
**SPC57EM80xx - 32-bit Power Architecture® based MCU with up to
4 Mbyte Flash and 304 Kbyte RAM memories**

Preface

Overview

The primary objective of this document is to define the functionality of the SPC57EM80xx microcontroