halted by stopping its clock. Therefore all time bases and counters are frozen.

Debug or halt mode requests should be enabled by setting the bit field DBE on the GTMDI GTMDI_DC register that is accessible by the JTAG interface (refer to GTMDI block guide for more details). GTM halt is only activated when no read- or write-access to GTM over AEI are taking place in parallel. Only in this condition the GTM is released to change to debug / halt mode read.

It is important to notice that any peripheral slave bus access is active in this mode . Debugger is able to read all GTM addresses read-/writeable from the peripheral bus when GTM is running or halted. All registers in the register map can be accessed by the peripheral bus, even the RAMs because they are in the register map. Of course, the clocks for the RAMs are not stopped in debug mode.

For more details about the debug mode, please refer to GTMDI documentation.

Note: *If this module is in disable mode by setting the MDIS bit at the GTMMCR register, the debug request is not considered until the MDIS bit is cleared.*

88.3.6 GTM-IP Timer Software Reset Description

The GTM-IP timer portion has the software reset possibility by writing a 1 in the RST bit field on the GTM_RST register.. This bit is self cleared and is always read as zero. In addition, this bit is write protected by the bit field RF_PROT in the GTM_CTRL register.

This is a global reset to GTM-IP block only. The GTMDI is not affected by this soft-reset.

88.3.7 AEI Interface Software Reset Description

The GTM-IP has software reset control for the AEI interface sub-block only. This block is the slave bus interface of GTM-IP and is not reset by the GTM-IP timer soft-reset. The AEI soft-reset occurs by writing a 1 in the AEISRST bit field on the GTMMAEICR register. This bit is self cleared and is always read as zero. In addition, this bit is write protected by the bit field AEISREN in the GTMMCR register.

A soft-reset in the AEI interface is equivalent to the hard-reset. It occurs in the next clock cycle of the request and takes one bus clock cycle. The AEI buffer and configuration registers are cleared, and some slave bus access can be aborted. Therefore, access commands in the buffer memory are lost and the configuration registers of the AEI interface change to their reset values.

88.3.8 Interrupt and DMA Support Logic

The GTM-IP provides several interrupts / DMA request signals to signalize internal events to other external modules. The list of all signals are provided in the GTM-IP documentation and all have the same type of controls and configuration options.

Each interrupt / DMA request line represents a set of internal interrupt / DMA request signals, and each of this internal signal has its own set of status / control / configuration registers: IRQ_EN, IRQ_NOTIFY, IRQ_FORCINT, and IRQ_MODE registers. Please, refer to *GTM-IP specification* for more details.

It is required to maintain the configuration register IRQ_MODE=00 that is the Level Interrupt Mode, the default mode to be compatible with the chip standard. the IRQ_NOTIFY register is the internal flag and can be enabled to set an external signal by the IRQ_EN register. For more details, please refer to the GTM-IP documentation.

The GTM integration module provides the same GTM-IP set of signals as interrupt requests and as DMA requests and the real functionality on the chip can be configured later. However, if a signal is configured to start a DMA request, the request can be cleared by the respective DMA answer, but it can be also cleared by software as occurs for interrupt requests.

88.3.8.1 Interrupt Request Clear Controls

Each interrupt request output can be a composition of several internal events flags that are enabled by configuration registers. After an interrupt request is recognized by the chip interrupt controller and it is serviced, the interrupt routine must clear the flags that originated that service request. The GTM integration module provides two ways to clear those flags, but each method has its limitations that are described below.

The first way to clear the events flags that originated the interrupt request is by a slave bus write operation in the interrupt mapped registers named *_IRQ_NOTIFY in [Table 2015](#). The main characteristics are listed below:

- For example, writing a 1 in the bit field DEST_ERR on the register BRC_IRQ_NOTIFY is going to clear this bit to clear the ipi_int_gtm_brc interrupt output signal
- Several flags in this register could have generated the interrupt request, therefore all of them can be cleared with this write operation.
- There is a delay between the reception of the clear command and the actual clear of the flags. This time interval can vary and depends on the number of commands inside the AEI buffer. Therefore it is not possible to know easily when the flags were cleared.
- This method of interrupt clear can generate a new service request if we are using write masked response mode for AEI interface.

The second way to clear the events flags of the interrupt requests is by using the mapped register GTMINTCLR that is described in [Section 88.2.2.2, GTM Interrupts Clear Register \(GTMINTCLR\)](#). The main characteristics of this method are listed below:

- For example, to clear the ipi_int_gtm_brc interrupt output signal, we execute a write operation in the GTMINTCLR register with data value 0x05 in the INTCLR_PTR bit field. This value selects to execute a clear in all flags that are used to generate that interrupt request.
- There is a delay between the reception of the clear command and the actual clear of the flags. This time interval can vary and depends on the number of commands inside the AEI buffer. However, the flags clear instant is well defined and can be seen by the integration module.
- As this method clear all flags for an interrupt request output, some flag that is set during the interrupt service is also cleared, and then some event can be lost.

88.4 Initialization/Application Information

The GTM integration module receives two active low reset signals, one on the slave bus clock domain, and the other in the peripheral clock domain. The last one resets all the timer logic, and registers inside the GTM-IP block. Just after this reset signal is negated, the GTM-IP is in the following condition:

- The GTM bridge is in asynchronous mode.
- after reset, write operations waits the response status (write response is not masked).
- If MDIS_DEFAULT is 1, a write access to GTMMCR is necessary to clear the MDIS bit register and have the GTM-IP clocks toggling.
- DPLL RAMs and MCSs RAMs starts the write initialization cycles. This is necessary for ECC parity bits storage on each RAM address.
- FIFO0 RAM is not automatically initialized. In normal operation mode, the initialization is not required because the FIFO memory always have to written first to be read later.

Please, refer to GTM-IP and GTMDI documentation to initialize the GTMINT module.

89 Emulation and Debug Device Introduction

The emulation and debug device is a multi-die MCU that adds additional functionality specifically for ease in calibration and debug. The Emulation and debug device (ED) consists of the production die (PD) and a buddy die (BD).

89.1 Functionality

The ED is a PD packaged with a BD to provide additional capability during development. The ED is used for development, debug, and calibration of automotive powertrain controller applications for 4- to 8-cylinder engines. To enable these operations, the buddy device supports the following functions:

- Debug and calibration tool interface—Allows tool read/write access to buddy device resources even if main MCU supplies are removed as long as special ED debug supplies are maintained. The BD duplicates the DCI, JTAGM and LFAST functionality that is also available in the PD.
- High speed tool trace port (based on the IEEE-ISTO 5001-2011 Nexus Aurora standard)
- 1 MB on-chip SRAM usable as calibration overlay or trace RAM—entire SRAM contents are maintained as long as ED debug supply is maintained

89.2 Feature summary

On-chip modules available on the BD include the following features:

- 1 MB on-chip SRAM
 - Access timing matches internal PD flash accesses when used in conjunction with PD calibration remap logic
 - Includes ECC
 - Implemented as 4 × 256 KB partitions where each partition can be accessed by different masters without causing blockages to access of any other partition
- XBAR switch architecture
- XBAR slave interface
 - 64-bit data width with ECC checkbits
 - Supports “Early Write” AHB protocol (AHB-EW) for one clock trace data writes
 - Allows a PD with AHB master to support read and write to buddy device memory-mapped resources—Memory-mapped resources include buddy device SRAM and AIPS resources
- Aurora trace port
 - 1.25 Gbit/s maximum data rate per lane
 - Support for up to 8-lane LVDS data out
 - Four lanes supported in ED package

- Port configurable to operate in 2- or 4-lane width
 - One lane LVDS reference clock in
 - Supports Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2011 standard.
- Data Write Processing Unit (DWPU)
 - Filters data trace stream to retain only writes to user selected locations
 - Detects user configured out of range condition on writes to selected locations
- Debug and Calibration Interface—Supports both JTAG (1149.1 and 1149.7) and LFAST modes
- Independent high and low voltage supplies allow tool control of BD debug and calibration resources even when the main MCU supplies are off
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1)
- Self test capability

89.3 Block diagram

This figure shows the top-level block diagram of the emulation and debug device.

Figure 2160. Emulation and debug device architecture

89.4 Clocking

Figure 2161 shows the clocking structure of the BD. There is one internal clock source and four external clock sources:

- Internal RC oscillator (IRC) clock
- System clock coming from the PD (identified as BD_CLK clock in the clock generation figure of the Clocking chapter)
- LFAST PLL reference clock coming from the PD (BD LFAST PLL clock in the clock generation figure of the Clocking chapter)
- JTAG clock coming from the TCK pin in the ED
- Aurora PHY clock coming from differential LVDS pins in the ED

Figure 2161. BD clock structure

The IRC is the source of the BD master clock when the PD is unpowered, or powered but still in reset state. It has a nominal frequency of 64 MHz, does not have any user accessible register and is always enabled. It does not have any trimming capability, therefore the expected precision is on the order of $\pm 30\%$.

The PD system clock is the source of the BD master clock when the PD is powered and out of reset state. When the PD PLL is engaged and locked this clock has a nominal frequency of 200 MHz, but while the PLL is not engaged the frequency is that of the PD internal RC oscillator.

The master clock directly feeds the XBAR, SRAMs and the Aurora sub-system. It is also divided down to generate the following internal clocks:

- Peripheral clock (divided by 4)—provides the clock to memory mapped registers and other low-speed logic
- Nexus RWA clock (divided by 2)—provides the clock to the Nexus Read Write Access module
- JTAGM TCK (divided by 1, 2, ..., 8)—provides a high speed TCK clock to the JTAGM module

The LFAST PLL clock from the PD (also referred to as `lfast_sysclk`) feeds the LFAST PLL, but it can also directly clock the LFAST in the low data rate mode. This clock is also made available as an output clock to the DRCLK package pin.

The internal TCK clock (referred to as muxed clock in [Figure 2161](#)) is used in the Nexus RWA, NAR, NAL, and it also goes to the PD to be used as the JTAG clock. (In the ED, the JTAG package pins are bonded to the BD JTAG interface; therefore, the PD receives the JTAG signals from the BD.) This clock can come from two sources (see the Buddy Device–Debug and Calibration Interface (DCI) chapter):

- TCK package pin, when using 1149.1 or 1149.7 access
- Divided down version of the master clock to be used in LFAST/JTAGM debug accesses

Note: The division factor for the LFAST/JTAGM clock is defined by the `TCKSEL` field of the `JTAGM_MCR` (refer to the JTAGM chapter for more details). However the division factor described there applies to an already divided-by-2 clock, as shown in [Figure 2161](#).

When the PD is unpowered, access through LFAST/JTAGM is not possible. In this case, JTAG accesses can be done only by 1149.1 or 1149.7 modes accessing through the Nexus RWA module. In this mode, the TCK clock comes from the package pin and the RWA clock is a divided-by-2 version of the IRC; therefore, these clocks are asynchronous to each other. When clocks at the input of the RWA are asynchronous, there is a restriction that the RWA clock must be at least double the frequency of the JTAG clock. This means that the master clock frequency must be at least four times the JTAG clock frequency.

In the LFAST/JTAGM mode of operation, both RWA clock and internal TCK are synchronous to each other, therefore they can both be the same frequency. This means that TCK frequency can be half of the master clock frequency. [Table 2023](#) summarizes the frequency restrictions on the Nexus RWA accesses.

Table 2023. JTAG operating frequencies

PD configuration	BD configuration	PD system clock frequency [MHz]	BD master clock frequency [MHz]	Max RWA JTAG frequency [MHz]	Notes
Unpowered or in reset state	1149.1 or 1149.7	—	44.8	11.2	Assuming 64 MHz BD IRC with 30% tolerance
Powered, out of reset, PLL not engaged, system clock at IRC frequency	1149.1 or 1149.7	15.52	15.52	3.88	Assuming 16 MHz PD IRC with 3% tolerance
Powered, out of reset, PLL engaged	1149.1 or 1149.7	200	200	27.7	JTAG speed is limited by TCK negedge to TDO delay (14 ns) plus external setup to TCK posedge (4 ns)
Powered, out of reset, PLL engaged	LFAST/JTAGM	200	200	100	—

89.5 Reset logic

There are five sources of reset that are combined to generate the reset of system portions as described by [Table 2024](#):

1. BD power-on reset—asserts immediately upon assertion of BD POR, and remains asserted for 10 clock cycles after negation of POR.
2. PD reset—asserts two clock rising edges after assertion of reset signal coming from PD and remains asserted while the PD reset signal is asserted plus two clock rising edges after the PD reset signal is de-asserted (this reset source is reflected in the PD_RST bit of the BD_SIU_RSR register).
3. DCI FBD reset—asserts immediately when the FBD_RESET bit of the DCI Control Register is set, and remains asserted for one clock cycle after FBD_RESET is negated.
4. JTAG controller reset—asserts immediately when a reset request signal is received from the JTAG Controller by the execution of EXTEST, CLAMP, HIZ, TEST_LEAKAGE, EZPORT boundary instructions, and remains asserted for one clock cycle after the reset request is negated.
5. Nexus reset—asserts by DCI logic based on JCOMP state and JTAG source selected. DCI FBD also generates a Nexus reset.

In [Table 2024](#), an 'X' indicates that the reset source generates a reset signal to the specified block. JTAG mode only indicates that those blocks are reset by the corresponding reset sources only in the case where the debug interface is running through the JTAG external pins. When the debug interface is running through the LFAST interface or by software through JTAGM, those blocks are not reset by the mentioned reset sources.

Table 2024. Reset sources and functional blocks

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
DCI	X	—	—	—	—
Z0 Nexus RWA	X	—	X	—	X

Table 2024. Reset sources and functional blocks

Blocks	BD POR	PD reset	DCI FBD reset	JTAGC reset	Nexus reset
BD XBAR	X	—	X	X	—
Overlay/Trace RAM	X	—	X	X	—
JTAGM	X	—	JTAG mode only	JTAG mode only	—
LFAST	X	—	JTAG mode only	JTAG mode only	—
NAR/DWPU	X	—	X	X	X
NAL	X	—	X	X	X
NAP	X	—	X	X	X
BD SIU	X	—	X	X	—
BD SIU GPIO registers	X	X	—	X	—
BD INIT flag	X	—	X	X	—
PD/BD interface logic	X	—	X	X	—

Note: The PD reset is not affected by the BD reset. The BD does not interfere with startup or shut down timing of the PD.

89.6 BD memory map

The BD memory map is contained within a 16 MB range. This entire range is accessed through the PD Flash BIU. The BD memory map is divided into two regions: overlay RAM and device registers.

The device register region allows the CPUs on the PD to access configuration registers of the peripherals in the BD, such as LFAST, JTAGM, XBAR configuration, etc. The device register region are divided into 16 KB regions for assignment to each peripheral block.

The memory map for the BD is shown below as an absolute address relative to the PD address map. Within the BD, only a 24-bit address bus is required. The upper 8 bits of the complete 32-bit address are decoded and removed by the PD PFLASH controller.

Table 2025. BD memory map

Start address	End address	Allocated size (KB)	Description
BD overlay RAM			
0x0C00_0000	0x0C0F_FFFF	1024	Extended overlay RAM
0x0C10_0000	0x0C1F_FFFF	1024	Reserved BD overlay RAM
0x0C20_0000	0x0C3F_FFFF	2048	Reserved BD overlay RAM
0x0C40_0000	0x0C5F_FFFF	2048	Reserved BD overlay RAM
0x0C60_0000	0x0C7F_FFFF	2048	Reserved BD overlay RAM
BD registers			

Table 2025. BD memory map (continued)

0x0C82_0000	0x0CFF_FFFF	8064	Reserved

90 Buddy Device—Crossbar and RAM (BD_XBS_RAM)

Within the buddy device (BD), there is a crossbar switch that provides the required connections between multiple bus masters and the overlay RAM. For a diagram of the Emulation device (ED) debug architecture that shows the BD blocks and crossbar, see the Emulation device introduction chapter. This section provides details on the structure of this function.

Note: Throughout this description, the term “overlay RAM” is applied to the BD memory, even though this memory can be used for both overlay and debug trace information.

The 64-bit BD crossbar and RAM structure consists of:

- Input registers to capture transfers (address, attributes and write data) targeted at the overlay RAM or memory-mapped peripheral space
- A 3 x 5 crossbar switch to route requests from masters to either the overlay RAM or the system bus
 - Bus masters include the BD’s Nexus Aurora Router (BD-NAR), the production device’s flash controller (PFLASH) and the BD’s Nexus Read/Write Access Client (RWA)
 - Bus slaves include 4 equal-sized regions of the overlay RAM and a peripheral bridge (AIPS-Lite) bus controller
 - 160-bit RAM arrays (128 bits of data, 32 bits of end-to-end ECC)
 - End-to-End ECC32 address and data protection
 - ECC scheme based on 29-bit address and 32-bit data
 - Overlay RAM supports a 64-bit “early write” datapath and a 128-bit read datapath
- Output alignment logic and registers to capture read data being driven to the requesting master

The result is an efficient structure supporting concurrent references of the overlay RAM for calibration accesses from the PFLASH controller on the Production Device (PD) and debug references from the other masters. The crossbar and RAM support 200 MHz operation.

Note: Calibration reads from the PFLASH have the same timing characteristics as normal data reads from the flash array.

90.1 3 x 5 Crossbar switch and attached controllers

In the same manner as the comparable crossbar switches in the PD, the BD crossbar concurrently supports up to 3 simultaneous connections between the master and the slave ports. It implements a 64-bit “early write” datapath and a 128-bit read datapath and fully supports concurrent accesses between calibration reads and debug trace writes to different overlay RAM regions.

This crossbar implements fixed priority arbitration on a per slave port basis where the master number defines the relative priority in a reverse numeric order, that is, $m_0 > m_1 > m_2$ (PFLASH > BD-NAR > Nexus RWA). Each slave port is “parked” on the last master making a request.

The design supports {8, 16, 32, 64}-bit SINGLE reads, {8, 16, 32, 64}-bit SINGLE writes along with 64-bit WRAP4 burst reads and writes. Two consecutive sequential 128-bit accesses of the RAM are used (only) on the WRAP4 burst read.

90.2 BD_XBS_RAM End-to-End ECC32 Checkbit/Syndrome Coding Scheme

The e2eECC scheme used in the BD overlay RAM is a simplified derivative of the algorithm used in the Production Device. The only difference is the code is based on a 32-bit data field, but the same H-matrix is used with the appropriate 32-bit data upper or lower word zeroed.

Consider the following Boolean equation definitions:

$$e2eECC64[7:0] = ecc_addr[7:0] \wedge ecc_data_upper[7:0] \wedge ecc_data_lower[7:0]$$

where ecc_addr is H-matrix evaluation of the 29-bit access address ($addr[31:3]$), ecc_data_upper is the H-matrix evaluation of the upper data word ($data[63:32]$) and ecc_data_lower is the comparable evaluation of the lower data word ($data[31:0]$).

For the BD RAM definition, the following (re)definitions apply:

$$e2eECC32_upper[7:0] = ecc_addr[7:0] \wedge ecc_data_upper[7:0]$$

$$e2eECC32_lower[7:0] = ecc_addr[7:0] \wedge ecc_data_lower[7:0]$$

As a result, the PD's H-matrix is used for the BD RAM's e2eECC32 scheme with the appropriate 32 bit data word zeroed out:

$$e2eECC32_upper[7:0] = ecc_addr[7:0] \wedge ecc_data_upper[7:0]; data_lower[31:00] = 0$$

$$e2eECC32_lower[7:0] = ecc_addr[7:0] \wedge ecc_data_lower[7:0]; data_upper[63:32] = 0$$

In any case, the resulting ECC32 is calculated based on the appropriate 32 data bits plus 29 address bits (the upper bits of the 32-bit address field).

The complete H-matrix for this (101, 93) code is shown in [Table 2026](#). A '*' in [Table 2026](#) indicates the corresponding data or address bit is XOR'd to form the final checkbit value on the left. For 32-bit data writes, the table sections corresponding to D[63:32] or D[31:0], together with A[31:3] are logically summed (output of each table section is XOR'd) together to the final value driven on the $hwchckbit[7:0]$ outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

```

As the ECC syndrome is calculated on a read operation by applying the H-matrix to the data plus the checkbits, an all zero syndrome indicates an error free operation. If the generated syndrome value is non-zero and matches one of the H-matrix values associated with the data or checkbits, it represents a single-bit error correction case and the specific bit is

complemented to produce the correct data value. If the syndrome value matches one of the H-matrix values associated with the address bits, the opposite data word, or is an even weight value, or represents an unused odd weight value, a non-correctable ECC event has been detected and the appropriate error termination response is initiated.

91 Buddy Device—System Integration Unit Lite (BD_SIUL2)

91.1 Introduction

The Buddy Device—System Integration Unit Lite2 (BD_SIUL2) provides control over the electrical pads of the buddy device (BD), as well as implementing various SoC functions that are not included in other modules.

The main functions supported by BD_SIUL2 are:

- Device identification
- Device status reporting
- Pad control and signal muxing

It should be noted that some other system level features are located in the BD DCI block including:

- Device identification available via the JTAG accessible Nexus Device ID (DID) register
- Reporting of reset status via the JTAG accessible reset status register
- Control of production device (PD) and BD reset via JTAG accessible reset control register

These registers are also indirectly accessible by software via BD_JTAGM in software debug mode.

91.2 Device identification

The BD_SIUL2 includes a device ID register (DIDR) that identifies the BD type and version, allowing a connected tool or development/calibration software running on a connected PD to determine what debug or calibration resources are available. The DIDR uses similar formatting to the MCU ID registers (MIDR1, MIDR2) included in the SIUL2 module.

This information is made available via the BD SIU rather than via the PD because it is either not available via the PD (for example, information on BD-specific resources, such as extended overlay RAM size) or because it is useful for the tool to be able to access the information before the PD is powered up.

Information available includes:

- An ID code that can be used to uniquely identify the BD type
- A version field that is changed for every major mask revision of the BD
- A parameterized field that indicates the amount of extended overlay RAM included
 - The field coding allows indication of up to 4 MB of RAM, with resolution of 256 KB steps

It should be noted that in addition to information available in the DIDR, a connected tool can also retrieve identification information from other sources including:

- The JTAG ID returned by the buddy DCI/JTAGC module, which is different than the JTAG ID returned by a standard PD DCI/JTAGC
- The MIDR register included in the PD SIUL2 module, which includes information on the PD device type, version and package type (including identification of emulation and debug device package variants)

91.3 Device status information

91.3.1 Initialization status

The BD SIU includes a flag (BD_INIT) that can be used by the connected PD or any connected debug or calibration tools to track the status of the BD.

The main expected usage mode for this bit is to allow the Boot Assist Flash (BAF) or user calibration software on the PD to determine whether the BD has lost power since it was last initialized. A typical usage sequence for BD_INIT is shown below.

- At BD power on reset (POR), BD_INIT is cleared automatically
 - BD_INIT is not cleared by external BD reset input
- A calibration tool or calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration)
- The calibration tool or calibration software sets BD_INIT
- After PD POR, the BAF executes and reads BD_INIT
 - If BD_INIT is clear, the BD overlay is assumed to be uninitialized and is not used for calibration remap
 - If BD_INIT is set, the BD overlay is assumed to be initialized and can be used for calibration remap. (Other tests to verify data integrity may be used.)

BD_INIT is cleared by BD POR, and can be set or cleared via the debug interface or writes from the PD. BD_INIT is only used to detect full power down events resulting in a subsequent POR. It does not detect brown out drops in the supply voltage.

91.3.2 PD reset status

The IPS accessible BD_SIUL2_RSR register shows what stage of reset processing the connected PD is in, and whether the PD is powered down or not. This is functionally different from the software accessible registers in the PD reset generation module that indicate which reset source has caused the last PD reset.

91.4 Memory map

[Table 2027](#) gives an overview of the BD_SIUL2 registers.

Table 2027. BD_SIUL2 register summary

Offset	Register	Access	Reset Value	Section/Page
0x0000	BD_SIUL2 Device Identification Register 1 (BD_SIUL2_DIDR1)	R	0x57BD_0000	91.4.1.1/3740
0x0004	BD_SIUL2 Device Identification Register 2 (BD_SIUL2_DIDR2)	R	0x0003_0100	91.4.1.2/3741
0x0100	BD_SIUL2 Initialization Status Register (BD_SIUL2_ISR)	R/W	0x0000_0000	91.4.1.3/3742
0x0104	BD_SIUL2 Reset Status Register (BD_SIUL2_RSR)	R	0x0000_0000	91.4.1.4/3743

91.4.1 Register descriptions

This section describes in address order all the BD_SIUL2 registers. Each description includes a standard register diagram with an associated figure number. Details of register bit and field function follow the register diagrams, in bit order.

Note: All registers support 32-bit accesses only.

91.4.1.1 BD_SIUL2 Device Identification Register 1 (BD_SIUL2_DIDR1)

The BD_SIUL2_DIDR1 contains the part number and mask number.

Figure 2166. BD_SIUL2 Device Identification Register 1 (BD_SIUL2_DIDR1)

Table 2028. BD_SIUL2_DIDR1 Bit Field Descriptions

Field	Description
0–15 PARTNUM	Device Part Number. Read-only, mask programmed part number of the device. Reads 0x57BD.
16–23	Reserved.
24–27 MASKNUM_MAJOR	Major Mask Revision Number. Read-only, mask programmed mask number of the device. Reads 0x0 for the initial mask set of the device, and changes sequentially for each mask set.
28–31 MASKNUM_MINOR	Minor Mask Revision Number. Read-only, mask programmed mask number of the MCU. Reads 0x0 for the initial mask set of the device, and changes sequentially for each mask set.

91.4.1.2 BD_SIUL2 Device Identification Register 2 (BD_SIUL2_DIDR2)

The BD_SIUL2_DIDR2 contains a complement to the part number and amount of RAM available.

Figure 2167. BD_SIUL2 Device Identification Register 2 (BD_SIUL2_DIDR2)

Offset BD_SIUL2_BASE + 0x04												Access: User read

Table 2029. BD_SIUL2_DIDR2 Bit Field Descriptions

Field	Description
0–11	Reserved.
12–15 RAM_SIZE	RAM Size. Read-only, indicates the amount of overlay RAM available in the device, with resolution of 256K byte steps 0000 0.25M byte. 0001 0.5M byte. 0010 0.75M byte. 0011 1M byte. 0100 1.25M byte. 0101 1.5M byte. 0110 1.75M byte. 0111 2M byte. 1000 2.25M byte. 1001 2.5M byte. 1010 2.75M byte. 1011 3M byte. 1100 3.25M byte. 1101 3.5M byte. 1110 3.75M byte. 1111 4M byte.
16–23 PARTNUM	Device Part Number. Read-only, mask programmed complement to the part number of the device. For the BD 1M byte part with part number 57BD1, BD_SIUL2_DIDR1.PARTNUM=57BD, and BD_SIUL2_DIDR2.PARTNUM=1. 01 1 (BD1M) 02 2 (BD2M)
24–31	Reserved.

91.4.1.3 BD_SIUL2 Initialization Status Register (BD_SIUL2_ISR)

The BD_SIUL2_ISR contains a flag that can be used by the PD or any connected debug or calibration tool to track the status of the BD. This register is reset by POR.

The main expected use case for this flag is to allow software on the PD to determine whether the BD has lost power since it was last initialized. A typical sequence is:

- At power on reset (POR), the flag is cleared automatically (not affected by software reset)
- A calibration tool or PD calibration software initializes the BD (for example, writing BD overlay RAM with calibration data and remap configuration)
- The calibration tool or PD calibration software sets the BD_INIT flag
- After PD POR, the PD boot software executes and reads BD_INIT
 - If BD_INIT is clear, BD overlay is assumed to be uninitialized and is not used for calibration remap
 - If BD_INIT is set, BD overlay is assumed to be initialized and can be used for calibration remap (other tests to verify data integrity may be used)

BD_INIT is cleared by BD POR, and can be set or cleared via writes from the PD or from the Nexus RWA.

Figure 2168. BD_SIUL2 Initialization Status Register (BD_SIUL2_ISR)

Table 2031. BD_SIUL2_RSR Bit Field Descriptions

Field	Description
0–28	Reserved.
29 PD_RST	PD Reset Flag. Read-only, indicates if PD has finished the reset sequence. 0 PD reset sequence not completed. 1 PD reset sequence completed.
30 PD_TRIM	PD Trim Flag. Read-only, indicates if PD has finished trimming phase during the reset sequence. 0 PD trimming phase not completed. 1 PD trimming phase completed.
31 PD_POR	PD POR Flag. Read-only, indicates whether PD is powered down or not. 0 PD is powered down or power on reset has not completed. 1 PD is powered and power on reset has completed.

92 Buddy Device—Debug and Calibration Interface (DCI)

92.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features in the Emulation and Debug Device (ED) that includes features in the Production device (PD) as well as features in the Buddy device (BD). There are two DCIs on the ED which are designated PD DCI and BD DCI.

92.1.1 Features

The ED DCI features are the following:

- Debug mode enable control for connected tool or software
- Dual DCI system for multi-device clients
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

92.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Buddy device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.
 - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
 - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.
- I.JTAG— JTAG signals interconnecting the two DCI implementations in the ED coming from the intra-die pads.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The ED DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as GTM/SPU, etc. The ED DCI also provides the Event Out (EVTO) signals to the debug tool in case of the occurrence of any internal debug event.

[Figure 2170](#) shows the DCI block diagram.

Figure 2170. DCI block diagram

When the DCI is used in an ED package (PD and the BD together) its configuration is shown as in [Figure 2171](#). In the ED package, a debug tool is connected to the BD pins and connects to the PD with the I.JTAG interface which are routed using inter-die pads.

Figure 2171. DCI in an emulation configuration

92.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

Table 2032 shows a summary of the configuration options.

Table 2032. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated. In the ED, the BD DCI is reset with BD POR/Low voltage detection on BD_VDD.

The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the BD LFAST and BD JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed. Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in [Section 92.1.3.1, Port sharing between JTAG and LFAST modes](#). During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. [Table 2033](#) shows the port mapping.

When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 2033. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

[Figure 2172](#) shows the DCI mode switching operation.

Figure 2172. DCI operating modes state diagram

Note: .JTAGM_MCR[jtagm_JCOMP] should not be asserted in LFAST mode to avoid any undesired behavior.

Table 2034 contains the operating mode descriptions.

Table 2034. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG or I.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.

Table 2034. DCI operating modes (continued)

Mode	Description
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

Figure 2173 shows a block diagram of the JTAG/LFAST connections.

Figure 2173. DCI JTAG/LFAST switch integration

92.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode by using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch

from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):

- EN_LFAST—Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2—Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure. The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in [Figure 2174](#).

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 2174. DCI switching between JTAG and LFAST modes

92.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
 - EN_LFAST
 - SWITCH_CNTR1
 - SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

[Figure 2175](#) shows the timing sequence.

Figure 2175. DCI JTAG to LFAST switching diagram

92.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

Table 2038 and Table 2040 summarize the MCU and tool behaviors. Figure 2176 shows the timing sequence.

Figure 2176. DCI LFAST to JTAG switching diagram

92.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

92.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

There is a software programmable bit, MCR[jtagm_JCOMP], present in JTAGM block which, when programmed to 0, asserts reset for the JTAGC block, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: .It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

92.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks, with the PD DCI providing the reset signal to all PD debug blocks, and the BD DCI providing the reset signal for all BD debug blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect (applicable to both PD and BD)
- JCOMP (applicable to both PD and BD)
- SoC Debug_Enable signal (applicable to PD only)
- System PLL is out of lock state and not bypassed (applicable to PD only)

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the BD Nexus reset signal remains asserted until the JCOMP signal is asserted. Any subsequent loss of

PLL lock does not generate a Nexus reset. This reset signal is unaffected by other sources of reset. The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 2035. Nexus reset truth table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

92.1.3.5 System watchdog control

The BD DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the EVTI[0] pin is used. If the EVTI[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the EVTI[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the EVTI[0] pin.

92.1.3.6 Break control

The PD DCI provides central break control among the CPUs and non-CPU debug modules such as GTM, DMA, Watchdog and other peripherals.

There are various different input sources that provide debug requests:

- [BLG_DCI_0044][Covers: ADD23.025][Covers: ADD23.029][Covers: ADD23.134]EVTI[1:0] signals from BD EVTI pads provided to the PD DCI via intra-die pads[end]
- EVTI[1:0] signals from BD JTAGM
- EVTI[1:0] signals from the Sequence Processing Unit (SPU)

The PD DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor coresAll break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 2177. DCI debug control mechanism

The various sources of $\overline{\text{EVTI}}[1:0]$ inputs are synchronized and logically ANDed in the DCI to generate two debug requests $\text{DCI_EVTI}[1:0]$ for the processor cores and non-CPU peripherals. Of these two inputs, $\text{EVTI}[0]$ is used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The other input, $\text{EVTI}[1]$, is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted. The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command. The $\overline{\text{EVTI}}[1:0]$ signals coming from the pads are enabled for debug control using $\text{DCI_CR}[5:4]$ bits.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

[Figure 2178](#) shows the timing sequence.

Figure 2178. DCI debug signal generation

92.1.3.7 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

92.1.3.8 Synchronous restart control

The PD DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (i.e. set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

92.1.3.9 EVTO management

The EVTO management block diagram is presented in [Figure 2179](#).

Figure 2179. DCI EVTO management

The PD DCI module controls sharing of the EVTO outputs between all Nexus Clients including the cores that produce EVTO[1:0] signals. The PD DCI uses a high frequency clock to sample EVTO signals coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted EVTO[1:0] signals from any Nexus client, the DCI immediately asserts EVTO[1:0] outputs and stretches it for a minimum of one output clock period for the output to the tool([Figure 2180](#)). The DCI also generates EVTO outputs in other device clock domains so that other Nexus clients can receive EVTO inputs without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

The PD DCI also allows the GTM to take control of the EVTO outputs by controlling the EOS0/EOS1 fields of the GTMDI_DC register. If these fields are programmed to HALT/TIM/TOM/ATOMEVTO value, the GTM EVTO outputs are directly available on the ports bypassing the stretch logic.

Figure 2180. DCI EVTO timing diagram

92.1.3.10 Reset control

The BD DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- [BLG_DCI_0042][Covers: ADD23.026][Covers: ADD23.032]Force BD Reset—This reset is generated by programming DCI_CR[FBD_RESET] bit. When set it forces reset. This bit has to be reset by the tool to negate the reset signal.[end]

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

92.1.3.11 Security

The SoC security logic provides a Debug_Enable signal to the PD DCI. The PD DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the PD DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

92.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

92.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. The BD DCI only contains the DCI_CR and does not contain the DCI_PINCR. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

92.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. [Figure 2181](#) shows the format of the DCI_CR.

In an ED which has both PD and BD instances of the DCI, all bits controlling the switch between LFAST and JTAGM must be programmed on the BD DCI instance. The only bits of this register that do not follow this rule are EVTI1_PAD_EN and EVTI0_PAD_EN, which must be programmed in both DCI instances.

Figure 2181. DCI control register (DCI_CR)

	31	30	29	28	27	26	25	24

W	ET	FAST	PAD_EN	PAD_EN			MODE	LFAST
Reset	0	0	0	0	0	0	0	0

The DCI_CR is described in [Table 2036](#).

Table 2036. DCI_CR field descriptions

Field	Description
31:16 SWITCH_CNTR2	Width of Switch_CNTR2. Decides the second timeout value while switching from JTAG to LFAST mode. The maximum timeout duration = $32,768 \times T_{lfast_sysclk}$
15:11 SWITCH_CNTR1	Width of Switch_CNTR1. Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = $32 \times T_{lfast_sysclk}$

Table 2036. DCI_CR field descriptions (continued)

Field	Description
10 FLVDS_PAD_FLT	Force LVDS Pad Fault. Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
7 FBD_RESET	Force Reset 0 Do not force Reset 1 Force Reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5 EVTI1_PAD_EN ⁽¹⁾	$\overline{\text{EVTI}}[1]$ feature enable 0 $\overline{\text{EVTI}}[1]$ disabled (default) 1 $\overline{\text{EVTI}}[1]$ enabled
4 EVTI0_PAD_EN ⁽²⁾	$\overline{\text{EVTI}}[0]$ feature enable 0 $\overline{\text{EVTI}}[0]$ disabled (default) 1 $\overline{\text{EVTI}}[0]$ enabled
1 EN_ESC_MODE	Enable Escape Mode. Fault detect feature enable for LFAST Rx pads 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST ⁽²⁾	Enable for LFAST-based tool selection. This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. In an ED that has both PD and BD, EVTI1_PAD_EN and EVTI0_PAD_EN must be programmed in both BD and PD instances of the DCI in order to allow events generated on the BD to pass through the BD DCI and reach the PD DCI.
2. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

92.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter which describes how the modules are configured.

92.4 Functional description

92.4.1 DCI mode transition

After power-on reset, the BD DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. [Table 2037](#) and [Table 2038](#) show the steps and expected states for the MCU

and tool for JTAG to LFAST switching. [Table 2039](#) and [Table 2040](#) contains the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 2037. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received

1. This state is used to set DCI_CR[EN_LFAST] bit.

Table 2039. MCU operation (LFAST to JTAG switching)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
TDI	LVDS Tx	Logic Input	Logic Input
TMS	LVDS Tx	Logic Input	Logic Input
TDO	LVDS Rx	Hi-Z	Logic Output
JCOMP	LVDS Rx	Logic Input Latch	Logic Input (sample JCOMP pin)
TCK	Logic Output	Logic Input	Logic Input

Table 2039. MCU operation (LFAST to JTAG switching) (continued)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
Mode Escape	Enable	Inhibit	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit	Inhibit

Table 2040. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

92.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the BD LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the BD DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. [Table 2041](#) and [Table 2042](#) contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 2041. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input
Mode Escape	Enable	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit
Internal TRST	Negated	Asserted

Table 2042. Tool operation (LFAST to JTAGRST switching)

Tool	LFAST mode	Tool forces JCOMP low
TDI	LVDS TxN	Don't Care
TMS	LVDS TxP	Don't Care
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Output (Low)
TCK	Logic Input	Don't Care

93 Buddy Device—JTAG Controller (JTAGC)

93.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

93.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 2182. JTAG (IEEE 1149.1) block diagram

93.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
 - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to [Table 2046](#) for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

93.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

93.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

93.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [Section 93.4.4, JTAGC block instructions](#).

93.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

93.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 2043. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z ⁽¹⁾	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

93.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

93.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

93.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [Section 93.4.3, TAP controller state machine](#).

93.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

93.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

93.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

93.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

Figure 2183. 6-bit instruction register

93.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

93.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

Figure 2184. Device identification register

The following table describes the device identification register functions.

Table 2044. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0.
DC	Design Center. Indicates the design center. Value is 0x2B.
PIN	Part Identification Number. Contains the part number of the device. Value is 0x381.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x020.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

93.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 2185. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 2045. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

93.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Section 93.4.5, Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

The BD boundary scan chain includes registers connected to all PD/BD interface signals at the BD side. These registers are controlled by the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions applied to the BD JTAG controller. Similarly, the PD boundary scan chain also contains registers connected to the interface signals at the PD side, which are controlled by instructions applied to the PD JTAG controller.

93.4 Functional description

This section explains the JTAGC functional description.

93.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

93.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to [Section 93.4.4.8, ACCESS_AUX_x instructions](#).

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

Figure 2186. Shifting data through a register

93.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

Figure 2187. IEEE 1149.1-2001 TAP controller finite state machine

93.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

93.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

93.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 2046. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Factory debug reserved	001010	Intended for factory debug only
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
Reserved	001111	Reserved
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
ACCESS_AUX_NR_BD	100000	Enables access to the NAR TAP controller on BD
Reserved	100001	Reserved

Table 2046. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
ACCESS_AUX_NAL	100010	Enables access to the NAL TAP controller
ACCESS_AUX_RWA_BD	100011	Enables access to the RWA TAP controller
Reserved	100100	Reserved
Factory test reserved	100101	Intended for factory test only
Reserved	100110	Reserved
Reserved	100111	Reserved
Reserved	101000	Reserved
Reserved	101001	Reserved
Reserved	101010	Reserved
Reserved	101011	Reserved
Reserved	101100	Reserved
Reserved	101101	Reserved
Reserved	101110	Reserved
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved

Reserved	110110	Reserved
Reserved	110111	Reserved
Reserved	111000	Reserved
ACCESS_AUX_DWPU	111001	Reserved
Reserved	111010	Reserved
Reserved	111011	Reserved
Reserved	111100	Reserved
Reserved	111101	Reserved
ACCESS_AUX_DCI_PD	111110	Enables access to pass control from BD to PD
BYPASS	111111	Selects bypass register for data operations
Reserved ⁽¹⁾	All other opcodes	Decoded to select bypass register

1. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

93.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

93.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

93.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

93.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

93.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

93.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

93.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

93.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

93.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

93.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

PD and the BD have their own separate boundary scan chains, each one controlled by the respective JTAG controller. Besides the package I/O pins, these chains also encompasses the interface signals between BD and PD. Testing of the interface can be done by applying EXTEST, SAMPLE or SAMPLE/PRELOAD instructions to both PD and BD JTAG.

93.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any

mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

94 Buddy Device—JTAG Master (JTAGM)

94.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

94.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:

- Configuration register
- Status register
- Four data output registers
- RxCRC receive register
- Two data input registers

All these registers, described in detail in [Section 94.4, Memory map and register definition](#), are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

[Figure 2188](#) shows the block diagram of the JTAGM.

Figure 2188. JTAGM block diagram

94.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

94.2 Functional description

94.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module interface. This concept allows complete flexible generation on TMS and TDI data and

capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

Figure 2189 shows the flow diagram of the LFAST to DCI connection.

Figure 2189. LFAST-to-DCI flow diagram

94.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAGM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
 - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
 - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

Note: The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

94.2.3 JTAGM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAGM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAGM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAGM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAGM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAGM status register (JTAGM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAGM to the LFAST also includes an 8-bit CRC. The data sent from the JTAGM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

94.2.4 JTAGM message tagging

The JTAGM, in conjunction with the LFAST, is pipelined to allow several JTAGM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAGM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAGM returns the response on channel E; if the tool sends a data command on channel F, the JTAGM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAGM are sent on channel A and response data is also sent back on channel A.

94.2.5 JTAGM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

94.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK

shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

94.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

94.2.6 EVTO and EVTI signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTIO and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAGM_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

94.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in [Section 94.2.5.1, Status register ready bit](#)). The configuration register is accessed via the parallel input port by a 128-bit

payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written +
- 32-bit value to be written to the configuration register +
- 24-bit mask of which bits within the status register should be written +
- 8 bits of zero-padding +
- 24-bits of data to be written to the status register +
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data).

The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

94.2.8 JTAGM to DCI serial interface

Figure 2190 shows the data transfer timings between JTAGM and DCI.

Figure 2190. JTAGM to DCI serial interface diagram

94.2.9 JTAGM data handling and CRC calculation in LFAST mode

Figure 2191 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

Figure 2191. Bit ordering for LFAST to JTAGM transfer

bit 127 to bit 68				bit 67 to bit 8				7	6	5	4	3	2	1	0
TMS (60 bits)				TDI (60 bits)				CRC (8 bits)							
bit 0 to bit 59				bit 0 to bit 59											
Last TMS bit transmitted by JTAGM		First TMS bit transmitted by JTAGM		Last TDI bit transmitted by JTAGM		First TDI bit transmitted by JTAGM									

[Figure 2192](#) shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

Figure 2192. Bit ordering for JTAGM to LFAST transfer

bit 95 to bit 36			bit 35 to bit 32			bit 31 to bit 8			7	6	5	4	3	2	1	0
TDO (60 bits)			0 pad (4 bits)			JTAGM_SR (24 bits)			CRC (8 bits)							
bit 0 to bit 59			bit 0 to bit 59			bit 31 to bit 8										
First TDO bit received by JTAGM		Last TDO bit received by JTAGM														

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in [Figure 2192](#)).

94.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

94.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

94.4 Memory map and register definition

[Table 2047](#) contains the memory map of the JTAGM registers.

Table 2047. Memory map

94.4.1 Register descriptions

94.4.1.1 Module configuration register (JTAGM_MCR)

This register contains the status bits for the current transfer. [Figure 2193](#) shows the format of the JTAGM_MCR. In the Emulation and Debug Device (ED), all bits of this register need to be programmed in the Buddy Device instance of the JTAGM. The only exception is the SIE bit, which always needs to be programmed in the Production Device instance of the JTAGM, regardless of being ED or not.

The JTAGM_MCR register is described in [Table 2048](#).

Table 2048. JTAGM_MCR register field descriptions

Field	Description
0 SWRESET	Software Reset. Writing a 1 resets the state machine and counters inside JTAGM. It is a self clearing bit. Writing a 0 has no effect. <i>Note: After being written to "1", this bit is auto cleared within 3 TCK cycles.</i>
1:2 evto0_sense	Determines JTAGM response to activity on $\overline{\text{EVTO0}}$ 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO0}}$ edges (default setting) 01 evto0_edge status bit is set whenever a falling edge is detected on $\overline{\text{EVTO0}}$ 10 evto0_edge status bit is set whenever a rising edge is detected on $\overline{\text{EVTO0}}$ 11 evto0_edge status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO0}}$
3:4 evto1_sense	Determines JTAGM response to activity on $\overline{\text{EVTO1}}$ line 00 No action is taken by the JTAGM in response to any $\overline{\text{EVTO1}}$ edges (default setting) 01 evto1_edge status bit is set whenever a falling edge is detected on $\overline{\text{EVTO1}}$ 10 evto1_edge status bit is set whenever a rising edge is detected on $\overline{\text{EVTO1}}$ 11 evto1_edge status bit is set whenever a falling or rising edge is detected on $\overline{\text{EVTO1}}$
5 evto_IE	Enables $\overline{\text{EVTO}}$ triggered JTAGM interrupt 0 No JTAGM interrupt is generated In response to any $\overline{\text{EVTO0}}$ or $\overline{\text{EVTO1}}$ activity 1 JTAGM interrupt is generated when evto0_edge or evto1_edge are set
6 evti0_assert	EVTI0 Assert. 0 Set jtagm_evti0 low/asserted 1 Set jtagm_evti0 high/de-asserted
7 evti1_assert	EVTI1 Assert. 0 Set jtagm_evti1 low/asserted 1 Set jtagm_evti1 high/de-asserted <i>Note: In the SW mode(when DTM =1) , regardless of the state of "evti1_assert" bit the internall "evti" signal remains de-asserted . Though this bit can be written , yet writing to this bit has no effect .</i>
8:17	Reserved
18:23 inter_jtag_frame_timer	TCK delay. 0000000 TCK delay 0000011 TCK delay ... 11111163 TCK delay
24	Reserved
25 SIE	SPU Interrupt Enable. ⁽¹⁾ 0 JTAGM does not generate an interrupt to the CPU 1 JTAGM generates an interrupt to the CPU if the SPU interrupt request is asserted
26 IIE	Idle Interrupt Enable. 0 JTAGM does not generate an interrupt to the CPU upon completion of a 60-bit JTAG transfer 1 JTAGM generates an interrupt to the CPU upon completion of a 60-bit JTAG transfer

Table 2048. JTAGM_MCR register field descriptions (continued)

Field	Description
27:29 TCKSEL	TCK clock frequency selection. 000 Not to be used 001 TCK is system clock ÷ 2 010 TCK is system clock ÷ 3 ... 111 TCK is system clock ÷ 8 <i>Note: When using the JTAGM, this bit should always be programmed with any value other than "000".</i>
30 jtagm_JCOMP	JTAG reset. 0 JCOMP low/asserted 1 JCOMP high/not asserted (default)
31 DTM	Data Transfer Mode. 0 Data for JTAG transferred by LFAST 1 Data for JTAG transferred by software

1. The BD JTAGM instance does not receive signals from the SPU. If required, this feature needs to be enabled in the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

94.4.1.2 Status register (JTAGM_SR)

94.4.1.2.1 LFAST mode

[Figure 2194](#) shows the format of the JTAGM_SR in LFAST mode. In the ED, all bits of this register need to be accessed in the BD instance of the JTAGM. The exceptions are the bits related to the SPU interrupts (SPU_INT, SPU_INT_CLR), which always need to be accessed from the PD JTAGM, regardless of being ED or not.

The JTAGM_SR register is described in Table 2049.

Table 2049. JTAGM_SR register field descriptions

Field	Description
0 overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
1	Reserved
2:7 lfast_status	Status information from the LFAST to be used by software. The composition of these bits are as follows: bit 2 Indicates either data frame or ping frame was transmitted successfully bit 3 Indicates Tx data Interface not enabled and a frame is ready to be transmitted bit 4 Indicates Rx data FIFO overflow bit 5 Indicates reception of frame with invalid frame payload size bit 6 Indicates reception of frame with invalid ICLC code bit 7 Indicates reception of illegal LCT frame
8:15 dci_status	Status information from the DCI. The composition of these bits are as follows: bit 8 Reserved to 0 bit 9 DCI LVDS port enable bit 10 DCI JTAG port enable bit 11 DCI LVDS safe mode bit 12 DCI JTAG safe mode bit 13 DCI LVDS escape mode bit 14 DCI enable LFAST bit 15 DCI tool present , set when a debug tool is connected

Table 2049. JTAGM_SR register field descriptions (continued)

Field	Description
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO0}}$ 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO0}}$
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO1}}$ 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO1}}$
18 SPU_INT_CLR	Write 1 clears the SPU_INT ⁽¹⁾ This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit. ⁽¹⁾
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to 1 when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read <i>Note: In LFAST mode (when DTM = 0), this bit has no effect and acts as a "don't care". This bit should not be used by the application in the LFAST mode</i>
24:31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode: Bit 24:31 reads the CRC. Write has no effect. SW Mode: – Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears evto0_edge – Writing 1 on bit 25 clears evto1_edge

1. The BD JTAGM instance does not receive signals from the SPU. If required, this bit needs to be read from the PD instance of the JTAGM, even when JTAG generation in LFAST mode is handled by the BD JTAGM.

94.4.1.3 Data out register 0 (JTAGM_DOR0)

[Figure 2196](#) shows the format of the JTAGM_DOR0.

Figure 2196. JTAGM_DOR0 register

0:27 TDO_HIGH	Higher word of data received on TDO, bits 32–59
28:31	Reserved

95 Buddy Device—Nexus Aurora Router (NAR)

95.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in [Figure 2203](#). Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured. The Nexus Aurora Link (NAL) takes the 32-bit Nexus message beats from the NAR and processes them in Aurora-ready data octets for the Nexus Aurora Phy (NAP) block, which interfaces directly with the high-bandwidth port. The Aurora output port of NAR can be fed as a client to another NAR.

Figure 2203. NAR top level block diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. The Nexus Out port provides additional flexibility to the channel trace data to memory on the Nexus recipient. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. These two partitions of the main queue are supported for better throughput each having 50% size. The two NAR output ports can be in operation simultaneously, with the output arbitration block splitting out messages by type or by source. Data going through the Aurora out port or the Trace port goes through

an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The Buddy Device (BD) NAR supports the following client interface:

- Aurora type interface with clock domain transfer at the same frequency

95.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port and/or the Trace port. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (1149.1) port.

95.3 Features

The NAR supports the following features:

- Connects 1 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Nexus out port for direct connection to pins (low-speed applications) or to another Nexus port controller
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Both output ports may operate simultaneously. Filtering logic sorts messages to determine destination port.
- Partitionable main queue makes it possible to simultaneously service multiple output ports. It can also be used to devote more bandwidth to high-priority message-types or split trace stream between on-chip memory and trace port.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Programmable Global stall signal on debug tool indication of memory overflow
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

95.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 2057. NAR registers

Register name	Read/ Write	JTAG index (NAR relative)	Location
NAR_CR—NAR Control Register	R/W	0	on page 3797
NAR_ST—NAR Status Register	R	1	on page 3799
NAR_SFR—Source Filter Register	R/W	2	on page 3801

95.4.1 Register descriptions

95.4.1.1 NAR control register (NAR_CR)

The NAR control register provides all the main control and enable bits for the NAR and its output ports. The following figure shows the format of the NAR_CR.

Figure 2204. NAR control register (NAR_CR)

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NCD	TEN	TRS	TSG	SED	SRD	TBW	AQP	0	0	0	0	0		
W

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_CR is described in the following table.

Table 2058. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See Section 95.5.2.2, Disabled for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). <i>Note: Some clients may only support timestamps on every message.</i> 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message

Table 2058. NAR_CR field descriptions (continued)

Field	Description
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 1/2 of queue is dedicated to alternate partition 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.
10–9 MSP	Message Select Port. Defines which port is the target for message type/source filtering. Only active in two-port applications. 00 No message select port. 0–1 port is active. 01 HBDP is the MSP 10 Trace memory bus is the MSP 11 Nexus is the MSP
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 HBDP is the ALT 10 Trace memory bus is the ALT 11 Nexus is the ALT
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2 FSD	Frame Serial Data. 0 Framing disabled. Data is streamed through the Aurora out port. 1 Framing enabled. Start/End frame symbol inserted between every 256 Aurora words.

Table 2058. NAR_CR field descriptions (continued)

Field	Description
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

95.4.1.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following figure shows the format of the NAR_ST.

Figure 2205. NAR status register (NAR_ST)

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

The NAR_ST register is described in the following table.

Table 2059. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode

Table 2059. NAR_ST field descriptions (continued)

Field	Description
27–24 NCE	NAR Config Error. See Table 2074 for coding
23 MPF	MSP Partition Full. 0 MSP partition not full 1 MSP partition full
22–21 MLV	MSP Partition Queue Level. This field is available only when both output ports are enabled i.e. the main queue is partitioned. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level < 100%
20 APF	ALT Partition Full. 0 ALT partition not full 1 ALT partition full
19–18 ALV	ALT Partition Queue Level. 00 0% < queue level < 25% 01 25% < queue level < 50% 10 50% < queue level < 75% 11 75% < queue level < 100%
17–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer of ALT partition (last valid write + 1)

95.4.2 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters determine which port receives a message, based on the message

source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See [Section 95.5.6, Output arbitration](#), for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

95.4.2.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Figure 2206. Source filter register (NAR_SFR)

Register index: 2

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SFI	FE0	SF0				0	0	0	FE1	SF1				0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	FE2	SF2				0	0	0	FE3	SF3				0	ACC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SF_n), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2060. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See Section 95.5.6, Output arbitration for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1

Table 2060. NAR_SFR field descriptions (continued)

Field	Description
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See Section 95.5.6, Output arbitration for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See Section 95.5.6, Output arbitration for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See Section 95.5.6, Output arbitration for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

95.4.2.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Figure 2207. Message type filter register (NAR_TFR)

Register index: 3

The NAR_TFR is described in the following table.

Table 2061. NAR_TFR field descriptions

Field	Description
31 TFI	Type Filter Invert. 0 Match if message TCODE equals any of the enabled filters 1 Match if message TCODE equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. TF0 ignored 1 Filter 0 enabled and contained in TF0
29–24 TF0	Type Filter 0. The message TCODE is compared with this field. See Section 95.5.6, Output arbitration for an example.
23	Reserved
22 FE1	Enable Filter 1. 0 Filter 1 disabled. TF1 ignored 1 Filter 1 enabled and contained in TF1
21–16 TF1	Type Filter 1. The message TCODE is compared with this field. See Section 95.5.6, Output arbitration for an example.
15	Reserved
16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See Section 95.5.6, Output arbitration for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See Section 95.5.6, Output arbitration for an example.

95.4.3 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

95.4.3.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can be transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following figures show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Figure 2208. Trace memory base address register NAR_TBAHI

Register index: 5

Figure 2209. Trace memory base address register NAR_TBALO

Register index: 4

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 2062. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 2063. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)

Table 2063. NAR_TBALO field descriptions (continued)

Field	Description
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

95.4.3.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following figure shows the format of the NAR_TCR.

Figure 2210. Trace memory bus control register (NAR_TCR)

Register index: 6

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R																
W	BTM	BTS		BTH		0	0	0	TBW	MXFR						
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R																
W	MXFR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TCR is described in the following table.

Table 2064. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes

Table 2064. NAR_TCR field description (continued)

Field	Description
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
32 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

95.4.4 Suppress mode triggers register (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in [Section 95.5.4, Suppress mode](#). The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress Trigger Control Register, shown in the following figure, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Figure 2211. Suppress trigger control registers (NAR_STCR1–4)

Register index: 7–A

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GST	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	LST

29–16	Reserved
15–0 LST	Local Suppress Trigger. 0000000000000000The associated trigger is disabled for local suppress mode for all clients xxxxxxxxxxxxxx1 Trigger is enabled for Client 1 local suppress xxxxxxxxxxxxxx1x Trigger is enabled for Client 2 local suppress xxxxxxxxxxxxxx1xx Trigger is enabled for Client 3 local suppress xxxxxxxxxxxxxx1xxx Trigger is enabled for Client 4 local suppress xxxxxxxxxx1xxxx Trigger is enabled for Client 5 local suppress xxxxxxxxxx1xxxxx Trigger is enabled for Client 6 local suppress xxxxxxxxxx1xxxxxx Trigger is enabled for Client 7 local suppress xxxxxxxxxx1xxxxxxx Trigger is enabled for Client 8 local suppress xxxxxxx1xxxxxxx Trigger is enabled for Client 9 local suppress xxxxxx1xxxxxxx Trigger is enabled for Client 10 local suppress xxxxx1xxxxxxx Trigger is enabled for Client 11 local suppress xxxx1xxxxxxx Trigger is enabled for Client 12 local suppress xxx1xxxxxxx Trigger is enabled for Client 13 local suppress xx1xxxxxxx Trigger is enabled for Client 14 local suppress x1xxxxxxx Trigger is enabled for Client 15 local suppress 1xxxxxxx Trigger is enabled for Client 16 local suppress All other options Reserved

95.4.4.1 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following figure, can then be read to determine which clients are suppressed, and which are active.

Figure 2212. Client suppress status register (NAR_CSSR)

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

The NAR_CSSR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress status, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2066. NAR_CCSR field descriptions

Field	Description
31–16 LSS	Local Suppress Status. 0000000000000000No client is in local suppress mode xxxxxxxxxxxxxxxx1 Client 1 is suppressed xxxxxxxxxxxxxxxx1x Client 2 is suppressed xxxxxxxxxxxxxxxx1xx Client 3 is suppressed xxxxxxxxxxxxxxxx1xxx Client 4 is suppressed xxxxxxxxxxxxx1xxxx Client 5 is suppressed xxxxxxxxxxxxx1xxxxx Client 6 is suppressed xxxxxxxxxx1xxxxxx Client 7 is suppressed xxxxxxxxx1xxxxxxx Client 8 is suppressed xxxxxxx1xxxxxxxx Client 9 is suppressed xxxxxx1xxxxxxxxx Client 10 is suppressed xxxxx1xxxxxxxxxx Client 11 is suppressed xxxx1xxxxxxxxxxx Client 12 is suppressed xxx1xxxxxxxxxxxx Client 13 is suppressed xx1xxxxxxxxxxxxx Client 14 is suppressed x1xxxxxxxxxxxxxx Client 15 is suppressed 1xxxxxxxxxxxxxxx Client 16 is suppressed All other options Reserved
15–0	Reserved

95.4.5 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following figure, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Note: Even though the BD NAR is described as only having one client, there is actually a second dummy client, client 2. To re-allocate the dummy RX queue to client 1 (the PD NAR), set the BD NAR client 2 RQD bit.

Figure 2213. Client disable register (NAR_CDR)

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 2067. NAR_CDR field descriptions

Field	Description
31–16 CAS	Client Activity Status. xxxxxxxxxxxxxxxx1 Client 1 is active with new data xxxxxxxxxxxxxxxx1x Client 2 is active with new data xxxxxxxxxxxxxxxx1xx Client 3 is active with new data xxxxxxxxxxxxxxxx1xxx Client 4 is active with new data xxxxxxxxxxxxxxxx1xxxx Client 5 is active with new data xxxxxxxxxxxxxxxx1xxxxx Client 6 is active with new data xxxxxxxxxxxxxxxx1xxxxxx Client 7 is active with new data xxxxxxxxxxxxxxxx1xxxxxxx Client 8 is active with new data xxxxxxxxxxxxxxxx1xxxxxxx Client 9 is active with new data xxxxxxxxxxxxxxxx1xxxxxxx Client 10 is active with new data xxxxxxxxxxxxxxxx1xxxxxxx Client 11 is active with new data xxxx1xxxxxxxxxxxxx Client 12 is active with new data xxx1xxxxxxxxxxxxxx Client 13 is active with new data xx1xxxxxxxxxxxxxxx Client 14 is active with new data x1xxxxxxxxxxxxxxx Client 15 is active with new data 1xxxxxxxxxxxxxxx Client 16 is active with new data All other options Reserved

The NAR_NAPCR is described in the following table.

Table 2068. NAR_NAPCR field descriptions

Field	Description
19–16 NUM_LANE	TX Lane Configuration. Number of enabled TX lanes. This field is device specific. For a description of this field see the Calibration and Debug configuration chapter which describes how the modules are configured.
11–8 LVDS_TXOPT	This is an internal characterization field.
7 LVDS_RX_TERM_EN	This is an internal characterization field.
6 LVDS_BIAS_PRG	This is an internal characterization field.
5–0 LVDS_RXOPT	This is an internal characterization field.

95.4.7 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the

partition related configuration for main queue (internal central queue). The following figure shows the format of the NAR_AHFPAR.

Figure 2215. Trace memory fill level and partition configuration register (NAR_AHFPAR)

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0	0	0	0	0	0	0	GSE	0	0	0	GLOBAL_STALL_COUNT				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0				

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	AHB65kEN	AHB01kEN	PART_CFG		AHB_65K_Marker				AHB_01K_Marker			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_AHFPAR is described in the following table.

Table 2069. NAR_AHFPAR field description

Field	Description
31-25	Reserved and must be written with 0s
24 GSE	Global Stall Enable. Setting this bit enables the NAR to act on dci_evti[0] event to generate a global stall
23-21	Reserved and must be written with 0s
20-16 GLOBAL_STALL_COUNT	Global Stall Count. Value at this field determines how many cycles, in the NAR's operating clock, the global stall remains asserted on a dci_evti event. This is a five bit field so the maximum value is 31 cycles. See Section 95.5.13
15-12	Reserved and must be written with 0s
11 AHB65kEN	Enable 65K Marker Event
10 AHB01kEN	Enable 1K Marker Event
9-8 PART_CFG	Partition Configuration. 00 No partition 01 Reserved 10 50% partition (in two partition two configuration case) 11 Reserved

Table 2069. NAR_AHFPAR field description (continued)

Field	Description
7–4 AHB_65K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 65K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Section 95.5.14 <i>Note: This is used in BD as it has memory ranges from 65K to 983K</i>
3–0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Section 95.5.14 <i>Note: This is used in PD as it has memory ranges from 1K to 15K</i>

95.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

95.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)
3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note: *The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.*

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see [Section 95.5.4, Suppress mode](#). Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

95.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in this table.

Table 2070. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

95.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

95.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

95.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

95.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity

from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

95.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in this table on the incoming messages before transmitting to one of the output ports.

Table 2071. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8×32 -bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8×32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

95.5.3 Data reception and arbitration

The BD NAR supports 1 client (although a second dummy client is used to increase the RX buffer size for client 1). Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (B_n) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There is one type of client supported at NAR client interface. One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits.

When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal

and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire $B_n \times 32$ data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

Figure 2216. AUX bus parsing

Each AUX word consists of B_n cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new

message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

95.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one

set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

95.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue. The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

95.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type and/or messages from a particular client, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Even though the NAR supports three outputs (HBDP, Nexus, and trace

memory bus) only two can be used at the same time. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types and/or four sources.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0) or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is $\sim(\text{data_trace}) \text{ AND } (\text{source} = 13)\text{HBDP}$

Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

95.5.7 Queue partitioning

It is possible to partition the queue into two sections, one that supports the MSP, and the other that supports the alternate port as shown in [Figure 2217](#). Messages are routed, based on the MSP bit field, to either the MSP queue partition or the alternate queue partition. This allows both ports to be active simultaneously, since messages can be taken directly from both partitions. Each partition uses an accumulator to store a full central queue width beats of data before writing into memory, since on any given cycle the full Nexus word out of receiver arbitration may be split between the two partitions. Queue partitioning is enabled by setting the AQP bits of the NAR_CR.

The main advantage of using a partitioned queue is that it can improve data throughput and performance when multiple ports are active. It allows the trace memory bus port to utilize block transfer mode, which also improves performance. The only drawback is that queue utilization efficiency can be negatively impacted.

Figure 2217. Queue partitioning

95.5.8 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

95.5.8.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16×4 -bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4×16 -bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = $16 \times$ number of lanes).

95.5.8.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

95.5.8.3 Nexus format

If the Nexus port is used, entries are sent directly out of the queue with no translation or resizing. The Nexus output, Nexus input, and queue are all the same width.

The Nexus port also includes an EVTO output. This allows EVTO signalling functionality to be maintained in systems with multiple NARs. EVTO can also be used as a trigger by an external event processing block, to allow events such as client halt to occur based on NAR events such as tracebuffer overflow. Currently, the only event that can cause an EVTO assertion is an HBDP hard error/reset, since data is almost certainly lost when the HBDP link goes down, the NAR needs to communicate that back to the clients so that they can generate sync messages.

Many Nexus message types use address/data compression, wherein the compressed data is generated by XORing the current data with the previous data sent. This type of compression can only work if there is no data lost; if data is lost, the client must start over by sending a new sync message which contains the full uncompressed address or data.

95.5.9 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

95.5.10 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not

available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (i.e. unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be $0x100 \times 0x40 = 0x4000$ bytes. The dedicated debug address range would then be 0x0D00_0000 – 0x0D00_3FFF.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

95.5.11 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- **Device_ID**—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.
- **Watchpoint**—The NAR generates its own watchpoint match message under the following circumstances as shown in [Table 2075](#).
- **NAR_Error (TCODE = 8)**—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
 - HBDP error
 - Illegal configuration
 - Stall Error
 - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 2072. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

Table 2072. NAR message formats (continued)

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Error Message ⁽¹⁾	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC ⁽²⁾	NAR source ID
	4	4	fixed	ETYPE	See Table 2073
	12	12	fixed	ECODE	See Table 2074
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message ⁽³⁾	6	6	fixed	TCODE	Value = 15
	6	6	fixed	SRC ⁽²⁾	NAR source ID
	6	6	fixed	WPHIT	See Table 2075
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2011 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2011 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

95.5.11.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in this table.

Table 2073. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see Table 2074 .

Table 2073. NAR error types (continued)

ETYPE	Description	Classification	NAR action	Comment
0011 (h'3)	Trace memory bus port read/write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes. ⁽¹⁾
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See Table 2074	The specific configuration error is conveyed in bits 0–3 of the ECODE field (Table 2074), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in this table.

Table 2074. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.

Table 2074. Configuration error codes (continued)

ECODE	ETYPE	Description	NAR action	Comment
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

95.5.11.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

Table 2075. Watchpoint Hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

95.5.12 Timestamp function

The NAR and all of its clients are required to transmit timestamps, to allow precise ordering of events. All clients synchronous or asynchronous uses NAR timer value broadcasted over a bus, this ensures that all timestamps are in sync as shown in [Figure 2218](#). The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

Figure 2218. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The Time stamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

95.5.13 Global (Development tool client) stall control

The external development tool has finite memory. To prevent data loss when this memory is full, the tool gives an event to the device. The DCI block processes this and forwards to

NAR block. The dci_evti[0] carries this information. NAR detects the falling edge of dci_evti[1] and loads a counter with a configurable value programmed in GLOBAL_STALL_COUNT field of NAR_AHFPAR. This counter starts decrementing immediately, reaches to zero and stops. During the running period of the counter the Global Stall signal remains asserted thus indicating to stall the message interface to the NAL by that many cycles. The GLOBAL_STALL_COUNT field is five bits so client can be stalled up to 31 cycles.

95.5.14 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
 - AHB start (base) address—Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
 - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
 - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is $(0xC0 \times 0x40) = 0x3000$ bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
 - Number of 1K blocks in 0x3000 bytes = $(3000 \text{ right shift by } 10 \text{ bits}) = C = 12$
 - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- $\text{NAR_AHFPAR}[3:0] = (\text{NAR_TBALO}[13:10] + 0xB) = (0x7 + 0xB) \times 2$ (upper bits truncated due to width) and enable this with NAR_AHFPAR[10] = 1.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

Similarly for 65 KB boundary matching NAR_AHFPAR[7:4] needs to be programmed and the corresponding enable bit needs to be set.

95.5.15 Configuration/debug interface JTAG (1149.1)

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in [Table 2076](#). Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

Figure 2219. Nexus controller state machine

Table 2076. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 2220. Shifting data into register

95.5.15.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

95.5.15.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in [Figure 2219](#), transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 2077. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

95.5.15.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register

address index, as illustrated in [Figure 2221](#). The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in [Table 2057](#).

MSB	LSB
7-bit register index	R/W

Figure 2221. Nexus command format for register selection

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 2078. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

95.5.16 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
 - Early Write (for higher BW in special module)
 - Configurable 32/64-bit address bus width
 - 64-bit data bus width
 - Transfer Types
 - IDLE, NONSEQ, SEQ
 - Single Transfers
 - Burst Transfers
 - Configurable support for INCR
 - Configurable support for INCR4, INCR8, INCR16, WRAP4
 - Response Type
 - OKAY, ERROR
 - Transfer Size
 - Byte, Half Word, Word, Double-Word
 - Protection Control
 - Cacheable/ Non Cacheable Access Control
 - User/Privilege Access
- Endianess Support
 - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
 - Total of two transactions (One plus one ongoing)

95.5.16.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

95.5.16.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

95.5.16.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

95.5.17 Aurora client controller

This block converts the Aurora client protocol from the PD NAR into an internal client protocol that is accepted by the NPC block. The Nexus beat size must be same at both interfaces. The relation between the Aurora client data width and the NPC client interface data width must be maintained as described here.

The Aurora data width is defined as the Aurora width $\times$ 16 bits, where 16 bits comprise one Aurora word. The Nexus client data width is defined as $B_n \times 32$, where $32 = \text{MDO bits} + 2 \text{ MSEO bits}$ and B_n is the number of beats.

Thus: Aurora data width = the Nexus client data

$$\text{Aurora width} \times 16 = B_n \times 32$$

$$\text{Aurora width} = 2 \times B_n.$$

This block works in a similar way to the legacy client controller block except for the interface level control. The Aurora client has the information about the FIFO size. It sends as many data as the FIFO size then waits for the data accept signal from this block. The controller gives the data accept only when a read occurs and sends data to the NPC interface. The FIFO act as a storage and serves the purpose of clock domain transfer as well.

95.6 Initialization information

The NAR is initialized by asserting the block reset signal for a minimum of one cycle of the slowest clock. Reset clears all latches to 0, with the only exception being the output queue, whose initialization state depends on the reset behavior of the compiled memory used. Upon exiting reset, the NAR is in the disabled state, as described in [Section 95.5.2.1, Reset](#).

Pointers and state machines are initialized by the starting of NAR functional clocks (which occurs either upon the setting of the NAR enable bit or upon the assertion of the Phy enable signal) or by an NAR soft reset.

95.7 Application information

The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in [Section 95.5.6, *Output arbitration*](#).

96 Buddy Device—Nexus Aurora Link (NAL)

The Aurora Protocol is used to send debug information over a high-speed serial link out of the device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer SerDes and transceivers; it includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol. [Figure 2222](#) details the NAL block diagram. The number of lanes, n , is 4.

Figure 2222. NAL block diagram

Debug data in the Nexus format from multiple clients is collected by the Nexus Aurora Controller (NAR); messages are then packetized and sent across an asynchronous clock boundary-crossing gasket to the Aurora Protocol Engine, which performs all the logical layer functions and flow control; data from the protocol engine is sent on to the Aurora Lane Control (ALC) block, which performs data-striping and sizing, based on the number of lanes selected for debug; it also performs the PCS functions of the link. The PCS drives the Nexus Aurora Physical (NAP) interface. The NAP, in conjunction with the NAL, supports one-way simplex high-speed serial communication with an external debugger.

The NAL is composed of three main blocks: the NAR/Aurora Gasket, the Aurora Protocol Engine, and Aurora Lane Control. [Table 2079](#) lists NAL functionality by block and lists the high level features for the Nexus Aurora PHY.

Table 2079. NAL and NAP feature summary

Sub-component	Feature
NAR Aurora Gasket (NAG)	– Transmit FIFO to buffer data as it crosses the NAR / NAL clock-domain boundary and Transmit FIFO space available indication to NAR. The NAR uses Transmit FIFO space available indication(s) to determine if data can be sent to the NAL. – Platform to Domain clock domain crossing. The NAR is on the core clock domain while the NAP is on a domain sourced from the external PHY clock input signals.
Aurora Protocol Engine (APE)	– Link training – Per the Aurora Protocol specification, clock-compensation, and data framing – Cyclic Redundancy Check (CRC) generator
Aurora Link Control (ALC)	– Striping of data stream from the Aurora core across all available lanes in two-byte chunks – PCS functionality for NAL
Nexus Aurora PHY (NAP)	– Physical transmission of serial data to device pins – External clock source for SerDes clock domain

96.1 Transmit operation

During transmit operation, the NAR collects debug data from Nexus clients over a 32-bit interface: 30 bits are used for MDO and 2 bits are used for MSEO information. The NAR places MDO data into a payload (maximum payload size depends on the number of lanes, each lane has a maximum of 7424 symbols before terminating the payload) and adds the following:

- 16-bit start symbol
- 16-bit end symbol
- 16-bit CRC if enabled before end of previous symbol

Each packet is transferred from the NAR to the NAR/NAL gasket, through the Aurora Protocol Engine, the Aurora Lane Control and finally out to the device SerDes/LVDS pins through the NAP.

After each payload transfer, the NAL adds a clock compensation sequence needed for downstream SerDes devices to remain synchronized to the MCU.

Note: Symbol counting for clock compensation starts just prior to the verification symbols; therefore, training symbols are excluded when counting.

96.2 Nexus Aurora formatting

The Aurora physical interface is the transport mechanism for Nexus messages. The Nexus messages are formatted by the Aurora formatter and striped into Aurora lanes. The Nexus messages themselves encapsulated into a virtual Nexus port that consists of a 30-bit Message Data Output (MDO) port and a 2-bit Message Start/End Output (MSEO) signal. The MSEO portion of the port is the two least significant bits (LSB) of the 32-bit Aurora message. The rest of the 32-bit Aurora frame consists of 30 MDO bits that are added LSB first.

96.3 Static training

The NAL supports static training. The NAL performs Static training by using programmable timers to determine how long to stay in each stage of the training process. In static training, there is no communication between the channel partners to exchange training status; rather the NAL sends the align/bond/verify sequence to its partner for a set amount of time sufficient for the receive partner to complete the training stage.

Note: Prior to initialization, the NAL must be reset to its POR state; to do this, assert the block reset. See the RST bit field description in the NAL General Control Register (NAL_GCR).

The following steps enable static training:

1. Program the counters in the NAL_TCR and set the STE bit
2. Set the RST bit

This resets the channel and start the training routine. The time spent in each stage can range from 16 to 3072 cycles; once a counter times out, a counter time-out signal is asserted to the Aurora Protocol Engine (APE) to prompt it to move to the next stage. Additionally, it is possible to hold the training procedure in any of the stages indefinitely, by setting one of the three hold bits (AHD/BHD/VHD). When set, these bits cause the channel to sit in Align/Bond/Verify until unset, allowing a user to interactively step through the training procedure by monitoring the status at the debugger side and then stepping the device side to the next stage.

During the Aurora training sequence, the NAL generates a specific set of character sequences per the Aurora protocol specification which are to be transmitted simultaneously on all lanes.

96.4 Programmable registers

The Nexus Aurora Link (NAL) module provides a Nexus parallel to Aurora formatting for the MCU trace information. There are several registers to control both transmit and receive functionality. These registers are not memory-mapped and can only be accessed via the JTAG interface.

Table 2080. NAL memory map

Offset	Register name	Width (in bits)	Access	Reset value
0h	NAL General Status Register (NAL_GSR)	32	R	0000_8000h
8h	NAL General Control Register (NAL_GCR)	32	R/W	0000_0000h

97 Buddy Device—Nexus Aurora PHY (NAP)

97.1 Introduction

The Nexus Aurora PHY (NAP), in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. Configuration settings in the Nexus Aurora Router (NAR) Nexus Aurora Phy control register (NAR_NAPCR) specify the NAP and NAL lane configuration. The NAL performs all logical layer functions, flow control, data-striping and sizing based on the number of data lanes available for use, and physical coding sublayer functions on the data being sent to the NAP for transmission. The NAP receives 8b/10b encoded data from the NAL then serializes and transmits this data through a given PHY lane's Low Voltage Differential Signaling (LVDS) buffers to an external debugger.

Each NAP lane consists of a data symbol character accumulator which registers the 10-bit character for that lane from the NAL on the rising edge of the NAL clock. Next, a serializer takes the 10-bit character and serializes it into the individual data bits that are then transmitted at the PHY clock rate via the LVDS output drivers to the external debugger receive channel.

Note: The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking in the received data stream.

Figure 2226 shows a high level block diagram of the High Speed Nexus Interface and the NAP.

Figure 2226. High speed Nexus interface block diagram

97.1.1 Features

The features of the NAP are as follows:

- Xilinx Aurora Protocol Specification V2.x compliant
- 1Gb/s per channel trace data payload bandwidth with 1.25 GHz clock
- Simplex mode with static (timer-based) channel training

97.1.2 Modes of operation

The operating mode of the NAP is determined by the device control signals. The functional configuration is determined by the NAR_NAPCR setting; functional operation is enabled by the NAR.

97.1.2.1 Reset

During Nexus Reset all internal NAP resources are reset, all output ports are disabled, and all inputs are ignored. Since there is no device clock domain logic in the NAP itself, the NAP is unaffected by device system reset. Depending on the NAP configuration settings, the NAP may activate upon exiting Nexus Reset if any Aurora lanes are enabled during this reset mode, else it remains disabled and inactive.

97.1.2.2 Disabled/enabled

The NAP is disabled when it comes out of reset if the device is configured for pure device functional mode operation with Nexus trace messaging inhibited. The Aurora LVDS transmit lanes also remain powered down. In addition, any time the NAP block enable is negated the NAP is disabled and the LVDS transmit lanes powered down. Conversely, if the NAP is enabled when it comes out of reset or enabled sometime later after reset is negated, the NAP channels become active and the LVDS output lanes are enabled and can begin to transmit Nexus trace data after the startup time.

97.1.2.3 Link training

Before beginning trace output mode operation, the Aurora Link must go through a training process conducted by the NAL to ensure that an external debugger can correctly reconstruct the transmitted data stream. Training proceeds once the link powers up, and must complete successfully before data transmission can occur.

The NAL initializes and trains the Aurora Link in a simplex configuration using a timer based static-training method. The initialization and training sequence described in Aurora Protocol Specification progresses from one step to the next via the use of programmable timers contained in the NAL. A timer is programmed for each stage of training and as each timer expires, the training sequence proceeds to the next stage until complete. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

97.1.2.4 Transmit

During Nexus trace output operation, it is the responsibility of the NAR to push data into the Aurora Link at a sufficiently high rate to ensure that the link does not become data-starved. The NAL and NAP support up to 4 Transmit lanes. The Aurora encapsulated data is modified by the NAL to ensure the appropriate number of symbols are transmitted through the NAP.

97.2 External signal description

The external signals of the NAP are listed in [Table 2084](#). Each of the NAP signals consists of a positive and negative differential pair.

Table 2084. NAP signals

Signal Name	Direction	Description
PHY_CLOCK (CLKP/CLKN)	Input	NAP clock input from external debug tool
TX Data0 (TX0P/TX0N)	Output	NAP Tx data for lane 0
TX Data1 (TX1P/TX1N)	Output	NAP Tx data for lane 1
TX Data2 (TX2P/TX2N)	Output	NAP Tx data for lane 2
TX Data3 (TX3P/TX3N)	Output	NAP Tx data for lane 3

97.3 Memory map and register definition

There are no control, configuration or status registers within the NAP. All control, configuration and status options for number of lanes and LVDS pads are handled in the NAR_NAPCR which is described in the NAR Chapter.

97.4 Functional description

High-level descriptions of the operation of the NAP and its main functional blocks are given in the following sections.

97.4.1 Data symbol character accumulator

The data symbol character accumulator portion of the NAP for each lane is made up of a symbol character register whose inputs are connected to the 10-bit NAL character bus. The data symbol character accumulator essentially registers a 10-bit character for that lane simultaneous with the rising edge of the NAL clock and presents the 10-bit quantity to the serializer at the appropriate times.

97.4.2 Serializer

The serializer portion of the NAP for each lane takes the data captured by that lane's Data Symbol Character Accumulator and demuxes the data to provide a single serial stream of symbol data to be output by the LVDS LO buffer for that lane at the PHY clock rate.

[Figure 2227](#) shows a high level timing diagram that demonstrates the operation of the serializer for a NAP lane, where S0–S9 represents a 10-bit symbol, S10–S19 represent the next symbol, and so on.

Figure 2227. Serializer timing diagram

97.4.3 Clock generation and control

The Clock Generation and Control block is responsible for generating the necessary clocks and state signals needed by the rest of the NAP. The Data Symbol Character Accumulators and serializers are the main consumers of the signals generated by the Clock Generation and Control block.

97.5 Initialization information

The NAP does not require initialization other than the Nexus Reset and programming of the NAR_NAPCR to configure the number of lanes and LVDS pads.

98 Buddy Device—Data Write Processing Unit (DWPU)

98.1 Introduction

The Data Write Processing Unit (DWPU) supports two specific debug and calibration functions:

- Data trace filtering
- Out of range parameter identification

DWPU takes the Nexus standard messages and processes the data write trace messages to filter out messages based on the tagged addressing schema contained in the Tag RAM. DWPU also generates triggers indicating out of range data values for a set of identified addresses and data ranges.

This figure shows the block diagram of the DWPU identifying various functional block and the data flow.

Figure 2228. DWPU block diagram

98.2 Features

DWPU supports the following features:

- Out of range data value detection and data write trace filtering simultaneously from up to five Nexus clients
- Filtering operation that can be individually enabled or disabled for each 64-bit word in system RAM or data memory
- High bandwidth throughput
- Filtered trace stream is returned to the BD NAR to allow routing to the trace port or overlay RAM.
- Detection of out of range data values writes within data write trace stream

98.3 Functional description

DWPU includes the following functional blocks:

- Nexus Out Interface (NOI)
- Message Concatenation and Allocation (MCA)
- Client Specific Processing (CSP)
- Address Tag Check (ATC)
- Out of Range Check (ORC)
- Message Formatter (MF)
- Nexus Client Interface (NCI)

98.3.1 Nexus Out Interface (NOI)

The Nexus Out Interface (NOI) enables DWPU to receive Nexus message for data write filtering from NAR. NOI maintains a minimum queue of two buffers to accommodate incoming messages. The NAR only initiates a transfer to the DWPU when it has full beats messages. The incoming messages are buffered and then forwarded to the Message Concatenation and Allocation (MCA) for message concatenation and allocation. NOI ensures the temporal order of the incoming messages while forwarding to MCA. NOI also acknowledges the processing of data write messages by MCA. The format for incoming message with NEXUS_WORD = 32 and NUM_BEAT_IN = 8 is shown below.

Figure 2229. Incoming message format

98.3.2 Message Concatenation and Allocation (MCA)

Message Concatenation and Allocation (MCA) starts concatenating message beats once the NOI has a valid input messages to form a complete message. Concatenated messages with selected source IDs contained in within Nexus messages are passed over to appropriate Client Specific Processing Unit (CSPU) for further processing. The following messages are dropped by MCA:

- Messages that do not have a selected source ID
- IDLE messages
- Messages with number of beats larger than defined beats for data-write messages

98.3.3 MCA has the capability of providing one fully concatenated message to a CSPU each clock. **Client Specific Processing (CSP)**

The Client Specific Processing (CSP) block receives the messages from MCA. The received message are processed after extracting all the relevant fields. Different types of message from various clients are received and processed differently based on their type by a specialized unit called the Client Specific Processing Unit (CSPU).

The CSPU receives concatenated data write messages (including synchronization messages) from MCA and provides the following for the Out of Range Check (ORC) and Address Tag Check (ATC) logic to perform filter checks:

- Reconstructed address
- Data value
- Source ID
- Master ID
- Timestamp

CSPU also confirms that each message is a data write message. All other message types are dropped.

There are two CSPU types, one associated with Core Nexus clients and another associated with NXMC clients. Each CSPU simultaneously supports data write messages with up to four different source IDs. Data write with synchronization message is always required to start an address thread for a particular source ID, then each subsequent data write message associated with that source ID contains an encoded address. This table shows the CSPU

type encoding to be used while mapping the source IDs to a CSPU type using SRC_MAP_CTRL.

Table 2085. CSPU encoding

CSTU type	Encoding
Standard	01
NXMC	10

98.3.3.1 Input message formats

DWPU supports various message formats from different source clients. These formats are further processed by the CSPU. The following message formats are supported by the CSPUs, as also described in details the sub-sections:

- Standard data write message format (SDWM)—Includes sync and non-sync type. This is used by most of the clients, i.e., e200 peripheral and e200 main cores.
- AHBMM (modified) data write message format (MDWM)—Includes both sync and non-sync type of messages. Used by NXMC clients only.

98.3.3.1.1 Standard data trace write message format

The standard data trace write messages are of two types, sync and non-sync. The non-sync type contains the data write value and the address of the write access, relative to the previous data trace message. The address and DATA field is considered variable. Data write message information is messaged out in the format shown below. The SRC field values are described in the device-specific chapter that describes how the clients are configured.

1-64 bits	1-32 bits	4 bits	1 bit	4 bits	6 bits
DATA	U-ADDR	DSZ	0	SRC	TCODE (000101)

Figure 2230. Non-sync data trace write message format

The TSTAMP field not shown is an optional fixed field of 26 bits, is inserted optionally by the core clients based on controls received from the BD NAR.

The second type is the DWM synchronization message, whose format is exactly same as above but with full-address (without leading zeros) instead of the relative address. This is to ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent DWMs, in which only the unique portion of the data trace address is transmitted. The format for data trace write with synchronization messages is shown below.

1-64 bits	1-32 bits	4 bits	1 bit	4 bits	6 bits
DATA	F-ADDR	DSZ	0	SRC	TCODE (001101)

Figure 2231. Sync data trace write message format

The table below shows the data size (DSZ) encoding for standard data trace message.

Table 2086. Standard DSZ encoding

DSZ	Data size
0000	0-byte
0001	1-byte
0010	2-byte
0011	3-byte
0100	4-byte
0101	5-byte
0110	6-byte
0111	7-byte
1000	8-byte
1001–1111	Reserved

98.3.3.1.2 NXMC (modified) data trace write message format

The NXMC (modified) data trace write sync messages contain the data write value and the address of the write access, relative to the previous data trace message. The DATA field is considered fixed based on the DSZ encoding to either 8, 16, 32 or 64. The TSTAMP field is 26 bits. Data write message information is messaged out in the format shown below. The SRC field values are described in the device-specific chapter that describes how the clients are configured.

8/16/32/64 bits	1-32 bits	3 bits	4 bits	4 bits	6 bits
DATA	U-ADDR	DSZ	MASTER	SRC	TCODE (111010)

Figure 2232. Non-sync M-Data data trace write message format

The TSTAMP field not shown over here is an optional fixed field of 26 bits, is inserted optionally by the AHBMM clients based on controls received from NAR.

The second type is the MDWM synchronization message, whose format is exactly same as above but with full-address (without leading zeros) instead of the relative address. This is to ensure that development tools fully synchronize with data trace regularly. Synchronization messages provide a reference address for subsequent MDWMs, in which only the unique

portion of the data trace address is transmitted. The format for data trace write with synchronization messages is shown below.

8/16/32/64 bits	1-32 bits	3 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111100)

Figure 2233. Sync M-Data data trace write message format

The table below shows the data size (DSZ) encoding for NXMC data trace message.

Table 2087. NXMC DSZ encoding

DSZ	Data size
001	1-byte
010	2-byte
011	3-byte
100	4-byte
000,101–111	Reserved

98.3.4 Address Tag Check (ATC)

DWPU allows filtering operation on data writes to any address within system RAM and tightly coupled data memory. Each 64-bit word in the supported system RAM or data memory address space corresponds to a single bit in Tag RAM; therefore, the required Tag RAM size is $1/64^{\text{th}}$ of the address space to be filtered. Data write messages within the supported address range are dropped by ATC if the corresponding bit in Tag RAM is not set. The data write messages with the corresponding Tag bit set are passed over to Message Formatter for further processing.

Writes to addresses outside of the supported address range can be configured to be either removed from the trace stream or retained. This option is controlled by a single user accessible control bit. Data reads and other Nexus message formats submitted in the DWPU trace stream are always dropped by DWPU. Tag RAM is accessible through software (IPS) as well as JTAG interface via PD addressing. All the IPS access is possible in supervisor mode only. The access to TAG RAM is carried out indirectly through three registers: TRC_CTRL, TRC_ADDR and TRC_DATA registers. Users should write the TRC_CTRL register followed by the TRC_ADDR register before accessing the TRC_DATA register. Any write access to the TRC_ADDR register results in a Tag RAM access request. Users should ensure that the Tag RAM request is completed by providing the required TRC_DATA access based on the length of the transfer. In case of block access, the TRC_DATA register is accessed subsequently and users should ensure that the block access length does not cross the region boundary. Deviation in the sequence of register access for TAG RAM access results in incorrect and incomplete transfers.

In PD addressing, the configured PD address in the TRC_ADR register is translated to a TAG RAM address using mapping derived from the FAR_SA_CFGn and FAR_RS_CFGn register. The PD address configured in the FAR_SA_CFG0 register is always translated to the zeroth address of Tag RAM.

The equation to convert system/PD address to Tag RAM address where the System/PD address falls within region n is given below:

$$\text{Tag RAM address} = \text{System/PD address}[31:8] - \text{Region n base address}[31:8] + \text{Total sum of previous region (n-1) size}[31:8]$$

The Tag RAM address for System/PD address that falls on region 2 is given by:

$$\text{System/PD address}[31:8] - \text{Region 2 base address}[31:8] + (\text{region 0 size}[31:8] + \text{region 1 size}[31:8])$$

This figure shows an example of the Tag RAM organization for 8 Kbyte Tag RAM with PD base address configured.

Figure 2234. Tag RAM organization example

The table below shows an example of address translation from PD addresses to Tag RAM address.

Table 2088. Address translation example

PD address		Tag RAM address
Start	End	
0x4000_0000	0x4000_00FF	0x0
0x4000_0100	0x4000_01FF	0x1
0x4004_FF00	0x4004_FFFF	0x4FF
0x5080_0000	0x5080_00FF	0x500
0x5180_0000	0x5180_00FF	0x600
0x5280_0000	0x5280_00FF	0x700
0x5280_FF00	0x5280_FFFF	0x7FF

During the data write filtering operation, the system RAM or data memory address is extracted from the input message. It is then compared to ascertain the address space (whether it is within system RAM space or data memory or outside the supported address range). Finally it is translated to Tag RAM address and initiate a read to Tag RAM. From the Tag RAM 32-bit read accessed, the system/PD address bit [7:3] determine the Tag bit position that is associated with the decoded absolute system/PD address. If the corresponding bit is set, then the input message is passed for message formatting else it is dropped by ATC.

This figure shows the data flow for address Tag filtering.

Figure 2235. Address tag filtering

98.3.5 Out of Range Check (ORC)

In addition to the trace filtering function, the DWPU also supports detection of outside/inside range writes to RAM locations. Both the data range values and address of RAM locations to be checked are user specified. It also has configurable support to detect target inside or outside data range values specified.

A total of four sets of address and data range comparators are supported, where each set of comparators include an address match comparator, a greater than or equal data value comparator and a less than or equal data value comparator. This figure shows the block diagram for range detect comparators.

Figure 2236. Range detect comparators

ORC supports unsigned, signed and floating point data ranges. Signed numbers are represented in 2's complement. 32-bit IEEE-754 single-precision floating-point format is used for floating point representation.

ORC has a configurable option to support for 8/16/32 bit unsigned/signed range detection. Each data comparator supports bit masking and configurable pairing of comparators. Address comparison is carried out with full the device address. An output signal from DWPU is triggered in response to a detected out of range condition along with a status bit being set in a ORC status register indicating which range comparator has caused the trigger.

98.3.5.1 Comparator capabilities

The primary usage for out of range detect function is to detect out of range conditions on unsigned integer and pointer variables, although it also supports signed and floating point data types comparison. It also has a configurable option to support for 8/16/32 bit unsigned range detection. The unsigned data is directly compared with the stored data ranges.

To support use with signed variables, each data comparator supports signed operation. All the signed numbers are represented in two's complement. Data comparison happens only when the sign bit matches.

To support range of floating point variables, each data comparator also supports bit masking and configurable pairing of comparators to generate a combined watch point trigger enabling individual comparators to compare the exponent and significand.

The pairing logic is shown in this figure.

Figure 2237. DWPU trigger mode

98.3.6 Message Formatter (MF)

Message Formatter (MF) module receives message information from ATC and reformats the data write messages to comply with output Nexus message format. A user defined message format is used for sending out the filtered messages as shown below.

8/16/32/64 bits	32 bits	4 bits	4 bits	4 bits	6 bits
DATA	F-ADDR	DSZ	MASTER	SRC	TCODE (111110)

Figure 2238. DWPU message format

Table 2089. Message field description

Message name	Min packet size (bits)	Max packet size (bits)	Packet name	Packet type	Packet description
DWPU message	6	6	TCODE	fixed	TCODE number = 62
	4	4	SRC	fixed	Source client identifier
	4	4	MASTER	fixed	Indicates which master (ID) initiated the data access. For core clients 1111 is inserted. For the NXMC clients, same value is inserted as received.
	4	4	DSZ	fixed	Data size
	32	32	F-ADDR	fixed	Full data write address
	8	64	DATA	fixed	Data write value (size fixed based on DSZ field)
	26	26	TSTAMP	fixed	Timestamp (Optional and omitted if there is no valid timestamp)

98.3.7 Nexus Client Interface (NCI)

The Nexus Client Interface (NCI) sends out the formatted filtered data write messages to BD NAR. It also supports the buffer reallocation to increase the Q size.

98.3.8 IEEE 1149.1 (JTAG) Test Access Port

The DWPU module uses the IEEE 1149.1 TAP controller for accessing Nexus resources. The JTAG signals themselves are shared by all TAP controllers on the device. The DWPU module implements a 4-bit Instruction Register (IR). The valid instructions and method for register access are outlined in [Section 98.3.11, Register access via JTAG](#).

98.3.9 Enabling DWPU operation

The DWPU module is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once enabled, the module is ready to accept control input via the JTAG pins.

The DWPU module is disabled when the JTAG state machine reaches the Test-Logic-Reset state. This state can be reached by the assertion of the $\overline{\text{TRST}}$ pin or by cycling through the state machine using the TMS pin. The DWPU module is also disabled if a Power-on-Reset (POR) event occurs.

If the DWPU module is disabled, no trace output is provided. Nexus registers are not available for reads or writes.

98.3.10 Enabling TAP controller

Assertion of a Power-on-Reset signal or assertion of the $\overline{\text{TRST}}$ pin resets all TAP controllers. Upon exit from the Test-Logic-Reset state, the IR value is loaded with the JTAG ID. When the DWPU TAP is accessed, this information helps the development tool obtain information about the DWPU module it is accessing, such as version, sequence, feature set, etc.

98.3.11 Register access via JTAG

Access to DWPU register resources is enabled by loading a single instruction into the JTAG Instruction Register (IR). Once the JTAG NEXUS-ACCESS instruction has been loaded, the JTAG port allows tool/target communications with all DWPU registers according to the map in [Table 2093](#).

Reading/writing of a DWPU register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the DWPU register to be accessed by providing an index (see [Table 2093](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the format shown below.

Figure 2239. JTAG DR for DWPU register access

Table 2090. JTAG DR field description for DWPU register access

Field	Description
DWPU register index	Selected from values in Table 2093
Read/Write (R/W)	0Read 1Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
 - a) During a read access, data is latched from the selected DWPU register when the JTAG state machine passes through the Capture-DR state.
 - b) During a write access, data is latched into the selected DWPU register when the JTAG state machine passes through the Update-DR state.

98.4 Configuration

DWPU has a set of registers and Tag RAM which has to be configured and initialized before enabling DWPU. The following sequence must be followed for configuring DWPU:

- Configure the GLB_CTRL register timestamp field (GLB_CTRL[TSC]) and data write outside the identified RAM areas (GLB_CTRL[ORC]) control.
- Configure the region enable GLB_CTRL[FAREn]. Ensure that there is no disabled region between two enabled region and regions are enabled such that they start from region 0 and increase by region number.
- Configure FAR_SA_CFGn. Start address for each region is aligned to 256-byte boundaries.
- Configure FAR_RS_CFGn. Region size is an integral multiple of 256-bytes.
- Initialize the Tag RAM for the total region configured
- Ensure all the Tag access request are completed without error by examining the TRC_CTRL[11:8] bit for JTAG access and TRC_CTRL[10:8] for IPS access
- Configure SRC_MAP_CTLRn register for all the sources.
- Configure ORC_CTRLn register and the data ranges and addresses.
- Enable DWPU by setting the GLB_CTRL[MEN] bit.

98.4.1 Tag RAM initialization

DWPU has a 32-bit Tag RAM for filtering data write traces with depth being configurable. Each bit of Tag RAM corresponds to 8 bytes of system RAM. The Tag RAM supports bit masking, enabling the software to configure at least single bit of Tag RAM. Tag RAM can be organized into four different regions with configurable base addresses and region sizes.

Tag RAM can be initialized either by JTAG or IPS interface through indirect access. In indirect access, the TRC_CTRL register is configured first followed by the TRC_ADDR register. Subsequently, write/read access to the TRC_DATA register results in Tag RAM write or read access respectively. Consider an 8 Kbyte Tag RAM, organized into four regions with the following start address and region size configured.

Table 2091. Tag RAM configuration

Region	FAR_SA_CFGn	FAR_RS_CFGn
0	0x4000_0000	0x0005_0000
1	0x5080_0000	0x0001_0000
2	0x5180_0000	0x0001_0000
3	0x5280_0000	0x0001_0000

The following table provides an overview for Tag RAM address translation and write data mask generation based on the TRC_CTRL[DSM] and TRC_ADDR registers for the above Tag RAM organization.

Table 2092. System address to Tag address translation

DSM	TRC_ADDR	Region	Tag address	Write mask	Comment
000	0x4000_0000	0	0x000	0x0000_0000	32-bit write
001	0x4000_0000	0	0x000	0xFFFF_0000	LSB 16-bit write
001	0x4000_0080	0	0x000	0x0000_FFFF	MSB 16-bit write
100	0x4004_FF08	0	0x4FF	0xFFFF_FFFD	Single-bit write
100	0x4005_0000	None	—	—	Outside the supported address range
010	0x5080_0000	1	0x500	0xFFFF_FF00	8-bit write
010	0x5080_0040	1	0x500	0xFFFF_00FF	8-bit write
010	0x5080_0180	1	0x501	0xFF00_FFFF	8-bit write
100	0x5180_FFF8	2	0x6FF	0x7FFF_FFFF	Single-bit write
000	0x5280_0000	3	0x700	0x000_0000	32-bit write
000	0x5280_0180	3	0x701	—	Address unaligned with DSM; Result in incorrect write to Tag RAM

98.5 Register definition

This section describes the DWPU Nexus register definition. Nexus registers are accessed using the JTAG port in compliance with IEEE 1149.1. In addition, some register are accessible through the IPS interface.

The table below shows the JTAG mapped DWPU registers.

Table 2093. JTAG DWPU registers

Nexus register index	Register	Access	Read address	Write address	Reset value
0x02	Global Control (GLB_CTRL)	R/W	0x04	0x05	0x0000_0002
0x03	Source Mapping Control 0 (SRC_MAP_CTLR0)	R/W	0x06	0x07	0x0000_0000
0x04	Source Mapping Control 1 (SRC_MAP_CTLR1)	R/W	0x08	0x09	0x0000_0000
0x05	Source Mapping Control 2 (SRC_MAP_CTLR2)	R/W	0x0A	0x0B	0x0000_0000
0x0A	Filter Address Range Start Address 0 (FAR_SA_CFG0)	R/W	0x14	0x15	0x0000_0000
0x0B	Filter Address Range Region Size 0 (FAR_RS_CFG0)	R/W	0x16	0x17	0x0000_0000
0x0C	Filter Address Range Start Address 1 (FAR_SA_CFG1)	R/W	0x18	0x19	0x0000_0000
0x0D	Filter Address Range Region Size 1 (FAR_RS_CFG1)	R/W	0x1A	0x1B	0x0000_0000
0x0E	Filter Address Range Start Address 2 (FAR_SA_CFG2)	R/W	0x1C	0x1D	0x0000_0000
0x0F	Filter Address Range Region Size 2 (FAR_RS_CFG2)	R/W	0x1E	0x1F	0x0000_0000
0x10	Filter Address Range Start Address 3 (FAR_SA_CFG3)	R/W	0x20	0x21	0x0000_0000
0x11	Filter Address Range Region Size 3 (FAR_RS_CFG3)	R/W	0x22	0x23	0x0000_0000

Table 2093. JTAG DWPU registers (continued)

Nexus register index	Register	Access	Read address	Write address	Reset value
0x1A	Tag RAM Control (TRC_CTRL)	R/W	0x34	0x35	0x0000_0000
0x1B	Tag RAM Configuration Address (TRC_ADR)	R/W	0x36	0x37	0x0000_0000
0x1C	Tag RAM Configuration Data (TRC_DATA)	R/W	0x38	0x39	0x0000_0000

99 Buddy Device—Nexus Read Write Access (RWA)

The Nexus Read Write Access (RWA) module allows an external tool connected to the Emulation and Debug Device (ED) to read or write the Buddy Die calibration and trace memory via the JTAG interface. All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). The RWA module supports single as well as block reads and writes.

The RWA module is enabled by loading a single instruction (ACCESS_AUX_RWA_BD = 0x23) into the JTAG Instruction Register (IR). After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE) into the JTAG IR, as described in [Section 99.2, Nexus register access via JTAG](#). The RWA module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. The RWA module is also disabled if a Power-on-Reset (POR) event occurs. When disabled, the RWA module registers are not available for (32-bit or less) reads or writes.

99.1 Register definition

[Table 2109](#) details the register map for the RWA module.

Table 2109. RWA register map

Register	Nexus access opcode	Read/write	Read address	Write address
Read/Write Access Control/Status (RWCS)	0x7	R/W	0x0E	0x0F
Read/Write Access Address (RWA)	0x9	R/W	0x12	0x13
Read/Write Access Data (RWD)	0xA	R/W	0x14	0x15

99.1.1 Register descriptions

99.1.1.1 Read/write access control/status (RWCS)

The Read/write access control/status register provides control and status for the RWA module as shown in [Table 2111](#).

Figure 2254. Read/Write access control/status (RWCS) register

Table 2110. RWCS fields (continued)

Field	Description
21:18 ATTR	Access Attributes. RWA accesses are run as privileged data non-cacheable accesses by default, and drive the p_d_hprot[5:0] bus access attributes to 6'b000011 accordingly. This field is provided to allow a portion of these default values to be modified when performing read or write accesses using the RWA as shown in Table 2112 . hprot[1] must be set to one. 0xxx Reserved 1xxx Reserved x0xx p_d_hprot[4] driven to 0 for accesses x1xx p_d_hprot[4] driven to 1 for accesses xx0x p_d_hprot[3] driven to 0 for accesses xx1x p_d_hprot[3] driven to 1 for accesses xxx0 p_d_hprot[2] driven to 0 for accesses xxx1 p_d_hprot[2] driven to 1 for accesses
17:16	Reserved for future functionality.
15:2 CNT	Access Control Count. Number of accesses of word size SZ.
1 ERR	Read/Write Access Error (see Table 2111).
0 DV	Read/Write Access Data Valid (see Table 2111).

Table 2111. Read/Write access status bit encoding

Read action	Write action	ERR	DV
Read access has not completed	Write access completed without error	0	0
Read access error has occurred	Write access error has occurred	1	0
Read access completed without error	Write access has not completed	0	1
Not allowed	Not allowed	1	1

Table 2112. Protection encoding

p_hprot[4]	p_hprot[3]	p_hprot[2]	Transfer type
0	0	0	Cache-inhibited
0	0	1	Guarded, not cache-inhibited
0	1	0	Reserved
0	1	1	Reserved
1	0	0	Reserved
1	0	1	Reserved
1	1	0	Cachable, writethrough
1	1	1	Cachable, writeback

99.1.2 Read/write access data (RWD)

The Read/write access data register (RWD) provides the data to/from memory when initiating a read or a write access.

Figure 2255. Read/write access data (RWD) register

Read/write accesses to the memory require that the debug firmware properly retrieve/place the data in the RWD. [Table 2113](#) shows the proper placement of data into the RWD.

Table 2113. RWD data placement for transfers

Transfer size and byte offset	RWA(2:0)	RWCS[SZ]	RWD ⁽¹⁾			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X

1. X indicates byte lanes with valid data; — indicated bytes lanes with unused data.

[Table 2114](#) shows the mapping of RWD bytes to byte lanes of the read and write data buses.

Table 2114. RWD byte lane mapping

Transfer size and byte offset	RWA(2:0)	RWD ⁽¹⁾			
		31:24	23:16	15:8	7:0
Byte @000	0 0 0	—	—	—	XBAR[7:0]
Byte @001	0 0 1	—	—	—	XBAR[15:8]
Byte @010	0 1 0	—	—	—	XBAR[23:16]
Byte @011	0 1 1	—	—	—	XBAR[31:24]
Byte @100	1 0 0	—	—	—	XBAR[39:32]
Byte @101	1 0 1	—	—	—	XBAR[47:40]
Byte @110	1 1 0	—	—	—	XBAR[55:48]
Byte @111	1 1 1	—	—	-	XBAR[63:56]
Half @000	0 0 0	—	—	XBAR[15:8]	XBAR[7:0]
Half @010	0 1 0	—	—	XBAR[31:24]	XBAR[23:16]
Half @100	1 0 0	—	—	XBAR[47:40]	XBAR[39:32]
Half @110	1 1 0	—	—	XBAR[63:56]	XBAR[55:48]

Table 2114. RWD byte lane mapping (continued)

Transfer size and byte offset	RWA(2:0)	RWD ⁽¹⁾			
		31:24	23:16	15:8	7:0
Word @000	0 0 0	XBAR[31:24]	XBAR[23:16]	XBAR[15:8]	XBAR[7:0]
Word @100	1 0 0	XBAR[63:56]	XBAR[55:48]	XBAR[47:40]	XBAR[39:32]

1. — indicates byte lanes that contain unused data

99.1.3 Read/write access address (RWA)

The Read/write access address register provides the address to be accessed when initiating a read or a write access.

Figure 2256. Read/write access address (RWA) register

99.2 Nexus register access via JTAG

After the RWA module has been enabled, access to the RWA registers is enabled by loading an instruction (CORE_ENABLE = 0x7C) into the JTAG Instruction Register (IR). Once the CORE_ENABLE instruction has been loaded, the JTAG port allows tool/target communications with all Nexus registers according to the map in [Table 2109](#).

Reading or writing of a RWA module register then requires two passes through the Data-Scan (DR) path of the JTAG state machine.

1. The first pass through the DR selects the RWA module register to be accessed by providing an index and the direction (read/write) as shown in [Table 2109](#). This is achieved by loading an 8-bit value into the JTAG data register (DR).

This register has the following format:

Figure 2257. JTAG DR for Nexus register access

Table 2115. JTAG DR field description for Nexus register access

Field	Description
Nexus Register Index	Selected from values in Table 2109
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
 - a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the Capture-DR state.
 - b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the Update-DR state.

99.3 Memory access examples

The following subsections describe the steps which are required to access memory.

99.3.1 Single write access

1. Initialize the RWA register through the JTAG. Configure as follows:
 - Write Address = 32h'xxxxxxx (write address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
 - Access Control (AC) = 1b'1 (to indicate start access)
 - Map Select (MAP) = 3b'000 (primary memory map)
 - Access Priority (PR) = 2b'00 (lowest priority)
 - Read/Write (RW) = 1b'1 (write access)
 - Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
 - Access Count (CNT) = 14h'0000 or 14h'0001 (single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. Initialize the RWD register through the JTAG. Configure as follows:
 - Write Data = 32h'xxxxxxx (write data)
4. The RWA module then transfers the data value from the data buffer RWD register to the memory mapped address in the RWA register. When the access has completed without error (ERR = 1'b0), the RWA clears the DV bit in the RWCS register. This indicates that the device is ready for the next access.

99.3.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in [Section 99.3.1, Single write access](#) to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the first data value from the RWD register to the memory mapped address in the RWA register. When the transfer has completed without error (ERR=1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates it is ready for the next access.
3. Repeat Step 3 in [Section 99.3.1, Single write access](#) until the internal CNT value is zero (0). When this occurs, the DV bit within the RWCS is cleared to indicate the end of the block write access.

Note: The actual RWA register value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

99.3.3 Single read access

1. Initialize the RWA register through the JTAG. Configure as follows:
 - Read Address = 32h'xxxxxxx (read address)
2. Initialize the RWCS register through the JTAG. Configure the bits as follows:
 - Access Control (AC) = 1b'1 (to indicate start access)
 - Map Select (MAP) = 3b'000 (primary memory map)
 - Access Priority (PR) = 2b'00 (lowest priority)
 - Read/Write (RW) = 1b'0 (read access)
 - Word Size (SZ) = 3b'0xx (32-bit, 16-bit, 8-bit)
 - Access Count (CNT) = 14h'0000 or 14h'0001 (single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 performs a single access.

3. The RWA module then transfers the data to the RWD register. When the transfer is completed without error (ERR = 1'b0), the RWA module sets the DV bit in the RWCS register. This indicates that the RWA module is ready for the next access.
4. The data can then be read from the RWD register through the JTAG.

99.3.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in [Section 99.3.3, Single read access](#) to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS register.
2. The RWA module then transfers the data to the RWD register. When the transfer has completed without error (ERR = 1'b0), the address from the RWA register is incremented to the next word size (specified in the SZ field) and the number from the CNT field is decremented. The RWA module then indicates that the device is ready for the next access.
3. The data can then be read from the RWD register through JTAG.
4. Repeat Steps 3 and 4 in [Section 99.3.3, Single read access](#) until the CNT value is zero (0). When this occurs, the DV bit within the RWCS register is set to indicate the end of the block read access.

Note: The data values must be shifted out 32-bits at a time LSB first. The actual RWA value as well as the CNT field within the RWCS register are not changed when executing a block read access. The original values can be read by the external development tool at any time.

100 Buddy Device—LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug

100.1 Introduction

This chapter describes the specifications of the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in slave only mode enabling high speed debug communications through the JTAG port.

100.2 Block diagram

[Figure 2258](#) depicts LFAST interaction with other modules on the device.

Figure 2258. LFAST block diagram

100.3 External signals

LFAST is a six pin interface with the following signals after enabling high speed debug mode:

- lfast_sysclk_en
 - Interface enable signal in LFAST Slave Only mode
- lfast_sysclk
 - Reference clock of the LFAST master and slave
- txdatap/txdatan
 - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
 - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface with maximum data rate of 320 Mbps.

100.3.1 LFAST operating data rates

[Table 2116](#) shows the operating modes for the LFAST interface.

Table 2116. Operating modes for LFAST interface

Interface	Tx/Rx Data Rate
LFAST Transmit	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps
LFAST Receive	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps ($\text{lfast_sysclk} \div 4$ or $\text{lfast_sysclk} \div 2$) is referred to as low and data rates 312 Mbps and 320 Mbps is referred to as high data rates.

100.4 LFAST frame structure

LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communication format.

A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length. A sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See [Figure 2259](#) for details of the LFAST frame.

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 2260. Serial frame structure

The frame structure is shown in [Figure 2260](#) and consists of the following:

- 16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- Header - 3 MSB (b7 - b5):** Defines the payload size according to [Table](#) .

Table 2117. Header payload sizes

b7-b5 (bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	288	312
111	—	—

- Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type.
- Header - (b0):** CTS on the both LFAST master and slave devices. In slave only mode the CTS field will always be 1.
- Payload: Content dependent upon frame type.**
- Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode).

100.5 Features

- Supports slave only mode.
- Supports asynchronous data transfer rates up to a maximum of 320 Mbps
- Transmits and receives data and unsolicited frames.
- Receives ICLC frames
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports flow control using sliding window protocol.
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation.
- Supports for detection of unsupported channel number and unsupported payload size.

100.6 Memory map and register definition

All registers are 32 bits wide.

100.6.1 Memory map

Table 2118. LFAST memory map

The conventions in [Figure 2261](#) and [Table 2119](#) serve as a key for the register summary and individual register diagrams.

Figure 2261. Key to Register Fields

Table 2119 provides a key for register figures and tables and the register summary.

Table 2119. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bits value (other than a hardware reset).
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but its cleared by the H/W once the operation defined by the bit is over
Reset Values	
0	Resets to zero.
1	Resets to one.
[signal_name]	Reset value is determined by polarity of indicated signal.

100.6.2 Register descriptions

100.6.2.1 Mode Configuration Register (MCR)

Figure 2262. Mode Configuration Register (MCR)

Offset: 0000h								Access: User read/write								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	IPGDBG	0	0	0	0	0	0	0	LSSEL
W																
Reset	0	0	0	0	0	0	0		0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

1. Set by user software and cleared by system hardware.

Table 2120. MCR field descriptions

Bits	Description
0-6	Reserved
7 IPGDBG	Control bit to enable support for IPG Debug mode. This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
8-14	Reserved
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode. Refer to Section 100.10.2, Slow speed clock for more detailed description. 0 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.

Table 2120. MCR field descriptions (continued)

Bits	Description
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS LR. 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface is not disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be set and cleared by LFAST slave H/W on reception of an ICLC command frame. 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 Not allowed. Do not set when in slave only mode.
19-26	Reserved
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28-29	Reserved
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after reset. 0 No soft reset. 1 Soft reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

100.6.2.2 Speed Control Register (SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Figure 2263. Speed Control Register (SCR)

Offset: 0004h								Access: User read/write								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	DRMD ⁽¹⁾
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	0	0	0	0	0	0	0	RDR	0	0	0	0	0	0	0	TDR
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Only writable when MCR[DRFEN] = 0.

Table 2121. SCR field descriptions

Bits	Description
0-14	Reserved
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. This bit should not be modified by S/W and left as SCR[DRMD] = 1.
16 - 22	Reserved
23 RDR	Receiver Data Rate. This bit defines the receiver data rate. This bit should not be modified by S/W.
24-30	Reserved
31 TDR	Transmit Data Rate. This bit defines the transmitter data rate. This bit should not be modified by S/W.

100.6.2.3 Correlator Control Register (COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Figure 2264. Correlator Control Register (COCR)

Table 2122. COCR field descriptions

Field	Description
0-7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. 00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected 40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8-27	Reserved

Table 2122. COCR field descriptions (continued)

Field	Description
28-30 CORRTH	Correlator threshold level. Defines the correlation threshold level. 000 9 Bits of correlation 001 10 Bits of correlation ... 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. 0 8 phases 1 4 phases

100.6.2.4 Test Mode Control Register (TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes

Figure 2265. Test Mode Control Register (TMCR)

Offset: 000Ch								Access: User read/write								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Writable only when TMCR[LPON] = 0.

Table 2123. TMCR field descriptions

Bits	Description
0-5	Reserved
6 CLKTST	Clock Test mode. S/W can define when the clock test mode is enabled. This bit can also be set and cleared by H/W on reception of an ICLC command. 1 Clock Test mode enabled 0 Clock Test mode disabled

Table 2123. TMCR field descriptions (continued)

Bits	Description
7 LPON	Loopback mode Logic Enable. S/W can define when the loopback logic is enabled. This bit can also be written by LFAST slave H/W on reception of an ICLC command. 1 Loopback mode is enabled 0 Loopback mode is disabled
8-12	Reserved
13-15 LPMOD	Loopback mode. Defines the type of loopback mode enabled. 000 Rx loopback 001 Rx LVDS loopback 010 Tx loopback without automatic frame generation 011 Tx loopback with automatic frame generation 100 Tx LVDS loopback (external) with automatic frame generation Others - Reserved (should not be written by S/W)
16-31 LPFRMTH	Loopback check mode valid pass frames threshold value. Defines the number of frames to verify before setting GCR[LPPFDV] when running in Automatic Loopback Frame mode. The loopback frame is considered pass when the payload is CBh, header is 13h and sync is valid. This mode is valid only when TMCR[LPMOD] = 011b or TMCR[LPMOD] = 100b. 0000h Reserved.(Not to be used) 0001h Check 1 frame have correct sync, header and payload. ... FFFEh Check 65534 frames have correct sync, header and payload. FFFFh Check 65535 frames have correct sync, header and payload.

100.6.2.5 Auto Loopback Control Register (ALCR)

Figure 2266. Auto Loopback Control Register (ALCR)

Offset: 0010h								Access: User read/write

Table 2129. LCR field description

Bits	Description
0-7	Reserved
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be put in sleep
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
13 SWONLD	SW signal to turn ON the LVDS LD. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.

Table 2129. LCR field description (continued)

Bits	Description
15 SWONLR	SW signal to turn ON the LVDS LR. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable. The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
21	Reserved
22-24 LVRXOP	LVRXOP[2] Termination resistance 0 Disable termination 1 Enable termination LVRXOP[1] Not used LVRXOP[0] Defines the LVDS LR Bias current reference
25-28	Reserved
29 LVTXOP	Control signal for LFAST and Micro-Second Bus selection. 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Data select. This bit is used for selecting use of clock sampled data or normal data in LVDS. 0 normal data to be used inside the LVDS 1 synchronised data to be used inside the LVDS
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

Figure 2281. Unsolicited Rx Data Registers (UNSRDR8–UNSRDR0)

Table 2139. UNSRDRn field descriptions

Bits	Description
0-31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data.It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNSRDR0[0] in case of 288 bit payload.

100.6.3 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements^(ae). All registers of the LFAST module are classified as non-safety relevant.

The MCR[IPGDBG] fulfills the safety requirements for monitoring of the debug freeze signal.

100.7 Functional description

100.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

ae. See the “Functional Safety” chapter for register classification details.

100.7.1.1 LFAST slave interface startup procedure

1. After POR the RCDCCR are programed according to the LVDS parameter in the device datasheet.
2. The PLLCR^(af) is programed with the configuration parameters of the PLL.
3. The LCR is programed with the configuration parameters of the LVDS.
4. MCR[DATAEN] fields is programmed to select the LFAST mode.
5. Write MCR[TXARBD] = 0 to enable Tx of frames.
6. Write MCR[DRFEN] = 1 to enable LFAST.
7. Write MCR[RXEN] = 1 to enable LFAST Rx.
8. On the assertion of the LFAST interface enable the signals LR power down and LR disable are negated.
9. When an ICLC frame with payload 31h is received H/W writes RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
10. The ping frame is sent when an ICLC frame with payload 00h frame is received and H/W writes RIISR[ICPRF] = 1.

Speed mode change:

11. The PLL starts when an ICLC frame with payload 02h is received and H/W writes RIISR[ICPONF] = 1.
12. The speed of the Tx interface is changed when an ICLC frame with payload 80h is received and H/W writes RIISR[ICTFF] = 1. This will cause SRC[TDR] = 1.
13. The speed of the Rx Interface is changed when an ICLC frame with payload 10h is received and H/W writes RIISR[ICRFF] = 1. This will cause SCR[RDR] = 1.
14. The ping frame is sent when an ICLC frame with payload 00h is received and H/W writes RIISR[ICPRF] = 1.

100.7.2 LFAST Interface enable signal (lfast_sysclk_en)

The lfast_sysclk_en signal comes from the DCI module. It is asserted by the DCI internal state machine when switching from JTAG to LFAST and vice-versa can safely be done. The detailed effects of lfast_sysclk_en on the module are:

LFAST interface enable (lfast_sysclk_en) negation:

1. If LCR[SWONLD] = 0 the LD LVDS pad is powered down.
2. If LCR[SWONLR] = 0 the LR LVDS pad is powered down.
3. The LFAST slave exits the test mode (for example, loopback mode or clock test mode). Then S/W writes MCR[CLKTST] = 0 and MCR[LPON] = 0.
4. The LFAST slave Rx and Tx interfaces are set to Low Speed mode. Then write SCR[TDR] = 0 and SCR[RDR] = 0.
5. The Tx and Rx interface controllers are disabled.
6. The status registers are cleared.

LFAST interface enable (lfast_sysclk_en) assertion:

af. The PLLCR is shared between the LFAST – Interprocessor Communications and the LFAST – High Speed Debug modules. The programming values for the PLLCR in the LFAST – Interprocessor Communications are also used by the LFAST – High Speed Debug module.

1. The LD LVDS pad is power up, if all conditions are met:
 - LCR[SwoffLD] = 0.
 - LCR[SWONLD] = 1.
 - MCR[TXEN] = 1.
 - When frame ICR[ICLCPLD] = 31h is received.
2. LR LVDS pad is powered up if all conditions are met:
 - LCR[SwoffLR] = 0.
 - LCR[SWONLR] = 1.
 - MCR[RXEN] = 1.

100.7.3 Line Receiver (LR)

100.7.3.1 Introduction

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 2282 shows the block diagram of Uplink Controller.

Figure 2282. Top Level Receive Controller

100.7.3.2 Edge-Detection & Auto correlation

The edge-detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge-detection circuitry is used or not. The edge-detection will be performed first if required before auto-correlation.

100.7.3.2.1 Auto correlation modes

100.7.3.2.1.1 Hunt correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 2283. Hunt Correlation mode**100.7.3.2.2 Edge detection**

The edge detector is disabled in Hunt Correlation mode.

100.7.3.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in [Figure 2284](#).

Figure 2284. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in [Figure 2285](#).

Figure 2285. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in [Figure 2286](#) and [Figure 2287](#).

Figure 2286. High Speed 4 Phase Clock Alignment Example

Figure 2287. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed (312/320 MHz) 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High Speed 8 Phases: Samplers 0,1,2,3,4,5,6,7
- High Speed 4 Phases: Samplers 0,2,4,6
- Low Speed 4 Phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and re-samples it to a intermediate phase as shown in [Table 2140](#), [Table 2141](#), and [Table 2142](#) before re-sampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 2140. High speed 8 phase selection - sampling procedure

Samplers	Initial Sample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 2141. High speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See [Table 2141](#), Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 2142. Low speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See [Table 2142](#), Samplers 4, 5, 6, 7 are disabled. The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

100.7.3.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in [Figure 2288](#).

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (e.g Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by de-asserting the respective phase enables.

Figure 2288. Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in [Figure 2289](#).

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

Figure 2289. Sampler 5 Logic

100.7.3.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in [Figure 2290](#)

Figure 2290. Extracting Header and Payload from the 16-bit output from Auto correlation.

100.7.3.3.1 Line Receiver states

The LD has the following states:

- Shutdown**
 The LR enters in the shutdown state when the power down signal is high. In this state the LR regulator is supplying a V_{dd} level, however the LR is not enabled. In this state the LR holds its off value. Once power down signal is negated, a predefined settling time is required before the LR may be used for communication. During the settling time the peer LFAST device should not start its transfer.
- Sleep**
 The LR enters in the Sleep state when the sleep signal is high. In the sleep state, the LR is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In this

mode the receiver current consumption is reduced. Hysteresis in the LR ensures that it continues to present a 1 to the LFAST module.

- **Normal**
In the Normal state, the LR is primed for reception. Receiver converts differential signals to a single ended logic signal.

Table 2143. Line Receiver State

LR State	LFAST Slave Triggers (at least one of the following)
Shutdown	– LFAST interface enable assertion/negation – Programing of LCR[SwoffLR] or LCR[SWONLR] – Programing MCR[RXEN] and MCR[TXEN]
Sleep	– Programing of LCR[SWSLPLR] or LSC[SWWKLR]
Normal	Absence of above mentioned conditions

100.7.4 Transmit Controller

100.7.4.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, ping etc. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Recieve Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in [Figure 2291](#).

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 2291. Transmit Controller Connections

100.7.4.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like:

- S/W programmable registers
- System side interface FIFO
- Rx interface controller
- LFAST Slave: LFAST interface enable (lfast_sysclk_en)

The level of priority for each request is shown in [Table 2144](#).

Table 2144. Priority Levels for the Transmit Controller

Request	LFAST Slave Priority	Triggering Conditions (at least one of the listed)
LFAST interface enable (lfast_sysclk_en)	1	– LFAST interface enable (lfast_sysclk_en) is asserted – LFAST interface enable (lfast_sysclk_en) is negated
Tx Interface disabled	2	– MCR[DRFEN] = 0 – MCR[TXEN] = 0 – MCR[DRFRST] = 1 – MCR[TXARBD] = 1 – LFAST Slave: ICLC frame with payload for “Disable Rx interface” received

Table 2144. Priority Levels for the Transmit Controller

Request	LFAST Slave Priority	Triggering Conditions (at least one of the listed)
Tx Interface speed mode change	3	– SCR[TDR] is modified – LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	– TMCR[LPON] = 1 – LFAST Slave: ICLC frame with payload for loopback mode enable received <i>Note:</i> Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
Ping response request	5	– LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 – LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	– Valid only if Last Frame with header b0 = 1 received from the peer LFAST – UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	– Tx FIFO contains one or more frames – Last Frame with header b0 = 1 received from the peer LFAST device – MCR[DATAEN] = 1
Clock mode test	8	– TMCR[CLKTST] = 0 – LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCCR[DRCNT].

100.7.4.3 Line Driver digital connections

100.7.4.3.1 Line Driver states

The LD has the following states:

- **Shutdown**
The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling

time is required before the LD may be used for communication. The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In the sleep state the LD outputs are connected to V_{cm} (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a predefined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

Figure 2292. Example of Sleep mode

As shown in [Figure 2292](#) before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 2145. Line Driver States

LD State	LFAST Slave Triggers
Shutdown	– LFAST interface enable (lfast_sysclk_en) negation/assertion – Programing LVDS[SWOFFLD] and LVDS[SWONLD] – ICLC command from LFAST master – Programing MCR[TXEN] and MCR[DRFEN]
Sleep	– Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions

100.7.5 Frames supported

Table 2146 provides the frames supported and their permissible payload sizes

Table 2146. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx 2. LFAST Slave Rx	Supported by 1. LFAST Slave Tx 2. LFAST Master Rx	Payload Size (bits)
Data Frame	Rx – 0100b, 1000b – 1011b Tx – All	YES	YES	TX: 96 RX: 128
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO ⁽¹⁾	8
CTS Frame	n/a	NO	NO	n/a
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

100.7.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

100.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

100.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO. Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

100.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTF] = 1 after each frame transfer.

100.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[TXEN] and MCR[DRFEN] bits should be set to enable the data frame reception. When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded.

100.7.6.2 Unsolicited flow**100.7.6.2.1 Unsolicited frame transmit flow**

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

100.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
 - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
 - UNSTCR[USNDRQ] = 0
 - TISR[TXUNSF] = 1.
 - If UNSTCR[USNDRQ] = 0 then:
 - Program the unsolicited payload in UNSTD0–UNSTD8, and can be written up to a payload of frame of a maximum of 288 bits.
 - Program the unsolicited frame header in UNSTCR[UNSHDR].
 - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.

100.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTD0–UNSTD8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.

100.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is defined as a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

100.7.6.3.1 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

100.7.6.3.1.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF] = 1. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

100.7.6.3.1.2 Start PLL ICLC

The Start PLL ICLC command will write bit RIISR[ICPONF] = 1.

100.7.6.3.1.3 Stop PLL ICLC

The Stop PLL ICLC command will write RIISR[ICPOFF] = 1.

100.7.6.3.1.4 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

100.7.6.3.1.5 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write `RIISR[ICTSF] = 1` (Low speed) or `RIISR[ICTFF] = 1` (High speed).

100.7.6.3.1.6 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes `RIISR[ICTEF] = 1` and `RIISR[ICTDF] = 1`. The ICLC Tx enable command will write `MCR[TXEN] = 1`.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs `MCR[TXEN] = 1`.

100.7.6.3.1.7 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write `TMCR[CLKTST] = 1`. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates `RIISR[ICCTF] = 1` on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

100.7.6.3.1.8 Loopback payload on ICLC

This ICLC command is decoded and `TMCR[LPON] = 1` to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes `RIISR[ICLPF] = 1` on reception of this ICLC command.

100.7.6.3.1.9 Test mode off ICLC

This ICLC command is decoded and `TMCR[LPON]` and `TMCR[CLKTST]` are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable (`lfast_sysclk_en`).

100.7.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

100.7.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode `TMCR[LPFRMTH]` should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 2147. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

100.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. Bit b0 of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

Figure 2293. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master
- For LFAST Slave: - Deassertion of the LFAST interface enable (lfast_sysclk_en).

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

100.7.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via “Rx LVDS LoopBack Mux”. Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 2294. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
 - S/W writes TMCR[LPON] = 1.
 - For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave:
 - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.
 - Deassertion of the LFAST interface enable (lfast_sysclk_en).

100.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 2295. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

All frames and error flags are decoded in this mode.

100.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where predefined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- ALCR[LPCNTEN] defines whether fixed number of auto loopback frames to be transmitted.
- ALCR[LPFMCNT] defines the number of loopback frames to be transmitted if ALCR[LPCNTEN] = 1.

The Status signals and register used for these modes are:

- GSR[LPCSDV]: Valid Synchronization received.
- GSR[LPCHDV]: Frame with Header of 13h received.
- GSR[LPCPDV]: Frame with Payload of CBh received.
- GSR[LPTXDN]: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to ALCR[LPFMCNT].

Figure 2296. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

- Tx Loopback with Automatic frame generation.
- Tx LVDS (external) with Automatic frame generation.

100.7.7.1.4.1 Tx LoopBack mode with automatic frame generation

When TMCR[LPMOD] = 011b (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

Figure 2297. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 011b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from the LFAST Master.

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

100.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 2298. Tx LVDS Loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on) from LFAST Master

Exit from Tx LVDS Loopback with automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

100.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 34h (Clock Test mode on) from LFAST Master.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by any of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode does not affect the functionality of the Rx Interface.

100.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has its own dedicated buffer, and they are not shared between each other.

Table 2148. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer (in bits)	Rx Buffer (in bits)	Memory Type
Data Frame	6 × 32 max 2 packets	8 × 32 max 2 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	N/A	1 × 8 max 1 packet ⁽¹⁾	Registers PICR[PNGPYLD]
CTS Frame	N/A	N/A	N/A

1. Ping response packet

100.9 Resets

The various blocks in LFAST are reset as described in [Table 2149](#).

Table 2149. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space

Table 2149. Recommended receive exception handling mechanism

Reset	Blocks Reset
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ]
LFAST interface enable (lfast_sysclk_en)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers except the following: TISR, RISR, RIISR, GSR[LPTXDN] and GSR[LPFPDV] These bits remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: Negedge only – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ] These bits does not remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: positive edge only – TISR, – RISR, – RIISR, – GSR[LPTXDN] and GSR[LPFPDV] These bits does not remain reset while the LFAST interface enable (lfast_sysclk_en) is High.

100.10 Clocks

The LFAST mainly works on three clocks:

- System Bus Clock, used to program the registers.
- Protocol clock, which is either High Speed PLL clock or Low Speed clock depending on the speed mode, used for LFAST protocol operation.
- System Side Module clock, which is synchronous to the System Bus clock.

100.10.1 Clocking strategy

[Figure 2299](#) shows the clock domain in which each module functions. The PLL provides eight phases of the high speed clock to the Clock Muxing portion of the Clock Control Module. The Clock Module will then generate four phases of slow speed clock using both the edges of lfast_sysclk, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 2299. LFAST module clock domains

100.10.2 Slow speed clock

100.10.2.1 External muxing

The Clock Control Module will receive lfast_sysclk from the clocking subsystem as shown in [Figure 2300](#), [Figure 2301](#) and [Figure 2302](#).

Figure 2300. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in [Figure 2300](#).

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in [Figure 2301](#) (selected clock path shown in green).

Figure 2301. External clock muxing of `lfast_sysclk` of 20/26 MHz

In this case, `lfast_sysclk` is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency `lfast_sysclk/2` when `MCR[LSSEL] = 0`. If `lfast_sysclk` is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in [Figure 2302](#) (selected clock path selected shown in magenta).

Figure 2302. External clock muxing of `lfast_sysclk` of 10 MHz

100.10.2.2 Slow speed 4-phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated.

[Figure 2303](#) Shows 4 phases getting generated using lfast_sysclk.

Figure 2303. Slow speed 4 phases generation

100.10.3 Rx controller clocks

100.10.3.1 Clocking module requirements for high speed phases

The high speed Phases are obtained from the PLL via the Clocking Module as shown in [Figure 2304](#).

Figure 2304. Clock Enables and Clock Paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore, the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

100.10.3.2 Clock module requirements for low speed phases

100.10.3.2.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq $\times$ 8 MHz clock from the PLL is not needed.

Table 2150. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

100.10.4 Tx controller clocks

100.10.4.1 Clocking module requirements for speed phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See [Table 2151](#).

Table 2151. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

100.10.4.2 Transmit clock muxing

Figure 2305. Transmit Clocks Muxing

100.10.4.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

101 Revision History

Table 2152. Document revision history

Date	Revision	Changes
11-Jun-2009	1	Initial release.
15-Dec-2011	2	Throughout: Formatting, spelling, grammar, and layout corrections. Added requirement tags. Added register classification column memory map tables. Chapter Introduction Added I/O processor functional description. In the Features list table: Peripheral Core, changed Local RAM from “32 KB” to “48 KB”. Peripheral Core, changed Software Watchdog Timer from “3” to “4”. Updated SPC57EM80xx block diagram, slow and fast cross bar slave/master assignments. In SPC57EM80xx periphery allocation figure changed “3 x SWT” to “4 x SWT”. In Features list: Changed MCAN/TTCAN 3 to 3/1. Chapter Embedded Memories Changed peripheral processor core “32 KB” data SRAM to “48 KB” data SRAM. Cross-references added to memory and memory controller chapters of reference manual. Chapter Signal Description Updates made to the Power supply and reference voltage pins table. Updates made to the Pin Muxing Description Table: Added a Signals Description column. Added pin descriptions for PA1.15[0-9]. Updated DSPI pin names for Ethernet, CAN, DSPI. Updated LINFlexD and FlexRay descriptions. Updated SCK / DSPI functions. Updated SOUT / DSPI functions. Updated SIN / DSPI functions. Updated DSI / DSPI functions. Updated SAR pin descriptions. Updated “Emulation package” section description, Updated “System terminal description” table, TESTMODE pin description. Added “LVDS pins/balls” table. Updated Power supply and reference voltage pins table.

Table 2152. Document revision history (continued)

Date	Revision	Changes
15-Dec-2011	2 (continued)	Chapter Memory Map Combine adjacent reserved rows into a single row and list space in terms of MB instead of KB in some instances. Used RAM space is 128 KB. SAR_x instances renamed to SARADC_x. SD_x instances renamed to SDADC_x. Slow XBAR (XBAR_1) renamed to Peripheral Shell XBAR; Fast XBAR (XBAR_0) renamed to Computational Shell XBAR. SEMA4 changed to "Semaphore (SEMA4)". SENT_0 renamed to SRX_0. TTCAN changed to TTCAN_0. PIT_RTC_x changed to PIT_x. No RTC is implemented. DIGRF_0 is for interprocessor communication (was incorrectly stated as I/O). Terminology changed: "Mirror" flash changed to say " - overlay enabled mapping". References to "FSL" changed to "factory". BAF block removed from UTest map. Chapter Device Configuration Clarified the PRS register reset values: The computational shell's XBAR0_PRSn registers reset to 0054_3210h. The peripheral shell's XBAR1_PRSn registers reset to 0000_3210h. Added Platform Configuration Module (PCM) registers. Added FEC interface selection table. Updated DMACHMUX configuration section. Updated DMAMUX memory map table and added footnote. Updated PIT Instantiation section. Updated PIT information table to include RTI. Added PIT clocking section. Updated interrupt sources table. Updated SWT configuration section: Added additional instance, SWT3. Added note on DCI ability to change the reset value of SWT_CR[WEN]. Added "Service mode watchpoint input" sub-section. Replaced 'HSM search' in "Device specific features" with "LINFlexD search". Added "Concurrent overflow register (OFLW) implementation" section to MEMU. Updated MEMU registers table. Added "DSPI HT External Trigger" section. Added "DSPI ITSB Mode" section. Identified SENT channels in "SENT channel configuration" table.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3	Throughout Formatting, spelling, grammar, and layout corrections. Chapter Preface Added Register conventions section that details the conventions used in register figures throughout the document. Added terms to Acronyms and abbreviations table. Chapter Introduction Noted that from a software perspective, every bus master (all CPUs, DMA, SIPI, ethernet, FlexRay, HSM) sees every memory and peripheral (all RAMs, flash, and peripherals) in a consistent flat memory map Correction to features table: peripheral core has 64 KB local data RAM (was 48 KB) Detail added to features list: MCU has 4000 KB code flash, 288 KB data flash, and 16 KB UTest flash. Corrections to features list: MCU's Sigma-Delta ADC are 16-bit (previously 12-bit) There is no on-chip voltage regulator for 1.2 VChip supports both 1149.1 and 1149.7 JTAG (was 1149.1) Updates to block diagram: In Figure 1, Block diagram: Split memory block to 64KB SRAM and 64KB Standby RAM. In Figure 2, Peripheral allocation: Removed TSENS_0 and TSENS_1 and added TSENS block to PMC. Added 2 x XBIC. Chapter Embedded Memories Added list of embedded peripherals that have local memory to features list in Overview section. The core SRAM supports zero single-cycle latency on processor local accesses. Information on standby RAM and standby voltage regulator added Corrections to flash memory segmentation and read-while-write partitioning figure Added new sentence to "Processor Core Local RAM" section describing single-cycle latency. Chapter Signal Description Signal muxing table moved to SIUL2 chapter.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Memory Map - Resized reserved address range 0xF8004000 to 0xFBE03FFF (was address range 0xF8004000 to 0xFBE07FFF) - Moved SARADC1 to address range 0xFBE04000 to 0xFBE07FFF (was address range 0xFFE04000 to 0xFFE07FFF) - Moved SARADC2 to address range 0xFBE08000 to 0xFBE0BFFF (was address range 0xFBE04000 to 0xFBE0BFFF) - Changed reserved address range 0xFFE04000 to 0xFFE0FFFF (was address range 0xFFE08000 to 0xFFE3BFFF) - Moved SARADC4 to address range 0xFFE10000 to 0xFFE13FFF (was address range 0xFBE10000 to 0xFBE13FFF) - Changed reserved address range 0xFBE10000 to 0xFBE17FFF (was address range 0xFBE14000 to 0xFBE17FFF) - Moved SARADC7 to address range 0xFBE1C000 to 0xFBE1FFFF (was address range 0xFBE1C000 to 0xFBE3FFFF) - Deleted CMU_CORE (was address range 0xFBFB0200 to 0xFBFB023F) - Added Clock Monitor Unit for Fast Crossbar (CMU_FXBAR) (address range 0xFBFB0200 to 0xFBFB023F) - Deleted CMU_SYS (was at address range 0xFBFB0240 to 0xFBFB027F) - Moved CMU_SXBAR to address range 0xFBFB0240 to 0xFBFB027F (was at address range 0xFBFB0280 to 0xFBFB02BF) - Moved CMU_PRIDGE to address range 0xFBFB0280 to 0xFBFB02BF (was at address range 0xFBFB02C0 to 0xFBFB02FF) - Moved CMU_PER to address range 0xFBFB02C0 to 0xFBFB02FF (was at address range 0xFBFB0300 to 0xFBFB03FF) - Moved CMU_ADCSD to address range 0xFBFB0300 to 0xFBFB033F (was at address range 0xFBFB0340 to 0xFBFB037F) - Moved CMU_ADCSAR to address range 0xFBFB0340 to 0xFBFB037F (was at address range 0xFBFB0380 to 0xFBFB03BF) - Deleted CMU_CAN (was at address range 0xFBFB03C0 to 0xFBFB03FF) - Moved CMU_PSI5_F189 to address range 0xFBFB03C0 to 0xFBFB03FF (was at address range 0xFBFB0480 to 0xFBFB04BF) - Moved CMU_SENT to address range 0xFBFB0380 to 0xFBFB03BF (was at address range 0xFBFB0440 to 0xFBFB047F) - Deleted CMU_FLEXRAY (was at address range 0xFBFB0400 to 0xFBFB043F) - Added CMU_PSI5_F125 (address range 0xFBFB0400 to 0xFBFB043F) - Moved CMU_PSI5_1US to address range 0xFBFB0440 to 0xFBFB047F (was at address range 0xFBFB04C0 to 0xFBFB04FF) - Added reserved address range 0xFBFB0480 to 0xFBFB04FF (was cmu_psi5_f189 and cmu_psi5_1us) - Added SWT_3 (address range 0xFC05C000 to 0xFC05FFFF) - Renamed FEC at address range 0xFC0B0000 to 0xFC0B3FFF to FEC_0 - Changed reserved address range 0xFFE04000 to 0xFFE0FFFF (was address range 0xFFE08000 to 0xFFE3BFFF) - Added Tamper Detection Module (TDM) to address range 0xFFFF34000 to 0xFFFF37FFF (was reserved address range) - Split DMAMUX address space (0xFFFF6C000 to 0xFFFF6FFFF) into its 6 (DMAMUX_0 - DMAMUX_5) component spaces plus reserved address space. - Changed reserved address range 0xFFFF6D400 to 0xFFFF7FFFF (was address range 0xFFFF70000 to 0xFFFF7FFFF)

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Memory Map (continued) - Deleted CMU_IOP at address range 0xFFFFB0200 to 0xFFFFB023F - Added CMU_PLL at address range 0xFFFFB0200 to 0xFFFFB023F Name of address range 0x00400080 - 0x0040009F changed from "Customer EDC after ECC Area" to "Flash ECC Error Words Area" Changes to Peripheral (PBRIDGE_A, PBRIDGE_B) Memory Map: 0xFBE20000 to 0xFBE3FFFF reserved space added - Requirements tag SCG05.061: Covers ADD06.016, ADD06.032, ADD06.047 added - Requirements tag SCG05.062: Covers ADD06.016, ADD06.019, ADD06.027, ADD06.047) Changes to RAM memory map - RAM address space split into two 64 KB ranges—64 KB standby RAM and 64 KB system RAM. 0x52800000 to 0x5280FFFF changed to 64 KB used (was 48 KB Changes to UTest flash memory map: 0x004000C0 to 0x004000C3 Soft DCFRecord Start Address record added 0x004000C4 to 0x004000FF Reserved space added - Address 0x00400000 contains a calculated constant used in die temperature calculation. - Address 0x00400002 contains a calculated constant used in die temperature calculation. Chapter Functional Safety New chapter Chapter Device Configuration Miscellaneous changes: "AIPS" changed to "PBRIDGE" New sections added: - Password and Device Security Module (PASS) configuration - Tamper Detection Module (TDM) Configuration Core modules section: - Footnote added to e200z4 reset settings table stating the levels that determine the bits are set by the factory and may change between revisions of the device. Crossbar switch configuration section: - Additional details added SMPU configuration section: - SMPU_HSM information moved to the <i>SPC57EM80xx Microcontroller Security Reference Manual</i> - New subsection added: Master Access permissions for SMPU0 - New subsection added: Master Access permissions for SMPU1

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Device Configuration (continued) Platform Configuration Module (PCM) section: • FBOMCR[ACCERR] field definition updated. • AHB_BE1[RSV] bit reset values changed to 0 (was undefined). • IAHB_BE1[RSV] field definition changed to read, "Reserved bits define the PRE, BRE and BWE of the bus gasket for the HSM." • IAHB_BE2[RSV] bit reset values changed to 0 (was undefined). Interrupt Controller (INTC) interrupt sources section: • Major rewrite of entire section. • Revised the descriptions and names for IRQs 558–593. • Deleted entries for IRQs 264, 265, 267, 273, 274, 276, 282, 283, 285, 291, 292, 294, 372, 373, and 375. • IRQ 266: removed DSPI_0_SR[DPEF]. • IRQ 275: removed DSPI_1_SR[DPEF]. • IRQ 284: removed DSPI_2_SR[DPEF]. • IRQ 293: removed DSPI_3_SR[DPEF]. • IRQ 374: removed DSPI_12_SR[DPEF]. New subsection added: Interrupt Latency DMACHMUX section updates: • DMAMUX peripheral DMA request to input source mapping table updated • Block diagram updated Memories and memory interfaces section: • New subsection added: Flash memory controller (PFLASH) configuration Timers section: • Secure SWT function clarified • New subsection added: Secure watchdog DSPI section: • Updated DSPI instantiation table, no LVDS support for DSPI2. • Updated DSPI2 instantiation for PCS signals. • Updated DSPI2 Instantiation for LVDS support and indicated DSPI12 availability in half duplex mode. CAN subsystem configuration section: • Updated MCAN CREL field values as per latest MCAN integration. DigRF and Signal Interprocessor Interface: • Block diagram updated New section added: Indirect Memory Access (IMA) configuration FCCU configuration section: • New subsection added: FOSU parameters • Register names changed to align with FCCU chapter Added Security Modules section, which includes: • PASS module • Tamper Detection Module (TDM)

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Device Configuration (continued) Updated SIPI/DigRF diagram and content Register protection section: Added SIUL2 protected registers: SIUL_IFER0, SIUL_IFMC0-SIULIFMC31, SIUL_IFCPR Offsets of all PMC_DIG protected registers have changed. Number of PMC_DIG protected registers in groups REE_VDn, RES_VDn, and CTL_TDn has changed. Added new section: IMA (Indirect Memory Access) protected registers Added new MC_RGM protected register group: RGM_PRSTn Chapter Reset and Boot No significant changes. Chapter Device Configuration Format (DCF) Records Added figure after UTEST DCF client table to describe bit positions of the UTEST Miscellaneous Register. Chapter Power Management Updated "Low power support and STOP mode implementation" section Deleted voltage regular safety implementation figure Flash uses the externally supplied 1.25 V for the low voltage supply, while high voltage (3.3 V) is being generated by a dedicated internal regulator. Chapter Security Noted that advanced security features require significant involvement Chapter Calibration and Debug Added text to core debug support section Added text to calibration section Added text to Debug DigRF section Added Debug over CAN section Chapter e200z4d Core Complex Overview EFPU2 Floating-Point Unit features section added LSP Lightweight Signal Processing Unit features section added Added "sign/zero bits" to bulleted item in Section 13.3.5: LSP Lightweight Signal Processing Unit features: Specialized operations such as field manipulation, count-leading sign/zero bits Chapter Core (z420n3) Overview In table for Machine Check Syndrome Register (MCSR) field descriptions, corrected positions of reserved bits (from 10:11 to 9:10) Vector integer non-MAC and Vector integer MAC columns were removed from Concurrent instruction issue capabilities table Vector integer MAC row was removed from Concurrent instruction issue capabilities table Footnote was added to Machine Check Syndrome Register regarding the setting of the MEA bit. The name of the DCECE bit was changed to DCPECE for all occurrences. The bit description of bit 21 of the DMEMCTL0 register was modified to include the stbdcbx, sthdcbx and stwdcbx instructions. The bit description of bit 22 of the DMEMCTL0 register was updated for clarity. The name of the ICECE bit was changed to ICPECE for all occurrences.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Core (z425n3) Overview In table for Machine Check Syndrome Register (MCSR) field descriptions, corrected positions of reserved bits (from 10:11 to 9:10) The Cache Registers L1CSR1 SPR 1011, L1FINV0 SPR 1016 and L1FINV1 SPR 959 were changed to L1CSR0 SPR 1010, L1CSR1 SPR 1011, and L1FINV1 SPR 959. Updated Concurrent instruction issue capabilities table to reflect additional capabilities. A footnote was added to the Machine Check Syndrome Register to reflect that the z420n3 does not have address translation so the MEA bit is always set to 0. Chapter System Integration Unit Lite2 (SIUL2) Signal muxing table added—was formerly in Signal Description chapter. Chapter Crossbar Switch (XBAR) Added sentence in Functional Description that describes how the crossbar returns all slave response information back to the requesting master. Chapter Crossbar Integrity Checker (XBIC) No significant changes Chapter Peripheral Bridge No significant changes Chapter System Memory Protection Unit (SMPU) No significant changes Chapter Intelligent AHB Gasket (IAHBG) No significant changes Chapter Semaphores2 (SEMA42) No significant changes Chapter Interrupt Controller (INTC) No significant changes Chapter Enhanced Direct Memory Access (eDMA) In Section 24.5.7, Dynamic programming removed subsection, "Dynamic channel linking and dynamic scatter/gather," and replaced with new subsections, "Dynamic channel linking" and "Dynamic scatter/gather". Chapter DMACHMUX No significant changes

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Clocking Updated device clock generation figure by adding the Ethernet clock selector and divider and modified the CAN clock divider to 1...64. Updated the "MC_CGM relationship to clocks" table to show the Ethernet (REF_CLK) being sourced by Auxiliary Clock 11 Select. Updated the "Clock generation" figure: - Removed duplicate clock source for the Ethernet (REF_CLK) that showed Aux. Clock 2 as the source - Added the Ethernet clock selector and divider and modified the CAN clock divider to 1...64. Updated all instances of μs representing microsecond to ms. Added "System Clock/GTM Output Clock/Ethernet Clock Pin Muxing" section. Added "TTCAN/MCAN clocking" section. Changed the signals names CLKOUT0, CLKOUT1 and SYSCLK to SYSCLK0, SYSCLK1 and CLKOUT, respectively. Chapter Dual PLL Digital Interface Updated equations 3 and 4 to $f_{VCO0} = \dots$ and $f_{VCO1} = \dots$ Chapter Clock Monitor Unit (CMU) Updated the CMU_FDR[FD] field description by changing CMU_MCR[MD] to CMU_MDR[MD] in the included formula. Chapter Clock Generation Module (MC_CGM) Aligned the register names in the memory map to those in the register descriptions. In the CGM_AC11_SC figure, changed the address offset (was 0x0940, is 0x0960). In the CGM_AC11_SS figure, changed the address offset (was 0x0944, is 0x0964). In the CGM_AC11_DC0 figure, changed the address offset (was 0x0928, is 0x0968). Revised the "Progressive system clock switching" section. Added the "Fractional divider details" section and a cross-reference to it from the CGM_AC5_DC0 section. Chapter OSC Digital Interface (XOSC) Reset value of XOSC[OSCBYP] updated to 1. Changed XOSC_CTL[RSTBYP] reset value to device specific entry of —. Updated XOSC_EN bit location in UTEST Misc row to 7 in "XOSC configurations" table. Chapter RCOSC Digital Interface Removed DEM_EN bit of CTL register Chapter RAM Controller (PRAM) No significant changes

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Flash Memory Controller Added new bullet to Calibration Overlay Summary describing per-master calibration remap capability. Added details to describe that calibration remapping will take effect immediately the cycle after PFCRCR[GRMEN] is enabled. PFDCDRE register renamed to PFCBRE Following deleted from Section 1.5.1.7.1, PFlash Calibration Region Descriptor n, Word0 (PFCRDn.Word0): “The hardware performs basic checks on the validity of the logical start address when this word is written; if a non-supported logical start address is defined, the register write is terminated with an error and the register left unchanged and the valid bit cleared.” Correction to PFlash Calibration Region Descriptor n, Word0 (PFCRDn.Word0) LSTARTADDR field description in Table 9 (PFlash Calibration Region Descriptor n, Word 0 description): bit range is 0-27 (was 31-4) Deleted from Section 1.5.1.7.2, PFlash Calibration Region Descriptor n, Word1 (PFCRDn.Word1): “Attempted writes to this register with illegal values, as defined by the sizes and locations of the overlay memories, are terminated with an error and clear the valid bit.” Correction to Section 1.6.19.2, Flash address generation check: failure in address generation or control logic or transmission path is forwarded to the FCCU (was MEMU). Also deleted following: “ The PFLASH_C55FM flash memory controller has a separate MEMU reporting interface associated with each AHB port, p0 and p1.” Chapter Embedded Flash Memory (c55fmc) Adjusted the definition of PFCR1[APC] Added timing diagrams for address pipelined accesses and read buffer misses Removed Interface Signal block diagram in Section 1.4 as it did not add any appreciable value to the document Updated Figure2 to depict two, separate on-chip RAM interfaces Added a warning that the programming model should not be updated while the flash controller is in use. Removed unused Section 1.7 Timing Diagrams Added new section: On-Chip Overlay RAM Feedback Check Corrected an error in the e2eECC calculation example under ‘Safety Considerations’ Added new bullet to Calibration Overlay Summary describing per-master calibration remap capability. Added details to describe that calibration remapping will take effect immediately the cycle after PFCRCR[GRMEN] is enabled. Chapter Decorated Storage Memory Controller (DSMC) No significant changes Chapter Configuring Flash Memory Write and Read Protection New chapter

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Analog-to-Digital Converters (ADC) Configuration Updated figure "Sigma-Delta ADC integration diagram" with Sigma-Delta input mux wrap-around and advance feature as well as watchdog trigger function and output to GTM channel. In "ADC overview", changed "256 FusionQuad ED" to "216 FusionQuad ED" Added "Sigma-Delta Mux Input Advance and Wrap Around" section Updated figure "SAR ADC integration diagram" to add SAR watchdog trigger output to GTM channel. In SAR ADC analog input pin multiplexing section: changed "Analog input pins in the 292 BGABGA292 that only connect to SAR ADCB use a single analog switch pad cell." to "Analog input pins that only connect to SAR ADCB use a single analog switch pad cell." Throughout: - CLKEXT changed to EXT_CLK - BEXT changed to EXT_DATA - Vddm changed to VDD_HV_ADV - Vssm changed to VSS_HV_ADV - Vss changed to VSS_LV - Vdd changed to VDD_LV - SARB changed to SARADC_B - SAR ADC or SARn -> SARADC or SARADC_n Removed "Sigma-Delta ADC external signal description" and "SAR ADC external signal description" sections as they are a duplicate of what is in the pin description chapter. Sigma-Delta ADC integration diagram: Updated signal names: MUX_ADV, DMA_IRQ_EN, VALID_DATA_AVAILABLE, WATCHDOG_LIMIT_TRIGGER In Clock Skew section, changed "decimation" to "oversampling", removed last sentence of first paragraph, removed 2nd paragraph (single sentence). Changed section heading from Clock/data inputs to "External modulator clock/data inputs" Changed section heading from Clock output to "External modulator clock outputs" Changed section heading from Conversion result interrupt/DMA gating signal to "Conversion result Interrupt/DMA" In "SAR ADC clock sources" section, changed 14.4 to 14.6: "The maximum frequency for the clock input to the converter is 14.6 MHz" In "SAR ADC diagnostic" section, changed VAREF1 to VDD_HV_ADR_S, and VAGND1 to VSS_HV_ADR_S - Updated figure: "Analog input pin pullup/pulldown pad cell" - Updated figure: "Analog input AN35 — discharge switch to AVSS" - Updated table: "SAR analog input channel assignment" - Updated table: "SARADC_B analog test channel assignment" and changed input channel 105 to VDD_HV_IO_EBI. Added the following to "Conversion result interrupt/DMA" section: "A DMA or interrupt can be generated for each conversion for each ADC. The Sigma-Delta ADC has an 8-deep result FIFO." Added "Conversion Limit Watchdog Output to GTM" section. Added "TOM/ATOM" signal names to "SARADC input trigger diagram" figure. Also added shaded box and changed "System Integration" to "SIUL2" Added following note to Section 39.2.2.2, "SAR ADC analog input pin multiplexing": "Simultaneous sampling of two ADCs on same analog input is not allowed." In Table 584 (SARADC_B analog test channel assignment), changed Description for input channel 109 from Reserved to VAGND1 (SARADC ground reference). Added CRES bit to SARx_CTR0–3 register definition tables. Added NTRGEN and NEDGESEL fields to SARx_MCR registers.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface Added four new conditional text tags • WDG_monitor_no in Table 618., Conditional Text Tags. Added two new features in Section 40.3, Features Added a new row in Table 602., SDADC Digital interface memory map Added 1-bit wide fields 'WDGEN' and 'WRMODE' in Section 40.6.2.1, Module Configuration Register (MCR). Added 3-bit wide field 'ANCHSEL_WRAP' in Section 40.6.2.2, Channel Selection Register (CSR). Added description of 'wraparound mode' in 'ANCHSEL' field of Section 40.6.2.2, Channel Selection Register (CSR) Added 3-bit wide field 'ANCHSEL_CNT', two 1-bit wide fields 'WTHH' and 'WTHL' in Section 40.6.2.4, Status Flag Register (SFR). Added two 1-bit wide fields 'WTHDIRS' and 'WTHDIRE' in Section 40.6.2.5, Request Select and Enable Register (RSER). Added a new register, Section 40.6.2.10, WDG Threshold Register (WTHHLR) Added 'Wraparound Control Mechanism' description in Section 40.7.8, Data conversion and Section 40.7.9, Hardware triggering. Added a description of 'WDG threshold crossover event' in Section 40.7.10, Interrupt/DMA request support. Chapter Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface Added a new sub-feature in Section 41.3, Feature description. Updated Section 41.4.8, Programmable analog watchdog Added new bit, WTRIGCUT in Section 41.5.1.1, Main Configuration Register (MCR). Chapter Temperature Sensor Following text added to Section 4.3.1, Temperature threshold detection (digital output generation): The threshold detection circuit is calibrated in respect to the factory-test temperatures: the low temperature threshold is trimmed to match the cold insertion test temperature (nominally equal to –40C) and the high temperature thresholds are trimmed such that one of them matches the hot insertion test temperature (nominally equal to 150 °C or 165 °C). In other words, the thresholds are not trimmed to absolute values of temperature but to the specific temperatures for which the device is validated during factory test. Chapter Timers Overview No significant changes Chapter System Timer Module (STM) No significant changes Chapter Software Watchdog Timer (SWT) Features section, 2nd buttlet. Changed to 'Internal 16MIRC oscillator clock is used for timer operation'. SWT_CR: Replaced CSL bit with Reserved. Periodic Interrupt Timer (PIT) No significant changes

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter CAN Subsystem • In the MCAN CCR register field descriptions table, corrected bit 29 to ASM and bit 30 to CCM. • In the MCAN Bit Timing and Prescaler Field Descriptions table, removed last two rows. • In the MCAN ECR figure and field descriptions, corrected bit 16 as RP and bit 17:23 as REC. • In the MCAN Global filter configuration register field descriptions table, corrected bits 28:29 as ANFE. • In the MCAN Standard ID Filter Configuration register figure, corrected LSP[7:0] to LSS[7:0] • In the MCAN Extended ID Filter Configuration register, corrected FLSSA[15:2] to FLESA[15:2] • Added a note in the M_CAN Feature list • In the MCAN Rx FIFO 1 Status register figure, added new bits 0:1 as DMS • Updated Standard Message ID Filter Element table • Updated Extended Message ID Filter Element • Added a note in the M_CAN BTP register • Updated MCAN Message RAM Configuration diagram • Added Interface to DMA Controller section • In Detailed mapping in CAN subblocks table, in the first comment, replaced SIDFC[SAFLS] with SIDFC[FLSSA]. In the second comment, replaced XIDFC[SAFLE] with XIDFC[FLESA]. Added a new row for debug messages MCAN block. • In the M_CAN message memory size requirement table, added, added a new row for the Rx Status FIFO 1 element. • Removed reference to PBRIDGE1 from the CAN subsystem generic block diagram • Updated MCAN CREL and TTCAN CREL register figure footnote. • Updated M_CAN message memory size requirement table • Added debug messages rows for each MCAN instance in the “Updated Shared memory map vs CAN transmit, receive and filters elements” table. • Updated MCAN Standard Message ID Filter Element table and figure • Updated MCAN Extended Message ID Filter Element table and figure Chapter Serial Interprocessor Interface (SIPI) No significant changes Chapter Deserial Serial Peripheral Interface (DSPI) • Renamed SDR to SDR0, ASDR to ASDR0, COMP1 to COMP0, DDR to DDR0, SSR to SSR0, DIMR to DIMR0, and DPIR to DPIR0. • Added New 32 bit Registers SDR1, ASDR1, COMP1, DDR1, SSR1, DIMR1, DPIR1, PISR4, PISR5, PISR6, PISR7, CTARE0-7, SREX. • Updated Features section about 8 extended CTAR registers; programmable serial frame size upto 64 bits; DMA Support for CMDFFF and DDIF; Interrupt Support for CMDFFF, CMDTCF, TFIWF. • Updated DSPI Memory Map • Added XSPI bit to MCR register • Added FMSZ6 to CTAR_SLAVE Register • Added BSYF, CMDTCF, CMDTFFF and TFIWF fields to SR register. • Added CMDTCF_RE, CMDTFF_DIRS, CMDTFFF_RE, TFIWF_RE, DDIF_DIRS fields to RSER Register.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Deserial Serial Peripheral Interface (DSPI) (continued) • Updated PUSHHR, TXFRn Register Descriptions. • Added FMSZ[5] field to DSICR0 • Updated "Serial Peripheral Interface (SPI) Configuration" functional description to mention about CMD FIFO and the new XSPI Mode and its usage. • Updated "Deserial Serial Interface (DSI) configuration" functional description to mention about the new DSI64 Mode and its usage. • Added a Note to "Multiple Transfer Operation (MTO)". • Updated "Combined Serial Interface (CSI) configuration" to include effects of the new XSPI and DSI64 modes. • Added "Command FIFO Fill Interrupt or DMA Request", "Transmit FIFO Invalid Write Interrupt Request", Command Transfer Complete Interrupt Request", "Deserialized Data Match DMA Request" to "Interrupts/DMA Requests". • Added "Address Calculation for first-in-entry and last-in-entry in the CMD FIFO. • Updated figures "DSPI Block Diagram", "DSI Serialization Diagram", "DSI Deserialization Diagram", "TSB Downstream Frames", and "TSB Data Frame Format for MSC Dual Receiver Operation". • Updated PUSHHR[CONT] bit description. • Updated Stop Mode, Module Disable Mode descriptions under Power Saving Feaures. • Updated DSPIx_PUSHHR and DSPIx_PUSHHR_SLAVE Register descriptions. • Added content to De-serial Serial Interface (DSI Mode) Functional Description. • Modified constraint on FMSZ field in DSPI_CTAR Register description. • Updated MCR[XSPI] register bit description. • Updated DSPI_PUSHHR description Chapter DigRF - Interprocessor Communications Added TISR, RISR and RIISR to the "DigRF memory map table. Chapter Fast Ethernet Controller (FEC) In the "FEC register map" table, changed "FIFO Receive FIFO Start Register" to "FIFO Receive Start Register" to align to the actual register name. In the "Functional description" section, added the "MII data frame" and "MII management frame structure" subsections. Added introductory content to the "Functional description" section. Chapter FlexRay Communication Controller (FlexRay) StopWatch logic description added Updated PLL Clocking section Chapter Inter-Integrated Circuit (I2C) Modified section 1.6.3.3 and 1.6.5.2 for stop mode generation in DMA Rx mode Moved content from the IBFD register description to its own section, "Clock rate and IBFD settings".

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Peripheral Sensor Interface (PSI5) Section 51.3.2.5, General Interrupt Control Register (PSI5_GICR): added field IE_INVALID_CMD_LEN Section 51.3.2.9, General Interrupt Status Register (PSI5_GISR): added field IS_INVALID_CMD_LEN Section 51.3.2.30, Data Output Block Configuration Register (PSI5_DOBCR): updated various fields Section 51.3.2.36, Data Preparation Register Low (PSI5_DPRL): updated to remove "Sensor Address and control Region" bits and to renumber the "Command Payload Region" bits Section 51.3.2.38, Data Buffer Register Low (PSI5_DBRL): updated register fields and note Section 51.3.2.39, Data Buffer Register High (PSI5_DBRH): updated register fields and note Section 51.3.2.40, Data Shift Register Low (PSI5_DSRL): updated register fields and note Section 51.3.2.41, Data Shift Register High (PSI5_DSRH): updated register fields and note Updated Section 51.4.3.4, Data transmission Updated Section 51.4.3.4.2, Data Preparation Register (64-bit register, DPRH + DPRL, DPRH is fixed at 0) Updated Section 51.4.3.4.3, Data Buffer Register (64-bit register) Updated Section 51.4.3.4.4, Data Shift Register (64-bit register) Updated Section 51.4.5, Interrupt handling Updated figure Data transmission block Updated figure ECU-to-sensor communication registers (implementation of Figure 1026) Change from MK Cut1: Updated the Stop mode description in Section 51.1.3.4, Stop mode Updated the description in Section 51.1.3.5, Debug mode to explicitly include HardWare clearing bits and the DMA message registers effected. Change from MK Cut1: Removed the dependency of the "DEBUG_EN" to enter the Debug mode. Updated Figure 973 to make PCI5_CH_CONFIG = "x" in the Normal state and PCI5_CH_CONFIG = "0" when moving from Config to Normal and also updated Table 1005 to reflect the changes. Change from MK Cut1: Removed the 3us constraint for switching among different modes(Normal-Disable-Config) Added Bullet-10 , in Table 1007 to show the reset value of GCR register dependency on the parameter PSI5_DIS_RST which is taken from the Device COnfiguration File. Updated the description of GLOBAL_DISABLE_REQ in Section 51.3.2.1, Global Control Register (PSI5_GCR) to show the reset value of GCR register dependency on the parameter PSI5_DIS_RST which is taken from the Device COnfiguration File Change from MK Cut1: Removed Debug_en bit from Section 51.3.2.2, PSI5 Channel Control Register (PSI5_PCCR) Updated the description of DSR_RDY, DBR_RDY and DPR_RDY in General Interrupt Status Register (PSI5_GISR). Updated the Bit 310 in Figure 989 , to "unwriteable" in test mode as this bit is the overwrite bit.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Peripheral Sensor Interface (PSI5) (continued) Updated the Bit 274 in Figure 990 , to “unwriteable” in test mode as this bit is the overwrite bit. Change from MK Cut1: Replaced the statement “As a corner caselater slot S1” in NOTES section after end of Table 1033 to “If S0 and S1 are...first slot(S0)” Added to the bit DRL description in Table 1034 , “..and optional messaging bits M0,M1” Added the statement “ As a special case if “S0” and “S1” are detected in different slots then NO T-bit error is set” in Section 51.3.2.29, Slot n End Boundary Register (PSI5_SnEBR) Change from MK Cut1: Replaced the statement As a special case if “S0” and “S1” are detected in different slots then NO T-bit error is set “ to “As a special case if “S0” and “S1” are detected in different slots then a T-bit error is set “. Change from MK Cut1: Added register bits and their descriptions , DATA_LENGTH[5:0] , CMD_TYPE[2:0] and SW_READY in Section 51.3.2.30, Data Output Block Configuration Register (PSI5_DOBCR) . Changed V13_EN bit name to DEFAULT_SYNC in Section 51.3.2.30, Data Output Block Configuration Register (PSI5_DOBCR) Updated the description of MDDIS_OFF in Section 51.3.2.31, Manchester Decoder Disable Offset Register (PSI5_MDDIS_OFF) Change from MK Cut1: Updated with the new jitter values , the NOTES section at the end of Table 1043 The whole description in Section 51.3.2.36, Data Preparation Register Low (PSI5_DPRL) updated to make it more clear , regarding the CRC dependence of the DPR[23:0] bits and the arrangement of data/address. Change from MK Cut1: Section 51.3.2.36, Data Preparation Register Low (PSI5_DPRL) updated to show the dependency of DPR[23:0] bits on CMD_TYPE[2:0] configuration. Updated NOTES section at end of Table 1044 Change from MK Cut1: Section 51.3.2.38, Data Buffer Register Low (PSI5_DBRL) updated to show the dependency of DBR[31:0] bits on CMD_TYPE[2:0] configuration. Updated NOTES section at end of Table 1046. The whole description of DBR[42:32] in Section 51.3.2.39, Data Buffer Register High (PSI5_DBRH) updated to make it more clear , w.r.t bit assignments . Change from MK Cut1: Section 51.3.2.39, Data Buffer Register High (PSI5_DBRH) updated to show the dependency of DBR[63:32] bits on CMD_TYPE[2:0] configuration. The DBR length increased to 64 bits. Updated NOTES section at end of Table 1047. The whole description of DSR[31:0] in Section 51.3.2.40, Data Shift Register Low (PSI5_DSRL) updated to make it more clear , w.r.t bit assignments . Change from MK Cut1: Section 51.3.2.40, Data Shift Register Low (PSI5_DSRL) updated to show the bit assignment of DSR[31:0] bits and it dependency on SW_READY bit . Updated NOTES section at end of Table 1048. The whole description of DSR[42:32] in Section 51.3.2.41, Data Shift Register High (PSI5_DSRH) updated to make it more clear , w.r.t bit assignments . Change from MK Cut1: Section 51.3.2.41, Data Shift Register High (PSI5_DSRH) updated to show the bit assignment of DSR[63:32] bits and it dependency on SW_READY bit . The DSR length increased to 64 bits. Updated NOTES section at end of Table 1049.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Peripheral Sensor Interface (PSI5) (continued) Added Bullet 2 to show the separate description of DPRL in Section 51.3.2.42, Device modes and Register bit accesses Section 51.3.2.42, Device modes and Register bit accesses also updated with other minor updates. Updated Figure 1020. Change from MK Cut1:Updated Section 51.4.3.4, Data transmission to include the complete support for standard length PSI5 frames and the non standard length frames.Updated Figure 1024 Change from MK Cut1:Updated Figure 1025 to include the enhanced ECU to Sensor communicatio support. Change from MK Cut1:Updates in Section 51.4.3.4.2, Data Preparation Register (64-bit register, DPRH + DPRL, DPRH is fixed at 0) and Section 51.4.3.4.3, Data Buffer Register (64-bit register) and Section 51.4.3.4.4, Data Shift Register (64-bit register). Updates in Section 51.4.3.4.5, Sync Pulse Trigger Generation and addition of "Programming and Control" bullet in the section. Updates in Section 51.4.3.4.5.1, Timing Pulses. Change from MK Cut1:Update in Figure 1026 to include the DEFAULT_SYNC bit and initialisation of all bits of DSR register to all "DEFAULT_SYNC" when DSR_RDY == 1. Change from MK Cut1:Update in Figure 1028 to show the control of GLOBAL_DISABLE_REQ bit also on _en(clock enables) of "rx" clock and "psi5" clock Change from MK Cut1:Update in 2nd bullet of "Jitter Related •" of Section 51.5.0.1, Latency and Jitter related requirements to show the jitter as "20ns". Change from MK Cut1:Updated Figure 1031 to show the updated jitters Added in the timestamp description in the data registers PSI5 Message Register High i (PSI5_PMRHi) {i: 0 to 31} etc. as "where "F" bit has been set ; the value of the Time Stamp appended to the message is "0" " Inserted Register sections in Section 51.4.6.1, Single DMA request for PSI5/diagnostic message buffers and Section 51.8.1, Internal SYNC Pulse generation and coordination across PSI5 channels Chapter SENT Receiver (SRX) No significant changes Chapter LINFlexD Added a note regarding baud rate under UART Mode features. Added a note in RDI field of LINSR register. Removed the Access and Reset value columns from Memory map table. Minor Editorial changes in the document Modified the LINS[3:0] fields of LINSR register from "w1c" to "read-only" Added table "Example of IBRR/FBRR and baud rate generated" under "Baud rate generation section" Updated note in "Baud rate generation section" Modified the description of DTU field from DISABLE timeout to RESET timeout in UARTCR register Removed line "PC[1:0] bit do not have any effect in parity" from 13-bit frames in "UART mode" section Modified "Example of IBRR/FBRR and baud rate generated" table

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Reset Generation Module (MC_RGM) Revised the definitions of the RGM_PRSTn registers. RGM_FBRE[BE_FCCU_HARD] reset value (was 0, is 1). RGM_FERD[D_JTAG_FUNC] bit type (was read/write, is read-only). Deleted the RGM_FEAR[AR_JTAG_FUNC] field (is reserved). Chapter Boot Assist Flash (BAF) Updated Table 10 Added soft DCF client, Secure watch dog, Callback and ADDR and DATAxx DCF client section Updated Figure 1 to incorporate DCF client Initialization. Chapter System Status and Configuration Module (SSCM) Added safety measures to Initialization and application information section Chapter Power Management Controller digital interface (PMC_dig) Significant updates to clarify design definition. Chapter Power Control Unit (MC_PCU) No significant changes Chapter Mode Entry Module (MC_ME) Register and field name changes: • PIT_RTI_0 to PIT_RTC_0 • DMA_CH_MUX0 to DMAMUX_0 • CRC_A0 to CRC_0 • ADCSD_A2 to ADCSD_4 • ADCSD_A1 to ADCSD_2 • ADCSD_A0 to ADCSD_0 • CAN_RAM_CTRL0 to CAN_RAM_CTRL • LINFlexD_A1 to LINFlexD_1 • LINFlexD_A0 to LINFlexD_0 • DSPI_A2 to DSPI_4 • DSPI_A1 to DSPI_1 • DSPI_A0 to DSPI_0 • IIC_A0 to IIC_0 • SENT_A0 to SENT_0 • FlexRay_A0 to FLEXRAY • PSI5_A0 to PSI5_0 • ADCSARB to ADCSAR_b • ADCSAR_A0 to ADCSAR_0 • CRC_B0 to CRC_1 • ADCSD_B2 to ADCSD_5 • ADCSD_B1 to ADCSD_3 • ADCSD_B0 to ADCSD_1 • LINFlexD_B0 to LINFlexD_2 • DSPI_B0 to DSPI_5 • DSPI_B1 to DSPI_3 • DSPI_B2 to DSPI_2 • SENT_B0 to SENT_1 • PSI5_B0 to PSI5_1

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Mode Entry Module (MC_ME) (continued) • ADCSAR_B4 to ADCSAR_6 • ADCSAR_B1 to ADCSAR_3 • ADCSAR_B0 to ADCSAR_2 In the "MC_ME register description" table, added entries for the following registers: • ME_PCTL31 • ME_PCTL85 In the "MC_ME register description" table, added requirement tags for the following registers: • ME_PCTL68 • ME_PCTL69 • ME_PCTL70 • ME_PCTL72 In the "MC_ME register description" table, deleted the following registers: ME_PCTL90 In the "MC_ME register description" table, added entries for the following registers: • ME_PCTL93 • ME_PCTL123 • ME_PCTL128 • ME_PCTL213 • ME_PCTL248 • ME_PCTL254 In the "MC_ME register description" table, deleted the following registers: • ME_PCTL126 • ME_PCTL164 • ME_PCTL219 • ME_PCTL250 • ME_PCTL251 Added the I_ICONF_CC field to the ME_IS register. Added the M_ICONF_CC field to the ME_IM register. Revised the definition of the ME_DMTS register. Added the S_PIT_RTC_1 and S_SIPI_0 fields to the ME_PS0 register. Added the S_LINFlexD_14 field to the ME_PS2 register. Revised the definition of the ME_PS3 register. Added the S_GTMINT field to the ME_PS4 register. Deleted the S_DMA_CH_MUX1 field from the ME_PS5 register. Revised the definition of the ME_PS6 register. Revised the definition of the ME_PS7 register. In the "MC_ME memory map" table, added fields to the ME_CS register (to align with the subsequent definition). Revised the definitions of the ME_CCTL registers. In the "MC_ME memory map" table, added entries for ME_CADDR1...4. Added the RMC field to the ME_CADDR registers. In the ME_RESET_MC and ME_DRUN_MC sections, added a note about chip configuration.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Mode Entry Module (MC_ME) (continued) Revised the field descriptions of the ME_CS register. Split the ME_CCTLn section into several sections, each describing one register. Split the ME_CADDRn section into several sections, each describing one register. In the “DRUN mode” section, added “The clock source configuration except system clock source 0 can be chosen by preloaded information in flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.” Revised the “SAFE mode” section. In the “Target mode request” section, deleted “including DRUN, RUN0...3, and TEST”. In the “MC_ME resource control overview” table, revised the entries for IRC and MVREG. In the “Peripheral clocks disable” section, added “ and the system clock frequency ramp-down of the System clock switching step”. Renamed “Processor and system memory clock disable” to “Processor clocks disable” and replaced the section's content. Deleted the “Additional Core Clocks Disable” section. Added the “System clock disable” section. Deleted the “Processor and Memory Clock Enable” section. Added the “System and processor clocks enable” section. Deleted the “Additional Core Clocks Enable” section. In the “System clock switching” section, deleted “if the value of the PWRLVL field of the ME_<target mode>_MC register is greater than that of the one of the ME_<current mode>_MC register,”. In the “Clock sources switch-off” section, added “For the clock sources related to the system clock”. In the “Flash memory switch-off” section, changed “This step is executed only when the Processor and System Memory Clock Disable process has completed” to “This step is executed only when the processor clocks disable and system clock disable processes have completed.” In the “Current mode update” section, changed “(halt/stop)” to “(stop)”. Replaced the Processor low-power mode exit” section. Chapter e200z4 Core Debug Support Split into two chapters—one for the e200z420n3 and one for the e200z425n3 Chapter Debug and Calibration Interface (DCI) Section 82.1.3, Operating modes updated for the usage of JTAGM_MCR[jtagm_JCOMP] when DCI is in DigRF mode Section 82.1.3.2, VSS detection updated to clarify the usage of LVDS fault condition not affecting operations of Nexus blocks. Corrected rev history Tagged Section 82.1.3.4, Nexus reset control with ADD23.138 (BLG_DCI_0046) Corrected the reference JTAGM_MCR[JCOMP] to JTAGM_MCR[jtagm_JCOMP] as used in JTAGM Block Guide Added tags to Synchronous restart control section Added bullet with tag (BLG_DCI_0047) to Break control section Added title to Enable Escape Mode field of DCI_CR

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter JTAG Controller (JTAGC) No significant changes
		Chapter IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG) No significant changes
		Chapter JTAG Data Communication (JDC) Updated Table 1310 to change JIN_WRITE opcode from 0x00011 to 0x01110.
		Chapter Sequence Processing Unit (SPU) No significant changes
		Chapter JTAG Master (JTAGM) Changed reset value of MCR from 0x0300_0002 to 0x0000_0002 Added a note in JTAM_MCR register Added section "JTAGM JCOMP usage in DigRF" Added table "Chapter type/source information" at the beginning of the BG
		Chapter DigRF - High Speed Debug No significant changes
		Chapter Development Tool Semaphore (DTS) No significant changes
		Chapter Nexus Aurora Router (NAR) Added NAR message formats table
		Chapter e200z4 Nexus 3 Module Split into two chapters—one for the e200z420n3 and one for the e200z425n3
		Chapter GTM Development Interface (GTMDI) Added section 1.5.9 Fetch trace Changed all references to NPC by NAR. Added DPLL and ARU Data Trace description in Features and Data Trace specific sections. Added Notes about timestamp meaning (no meaning) in Error Messages. Changed HWO bit description in Table 31 Fixed DPLL Data trace message Added Timestamp field description for Nexus messages Fixed conditional text Added note about GTM IP reset related to Fetch End message. Added a note after Figure 34 to explain fields are relative to MCS address map, not CPU map. Added a note after Figure 39 to explain fields are relative to MCS address map, not CPU map. Changed SRC value in Table 50 to 0x7 which is the usual SRC value for several devices (this is a variable that can be changed in the future). Added a footnote for Table 50 to explain FSCNT field. Added info about FSCNT in section 1.5.9.2/92. Added a note in section 1.5.9.2/92 about the MCS multi-thread behavior.

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Nexus Crossbar Multi-Master Client (NXMC) No significant changes Chapter Cyclic Redundancy Check Unit (CRC) Modified CRC unit memory map and registers. Chapter Memory Error Management Unit (MEMU) No significant changes Chapter Indirect Memory Access (IMA) All new content Chapter Fault Collection and Control Unit (FCCU) Removed Dual rail protocol (slow switching modes) diagram Removed Dual rail protocol (fast switching modes) diagram Removed time switching protocol diagram Removed Bi-stable protocol diagram Modified description of FCCU_SET_CLEAR field of FCCU_CFG register Changed all occurrences of FCCU_CFS0_3 to FCCU_CF_S0_3 Changed all occurrences of FCCU_NCFS0_3 to FCCU_NCF_S0_3 Changed all occurrences of FCCU_NCFE0_3 to FCCU_NCF_E0_3 for defect 8605 - Register naming leads to conflicts Replaced all occurrences of FCCU_NAFS with N2AF_STATUS Replaced all occurrences of FCCU_NFFS to N2FF_STATUS Replaced all occurrences of FCCU_NAFS with N2AF_STATUS Replaced all occurrences of FCCU_AFFS with A2FF_STATUS Replaced all occurrences of FCCU_FAFS to F2A_STATUS In FCCU AF Freeze Status Register (A2FF_STATUS) replaced SRC field with AF_SRC In FCCU NF Freeze Status Register (N2FF_STATUS) replaced SRC field with NF_SRC In FCCU FA Freeze Status Register (F2A_STATUS) diagram changed FAFS field from 9 bits wide to 8 bits wide Added a note in FCCU CF Fake Register (FCCU_CFF) description Added a note in FCCU NCF Fake Register (FCCU_NCFF) description In FCCU Transient Register (FCCU_TRANS_LOCK) diagram modified TRANSKEY field from 7 bits to 8 bits In FCCU Transient Register (FCCU_PERMNT_LOCK) diagram modified PERMNTKEY field from 7 to 8 bits Added a table "FCCU error pin behavior" under section "EOUT interface" Modified 12th bullet point in "Introduction" section Modified "EOUT interface" section Modified the description of FCCU_SET_CLEAR field of FCCU_CFG register Changed reset values of all the bits from "0" to "1" of FCCU_EOUT_SIG_EN0..3 register Added a note to the description of EOUTENx field of FCCU_EOUT_SIG_EN0..3 register Updated FCCU Output Supervision Unit (FOSU) section

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Self-Test Control Unit (STCU2) No significant changes Chapter Register Protection (REG_PROT) No significant changes Chapter ASC Modeling Unit No significant changes Chapter Wakeup Unit (WKPU) No significant changes Chapter GTM103 Integration (GTMINT) Module No significant changes Chapter Emulation Device Introduction No significant changes Chapter Buddy Device Crossbar and RAM No significant changes Chapter Buddy Device-System Integration Unit Lite (BD_SIUL2) No significant changes Chapter Buddy Device-Debug and Calibration Interface (DCI) Section 82.1.3, Operating modes updated for the usage of JTAGM_MCR[jtagm_JCOMP] when DCI is in DigRF mode Section 82.1.3.2, VSS detection updated to clarify the usage of LVDS fault condition not affecting operations of Nexus blocks. Corrected rev history Tagged Section 82.1.3.4, Nexus reset control with ADD23.138 (BLG_DCI_0046) Corrected the reference JTAGM_MCR[JCOMP] to JTAGM_MCR[jtagm_JCOMP] as used in JTAGM Block Guide Added tags to Synchronous restart control section Added bullet with tag (BLG_DCI_0047) to Break control section Added title to Enable Escape Mode field of DCI_CR Chapter Buddy Device-JTAG Controller (JTAGC) No significant changes Chapter Buddy Device - JTAG Master (JTAGM) Editorial updates throughout the document Removed "Access" and "Reset Value" columns from the Memory Map table. Added "FSL_Specific" and "ST_Specific" tags in Conditional text table. Added description of "non_cust" tag. Changed reset value of MCR from 0x0300_0002 to 0x0000_0002 Added a note in JTAM_MCR register Added section "JTAGM JCOMP usage in DigRF" Added table "Chapter type/source information" at the beginning of the BG

Table 2152. Document revision history (continued)

Date	Revision	Changes
01-Mar-2012	3 (continued)	Chapter Buddy Device-Nexus Aurora Router (NAR) Added NAR message formats table Chapter Buddy Device-Nexus Aurora Link (NAL) Added offsets to NAL memory map table Changed reset value of GSR bit 19 to one Bits 27–23 of TCR must be written with zeros. Chapter Buddy Device-Nexus Aurora PHY (NAP) No significant changes Chapter Buddy Device-Nexus Read Write Access (RWA) No significant changes Chapter Buddy Device - DigRF - High Speed Debug No significant changes
06-Jun-2013	4	Throughout – “MCAN” changed to “M_CAN” – “TTCAN” changed to “M_TTCAN” – DigRF replaced by LFAST (LVDS Fast Asynchronous Serial Transmission) – The combination of SIPI running on top of the LFAST interface is now referred to as Zipwire® – Removed ASC Modeling Unit (AMU) content Chapter Preface Following note added: “Any register bit described as “Reserved” should not be written. Reserved bits are not intended for customer use.” Section 1.1, Acronyms and abbreviations: – DTS definition changed to “Development Trigger Semaphore” (was “Development Tool Semaphore”) – FCCU definition changed to “Fault Collection and Control Unit” (was “Fault Control and Collection Unit”) Chapter Introduction Statement added: “For this reason, safety measures have been added which are further described in Chapter 6, Functional Safety, as well as the SPC57EM80xx Safety Manual”. Correction: I/O Processor (IOP) does not have internal data cache. Changes in features list: – Clarification of on-chip SRAM: “Up to 450 KB of total on-chip SRAM (128 KB general purpose SRAM, 192 KB data RAM, 48 KB instruction RAM, 35 KB GTM RAM, 16 KB overlay RAM, and 32 KB peripheral RAM)” – Item describing Boot Assist Flash support of factory programming via serial bootloader updated to include UART/LIN. – Correction: The SPC57EM80xx GTM103 has 34 KB of RAM (was 35 KB) – Specification change: CPU cores are not dual-issue – Added detail to on-chip SRAM item. – Changed Flash fetch accelerator description to, “Two 64-bit AHB ports, 256-bit read data interface. Each AHB port contains 4-entry, 2-way set-associative mini-cache”. (was “4 × 256-bit”)

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Introduction (continued) Changes to Block diagram figure: – Changed figure 1 to include “Triple INTC” and added Standby Regulator. Changes to Periphery allocation figure: – Changed “Peripheral Cluster A” to “Peripheral Cluster B”. – Changed “Peripheral Cluster B” to “Peripheral Cluster A”. – PS15_S_0 added to Peripheral Cluster B – Removed AMU – Added 32 KB RAM to Peripheral Cluster A Chapter Embedded Memories Extraneous flash layout removed from Figure 6 (Flash memory segmentation and read-while-write partitioning) Section 3.2.2.1, Standby voltage regulator deleted Section 3.2.2, Standby SRAM Regulator – First paragraph: changed “Standby SRAM functions....” to “The 64 KB standby SRAM on the MCU functions...” – 2nd paragraph replaced: “Change 2nd paragraph to: “The 64 KB standby RAM array is optionally powered by the VDDSTBY pin on the MCU. When the MCU core supply (VDD_LV) is powered down, the standby RAM contents can be maintained by supplying the VDDSTBY pin. See Section 59.7, Standby RAM Regulator Interface Logic, for more information on the VDDSTBY pin and the standby SRAM regulator.” – 3rd paragraph: Deleted (was “The standby regulator includes a switch to switch between core voltage and standby voltage; and a brown out detection circuit to detect when the standby supply has dropped below the RAM retention voltage”) – Clarification: There is 64 KB of standby SRAM – Details regarding brownout detection moved to PMC Digital Interface chapter Following sentence added to Section 3.2.3, Overlay SRAM: “Code can be executed from internal overlay RAM and extended overlay RAM where available. Execution from overlay RAM remapped over Flash can be enabled or disabled by use of PFCRCR[IRMEM]. Code can be executed directly from Extended Overlay RAM (address range beginning 0x0C000000) on the ED device or internal Overlay RAM (address range beginning 0x0D000000) regardless of the PFCRCR[IRMEM] setting.” – Section 3.3.3, Selecting flash blocks and all subsections deleted. Please see Chapter 37: Flash Memory Programming and Configuration for related content.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Signal Description <i>Note: I/O signal muxing information now appears in a Microsoft Excel® workbook attached to the device reference manual.</i> Section 4.4.1, Pin/ball startup and reset states: Table 6 (Pin/ball startup and reset states)—pin state changes: – TDI pin <i>startup state</i> is Weak pullup (was High-impedance) – TDO pin <i>State during reset</i> is High-impedance (was Weak pullup) – TMS pin <i>startup state</i> is Weak pullup (was High-impedance) – ESR0 <i>State during reset</i> is Output, strong pulldown (previously stated as Output, open drain) – Footnote clarification: “Analog input without output function—weak pull-up/weak pull-down can be activated only after reset sequence completion” – Footnote added: “F0 is also referred to as ERROR0 and FI0.” – Footnote added: “The SPC57EM80xx MCU does not implement a system configuration pin—TESTMODE is the only pin that affects device configuration. It is latched on the PORST rising edge and internally pulled-down.” Section 4.4.2, Power supply and reference voltage pins/balls: – Pin A20 moved from VSS_LV to VSS_HV. There is no VSS_LV on either the 176- or 216-pin packages – <i>Changed</i> $V_{DD_HV_JTAG_OSC}$ to $V_{DD_HV_IO_JTAG}$ – $V_{DD_HV_PMC}$ split into 2 rows: $V_{DD_HV_PMC}$ pin 153 in the QFP, dash for the BGA; second row is $V_{DD_HV_PMC_BYP}$ with dash for the QFP, and balls A19/B18 for the BGA – A1 added to VSS_HV for BGA292 PD and ED Section 4.4.3, System pins/balls: – Clarification of TESTMODE pin definition: “TESTMODE pull-down is implemented to prevent the device from entering TESTMODE. It is recommended to connect the TESTMODE pin to $V_{SS_HV_IO}$ on the board. The value of the TESTMODE pin is latched at the negation of reset and has no affect afterward. The device will not exit reset with the TESTMODE pin asserted during power-up.” (added detail regarding when TESTMODE pin value is latched and that device will not exit reset when pin is asserted during power-up) – Clarification on TESTMODE pin. Pin has an internal pull-down implemented to prevent the device from entering TESTMODE. Section 4.4.4, LVDS pins/balls: Table 11 (LVDSF pin descriptions): – Renamed to Aurora pin descriptions – LPBK_N signals deleted – LPBK_P signal deleted

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Signal Description Table 9 (LVDS pin descriptions): – Table title changed to “LVDS pin descriptions” (was LVDSM pin descriptions) – Pin numbers and ball coordinates added. – Changed “Interprocessor Bus LFAST” to “LFAST” – Title changed to “LVDS pin descriptions” (was LVDSM pin descriptions) – Pin numbers and ball coordinates added. – Functional block “Debug LFAST” changed to “High-Speed Debug (HSD) / LFAST” – Differential input pair added to DSPI 2: SIN_P (PH[7]) and SIN_N (PH[8]) – “_N” and “_P” suffixed deleted from DSPI signal names SCK, SIN, and SOUT – Correction: DEBUG_RXN is on port pin PA[5] (was PA[9]) – Correction: DEBUG_RXN is on pin 114 in the 176/216 package and L19 in the 292 package (was 113/H16) – Correction: DEBUG_RXP is on port pin PA[9] (was PA[7]) – Correction: DEBUG_RXP is on pin 113 in the 176/216 package and H16 in the 292 package (was 114/L19) – DEBUG_TXN is the “Debug LFAST, LVDS Transmit Negative terminal” (was incorrectly described as “...Positive Terminal”. – DEBUG_TXP is the “Debug LFAST, LVDS Transmit Positive terminal” (was incorrectly described as “...Negative Terminal”. – Added: DSPI 5 SIN LVDS pair (pos. is PI[15], neg. is PI[14]) – SIPI / LFAST changed to Zipwire / LFAST Section 4.4.5, Generic pins/balls: – Removed I/O Signal Description table and replaced with reference text: See the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab. Chapter Memory Map Introduction to memory map section expanded. Table 11 (Overview Memory Map): – 0x00A00000 to 0x00FFFFFF region description changed from “Small & Medium Flash Blocks...” to “Low and Mid Flash Blocks...” – Clarification: End address of UTEST NVM block changed to 0x00403FFF – Used Size for UTest NVM block is 16 KB – Clarification: BAF flash block added – Clarification: Reserved space added after BAF flash block – TTCAN changed to M_TTCAN – MCAN changed to M_CAN Table 12 (Peripheral (PBRIDGE_A, PBRIDGE_B) Memory Map): – AMU content deleted – SIPI module (SIPI_1) added (0xFFFD4000 to 0xFFFD7FFF) – PS15_S (PS15 UART Module) added (0xFBF74000 to 0xFBF77FFF) – Two columns added to indicate which PBRIDGE/slot each peripheral is mapped to

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Memory Map (continued) Table 13 (Flash memory and overlay RAM map): – Added “Address Space” column Table 15 (RAM memory map): – Correction: Standby RAM address range is 0x4000_0000 to 0x4000_FFFF. System RAM address range is 4001_0000 to 0x4001_FFFF. Table 16 (UTest flash memory map): – Reserved space at address 0x00400004 extended to 0x0040000B – Reserved spaces at addresses 0x004000C4 and 0x004000C8 combined – Area from 0x00400200 through 0x004002FF is now occupied by Lifecycle functions followed by reserved space (was part of DCF records). – Area from 0x00400300 through 0x00400307 is now the DCF Start Record – Area from 0x00400308 through 0x00400347 is now DCF HSM 'ROM' key Records – Area from 0x00400348 through 0x00400FFF contains remainder of DCF records – Area from 0x00404000 through 0x00407FFF is reserved for BAF code – Description of temperature sensor calibration constants updated Chapter Functional Safety Throughout: – PBRIDGE_0 is now PBRIDGE_A Section 6.4.1.1, End-to-End protection on data path: Removed the sentence “This is particularly true with peripherals connected to the I/O bridges.” - Updated last two sentences in paragraph tagged SCG17.001 in section “End-to-End protection on data path” to “This setup leaves the data path downstream of the ECC units (for example, starting at, and downstream of, the peripheral bridges) unprotected by ECC. To detect corruptions introduced on those unprotected data paths, the PBRIDGES and peripherals can be used redundantly (see Section 6.5.1.3, I/O peripherals), or other mechanisms may be used to validate peripheral operation.” Section 6.5.1.2.1, Clock: – Changed CMU_11 to CMU_1 as appears in Chapter 27, Clocking

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Functional Safety (continued) Section 6.5.1.4.1, Disabling of communication controllers: - Updated the second paragraph in section "Disabling of communication controllers" to read "When the FCCU intends to drive FI[0] to a fault condition, the SIUL2 disables the output buffers of all pins whose SIUL2_MSCRn[SMC]=0. This disables the possible transmission of erroneous messages until the FCCU intends to drive FI[0] to a non-fault condition. Once the communication controller transmission ports are disabled, they remain in the disabled state as long as the FCCU is driving a fault condition on FI[0]." - Clarification: "As long as the FCCU drives FI[0] to a fault state, the communication controller's Tx pins are disabled. As soon as FI[0] is driven to a non-fault state, the communication controller's Tx pins are automatically enabled." - Updated description of automatic disabling of output drivers Added NOTE: "Disabling of communication controllers occurs on the Tx pins of the communication controller (for example, CAN, FlexRay) of the MCU even while the communication controller continues operating. Failed transmissions, when detected by the communication controller, may lead to additional error events". Section 6.5.1.5.2, Online Logical BIST (LBIST) Added "Not in LBIST partitions" and "LBIST partitions" tables. Section 6.5.1.9, FCCU supervision (FOSU): - Clarification: If the FCCU does not react within a predefined interval as specified in the "FCCU configuration" section of the "Device configuration" chapter, on one of those outputs to the incoming failure indication, the FOSU assumes the FCCU has failed, and causes a <i>destructive</i> reset. ("destructive" added) Section 6.5.2, Dual-core lockstep: - Updated LSM description Section 6.4.4.1, ECC for storage: - Changed "ECC RAM implementations" table column name from "Halts on uncorrectable error" to "Reacts to uncorrectable error" - Renamed Core_0 (Main Safety) to Core_0(Safety Core) (Master and Checker cores) in "ECC RAM implementations" table - Renamed Core_0 - Checker to Core_1 in "ECC RAM implementations" table - Renamed Core_1 to Core_2 in "ECC RAM implementations" table Table 21 (FCCU failure inputs): Table headings changed: - Changed column heading 'FI[0] indication default at POR' to 'Source Enabled at POR' - Changed heading 'Source' to 'Failure'. Contents of column unchanged except where noted below. - Changed heading 'Signal(s)' to 'Failure description'. Detailed fault description replaces previous content. - New column: 'Reference Manual related information' contains links to relevant content of reference manual. FCCU channel 0 (TEMP_ERROR): - Changed 'Failure description' (formerly 'Signal(s)'): "Event indication from temperature sensor. The fault is cleared by clearing the status in MEMU_EPR_TD, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Temperature detector")

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Functional Safety (continued) Table 21 (FCCU failure inputs): FCCU channel 1 (LVD_ERROR): – Changed 'Failure description' (formerly 'Signal(s)'): "Voltage out of range indication from LVDs. The fault is cleared by clearing the status in MEMU_EPR_VDn, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Voltage out of range from LVDs.") FCCU channel 2 (HVD_ERROR): – Changed 'Failure description' (formerly 'Signal(s)'): "Voltage out of range indication from HVDs. The fault is cleared by clearing the status in MEMU_EPR_VDn, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Voltage out of range from HVDs") FCCU channel 3 (DPMC_DCF_SAFETY_ERR): – Changed 'Failure description' (formerly 'Signal(s)'): "Digital PMC initialization error during DCF data load. The status gets cleared if the fault is not persistent." (was "Digital PMC DCF Safety Error") FCCU channel 4 (MEMORY_DCF_SAFETY_ERR): – Changed 'Failure description' (formerly 'Signal(s)'): "Indication of fault during timing/repair configuration initialization by SSCM of different memories. The status is cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]. The status gets cleared if the fault is not persistent." (was "Memory Timing/Repair DCF Safety Error") FCCU channel 5 (SSCM_XFER_ERR): – Changed 'Failure description' (formerly 'Signal(s)'): "SSCM transfer error (during the SSCM and STCU DCF loading). The fault is cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "SSCM transfer error (during the SSCM and STCU DCF loading)") FCCU channel 6 (STCU_UF): – Changed 'Failure description' (formerly 'Signal(s)'): "STCU2 unrecoverable fault indication during self-test. Fault is cleared by clearing STCU_ERR_STAT[UFSF] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "BIST result—wrong signature (STCU unrecoverable fault)") FCCU channel 7 (STCU_RF): – Changed 'Failure description' (formerly 'Signal(s)'): "STCU2 recoverable fault indication during self-test. Fault is cleared by clearing STCU_ERR_STAT[RFSF] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "BIST result - wrong signature (STCU recoverable fault)") FCCU channel 8 (STCU_LMBIST_USR_ERR): – Changed 'Failure description' (formerly 'Signal(s)'): "Activation of LBIST or MBIST control during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "STCU Fault in case LBIST or MBIST control signals go to wrong condition during user application.") Channel 9 (SPURIOUS_DEBUG_SSCM_ACTIVATION): – New Failure (formerly 'Source') name is SPURIOUS_DEBUG_SSCM_ACTIVATION) (was "JTAG_NPC_MON")

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Functional Safety (continued) Table 21 (FCCU failure inputs): FCCU channel 9 (SPURIOUS_DEBUG_SSCM_ACTIVATION): Changed 'Failure description' (formerly 'Signal(s)'): "JTAG, NPC or Debug functionality out of reset or SSCM activation during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "JTAG or NPC not in reset or activations of dangerous debug functionality") FCCU channel 10 (RCCU_0): – Changed 'Failure description' (formerly 'Signal(s)'): "Safety cores out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "rcc_out") FCCU channel 11 (RCCU_1): – Changed 'Failure description' (formerly 'Signal(s)'): "Safety cores out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "rcc_out") FCCU channel 12 (SWT2_ResetReq): – Changed 'Failure description' (formerly 'Signal(s)'): "Reset request from Software Watchdog of Peripheral Core_2 domain" (was "Software watchdog timer2 Reset Request") FCCU channel 13 (SWT1_ResetReq): – Changed 'Failure description' (formerly 'Signal(s)'): "Reset request from Software Watchdog of Peripheral Core_1 domain" (was "Software watchdog timer1 Reset Request") – Changed 'Default reaction...': "No reaction" (was "Long Reset") – Changed 'Source enabled at POR': "No" (was "Yes") FCCU channel 14 (SWT0_InterrupReq): – Changed 'Failure description' (formerly 'Signal(s)'): "First timeout interrupt request from Software Watchdog of Safety Core (Main Core_0)" (was "LBIST + SW test by not triggering SWT during startup") FCCU channel 15 (SWT0_ResetReq): – Changed 'Failure description' (formerly 'Signal(s)'): "Second timeout (reset) request from Software Watchdog of Safety Core (Main Core_0)" (was "Software watchdog timer of Safety Core, second timeout (reset)") FCCU channel 16 (MEMU_RAM_CE): – Changed 'Failure description' (formerly 'Signal(s)'): "Indication by MEMU of occurrence of correctable errors in system RAMs. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_CE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "MEMU RAM correctable error") FCCU channel 17 (MEMU_RAM_UCE): – Changed 'Failure description' (formerly 'Signal(s)'): "Indication by MEMU of occurrence of uncorrectable errors in system RAMs. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_UCE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "MEMU RAM uncorrectable error") FCCU channel 18 (MEMU_RAM_BOV): – Changed 'Failure description' (formerly 'Signal(s)'): "Indication of overflow of system RAM ECC buffer in MEMU. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "MEMU RAM buffer overflow")

Table 2152. Document revision history (continued)

Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "EDC after ECC for RAM (read-modify-write ECC)") FCCU channel 46 (DFT1): – Changed 'Failure description' (formerly 'Signal(s)'): "Test circuitry Group 1 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Test circuitry Group 1 activation") FCCU channel 47 (DFT2): – Changed 'Failure description' (formerly 'Signal(s)'): "Test circuitry Group 2 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Test circuitry Group 2 activation")

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Functional Safety (continued) Table 21 (FCCU failure inputs): FCCU channel 48 (DFT3): – Changed 'Failure description' (formerly 'Signal(s)'): "Test circuitry Group 3 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]. (was "Test circuitry Group 3 activation") FCCU channel 49 (DFT4): – Changed 'Failure description' (formerly 'Signal(s)'): "Test circuitry Group 4 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Test circuitry Group 4 activation") FCCU channel 50 (Safety Core Machine Check Exception): – Changed 'Failure description' (formerly 'Signal(s)'): "Safety Core Machine Check Exception" (was "Safety Core Exception") – Added note that begins "See 'Exceptions and Conditions' table in the <i>e200z4 Core Reference Manual</i> for..." FCCU channel 51 (Lockstep mode): – Changed 'Failure description' (formerly 'Signal(s)'): "Indication of disabled Checker Core or RCCUs. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Indication of disablement of Checker Core or RCCUs") FCCU channel 52 (Safe_Mode): – Changed 'Failure description' (formerly 'Signal(s)'): "Indication of safe mode request assertion from MC_RGM. The event is also captured in MC_ME and available as status for crosscheck. Status should be cleared first in the MC_RGM_FES, then followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Safe Mode Entry Indication") FCCU channel 53 (Compensation Disable): – Changed 'Failure description' (formerly 'Signal(s)'): "Pad Compensation Disabled Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Pad Compensation Disabled") FCCU channel 54 (EIN_ERR): – Changed 'Failure description' (formerly 'Signal(s)'): "Error input pin (FI[0], external of the MCU)The fault is cleared by clearing the fault driving FI[0] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]." (was "Error input pin (from the external world)") – Added table footnote: "EIN_ERR can be used only when bistable protocol is selected for external error indication." FCCU channel 55 (SWT3_ResetReq): – Changed 'Failure description' (formerly 'Signal(s)'): "Reset request from Security Watchdog" (was "Software watchdog timer3 Reset Request") Section 6.4.5, Register classifications: – Content removed because it is still under development. Will be added in a future revision.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Device Configuration Section 7.2, Core modules – Details about locations of core modules added to introduction Section 7.3.7.3, Interrupt sources – IRQ 671 (SPU_INTS[INT]) deleted – IRQ 226 PIT1 Channel 0 PIT_1_TFLG0[TIF] changed to PIT0 Channel 0 PIT_0_TFLG0[TIF] – IRQ 227 PIT1 Channel 1 PIT_1_TFLG1[TIF] changed to PIT0 Channel 1 PIT_0_TFLG1[TIF] – IRQ 228 PIT1 Channel 2 PIT_1_TFLG2[TIF] changed to PIT0 Channel 2 PIT_0_TFLG2[TIF] – IRQ 229 PIT1 Channel 3 PIT_1_TFLG3[TIF] changed to PIT0 Channel 3 PIT_0_TFLG3[TIF] – IRQ 230 PIT1 Channel 4 PIT_1_TFLG4[TIF] changed to PIT0 Channel 4 PIT_0_TFLG4[TIF] – IRQ 231 PIT1 Channel 5 PIT_1_TFLG5[TIF] changed to PIT0 Channel 5 PIT_0_TFLG5[TIF] – IRQ 232 PIT1 Channel 6 PIT_1_TFLG6[TIF] changed to PIT0 Channel 6 PIT_0_TFLG6[TIF] – IRQ 233 PIT1 Channel 7 PIT_1_TFLG7[TIF] changed to PIT0 Channel 7 PIT_0_TFLG7[TIF] – IRQ 239 PIT1 RTI Channel PIT_1_RTI_TFLG[TIF] changed to PIT0 RTI Channel PIT_0_RTI_TFLG[TIF] – IRQ 240 PIT0 Channel 0 PIT_0_TFLG0[TIF] changed to PIT1 Channel 0 PIT_1_TFLG0[TIF] – IRQ 241 PIT0 Channel 1 PIT_0_TFLG1[TIF] changed to PIT1 Channel 1 PIT_1_TFLG1[TIF] – Deleted IRQ 481 Loss-of-clock interrupt request for PLL0 PLL0SR[LOCF] – Deleted IRQ 483 Loss-of-clock interrupt request for PLL1 PLL1SR[LOCF] – Interrupt sources 494 and 495 added – Interrupt source 831 (GTM error) added – Interrupt sources 946–961 (PSI5-S error) added Updated source descriptions and source names for IRQs 484–485: – IRQ 484—was ipi_int_ext_pd1_done / ipi_int_ext_pd1_done; is PLL0 External Power Down Cycle Complete indication interrupt / PLL0SR[EXTPDF] – IRQ 485—was ipi_int_ext_pd2_done / ipi_int_ext_pd2_done; is PLL1 External Power Down Cycle Complete indication interrupt / PLL1SR[EXTPDF] Deleted IRQ 486 (ipi_int_pll1_clk_sw) Deleted IRQ 487 (ipi_int_pll2_clk_sw) Section 7.3.9, DMACHMUX configuration, Table 43 (DMAMUX peripheral DMA request to input source mapping): – Changed DMA_CH_MUX_3 source 46 from “DSPI_1_TX” to “DSPI_1_RX” and source 47 from “DSPI_1_RX” to “DSPI_1_TX” – Added source: DMA_CH_MUX_2: 49 (PSI5-S) – Added source: DMA_CH_MUX_3: 50 (PSI5-S)

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Device Configuration (continued) Section 7.4, Clocking – Added cross-reference to Clock Monitor Unit (CMU) chapter Section 7.5.1.1, Calibration remapping support – New section Section 7.5.1.2, Wait state settings for overlay flash latency matching – New section added Section 7.6.1, Temperature sensor configuration – “temperature sensor bandgap voltage” changed to “ADC bandgap voltage” Section 7.7.2, Software Watchdog Timer (SWT) configuration, Table 55 (Software Watchdog Timer (SWT) instances): – Replaced description of SWT3. – Added “Internal 16 MHz RC oscillator clock that is used for timer operation” to features list Section 7.7.2.3, Default configuration: – Added brief explanation of how Security Watchdog is enabled and cross-reference to BAF chapter. – added details on SWT default configurations per SWT_CR register reset values. Section 7.8.2, FEC interface selection, Table 62 (FEC interface selection): – Revised to reflect the correct method for selecting interfaces using RCR[MII_MODE] and SIUL_SCR0[FEC_MODE]. – Footnote added: MII supported only in BGA packages Section 7.8.5.4, High Speed and MicroSecond Channel (MSC) Support: – There are four package input pins to be muxed onto any of the 32 DSPI parallel inputs (was two input pins) – Listed pins that can be inserted into the MSC datastream: PC[2], PD[8], PF[3], and PJ[4]. – Added bit 28 “XSPI to Figure 25 (DSPI Module Configuration Register (DSPIx_MCR))). – Note added: DOZE mode is not implemented Section 7.8.6.2, Stopwatch timer input: – New section Section 7.9.1.2, Device specific features, Section Table 73., SSCM_MEMCONFIG Reset Values: – Footnotes added to emphasize that values will change with each revision of the device. – Added Table 74 (SSCM startup information addresses) and introductory sentence, “Table 74 shows the address locations that the SSCM uses to search for startup information.” Section 7.10.2.5, MEMU registers, Table 83 (Corresponding error sources for FLASH OFLW register): – Revised the address offsets to align with the main MEMU content. – Added the PERIPH_RAM_OFLW0 register. – Changed FLASH_OFLW to FLASH_OFLW0 for consistency in naming with the other OFLW registers.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Device Configuration (continued) Section 7.10.3.1, SRAM Arrays accessible by processor cores: – Specified processors that can access SRAM arrays – Cross-reference to IMA chapter added Section 7.10.3.1, SRAM Arrays accessible by processor cores, Table 86 (SRAM arrays accessible via IMA): – GTM FIFO ECC bits changed to 35–29 (was 36–30) – GTM MCS RAM0 and MCS RAM1 ECC bits changed to 38–32 (was 38–33) – GTM DPLL RAM1a and RAM1b ECC bits changed to 30–24 (was 31–25) Section 7.10.4.2, FOSU parameters: – Replaced 'safe clock' with 'IRCOSC' Section 7.10.5, Register protection (REG_PROT) configuration: – Added Section 7.10.5.14, JTAG Master (JTAGM) protected registers Table 89 (Reference links to related information) – Deleted Power Control Unit (MC_PCU) register(s) from Table 89 (Reference links to related information). Section 7.10.5.1, SIUL2 protected registers: – SIUL2_IFER0, SIUL2_IFMC0-SIULIFMC31, and SIUL2_IFCPR registers deleted – MSCR512-543, MSCR576-587, MSCR608-612, MSCR614-615, MSCR619, MSCR624-628, MSCR630-631, MSCR638-645, MSCR656-719, MSCR752-754, MSCR758-760 registers added – MCSR1023 register deleted Section 7.10.5.2, Core Clock Monitor Unit (CMU_CORE) protected registers: – CMU section split into two sections—one for the core CMU and another for the I/O processor CMU Section 7.10.5.4, PMC Digital Interface (PMC_DIG) protected registers: – Registers listed individually instead of summarized, e.g., REE_VD3 and REE_VD4 instead of REE_VDn. – FEE_VD3, FEE_VD4, FEE_VD7, FEE_VD9, FEE_VD10, FEE_VD12, FEE_VD13, FEE_VD14, FEE_VD15 registers added – ADC_CH register added – CTL_TDn register renamed to CTL_TD – VD_UTST register added – Deleted NT_TDn registers Section 7.10.5.5, PLL Digital Interface (PLL_DIG) protected registers: – PLL0_CR and PLL0_DIVR registers added – PLL2CR, PLL2DV, PLL2FM, and PLL2FD registers deleted – PLL1DV register renamed to PLL1_DIVR – PLL1CR register renamed to PLL1_CR Section 7.10.5.10, Clock Generation Module (MC_CGM) protected registers: – Clarification: Byte 3 of CGM_AC[0..15]_SC registers are protected Section 7.10.5.11, Reset Generation Module (MC_RGM) protected registers: – RGM_STDBY register deleted Section 7.10.5.12, System Status and Control Module (SSCM) protected registers: – Error_Config register renamed to ERROR – Protected size of ERROR changed to 16 bits (was 8)

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Device Configuration (continued) Section 7.11.1.2, PASS Module DCF Records (includes life cycle state and censorship): – Figure 28 (PASS_LOCK0_PGn Register) and related tables: footnote added detailing where to find more information. – Added ATSL bit to Figure 28 (PASS_LOCK0_PGn Register). Chapter Reset and Boot Section 8.4.3.7, Locate HSM Boot Header (state 44): – Correction: List of locations checked by SSCM for a valid boot header changed to 0x60_C000, 0x61_0000, and 0x62_0000 (was 0x60_0000, 0x60_4000, and 0x61_4000). Section 8.3.3, PHASE0 Phase: analog supply initial configuration: Correction: Flash memory is not initialized during PHASE0 and the flash memory module does not have a self test capability. Chapter Device Configuration Format (DCF) Records Table 112 (DCF client list): – Added STCU_MB_CTRL registers 70 thru 77 – Changed the Tamper Detect Diary Base Address reset value for the DCF client to “0xFFFFFFFF”. – Changed the Tamper Region Override for DCF client special strategy to “Once+Write ‘1’ only”. – Changed TDR0_LOCKx for DCF client special strategy to “Write Once+Write ‘1’ only”. – Changed Miscellaneous - UTEST Miscellaneous, Reset value of DCF client to “0x00000941” – Corrected Reserved space ranges for TDM DCF clients – Corrected CS bits for PMCDIG REE bits client – Corrected Reserved space ranges for TDM DCF clients Table 113 (UTEST Miscellaneous DCF Client field descriptions): – Changed bit 19 and bit 20 to “RESERVED”. Chapter Power Management Table 120 (Functional terminal state during power-up and reset): – Changed TMS POWERUP pad state from “high impedance” to “weak pull-up” – Changed TDI POWERUP pad state from “high impedance” to “weak pull-up” – Changed TDO RESET pad state from to “weak pull-up” to “high impedance” Chapter Security Editorial updates Chapter Calibration and Debug Section 12.3.2, Debug LFAST: – Added sentence “In addition, the LFAST switch allows direct access to read and write memory.”

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Core Complex Overview Section 13.2, Features: – Correction: e200z425n3 core has 64 KB DMEM (was 32 KB) Section 13.3.8, Local memory features: – Correction: e200z425n3 core has 64 KB DMEM (was 32 KB) Section 13.3.7, Cache features: – Clarification: DBL1CCSR0 register provides hardware debug cache invalidate support for data cache. – CDANTL and CDADATA registers provide software and hardware debug access to cache tag, status, and data storage. Chapter Core e200z420n3 description Editorial changes Chapter Core e200z425n3 description Editorial changes Chapter System Integration Unit Lite2 (SIUL2) Register name correction: Changed occurrences of "Multiplexed Single Configuration Register" to "Multiplexed Signal Configuration Register". Register mnemonic (MSCR) is unchanged. Table 225 (SIUL2_MIDR2 field description): – Updates made to FLASH_SIZE_1 memory sizes in description column. Table 235 (SIUL2_MSCR0 - SIUL2_MSCR511 field description): – Updated "OERC" field description column. – INV bit (16), added note: "Use of the INV bit is not supported when the ODC is configured for open-drain or open-source modes, and the output data will not be as expected for an inverted open-drain or open-source connection." – Added note: Not all pads have all bits i.e., only some pads have hysteresis, see the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab. – Changed cross reference from Chapter 4, I/O Signal Description table, to the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. – Added note to OERC field description: OERC[2] programming is required for forward compatibility. – Updated WPDE bit description: Weak Pullup Enable—Used only when the associated destination is a chip pin. Enables the associated pin's weak pullup resistor. It is OK for both WPDE and WPUE to be enabled, if they are, the pad is neither a weak pullup and a weak pulldown. – Updated WPUE bit description: Weak Pulldown Enable—Used only when the associated destination is a chip pin. Enables the associated pin's weak pulldown resistor. It is OK for both WPDE and WPUE to be enabled, if they are, the pad is neither a weak pullup and a weak pulldown.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter System Integration Unit Lite2 (SIUL2) (continued) Section 14.3.2.16, Module-port MSCR assignments and SSS values – Removed reference text and Table 271. Peripheral and input multiplexing assignments. Replaced with: For each internal module port that is or can be configured as an input and has more than one possible source. See the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the Input Multiplexing Table tab. The Input Multiplexing Table shows the assigned MSCR, and the SSS values and their corresponding source signals. Section 16.2.2.17, SIUL2 GPIO Pad Data Output Registers (SIUL2_GPDO0_3–SIUL2_GPDO508_511): – Removed: See the Chapter 4, Signal Description for mapping of ports to GPDI registers. Replaced with: For mapping of ports to GPDO registers, see the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab. Table 16.3.4.1 (External interrupt initialization) – Added “(For DMA, its self clearing)” to following item: ““Write to EIFn bits in DISR0 to as desired to clear any flags Chapter Crossbar Switch (XBAR) Editorial changes Chapter Crossbar Integrity Checker (XBIC) Section 18.1, Overview: Detail added regarding new functionality: – Forward signals (master to slave) crossbar transfer integrity is checked by verifying the attribute information using an 8-bit Error Detection Code (EDC). – During the data phase of the system bus pipelined protocol, the XBIC compares the three signals of hready, hresp0, hresp2 from entering the crossbar on the slave side to leaving the crossbar on the master side. Data phase is often more than one clock cycle due to wait cycles. All three signals are compared clock by clock during the whole data cycle Section 18.2, Features: – New feature: Verification of feedback information for each data phase during crossbar transfer. – New feature: Programmable integrity check enable on a per-master-port basis Section 18.5.2.1, XBIC Module Control Register (XBIC_MCR): – The XBIC_MCR allows attribute integrity checking to be enabled on a per-port basis. (previously stated, “...to be enable on a per-slave-port basis.” – Field description changed: Slave Port Enable (SEn) field description changed to “Slave Port Enable for EDC error detect” – Fields added: Master Port Enable for slave driven signal safety check (ME0–ME7)

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Crossbar Integrity Checker (XBIC) (continued) Section 18.5.2.3, XBIC Error Status Register (XBIC_ESR): – Functional description changed: The Error Status Register (XBIC_ESR) contains two types of error information about the last transfer. If an attribute integrity check error was detected, the slave port, the master port and the syndrome are captured in the SLV, MST and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are captured in the DPSE0-7 and DPME0-7 fields. – Fields added: Data phase slave port error (DPSE0-DPSE7) – Fields added: Data phase master port error (DPME0-DPME7) – Minor editorial updates Section 18.6, Functional description: Detail added: – The above for XBIC to catch forwarding (master to slave) signal errors during AHB address phase. XBIC also detect backward signal (slave to master) errors during AHB data phase. – For the three slave driven signals (hready, hresp0 and hresp2), XBIC perform the comparison between the input of the slave port and output of the master port during the AHB data phase. When mis-match happening, the error will be captured. The current slave port will be registered in XBIC_ESR bit field DPSE0-7, and the current master port will be registered in XBIC_ESR bit field DSME0-7. Chapter Crossbar Locking Control (CLC) Editorial changes Chapter Peripheral Bridge (PBRIDGE) Editorial changes Chapter System Memory Protection Unit (SMPU) Clarified the maximum allowed size of regions. Clarified that access control permissions are defined per region descriptor, not globally. Section 21.4.2.7, Region Descriptor n, Word 2 Format 0 (SMPUX_RGD_WORD2_FMT0) – Clarification: “RGD_WORD2_FMT0 defines the access control rights of the memory region” to “...of the memory region <i>on a per master basis</i>” Chapter Intelligent AHB Gasket (IAHBG) Added new sections on 64->32 and 32->64 interfaces Chapter Semaphores2 (SEMA42) Section 23.2, Memory map/register definition: – Corrected the representation of RSTGT (is one register at offset 0x0040). – Added the following to the RSTGSM field of the SEMA4_RSTGT register. “The “10” state persists for only one clock cycle. Software will never be able to observe this state.” – Modified Semaphores (Secure) Reset Gate (SEMA4_RSTGT) note 2 to state that write sequence errors will cause reset sequence to abort.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Interrupt Controller (INTC) Section 24.4.1, Software vector mode: - Deleted “Furthermore, the interrupt vector to the processor is driven as all zeroes. The interrupt acknowledge signal from the associated processor is ignored.”. Section 24.4.2, Hardware vector mode: - Deleted the paragraph beginning with “The processor negates the interrupt request...”. Section 24.5, Memory map and register definition: - Deleted “IPS” from the note. - Added new programmable register to the memory map, Master Protection Register (INTC_MPROT). This register is used to protect cores from writing to other cores INTC registers. Adding this register impacts other programmable registers in the chapter which now rely on INTC_MPROT. Section 24.5.2.7, INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023): - Removed the note, “The PRC_SELn or PRIn field of an INTC_PSRn must not be modified while its corresponding peripheral or software-settable interrupt request is asserted.” and the note about area optimization. Section 24.5.2.7, INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023): - Revised Table 279 (INTC memory map) and to represent the fact that each PSR is 16 bits wide, containing a PRC_SEL and PRI field. In Section 24.6.1.3, Unique vector for each interrupt request source, rewrote the last sentence to include the correct starting peripheral interrupt request number. Chapter Enhanced Direct Memory Access (eDMA) Editorial changes Chapter DMACHMUX No changes Chapter Clocking Throughout: - Removed all references to CGL (Clock Gating Logic). It is an internal module not visible to the customer Section 27.3, System clock frequency limitations: - Removed NOTE, “HSM_CLK and PBRIDGEEx_CLK are not required to be at the same frequency, but the COMP_CLK, CHKR_CLK, FXBAR_CLK, and IOP_CLK must always be at the same frequency.” Section Figure 263., Device Ethernet clocking: - Corrected diagram to show the MSCR in the SIUL module, and not the MC_CGM.A - Added the sentence, “When a 40MHz oscillator is used as the input clock to the FlexRay controller, both edges of the clock are used by the module to achieve the required 80 MHz frequency.” - Corrected diagram to show the MSCR in the SIUL module, and not the MC_CGM.A

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Clocking (continued) Section 27.6.5, FlexRay clocking: – Added the sentence, “When a 40MHz oscillator is used as the input clock to the FlexRay controller, both edges of the clock are used by the module to achieve the required 80 MHz frequency.” – Added sentence, “Selection of PLL or external oscillator as the FlexRay clock is configured in the MC_CGM (see Figure 350 (MC_CGM auxiliary clock 2 generation overview) in Chapter 30: Clock Generation Module (MC_CGM))” Figure 258 (Clock generation (part 1 of 2)): – Added footnote “The clock trees COMP_CLK and CHKR_CLK are isolated after System Clock Divider x. This isolation is maintained in the physical design of the clock trees on the device.” to diagram and enclosed effected area referencing footnote – Removed DSPI_6 – Added footnote “The clock trees COMP_CLK and CHKR_CLK are isolated after System Clock Divider x. This isolation is maintained in the physical design of the clock trees on the device.” to diagram and enclosed effected area referencing footnote – Added Figure Footnote “DSPI_CLK1 and DSPI_CLK0 are the protocol clocks as described in the “Deserial Serial Peripheral Interface (DSPI)” chapter.” – Moved PSI5 clock tree details to separate diagram. Details have received significant updates. Figure 259 (Clock generation (part 2 of 2)): – New diagram contains details of PSI5 clock tree Table 340 (MC_CGM relationship to clocks): – Removed DSPI_6 from 'MC_CGM relationship to clocks', CGM_AC0_DC3 row, Output clock column. Section Figure 262., Device LFAST clocking: – Correction: TCK/DRCLK maps to PA[6] (was PA[5]) Section 27.3, System clock frequency limitations: – Removed NOTE, “HSM_CLK and PBRIDGEEx_CLK are not required to be at the same frequency, but the COMP_CLK, CHKR_CLK, FXBAR_CLK, and IOP_CLK must always be at the same frequency.” – Clock dividers added Section 27.7.1.2, CMU registers and field availability: – Removed CMU_ISR[FLCI] from Table 350 (CMU registers availability) 'CMU registers availability'. Figure 261 (Clock distribution): – PSI5-S added Figure 268 (Loss of clock logic): – Interrupt connection from CMU_0 to INTC deleted

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Clocking (continued) Table 340 (MC_CGM relationship to clocks) New clock dividers added: – CGM_AC5_CDC10 – CGM_AC5_CDC11 – CGM_AC5_CDC12 – CGM_AC5_CDC13 – CGM_AC5_CDC20 – CGM_AC5_CDC21 – CGM_AC5_CDC22 – CGM_AC5_CDC23 Table 342 (Maximum system level clock frequencies) New clocks and clock dividers added: – CDC10/PSI5_S_DDSR0_CLK – CDC11/PSI5_S_DDSR1_CLK – CDC12/PSI5_S_DDSR2_CLK – CDC13/PSI5_S_DDSR3_CLK – CDC2/PSI5_S_WD_CLK – CDC20/PSI5_S_WD_CLK0 – CDC21/PSI5_S_WD_CLK1 – CDC22/PSI5_S_WD_CLK2 – CDC23/PSI5_S_WD_CLK3 Section 27.6.2, PSI5 clock dividers: Frequencies for new clocks added: – F_{PSI5_S_TS_CLK} – F_{PSI5_S_DDSR0_CLK} – F_{PSI5_S_DDSR1_CLK} – F_{PSI5_S_DDSR2_CLK} – F_{PSI5_S_DDSR3_CLK} – F_{PSI5_S_WD0_CLK} – F_{PSI5_S_WD1_CLK} – F_{PSI5_S_WD2_CLK} – F_{PSI5_S_WD3_CLK}

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Dual PLL Digital Interface (PLLDIG) Section 28.6.2, Clock configuration: – Updated NOTE that starts “The PLL must be powered down and powered up in the MC_ME...” to remove the unclear text. – Updated equations Equation 4, Equation 5, Equation 8 and Equation 10 to show particular relationship of each equation contents to PLL0, PLL1 or both. – Added equations Equation 6, Equation 7 and Equation 12. – Equation 5: Added which shows relationship between PLL1 input (fpll1_ref) and PLL1 output (fpll1_phi). – Equation 5: Updated by adding divide by 2. – Equation 7: Updated due to the update to Equation 5. – Equation 8: Added which shows relationship between PLL1 input (fpll1_VCO) and PLL1 output (fpll1_phi). – Equation 10: Updated Eqn 8 by changing PLL0DV[RFDPHI] to PLL0DV[RFDPHI] – Equation 8: Removed 'x 2' from each equation. Section 28.4, Modes of operation: – Added note “Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<mode>_MC).” – Added the bullet “Bypass mode with reference, and PLL1PLL0either PLL0PLL1 or both PLLs enabled” as one of the modes of operation. Section 28.5.2, Register descriptions: – Removed the dimensioned registers PLLnCR, PLLnSR and PLLnDV, and replaced them with the non-dimensioned versions, PLL0CR, PLL1CR, PLL0SR, PLL1SR, PLL0DV and PLL1DV. Chapter Clock Monitor Unit (CMU) Editorial updates Chapter Clock Generation Module (MC_CGM) Table 430 (MC_CGM CGM_PCS_DIVCn[RATE] values): – Multiplied the values in the “d = CGM_PCS_DIVCn[RATE]” column by 1000. – Deleted entries for $a_{max} = 0.25$ and higher. Chapter OSC Digital Interface (XOSC) Section 31.3.1.1, XOSC control register (XOSC_CTL): – Updated reset value for M_OSC to ‘–’ and added note referring customers to the “Clocking” chapter. Chapter RCOSC Digital Interface Section 32.1, Functional description: – “During power on reset sequence, native trimming bits are initialized from the TEST flash memory” is updated to read “During power on reset sequence, native trimming bits, fine trimming bits, and TSENS code bits are initialized from the TEST flash memory”. Section 32.2.1.2, Native trimming register (NT): – Bits 2-7 are updated from “Reserved” to “FT Code”. – Bits 10:15 are updated from “Reserved” to “TX Code”.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter RAM Controller (PRAM) Throughout: minor editorial updates. Table 441 (RAM controller memory map) - Table footnote updated to indicate that accessing PRCR1 register outside of supervisor mode results in a transfer error. Section 33.3.1.2, Optional read wait-state: "...access will take 2T to complete..." changed to "...access will take 2 clock cycles (2T) to complete..." "3T" changed to "3 clock cycles (3T)" Section 33.3.1.2, Optional read wait-state: - Following note added: "The number of cycles taken for a RAM access can vary ± 1 clock cycle depending on the RAM speed relative to the PRAM controller clock frequency. If system RAM is running at the same frequency as the PRAM controller a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to PRAM controller clock frequency." Section 33.2.1, Platform RAM Configuration Register 1 (PRAMC_PRCR1): Section Table 442., Platform RAM Configuration Register 1 description in - Following footnote added: "The number of cycles taken for a RAM access can vary ± 1 clock cycle depending on the RAM speed relative to the PRAM controller clock frequency. If system RAM is running at the same frequency as the PRAM controller a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to PRAM controller clock frequency." Section 33.2.1, Platform RAM Configuration Register 1 (PRAMC_PRCR1): - Field deleted: Port p1 read buffer disable (P1_RB_DIS) - Field deleted: Port p0 read buffer disable (P0_RB_DIS) - Field added: Port p0 read burst optimization disable (P0_BO_DIS) - Field added: Port p1 read burst optimization disable (P1_BO_DIS) - Field deleted: Read One Wait State (RD1WS) - Field added: Flow through disabled (FT_DIS) - Note added: "This register is accessible only in supervisor mode. Accesses in user mode returns a transfer error." Section 33.3.1.2, Optional read wait-state: - First paragraph revised subsequent to deleting PRCR1[RD1WS] field and adding PRCR1[FT_DIS] field. Changed, "The controller can be optionally programmed to insert one additional wait-state in the AHB response on reads. Setting the PRCR1[RD1WS] field inserts additional one wait state in the AHB dataphase on read requests. The state of PRCR1[RD1WS] field has no effect on write." to "The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCR1[FT_DIS] field inserts a register in the read data path for use when operating the controller at high frequencies. The state of PRCR1[FT_DIS] field has no effect on writes."

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Flash Memory Controller Throughout: – Editorial changes – Formerly each AHB port contained a 4-way set associative mini-cache. The mini-cache has been changed to 2-way. Section 34.1, Introduction: – Added item to list of functions: “It acts as the interface between the ASC Modeling Unit (AMU) and the c55fm flash memory array.” Section 34.1, Introduction: – Detail added to feature item. The two AHB ports allow simultaneous access to dedicated prefetch mini-cache per slave port. Section 34.4.1, Overview: – Added detail to statement that attempted updates to the programming model while the flash memory controller is in the midst of an operation will result in non-deterministic behavior: “Software must be architected to avoid this scenario. – Added: “There is no idle indicator for the flash controller. The recommended flow for multi-core devices is to start only one core and execute initialization code to completion before starting the remaining cores. If the user needs to reconfigure the flash, code execution must be temporarily moved to system RAM.” Section 34.4.1.1, Platform Flash Configuration Register 1 (PFCR1): Changes to PFCR1[P0_BFEN] function: – Deleted: “This bit is cleared by hardware reset.” – Added: “This bit can only be updated while PFCR3[BAF_DIS] = 0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset.” Section 34.4.1.2, Platform Flash Configuration Register 2 (PFCR2): Changes to PFCR2[P1_BFEN] function: – Added: “This bit can only be updated while PFCR3[BAF_DIS] = 0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset.” Section 34.5.6, Flash error response operation: – “or upon detection of an ECC event” deleted from following sentence: “The flash array may signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing or upon detection of an ECC event.” Section 34.5.9, Access pipelining: – Following note added: “Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.”

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Flash Memory Controller (continued) Section 34.5.14, PFlash calibration remap support: – Added: “Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data” – Deleted: Note that when a reset event asserts while an access to the on-chip overlay RAM is requested, the flash controller aborts the array access to ensure that RAM contents are not corrupted.” – Deleted: “Since the calibration access is defined to have the same access time as a normal flash array access, remapped references to the system RAM are treated as the highest priority request by the platform’s RAM controller.” – “for a flash access as well as the required access time” deleted from statement: “Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency.” – Deleted: “The translation function is performed during the first AHB data phase cycle.” Section 34.5.16.2.2, e2eECC and Calibration Accesses: – Clarification and corrections to example of where contents of CRD contents are redundantly defined. Chapter Embedded Flash Memory (c55fmc) Table 456 (Block Memory Map): – Correction: Register LOCK2 has R/W access (was previously listed as read-only) – Correction: Register LOCK3 has R/W access (was previously listed as read-only) – Correction: Register SEL2 has R/W access (was previously listed as read-only) – Correction: Register SEL3 has R/W access (was previously listed as read-only) Section 35.2.1.1, UTest NVM block: – Test mode disable seal content moved to new section Section 35.2.1.2, Test Mode Disable Seal – New. Content was previously included in Section 35.2.1.1, UTest NVM block. – Test mode disable value is 0x2D3C_4B5A (was incorrectly stated as 0x5A4B_3C2D). – Clarification: “Once sealed, the Utest block becomes OTP (Erase Locked, and Over Program Protection enabled). The Utest Block also is not accessible in Test Mode” – Clarification: “Utest operations Margin Read and Array Integrity are also protected by preventing MISR updates on blocks selected for protection, although reads will still be done and Single Bit Corrections and Double Bit Detections will be logged.” – Added: “In order to let two opportunities to select blocks for the Test Mode Disable, two regions are available, Test Mode Disable Block Select - 0 and Test Mode Disable Block Select - 1.”

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Embedded Flash Memory (c55fmc) (continued) Section 35.2.2, Register Summary, Section Table 459., Register summary: – Register added: TMD Section 35.2.3, Register descriptions: – Detail added to field descriptions in SELn registers. – New fields (CPR, CPA, CPE) added to UT0 register – Clarification: UT0[AIE] remains at 1 when the Array Integrity Check, or Margin Read are suspended or are in a breakpoint, and cannot be cleared. – Clarification: "Writing the MISR register during an array integrity operation (including suspend or breakpoint) although possible, is not recommended. A write of the MISR registers at this point may alter the final signature in an unpredictable way." Chapter Decorated Storage Memory Controller (DSMC) Minor editorial changes Chapter Configuring Flash Memory Write and Read Protection Completely rewritten Chapter Analog-to-Digital Converters (ADC) Configuration Section 38.2.2.7.4, Analog input pin switch to VSS_HV_ADV: – Figure 451 (Analog input AN35 — discharge switch to AVSS): pull up/down pad cell removed – "The ground switch for AN7/AN35 is controlled in input multiplexing MSCR registers in the SIUL2." changed to "...MSCR registers (MSCR[WPDE]) in the". Figure 411 (ADC subsystem): – Added lines between SARADC instances and GTM. Section 38.2.1.2, Sigma-Delta ADC analog input multiplexing: – SARADC_B analog inputs are switchable by the SIUL2_MSCRn[APC] bit. – SDADC analog inputs have no SIUL2_MSCRn[APC] bit control, but are directly connected to the pad. Table 507 (SAR ADC test channel register descriptions (SARB only)): – Changed SARADC_B input channel 108 to "Trimmed PMC bandgap reference" – Changed VAGND1 to VSS_HV_ADV (ground supply for ADC) – Changed Vssm to VSS_HV_ADR_S – Changed Vddm to (VDD_HV_ADR_S - VSS_HV_ADR_S) Chapter Sigma Delta Analog-to-Digital Converter (SDADC) Digital Interface Section 39.7.12, Offset calibration support: – Step ⁽²⁾ ("Configure the mux selection ANCHSEL field of CSR to '100' or '101' as required") expanded with two sub-steps. – Editorial updates

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface <i>Section 40.5.1.40, External Channel Mapping to Internal Channel Registers 0–3 (ECMICR0–3):</i> – The register name and offset address above the figure has been corrected. Changed from “TCCAPR0–7: 0x050–0x05CC” to “ECMICR0–3: 0x5C0–0x05CC”. <i>Figure 464 (SARADC block diagram):</i> – Footnote added: “Test channels are mapped to internal analog channels via the SARADCB_TCCAPRx registers” – Added pointers to functional equivalent of TCCAPR7 register fields ICSEL_TCH0, ICSEL_TCH1, ICSEL_TCH2, and ICSEL_TCH3 <i>Section 40.5.1.1, Main Configuration Register (MCR):</i> – Changed reset value of WTRGOUT bit <i>Section 40.4.5, Test channel connection with internal analog channel:</i> – Updated the TCCAPRX register description for BigEndian format Editorial changes Chapter Temperature Sensor Editorial changes Chapter Timers Overview Added footnote to GTM103 Wrapper Module Configuration in “Timers” table. Chapter System Timer Module (STM) No changes Chapter Software Watchdog Timer (SWT) Editorial changes Chapter Periodic Interrupt Timer (PIT) Editorial changes Chapter CAN Subsystem – Added a note in the M_TTCAN BTP register – Added a note under M_CAN Dual clock sources – Added a note under M_TTCAN Dual clock sources – Minor editorial changes – Added Example code in the M_CAN Software initialization – Added a new feature as a note below M_CAN features section – Added two new notes below M_CAN and M_TTCAN Dual clock sources respectively. – In the M_CAN CCCR register, corrected the access of TEST bit as RW. – In the M_CAN TOCV register, corrected Bits 16:31 name to TOC. Corrected bit field description. – In the M_CAN IR register, corrected HPM bit map description. – In the M_CAN IR register, corrected RF1L bit map description.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter CAN Subsystem (continued) – In the M_CAN RXF0C register, corrected bit access to RW. – In the M_CAN section, added a new section "Filtering for Debug Messages". – In the M_TTCAN RWD register, corrected Bits24:31 name to WDC. – Updated M_CAN Block diagram – Updated Rx handler description – M_CAN Registers Description: added FBTP, NDAT1,NDAT2, RXBC registers, updated TEST, CCCR, BTP, PSR,IR,IE,ILS, RxF1S – Updated Message RAM section – Update Standard and Extended Message ID Filter Element bit field descriptions – Functional Description: Added a new section "CAN FD Operation", updated Acceptance filtering features, added a new section "Filter for specific IDs", added a new section "Dedicated Rx Buffers", added a new section "Debug on CAN Support" – Updated M_CAN message memory size requirement table – Updated M_TTCAN feature list, Rx handler description, Message RAM Configuration – Updated M_TTCAN Rx Buffer and FIFO Element, Tx Event FIFO Element, – Added M_TTCAN CAN FD Operation. – Updated M_TTCAN Timeout counter, Rx Handling, Acceptance filtering – Added M_TTCAN Dedicated Rx Buffers section – Corrected M_CAN TOCV register reset. – Converted M_CAN and M_TTCAN PSR[LEC] bit map to binary – Corrected M_TTCAN BTP registers field description table – Added M_TTCAN_RXF1S[DMS] bit – Added M_TTCAN_IR[DRX], M_TTCAN_IE[DRXE], M_TTCAN_ILS[DRXL] – Added M_TTCAN_RXF1S[DMS] – Corrected M_CAN_IR[DRX], M_CAN_IE[DRXE], M_CAN_ILS[DRXL] bit access as "w1c" – Updated M_CAN[CCCR] register – Added few cross-references in the M_CAN and M_TTCAN registers. – Added M_TTCA_TTMLM[CSS], M_TTCA_TTOCN[TTIE] – M_TTCAN Extended message ID filter element section : Replaced EIDFC with XIDFC – M_TTCAN: Renamed Rx FIFO element section with Rx Buffer and FIFO element section – Updated M_CAN FD Operation – Updated M_TTCAN FD Operation – Updated "Hardware control for M_TTCAN cycles management" figure – Replaced MCAN with M_CAN and TTCAN/TT_CAN with M_TTCAN throughout the document. – Section 46.3.5.2.11, Timeout Counter Value Register (TOCV): Corrected the register access from "R/W" to "W1C". – Section 46.3.5.2.25, Rx FIFO 0 Configuration Register (RXF0C): Corrected the FOS bit field length from [10:15] to [9:15] – Section 46.3.5.2.26, Rx FIFO 0 Status Register (RXF0S): Added new bits FOPI[10:15]

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter CAN Subsystem (continued) – Section 46.3.5.2.30, Rx FIFO 1 Status Register (RXF1S): Added new bits F1PI[10:15] – Section 46.3.5.2.32, Tx Buffer Configuration Register (TXBC): Corrected the register access from “R” to “RP”. – Section 46.3.5.2.33, Tx FIFO/Queue Status Register (TXFQS): Added new bits TFGI[19:23] – Section 46.3.5.2.42, Tx Event FIFO Status Register (TXEFS): Added new bits EFGI[19:23] Chapter Serial Interprocessor Interface (SIPI) Section 47.2, Overview: – Following added to end of section: “The IPS clock and HCLK(AHB interface clock) for SIPI are of the same frequency and synchronous.” – Updated Section 47.14.1.8, SIPI Module Configuration Register (SIPIMCR) – Added new bit “CHNSB” in Section 47.14.1.8, SIPI Module Configuration Register (SIPIMCR) – Replaced table “SIPI header channel number coding” with Section Table 759., SIPI Header Channel Number Coding. Section Figure 689., SIPI module: – “Channel 2 is given the highest priority for transmission, and is the only channel that is capable of data streaming” is updated to read “Channel 0 is given the highest priority for transmission, and channel 2 is the only channel that is capable of data streaming”. Section 47.14.1.1, Channel Control Register (CCRn): – “channel 2 – channel 0 – channel 1 – channel 3” is updated to read “channel 0 – channel 1 – channel 2 – channel 3”. Section 47.14.1.1, Channel Control Register (CCRn): – The “note” text is updated to read “ This register is only writable in Initialization mode (MCR[INIT] = 1), except for command type bits ie. TC, WL, ST, IDT, RRT and WRT. Also, the command bit types can be written only when corresponding Channel busy bit, CB, is not asserted so SW has to poll the respective channel busy bits before trying to change the command type. At a time only one channel can transmit so only one channel can remain 'busy' and maximum time needed to transmit a full command is 9 clock cycles. Once a channel is not busy then its Command Type can be changed. Also, to send a command, we need to write to the corresponding CARn register(address register)”. Section 47.14.1.1, Channel Control Register (CCRn): – The description of bit “CHEN” read “If all the channel enables are enabled simultaneously, channel 2 will be given the highest priority for transmission. For channels 0, 1 and 3, the lowest channel number is given highest priority.” Here Channel 2 is now Channel 0 and references to Channels 0, 1 and 3 has been removed.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Deserial Serial Peripheral Interface (DSPI) – Modified Async Clocking Scheme and CMDTCF Feature Descriptions. – Updated descriptions of following bit fields - MCR[MDIS], CTAR[FMSZ], SR[CMDTCF], SR[TFFF], PUSH[PE_MASC], PUSH[PP_MCSC], DSICR0[FMSZ5], DSICR0[TSBC], DSICR1[TRGPRD], DSICR1[DPCSx]. – Updated register description for DSPI_PUSH_Slave, DSPI_RXFRx – Changed CTAR_SLAVE[FMSZ6] to CTAR_SLAVE[FMSZ[5]]. – Updated description within DSI Transfer Initiation Control, DSI Serialization, Modified Transfer Format, Interleaved TSB (ITSB) Mode. – Updated mention of system clock to protocol clock at all places appropriate. Chapter DigRF - Interprocessor Communications Table 848 "LCR field description": – Added text "The internal loopback is not intended for board level functionality, so this feature should not be implemented." to the end of the field description of LCR[LVLPE]. Section 49.6.2.16, Unsolicited Tx Control Register (UNSTCR): – Updated field name for UNSTCR[25:31] to UNSHDR Section 49.7.6.2.2, Unsolicited frame receive flow: – Updated UNSRSR[USXDV] to UNSRSR[URXDV]. – Updated RISR[TXUNSF] to RISR[RXUNSF], bullet 3. Section 49.6.2.24, PLL and LVDS Status Register (PLLSR): – Table 857, 'PLLSR field descriptions'. Swapped fields LDSLPS and LRSPLS. Section 49.6.2.15, LVDS Control Register (LCR): – Updated reset value of the LVRXOP field to 100b. Reset value of LCR is now 0000_5024h. Chapter Fast Ethernet Controller (FEC) Section 50.4, Memory map and register definition: – Added "Do not modify the content of reserved fields." Re-architected the register information to present the MIB block counter registers as "real" registers (each register is presented in the overall memory map and has a separate section with the typical register figure and field description). In Section 50.4, Memory map and register definition: – Deleted "You control the FEC by writing into control registers located in each block." – Added "All accesses to and from the registers must be via 32-bit accesses. There is no support for accesses other than 32-bit." In Section 50.4.21, Receive Descriptor Ring Start Register (ERDSR): – Added "You should write zeros to bits 1 and 0. Hardware ignores non-zero values in these two bit positions." – Changed "This register is not reset" to "This register is undefined at reset". – Changed all RMON and IEEE registers from read-write to read-only. Chapter FlexRay Communication Controller (FlexRay) Editorial changes

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Inter-Integrated Circuit (I2C) In Figure 1115 (I2C transaction protocol), changed “XX” to “Data”. In Figure 1121 (I2C high-level protocol steps), added “Acknowledgment from slave” after step 2. In Figure 1122 (Slave address transmission process), in step 4, changed “The master must generate a STOP condition or a repeated START condition” to “The master must initiate a data transfer followed by either a STOP condition or a repeated START condition”. In Section 52.6.5, DMA application information, changed “is configured in master mode” to “is configured in slave mode”. In Table 1108 (Chip modes supported by the I2C module), deleted the entry for DOZE mode (not supported on this chip). In Section 52.4.6, I2C Bus Control Register (IBCR), deleted the IBDOZE field (that bit position is reserved). Section 52.2.4, Features: Added following footnote to features list: “Compliant with I2C 2.0 standard with the exception that HS (high speed) mode is not supported” Chapter Peripheral Sensor Interface (PSI5) Changed the Jitter values to “end of last CRC bit of message” in Section 53.5.1, Latency and Jitter related requirements. Corrected the position of the last stuff bit (in CRC field) of “long” and “xlong” frames in Table 1188 (Standard Frame Formats Supported). Updated Table 1131 (PSI5 port list) to change the pad names to SDINn_PSI5_m and SDOUn_PSI5_m. Replaced “ipp_sdin” to “sdin” and “ipp_sdout” to “sdout” throughout the doc. – Updated Table 1172 (Start Bit Detection) and Table 1173 (Bit Extraction). – Updated Section 53.4.2.3.4.10, Message Too Early (in first slot and overlaps Manchester Decoder disable) and Section 53.4.2.3.4.11, Message Too Late (overlaps next message) to replace 32 samples of idle bit duration by 42 samples. Section 53.3.2.1, Global Control Register (PSI5_GCR): – Changed “Device Configuration File” to “Device Configuration Chapter” in two places. Table 1132 (PSI5 memory map): – Changed “Device Configuration File” to “Device Configuration Chapter” in note 4 at end of table. Removed the statement “DND == 1, if the FIRST_TRANSITION_DETECT occurs and $43 \leq \text{psi5_clk32x_idle_detect_cnt} \leq 45$ and invalid SECOND_TRANSITION_DETECT” from Table 1172 (Start Bit Detection) Updated 1ms in 5th bullet of Figure 1195 (Sync Pulse Generation Parameters and Jitters) to 1us. Table 1129 (Normal operating states): Under “Cycle Time”, “Number to time slots per cycle” is modified to read “Number of time slots per cycle”. Chapter Peripheral Sensor Interface UART interface (PSI5-S) New chapter

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter SENT Receiver (SRX) In Section 55.3.2.15, DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3), some of the LSB bits in the Field Descriptions table were always visible; conditioned all to be LSB. In Section 55.3.2.20, Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG), some of the LSB bits in the Field Descriptions table were always visible; conditioned all to be LSB. – In Section 55.3.2.5, Slow Serial Message Ready Status Register (SMSG_RDY), first paragraph, third sentence: changed “register will get asserted on Fast Message reception” to “register will get asserted on Slow Message reception.” – In Section 55.4.8, Time stamp logic, corrected cross-reference to STATUS register by changing its target to CTRL register. – In Section 55.3.2.4, Fast Message Ready Status Register (FMSG_RDY), first paragraph, third sentence: changed “register will get asserted on Slow Message reception” to “register will be asserted on Fast Message reception.” – In Section 55.3.2.5, Slow Serial Message Ready Status Register (SMSG_RDY), first paragraph, third sentence: changed “register will get asserted on Fast Message reception” to “register will be asserted on Slow Message reception.” Chapter LINFlexD Updated Section 56.2.2, UART mode features In Table 1268 (UARTCR field descriptions) updated description of CSP field, updated description of OSR field and changed field “RSE” to “ROSE” Added a bullet point in Section 56.2.1, LIN mode features Replaced “reset” with “set” in “slave mode” in Section 56.3.2.5.5, Overrun error Updated DRBNE bit from “read only” to “w1c” in Section 56.4.2.3, LIN Status Register (LINSR) Changed the reset value of SLEEP field from “0” to ‘1’ in Section 56.4.2.1, LIN Control Register 1 (LINCR1) Added field “AUTOSYNC_COMP” in Section 56.4.2.3, LIN Status Register (LINSR) Updated the description of DTU field in Section 56.4.2.5, UART Mode Control Register (UARTCR) Updated the description of LSIE field in Section 56.4.2.2, LIN Interrupt enable register (LINIER) Updated Figure 1317 (Master node — DMA Tx FSM (concept scheme)) Editorial updates Changed the description of signals “ipg_stop” and “ipg_stop_ack” in Table 1292 (Interface signals) Updated description of Section 56.4.2.24, UART Current Timeout Register (UARTCTO) Updated description of Section 56.4.2.23, UART Preset Timeout Register (UARTPTO) Updated description of WL0, WL1, WLS and DTU fields in Section 56.4.2.5, UART Mode Control Register (UARTCR) Updated description of Noise flag field in Section 56.4.2.6, UART Mode Status Register (UARTSR) Updated Figure 1291 (Block diagram) Updated Figure 1319 (Master node — DMA Rx FSM (concept scheme)) Updated Section 56.3.2.5.2, Bit error Updated bit description of NF field in Section 56.4.2.6, UART Mode Status Register (UARTSR)

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter LINFlexD (continued) Updated Section 56.3.2.2, Test mode Updated Section 56.2.1, LIN mode features Updated Section 56.4.2.23, UART Preset Timeout Register (UARTPTO) and Section 56.4.2.24, UART Current Timeout Register (UARTCTO) Added MIS field to Section 56.4.2.5, UART Mode Control Register (UARTCR) Section 56.2.2, UART mode features: – Features list item, “1/2 stop bits” changed to, “1/2/3 stop bits” Section 56.2.2, UART mode features: Features list item: “For bit rate $\leq$ 5 Mbit/s / Sixteen times oversampling / 3:1 majority voting” changed to, “For bit rate $\leq$ 12.5 Mbit/s...” Section 56.2.2, UART mode features: Features list item: “For 5 Mbit/s < bit rate $\leq$ 25 Mbit/s / Reduced over sampling programmable by the user / 1:1 voting” changed to “For 12.5 Mbit/s < bit rate $\leq$ 25 Mbit/s / Reduced over sampling programmable by the user / 3:1 majority voting for reduced over sampling of 8 / 1:1 voting for all reduced over sampling of 4, 5 and 6” Changes made throughout chapter for 25 Mbit/s support. Section 56.3.2.2, Test mode Clarification added to Loopback Mode: The TX pin can be disconnected from LINTX pin by SIUL2 setting Section 56.3.2.5.2, Bit error: Calculation of allowable transceiver delay expanded. Section 56.3.2.8, Baud rate generation: Sentence rewritten to note that $ipg_baud_clk = f_{CPU} = LIN_CLK$. Section 56.4.2.5, UART Mode Control Register (UARTCR): Clarification added. The NEF field is read/write Section 56.4.2.5, UART Mode Control Register (UARTCR): Valid configuration values added to RSE (Reduced Over Sampling Enable) field description. Section 56.4.2.5, UART Mode Control Register (UARTCR): Clarification added to DTU (Disable Timeout in UART mode) field description Section 56.4.2.5, UART Mode Control Register (UARTCR): Clarification added to WLS (Special Word Length in UART mode) field description Section 56.4.2.5, UART Mode Control Register (UARTCR): – Correction to WL1 field description for value 01: ““Parity sent is Even” deleted from “8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1Parity sent is Even” – Correction to WL0 field description for value 01: ““Parity sent is Even” deleted from “8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1Parity sent is Even” Section 56.4.2.6, UART Mode Status Register (UARTSR): Clarification added to NF field description. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8. Figure 1291 (Block diagram): Correction: “Rxbysy” changed to “Rxbusy” Updated Section 56.4.2.24, UART Current Timeout Register (UARTCTO) Updated Section 56.2.2, UART mode features

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter LINFlexD (continued) Updated Section 56.3.2.8, Baud rate generation Updated Figure 1291 (Block diagram) Updated Section 56.2.2, UART mode features Updated Section 56.3.2.5.1, Header error Updated Section 56.3.2.5.2, Bit error Updated Section 56.4.2.5, UART Mode Control Register (UARTCR) Updated Section 56.4.2.24, UART Current Timeout Register (UARTCTO) Updated Table 1292 (Interface signals) Updated Section 56.3.2.8, Baud rate generation Updated Section 56.3.2.8, Baud rate generation Updated description of MIS, CSP, ROSE, DTU, SBUR and OSR fields in Section 56.4.2.5, UART Mode Control Register (UARTCR) Changed the reset value of IOBE bit from 0 to 1 in Section 56.4.2.13, LIN Control Register 2 (LINCRR2) Updated description of CSP and OSR fields in Section 56.4.2.5, UART Mode Control Register (UARTCR) Added note to Section 56.4.2.12, LIN Checksum Field Register (LINCRR) Added note to Section 56.4.2.24, UART Current Timeout Register (UARTCTO) Updated Section 56.4.3, Register map Added note to PE bit in Section 56.4.2.6, UART Mode Status Register (UARTSR) Removed note in Section 56.4.2.12, LIN Checksum Field Register (LINCRR) Updated DTU bit description in Table 1268 (UARTCR field descriptions) Changed FRR to FBRR in Figure 1291 (Block diagram) and the note below the figure Updated description of PE bit in Section 56.4.2.6, UART Mode Status Register (UARTSR) Updated Section 56.2.1, LIN mode features Updated Section 56.2.2, UART mode features Updated "Noise" subsection in Section 56.3.2.5.6, Timeout error Updated note in Section 56.3.2.8, Baud rate generation Added note in Section 56.4.2.10, LIN Fractional Baud Rate Register (LINFRR) Added note in Section 56.4.2.11, LIN Integer Baud Rate Register (LINIBRR) Changed the reset value from "0" to "1" in Section 56.4.2.1, LIN Control Register 1 (LINCRR1) Section 56.4.2.5, UART Mode Control Register (UARTCR): Added note in MIS bit description Changed "RFC0" bit to "RFC" in the register diagram Updated WLS bit description Updated TDFL/TFC bit description Updated WL1 bit description Updated WLO bit description Section 56.4.2.6, UART Mode Status Register (UARTSR): Added note to OCF bit description Updated DRF/RFE bit description Added note under Table 1250 (BDRM access in UART mode) Updated RDFBM bit description in Section 56.4.2.22, Global Control Register (GCR) Updated Section 56.3.1.3, Break Note added in Section 56.3.4.7, UART transmitter Note added in Section 56.3.5.10, Use cases and limitations

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter LINFlexD (continued) Table 1292 (Interface signals): Added the following LIN signals- in_ps_clr_DRF in_ps_clr_DTF in_ps_clr_PE[3:0] in_ps_clr_FEF in_ps_clr_BOF in_ps_clr_TOF out_ps_clr_DRF out_ps_clr_DTF out_ps_clr_PE[3:0] out_ps_clr_FEF out_ps_clr_BOF out_ps_clr_TOF out_bdr32b_rx[31:0] Section 56.4.1, Memory map: Added a note Section 56.4.2.22, Global Control Register (GCR): Replaced the address offset from "4C+4×no_of_filters" with "4C+4×no_of_filters×slave" Table 1268 (UARTCR field descriptions): Replaced "Bit 12 is reserved and not implemented" with "Bit 19 is reserved and not implemented" in RDFL bit Section 56.3.2.5.6, Timeout error: added subheadings: "Response timeout mechanism" and "Header timeout mechanism". Section 56.3.2.5.7, Noise: content reorganized into new section subheading replaced Figure 13 (Start detection and sampling for over sampling rate = 4 with six separate figures from Figure 1303 (Start detection and sampling for over sampling rate = 4 (Case 1)) to Figure 1308 (Start detection and sampling for over sampling rate = 4 (Case 5)) Table 1292 (Interface signals): Replaced out_ps_clr_DRF with out_ps_DRF Replace out_ps_clr_DTF with out_ps_DTF Replace out_ps_clr_PE[3:0] with out_ps_PE[3:0] Replace out_ps_clr_FEF with out_ps_FEF Replace out_ps_clr_BOF with out_ps_BOF Replace out_ps_clr_TOF with out_ps_TOF Converted content tagged "PSI5-S_yes" to "Baud_rate_25=yes" Added footnotes in Table 1292 (Interface signals) for all PSI5-S UART interface signals. Added Section 56.3.2.7.1, Start detection mechanism Added Section 56.3.2.7.2, Delimiter detection mechanism Table 1292 (Interface signals): – Added input signals in_ps_clr_RMB, in_ps_bit_remap, in_ps_sleep, and in_ps_init – Added output signals out_ps_RMB, and out_ps_mode[1:0] Updated PCE, and DTU bit description in Section 56.4.2.5, UART Mode Control Register (UARTCR) Added note to SLEEP, and INIT bits in Section 56.4.2.1, LIN Control Register 1 (LINC1)

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Reset Generation Module (MC_RGM) Figure 1393 ('Functional' Event Short Sequence Register (RGM_FESS)): - Register bit 30 renamed from SS_ESR0 to SS_ESR1 Figure 1388 ('Destructive' Bidirectional Reset Enable Register (RGM_DBRE)): - Reset value changed to 0x0000_0000 (was 0x0000_8400) Section 57.3.1.13, Peripheral Reset Register 0 (RGM_PRST0): - SIUL_RST field added Table 1294 (MC_RGM memory map), Section 57.3.1.6, 'Functional' Event Reset Disable Register (RGM_FERD), Section 57.3.1.7, 'Functional' Event Alternate Request Register (RGM_FEAR), Section 57.4.3, External reset - RGM_FEAR[AR_ESR0] changed to Read Only (always reads 0) - RGM_FERD[D_ESR0] changed to Read Only (always reads 0) Table 1294 (MC_RGM memory map): - SIUL_RST R/W added to RGM_PRST0[16] at 0x610 Chapter Boot Assist Flash (BAF) Section 58.3.4, Optionally remap calibration RAM: - Correction: Initialization status register of the buddy device is BD_SIUL2_ISR (was BD_SIU_ISR) - Updated Section 58.3.3, Flow of control to include instructions for operation X and Y - Updated Figure 1422 (Flow of control during serial boot). The decision block "Life Cycle "In Field" removed because the main flowchart (Figure 1414 (Flow of control)) already checks this lifecycle status. - Minor editorial changes - Updated the following sections: Section 58.3.2, Device initialization Section 58.3.6.2, Security watchdog configuration Section 58.3.6.2.4, Security Watchdog CPU select (SEC_SWT_CPU) Section 58.1, Introduction Section 58.3.7, Search boot header and boot options Chapter System Status and Configuration Module (SSCM) - In "Serial boot from SCI" section, changed Boot Assist ROM (BAR) to Boot Assist Module (BAM). Chapter Power Management Controller digital interface (PMC_dig) Removed incorrect description that the RES bits could not be updated if they had been loaded from the Flash (DCF) as a destructive reset. - Removed LVD9 RES registers and references (other than LVDIF) - updated reset of REE_VD9_EBI to be 0 - updated reset of FEE_VD0_IF & IF_2 to be 0 - Added the StandbyRAM logic description into the document - For REE_15 and FEE_15 registers and DEVICE2, corrected reset values for bit16 from 1 to 0.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Power Management Controller digital interface (PMC_dig) (continued) – Corrected TRIM_ADJ_UNDER and TIM_ADJ_OVER in CTL_TD register to show 4-bit fields, not 5-bit fields. – Corrected CTL_TD register informations to say “included two four bit fields” rather than “includes two five bit fields”. – updated reset value EBI RES, FEE, REE registers – updated reset value EBI RES, FEE, REE registers – Removed LVD10_a RES regisiter – adding new VSIO_IF2 bit – adding description of 2nd Temp Sensor output to HSM – updating conditional text for TRIM register reset values to match updated Analog values – updated Temperature Sensor section to refer to four bit User adjust bits instead of 5 bit User adjust registers – added clarification of LVD/HVD bypass via TESTPIN – Updated TEMP_0,1,2,3 names to be consistent – Fixed wording of VD9 REE description to remove the reference to DCF loading – Added VREG1P2_CTRL register and description of VREG1P2_ENB bit – Fixed wording of GR_P HVD entries to say “high voltage detect” instead of “low” – Updated GR_P with removal of VD7F and adding of VD8F in same location – Removed HVD7_F from EPR_VD7, REE_VD7, RES_VD7, and FEE_VD7 – Added HVD8_F to EPR_VD8, REE_VD8, RES_VD8, and FEE_VD8 – Described new PORs in reset section. – Fixed the reset value of the TM_CTRL and VREG1P2_ENB in the TEST_CTRL reg and memory map – Updated the IE register description to replace IE7_F with IE8_F – Updated section 1.14 to replace HVD140_F with HVD145_F Other Modules Interfaces section. Changed LVD names. – LVD114_H renamed to LVD108_C – LVD114_F renamed to LVD108_F – LVD114_P renamed to LVD108_P – LVD114_C renamed to LVD112_C – LVD280_C renamed to LVD270_C – LVD280_F renamed to LVD270_F – LVD280_IF renamed to LVD270_IF – LVD280_IJ renamed to LVD270_IJ – LVD280_IM renamed to LVD270_IM – LVD300_A renamed to LVD295_A – LVD300_F renamed to LVD295_F Memory Map/Register Definition section. Changed LVD names. – LVD114 renamed to LVD108 – LVD280 renamed to LVD270 – LVD300 renamed to LVD295

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Power Control Unit (MC_PCU) Editorial changes Chapter Mode Entry Module (MC_ME) Table 1410 (Mode Configuration Registers (ME_<mode>_MC) Field Descriptions): – Added footnote to XOSCON bit regarding loss of oscillator clock. Table 1406 (Interrupt Status Register (ME_IS) Field Descriptions): – I_ICONF_CC: "ME_CCTLn" changed to "ME_CADDRn" in bit value descriptions Section 62.3.2.27, Core Control Register 0 (ME_CCTL0): – Following sentence deleted: "A write access to this register during this time will result in the ME_IS[ICONF_CC] flag being asserted." Section 62.3.2.28, Core Control Register (ME_CCTL1): – Following sentence deleted: "A write access to this register during this time will result in the ME_IS[ICONF_CC] flag being asserted." Section 62.3.2.29, Core Control Register (ME_CCTL2): – Following sentence deleted: "A write access to this register during this time will result in the ME_IS[ICONF_CC] flag being asserted." Section 62.3.2.30, Core Control Register 3 (ME_CCTL3): – Following sentence deleted: "A write access to this register during this time will result in the ICONF_CC flag in the ME_IS register being asserted." Section 62.3.2.31, Core Control Register (ME_CCTL4): Following sentence deleted: "A write access to this register during this time will result in the ME_IS[ICONF_CC] flag being asserted." Deleted CADDR2 (not used on this chip) Chapter e200z420n3 Core Debug Support In Section 63.5.3, JTAG/OnCE pins, changed the sentence "Asserting dbg_dbgrq will cause the chip to exit the low power mode enabled by the setting of MSR_{WE}, as well as temporarily exiting the Waiting, Stopped or Halted power management states." to "Asserting dbg_dbgrq will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states." Chapter e200z425n3 Core Debug Support In Section 64.5.3, JTAG/OnCE pins, changed the sentence "Asserting dbg_dbgrq will cause the chip to exit the low power mode enabled by the setting of MSR_{WE}, as well as temporarily exiting the Waiting, Stopped or Halted power management states." to "Asserting dbg_dbgrq will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states."

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Debug and Calibration Interface (DCI) Added a note to provide more details about simultaneous usage of SW debug & HW debug modes Changed references to non-secure mode to SoC Debug_Enable signal in: – Section 65.1.3.4, Nexus reset control – Section 65.1.3.11, Security Added Table 1488 (Nexus reset truth table) Section 65.1.3.4, Nexus reset control: – Following note added: If Debug_Enable is de-asserted by SOC security modules (HSM or PASS), then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets Figure 1586 (DCI operating modes state diagram) updated to '1st Timeout + 1' in DCI_LFAST_SAFE -> DCI_JTAG transition Chapter JTAG Controller (JTAGC) Removed arrow from TDI to TAP instruction decoder in Figure 1596 (JTAG (IEEE 1149.1) block diagram). Chapter IEEE 1149.7 Compact JTAG Test Access Port Controller (CJTAG) In Section 67.3, Introduction, changed "Operation with both 4-pin and 2-pin star scan topologies and a 4-pin series scan topology" to "Operation with both 4-pin and 2-pin scan topologies". Renamed Section 67.4, CJTAG implementation summary (was "TAP.7 controller classes) and removed all content except that previously contained in "CJTAG implementation summary". Deleted the "Scan Selection Directive (SSD)" section. Deleted content pertaining to the SSCAN function in Section 67.7.1, Overview, and Section 67.7.8, SP Format Chapter JTAG Data Communication (JDC) Editorial changes Chapter Sequence Processing Unit (SPU) Editorial changes Chapter JTAG Master (JTAGM) Editorial changes

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter DigRF - High Speed Debug Table 1587 (LCR field description) "LCR field description" - Added text "The internal loopback is not intended for board level functionality, so this feature should not be implemented." to the end of the field description of LCR[LVLPEN]. Section 71.6.2.10, Unsolicited Tx Control Register (UNSTCR) Updated field name for UNSTCR[25:31] to UNSHDR Section 71.7.6.2.2, Unsolicited frame receive flow - Updated UNSRSR[USXDV] to UNSRSR[URXDV]. - Updated RISR[TXUNSF] to RISR[RXUNSF], bullet 3. Section 71.6.2.17, PLL and LVDS Status Register (PLLLSR) Table 1595 (PLLLSR field descriptions), 'PLLSR field descriptions'. Swapped fields LDSLPS and LRSLPS. Section 71.6.2.9, LVDS Control Register (LCR) Updated reset value of the LVRXOP field to 100b. Reset value of LCR is now 0000_5024h. Chapter Development Tool Semaphore (DTS) Editorial changes Chapter Nexus Aurora Router (NAR) Bit 20 of NAR_CR must be written with 0 in Section 73.4.1.1, NAR control register (NAR_CR). Changed reset value of Section 73.4.1.2, NAR status register (NAR_ST) to 0x00000001 (QWA=1). Chapter e200z420n3 Nexus 3 Module - In Section 74.3, TCODEs supported: changed standard to IEEE-ISTO 5001-2003 In Section 74.2, Enabling Nexus 3 Operation, added sentence about Nexus3 enabling with EVTI on TRST_B negation or during Test-Logic-Reset TAP state. Added the following text to Section 74.4.13, Read/Write Access Control/Status (RWCS) register: "Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values." Added the following text to Section 74.17.1, Single write access procedure step 4, "The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer." Added nex_ahb_start pin to note following this procedure. Added the following text to Section 74.17.2, Block write access, procedure step 2, "The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer." Added the following text to Section 74.17.3, Single read access, procedure step 3, "The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer." Added nex_ahb_start pin to note following this procedure. Added the following text to Section 74.17.4, Block read access, procedure step 2, "The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer."

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter e200z420n3 Nexus 3 Module (continued) In Table 1651 (DS field descriptions), updated LPS field description In Section 74.2.1, Interaction with Low Power Modes, replaced the paragraph with: "The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as nex_clk remains active. In the Stopped state, nex_clk is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming nex_clk is active." Chapter e200z425n3 Nexus 3 Module – In Section 75.3, TCODEs supported: changed standard to IEEE-ISTO 5001-2003 In Section 75.2, Enabling Nexus 3 Operation, added sentence about Nexus3 enabling with EVTI on TRST_B negation or during Test-Logic-Reset TAP state. Added the following text to Section 75.4.13, Read/Write Access Control/Status (RWCS) register: "Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values." Added the following text to Section 75.17.1, Single write access procedure step 4, "The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer." Added nex_ahb_start pin to note following this procedure. Added the following text to Section 75.17.2, Block write access, procedure step 2, "The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer." Added the following text to Section 75.17.3, Single read access, procedure step 3, "The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer." Added nex_ahb_start pin to note following this procedure. Added the following text to Section 75.17.4, Block read access, procedure step 2, "The nex_ahb_start output will be asserted during the first clock of the address phase of the transfer." In Table 1704 (DS field descriptions), updated LPS field description Section 75.2.1, Interaction with Low Power Modes, replaced the paragraph with: "The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as nex_clk remains active. In the Stopped state, nex_clk is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming nex_clk is active."

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter GTM Development Interface (GTMDI) Changed SSEL1/2 fields in GTMDI_ATOM_WPC1 register description figure. It was read only, the correct is read/write for these fields. Added variable for PIN value of PIN field of DID register and added to variable table. Changed conditional text for SPEA/B SSEL field selection. The current implementation only allows SPE0 selection for SPEA and SPE1 selection for SPEB. This is for backwards compatibility with previous version which had just one possible SPE selection for SPEA.B (SPE1/2 at in previous version). Chapter Nexus Crossbar Multi-Master Client (NXMC) Changed WPHIT packet type to variable in Supported public TCODE table Table 1810 (DC2 register field description): Added descriptive phrase to DC2[PME0] field: "... for the In-Circuit Trace (ICT) feature" Chapter Cyclic Redundancy Check Unit (CRC) Corrected the INV field from "read only" to read/write in Section 78.5.1.1, CRC Configuration Register (CRC_CFG) Corrected CRC-32 polynomial Equation 90. Deleted "and limitations" from section title Section 78.7, Use cases. Changed "IPS" to "peripheral bus" in Section 78.2.1, Standard features, Section 78.4.1, Peripheral bus interface, Table 1960 (CRC top level diagram) and Section 78.6, Functional description. Moved footnote in Table 1820 (CRC unit memory map) because it appeared to say N-squared. Replace CRC_CNTX_NUM with N. Added row to Table 1820 (CRC unit memory map) for CRC_OUTP_CHK. Changed INV bit in Section 78.5.1.1, CRC Configuration Register (CRC_CFG) from RO to R/W. Section 78.5.1.1, CRC Configuration Register (CRC_CFG): Added field "swap_bitwise" to bit 27 and field "swap_bytewise" to bit 26 Section 78.5.1.1, CRC Configuration Register (CRC_CFG): Swapped the bit description of bit 26 and bit 27 Chapter Memory Error Management Unit (MEMU) In Table 1825 (MEMU memory map), changed the reset values of the SYS_RAM_CERR_STS, PERIPH_RAM_CERR_STS, and FLASH_CERR_STS registers (were 0000_00FF, are 0000_0000). In Figure 1975 (System RAM correctable error reporting table address register (SYS_RAM_CERR_ADDRn)), added the missing offset (as present in Table 1825 (MEMU memory map)). In Section 79.6.2.2, Error flag register (ERR_FLAG), deleted the duplicate paragraph ("Individual flags... cleared by SW").

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Indirect Memory Access (IMA) Section 80.3.4.5, IMA access: – Added IMA_STATUS register name to bits for clarification – Correction: READ_LOCK needs to be cleared for reads (not READ_UNLOCK). Changed “31 READ” to “31 EN” in Table 1849 (IMA_ENABLE field descriptions). Section 80.3.4.5.1, Read access: – Clarification: Step 1 is to perform the required consecutive writes to the READ_UNLOCK register Section 80.3.4.5.2, Write access: – Clarification: Step 1 is to perform the required consecutive writes to the READ_UNLOCK register Section 80.3.3.2, IMA Enable Access Register (IMA_ENABLE): – Note added: Back to back writes to the enable bit is not valid. It will still generate a two clock enable pulse and will be considered as a single access initiation. Section 80.3.4.4, IMA lock – New section Chapter Fault Collection and Control Unit (FCCU) -Added OD field in Section 81.6.3, FCCU Configuration Register (FCCU_CFG) register. -Changed “WKUP module” to “WKPU” in Section 81.5.6, NMI interface - Updated Section 81.5.9, EOUT interface - Updated the bit description of “FCCU_SET_CLEAR” bit in Section 81.6.3, FCCU Configuration Register (FCCU_CFG) - Section 81.5.9, EOUT interface: Removed the Note section. - Updated Table 1862 (FCCU error pin behavior on STATE transitions) Updated PS field description in Section 81.6.3, FCCU Configuration Register (FCCU_CFG) Applied Saf1129 in OD field description in Section 81.6.3, FCCU Configuration Register (FCCU_CFG) Updated ESTAT field description in Section 81.6.13, FCCU Status Register (FCCU_STAT) Updated DEBUG field descriptions in Section 81.6.1, FCCU Control Register (FCCU_CTRL) Section 81.9.1, Misconfigurations : Added a new point, “If the user programs the FCCU for a higher timeout value than what is hardcoded for FOSU, then FCCU reacts later than what FOSU would be expecting and as a result, FOSU will not generate destructive reset request on its timeout”. Updated Table 1905 (FCCU register map) with all the new bits added in registers. Replaced all instances of ‘safe clock’ with ‘IRCOSC clock’. Table 1862 (FCCU error pin behavior on STATE transitions): – Updated table name to “FCCU error pin behavior on STATE transitions” from “FCCU error pin behavior”. – “FAULT state” updated to read “Transition from NORMAL to FAULT state”. – “ALARM state” updated to read “Transition from NORMAL to ALARM state”. – “Fault disabled/enabled” updated to read “with Fault disabled/enabled”. Added note 2 in Section 81.6.28, FCCU EOUT Signaling Enable Registers (FCCU_EOUT_SIG_EN[0:3]) Added note in Section 81.6.12, FCCU IO Control Register (FCCU_EINOUT)

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Self-Test Control Unit (STCU2) Removed section “Glossary, Acronyms & Abbreviations” Section 82.7.1, Off-Line Self-Test Sequence: deleted instance of “when pll_lock is high” Section 82.7.2, On-Line Self-Test Sequence: deleted instance of “also when pll_lock is high” Section 82.4.8.3, Write access time-out: replaced “that after AUTOLOCK_VALUE number of clock pulses lock” with “that, after 1024 STCU2 clock cycles, lock” Table 1908, STCU_RUNSW field descriptions: replaced instances of “pll_lock” with “PLL lock signal” Section 82.7.2, On-Line Self-Test Sequence: replaced instance of “pll_lock monitor” with “PLL lock signal monitor” Section 82.4.5, PLL interface: Replaced “As soon as it happens, forces the switch with the PLL output clock” with “As soon as the lock happens, the STCU forces the clock to switch to the PLL output clock” Chapter Register Protection (REG_PROT) Editorial changes Section 83.3.2.4, Global Configuration Register (GCR): – UAA bit moved to bit 8 Section 83.1.1, Overview: – Following note added: Please see the device configuration chapter of the device reference manual for details of the protected registers and bytes. Section 83.3.2.4, Global Configuration Register (GCR): – Intro text changed to: “This register controls the configuration of the locking of the SLB's and the level of user access allowed to the protected registers” Section 83.1.3, Modes of operation: – Following sentence removed: “For further details about the availability please see the chapter of the corresponding module” Chapter Password module (PASS) Section 84.3.1.4, Challenge Input register (CINn): – Following paragraph deleted: “To protect against voltage manipulations, complete 256-bit password must be considered a valid password challenge. An illegal value results in a failed challenge, so the password must be chosen appropriately.” Section 84.3.1.6.2, Hardware Interlock (HI): – “Once the hardware pin is <i>negated</i>, programming of BAF is controlled by PASS_LOCK0[BAF] bits” changed to “Once the hardware pin is <i>asserted high</i>....” Section 84.3.1.11, Password Group n - Lock 3 status register (LOCK3_PGn): Figure 2114 (LOCK3_PGn Register): – Note added to RL field bits: “Not all devices include this field. See the device reference manual's chip configuration chapter for details.” Section 84.5.4, Censoring/uncensoring the device: – Example, including “Censoring the device” table, deleted – Fixed conditional text error that was causing content to run into the heading of the next section.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Password module (PASS) (continued) Section 84.5.5, Unlocking the debug interface via JTAG: – Following text deleted: “The password needs to be set in UTest, and the same rules apply as to other passwords. The result of setting an invalid JTAG password is the debug interface cannot be unlocked via the JTAG password challenge register.” Chapter Tamper Detect Module (TDM) Minor editorial changes Chapter ASC Modeling Unit Section 86.1, Introduction: – Correction: The [AMU] block consists of a local 32 KB RAM with 64-bit ECC. (was incorrectly stated as 50 KB RAM. Chapter Wakeup Unit (WKPU) Table 2012 (NSR field descriptions): repaired unresolved cross-reference to footnote “Index ‘x’ designates ... and 2 is the IOP.” Renamed Section 87.5.2, Non-maskable interrupt initialization (was “Non-Maskable Interrupts”) Numerous editorial changes. Chapter GTM103 Integration (GTMINT) Module Table 2014 (High level memory map): – Moved: FIFO0_MEMORY moved from 0x0001A000 to 0x00019000 – Moved: MAP moved from 0x00000040 to 0x00000F00 – Moved: MCFG moved from 0x00000080 to 0x00000F40 – Moved: MCS1 moved from 0x00040000 to 0x00031000 – Moved: MCS2 moved from 0x00050000 to 0x00032000 – Moved: MCS3 moved from 0x00060000 to 0x00033000 – Moved: MCS4 moved from 0x00070000 to 0x00034000 – Moved: MCS5 moved from 0x00080000 to 0x00035000 – Moved: MCS6 moved from 0x00088000 to 0x00036000 – Moved: MCS0_MEMORY moved from 0x00038000 to 0x00038000 – Moved: MCS1_MEMORY moved from 0x00048000 to 0x00040000 – Moved: MCS2_MEMORY moved from 0x00058000 to 0x00048000 – Moved: MCS3_MEMORY moved from 0x00068000 to 0x00050000 – Moved: MCS4_MEMORY moved from 0x00078000 to 0x00058000 – Moved: MCS5_MEMORY moved from 0x00088000 to 0x00060000 – Moved: MCS6_MEMORY moved from 0x00098000 to 0x00068000 – New: GTM-IP AEI Bridge Registers at 0x00000030 – New: DPLL REGION EXT at 0x00028E00

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Buddy Device-Debug and Calibration Interface (DCI) Throughout: – “DigRF” is now “LFAST” – Formatting and other editorial changes Section 92.1.3.3, Software enabled debug and calibration mode: – Note added recommending using either hardware-based debug or software-based debug, but not both. Section 92.1.3.4, Nexus reset control: – Changed references to non-secure mode to SoC Debug_Enable signal Section 92.1.3.11, Security: – Changed references to non-secure mode to SoC Debug_Enable signal – Added Figure 2035 (Nexus reset truth table) Figure 2172 (DCI operating modes state diagram) updated to ‘1st Timeout + 1’ in DCI_LFAST_SAFE -> DCI_JTAG transition Chapter Buddy Device-JTAG Controller (JTAGC) Section 93.1.2, Features: – Changed CENSOR_CTRL to JTAG_PASSWORD Section 93.3.4, JTAG_PASSWORD register: – Changed CENSOR_CTRL to JTAG_PASSWORD (was CENSOR_CTRL register) Section 93.3.4, JTAG_PASSWORD register: – Changed CENSOR_CTRL to JTAG_PASSWORD (was CENSOR_CTRL register) Section 93.4.4, JTAGC block instructions: – Changed CENSOR_CTRL to JTAG_PASSWORD Section 93.4.4.5, ENABLE_JTAG_PASSWORD instruction: – Changed CENSOR_CTRL to JTAG_PASSWORD (was ENABLE_CENSOR_CTRL instruction) Chapter Buddy Device - JTAG Master (JTAGM) Throughout: – “DigRF” is now “LFAST” Chapter Buddy Device-Nexus Aurora Router (NAR) Section 95.4.1.1, NAR control register (NAR_CR): Table 2058 (NAR_CR field descriptions): – Bits 20–16 must be written with 0. Section 95.4.1.2, NAR status register (NAR_ST): Figure 2205 (NAR status register (NAR_ST)): – Changed reset value to 0x00000001 (QWA=1). Section 95.4.7, Trace Memory fill level and partition configuration register (NAR_AHFPAR): Table 2069 (NAR_AHFPAR field description): – Bits 31–25 must be written with 0. – Bits 23–21 must be written with 0. – Bits 15–12 must be written with 0.

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter Buddy Device-Nexus Aurora Link (NAL) <i>Figure 2222 (NAL block diagram):</i> – UFC output removed from Flow Control block in Aurora Protocol Engine block <i>Section 96.1, Transmit operation:</i> – “After each packet transfer, the NAL adds...” changed to “After each payload transfer, the NAL adds...” – Note regarding clock compensation added <i>Section 96.4.2, NAL General Control Register (NAL_GCR):</i> <i>Figure 2224 (NAL General Control Register (NAL_GCR)):</i> – Removed ALCLBE and APELBE fields. These are internal test bits that should not be changed. <i>Table 2082 (NAL_GCR field descriptions):</i> – Removed ALCLBE and APELBE fields. These are internal test bits that should not be changed. <i>Section 96.4.3, NAL Training Control Register (NAL_TCR):</i> <i>Table 2083 (NAL_TCR field descriptions):</i> – Changed STE field 0 setting to Reserved. Chapter Buddy Device-Nexus Aurora PHY (NAP) <i>Section 97.1, Introduction:</i> – “and CRC checking” removed from following sentence: “...it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called Lane Alignment in Aurora terminology), 10b/8b decoding, decode and disparity error tracking and CRC checking in the received data stream.” <i>Section 97.1.2, Modes of operation:</i> – “The functional configuration is determined by the IO Port Control setting ...” changed to “The functional configuration is determined by the NAR_NAPCR setting...” <i>Section 97.2, External signal description:</i> – Clarification: Each of the NAP signals consists of a positive and negative differential pair. – Differential pair signal names added to NAP signals table Chapter DWPU <i>Section 98.3.1, Nexus Out Interface (NOI):</i> Detail added: – Messages received for filtering are from NAR – The NAR only initiates a transfer to the DWPU when it has full beats messages – Incoming messages are buffered – New figure: <i>Figure 2229 (Incoming message format)</i>

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter DWPU (continued) Section 98.3.3, MCA has the capability of providing one fully concatenated message to a CSPU each clock. Client Specific Processing (CSP): Detail added: – The Client Specific Processing (CSP) block receives the messages from MCA. The received message are processed after extracting all the relevant fields. Different types of message from various clients are received and processed differently based on their type by a specialized unit called the Client Specific Processing Unit (CSPU). – All message types other than data write messages are dropped Section 98.3.3.1.1, Standard data trace write message format: – Optional TSTAMP) field is 26 bits (was 32 bits) Section 98.3.4, Address Tag Check (ATC): – Section significantly rewritten with added detail Section 98.3.7, Nexus Client Interface (NCI): – NCI also supports the buffer reallocation to increase the Q size Section 98.3.8, IEEE 1149.1 (JTAG) Test Access Port: – New Section 98.3.9, Enabling DWPU operation: – New Section 98.3.10, Enabling TAP controller: – New Section 98.3.11, Register access via JTAG: – New Section 98.4, Configuration: – New Section 98.4.1, Tag RAM initialization: – New Section 98.5, Register definition: Table 2093 (JTAG DWPU registers): – Reset value for Global Control (GLB_CTRL) register changed to 0x0000_0002 (was 0x0000_0000) – Reset value for Out of Range Check Control 1 (ORC_CTRL1) register changed to 0x0000_0000 (was 0x0000_000F) – Reset value for Global Status (GLB_STAT) register changed to 0x0000_0000 (was 0x0004_0000) Register figures in register subsections: – Access level deleted—see Table 2093 (JTAG DWPU registers) for access – “Offset” replaced with “Index” in JTAG DWPU registers Section 98.5.1.2, Source Mapping Control n (SRC_MAP_CTLRn): Figure 2241 (SRC_MAP_CTLRn register): – Bit numbering changed. Least significant bit is bit 0. Table 2096 (SRC_MAP_CTLRn field descriptions): – CSP_TYPE0 field value list updated to reflect field's 3-bit width and include all values – CSP_TYPE1 field value list added

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter DWPU (continued) Section 98.5.1.3, Filter Address Range Start Address n (FAR_SA_CFGn): Figure 2242 (FAR_SA_CFGn register): – Bit numbering changed. Least significant bit is bit 0. Section 98.5.1.4, Filter Address Range Region Size n (FAR_RS_CFGn): Figure 2243 (FAR_RS_CFGn register): – Bit numbering changed. Least significant bit is bit 0. Section 98.5.1.5, Tag RAM Control (TRC_CTRL): Figure 2244 (TRC_CTRL register): – Bit numbering changed. Least significant bit is bit 0. – New fields added: ERR, EXC, PROG, INV, DSM – Reserved bits all read only 0 Table 2099 (TRC_CTRL field descriptions): – New fields added: ERR, EXC, PROG, INV, DSM – Note: ERR field is not present in the IPS mapped version of register. Section 98.5.1.6, Tag RAM Configuration Address (TRC_ADR): Figure 2245 (TRC_ADR register): – Bit numbering changed. Least significant bit is bit 0. Section 98.5.1.7, Tag RAM Configuration Data (TRC_DATA): Figure 2246 (TRC_DATA register): – Bit numbering changed. Least significant bit is bit 0. Section 98.5.1.8, Out of Range Check Control 1 (ORC_CTRL1): Figure 2247 (ORC_CTRL1 register): – Bit numbering changed. Least significant bit is bit 0. – Reserved bits all read only 0 Table 2102 (ORC_CTRL1 field descriptions): – TORn fields' "0" value definitions changed: Trigger is generated if data write value is within the range $ORC_CFGn_DL \leq data_wr_value \leq ORC_CFGn_DH$ ("$< ORC_CFGn_DH$" changed to "$\leq ORC_CFGn_DH$") – TORn fields' "1" value definitions changed: Trigger is generated if data write value is outside the range $data_wr_value < ORC_CFGn_DL$ or $data_wr_value > ORC_CFG0_DH$ ("or $data_wr_value \geq ORC_CFGn_DH$" changed to "or $data_wr_value > ORC_CFGn_DH$") Section 98.5.1.9, Out of Range Check Control 2 (ORC_CTRL2): Figure 2248 (ORC_CTRL2 register): – Bit numbering changed. Least significant bit is bit 0. – MODE field deleted Table 2103 (ORC_CTRL2 field descriptions): – MODE field deleted Section 98.5.1.10, Global Status (GLB_STAT): Table 2104 (GLB_STAT field descriptions): – Bit numbering changed. Least significant bit is bit 0. – DIDLE field added Table 2104 (GLB_STAT field descriptions): – DIDLE field added

Table 2152. Document revision history (continued)

Date	Revision	Changes
06-Jun-2013	4 (continued)	Chapter DWPU (continued) Section 98.5.1.11, Out of Range Configuration Address n (ORC_CFGn_ADR): Figure 2250 (ORC_CFGn_ADR register): – Bit numbering changed. Least significant bit is bit 0. Section 98.5.1.12, Out of Range Configuration Data High n (ORC_CFGn_DH): Figure 2251 (ORC_CFGn_DH register): – Bit numbering changed. Least significant bit is bit 0. Section 98.5.1.13, Out of Range Configuration Data Low n (ORC_CFGn_DL): Figure 2252 (ORC_CFGn_DL register): – Bit numbering changed. Least significant bit is bit 0. Section 98.5.1.14, Out of Range Configuration Data Mask n (ORC_CFGn_DM): Figure 2253 (ORC_CFGn_DM register): – Bit numbering changed. Least significant bit is bit 0. Chapter Buddy Device-Nexus Read Write Access (RWA) No changes Chapter Buddy Device-DigRF - High Speed Debug Throughout: – “DigRF” is now “LFAST” – Minor editorial changes Table 2129 “LCR field description”: – Added text “The internal loopback is not intended for board level functionality, so this feature should not be implemented.” to the end of the field description of LCR[LVLPEN]. Section 100.6.2.11, Unsolicited Tx Control Register (UNSTCR): – Updated field name for UNSTCR[25:31] to UNSHDR Section 100.7.3.2.3, Auto correlation: – Detail added regarding clock phases Section 100.7.6.2.2, Unsolicited frame receive flow: – Correction: At beginning of section, “If UNSRSR[USXDV] = 0” changed to “If UNSRSR[URXDV] = 0”. – Correction: In step 3 at beginning of section, “...and the RISR[TXUNSF] = 1...” changed to “...and the RISR[RXUNSF] = 1”.. Section 100.6.2.18, PLL and LVDS Status Register (PLLSR): – Table 2137, ‘PLLSR field descriptions’. Swapped fields LDSLPS and LRSPLS. Section 100.6.2.10, LVDS Control Register (LCR): – Updated reset value of the LVRXOP field to 100b. Reset value of LCR is now 0000_5024h. Section 100.10.3.1, Clocking module requirements for high speed phases: – Detail added on connections and routing.

Please Read Carefully:

Information in this document is provided solely in connection with ST products. STMicroelectronics NV and its subsidiaries ("ST") reserve the right to make changes, corrections, modifications or improvements, to this document, and the products and services described herein at any time, without notice.

All ST products are sold pursuant to ST's terms and conditions of sale.

Purchasers are solely responsible for the choice, selection and use of the ST products and services described herein, and ST assumes no liability whatsoever relating to the choice, selection or use of the ST products and services described herein.

No license, express or implied, by estoppel or otherwise, to any intellectual property rights is granted under this document. If any part of this document refers to any third party products or services it shall not be deemed a license grant by ST for the use of such third party products or services, or any intellectual property contained therein or considered as a warranty covering the use in any manner whatsoever of such third party products or services or any intellectual property contained therein.

UNLESS OTHERWISE SET FORTH IN ST'S TERMS AND CONDITIONS OF SALE ST DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY WITH RESPECT TO THE USE AND/OR SALE OF ST PRODUCTS INCLUDING WITHOUT LIMITATION IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE (AND THEIR EQUIVALENTS UNDER THE LAWS OF ANY JURISDICTION), OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

ST PRODUCTS ARE NOT DESIGNED OR AUTHORIZED FOR USE IN: (A) SAFETY CRITICAL APPLICATIONS SUCH AS LIFE SUPPORTING, ACTIVE IMPLANTED DEVICES OR SYSTEMS WITH PRODUCT FUNCTIONAL SAFETY REQUIREMENTS; (B) AERONAUTIC APPLICATIONS; (C) AUTOMOTIVE APPLICATIONS OR ENVIRONMENTS, AND/OR (D) AEROSPACE APPLICATIONS OR ENVIRONMENTS. WHERE ST PRODUCTS ARE NOT DESIGNED FOR SUCH USE, THE PURCHASER SHALL USE PRODUCTS AT PURCHASER'S SOLE RISK, EVEN IF ST HAS BEEN INFORMED IN WRITING OF SUCH USAGE, UNLESS A PRODUCT IS EXPRESSLY DESIGNATED BY ST AS BEING INTENDED FOR "AUTOMOTIVE, AUTOMOTIVE SAFETY OR MEDICAL" INDUSTRY DOMAINS ACCORDING TO ST PRODUCT DESIGN SPECIFICATIONS. PRODUCTS FORMALLY ESCC, QML OR JAN QUALIFIED ARE DEEMED SUITABLE FOR USE IN AEROSPACE BY THE CORRESPONDING GOVERNMENTAL AGENCY.

Resale of ST products with provisions different from the statements and/or technical features set forth in this document shall immediately void any warranty granted by ST for the ST product or service described herein and shall not create or extend in any manner whatsoever, any liability of ST.
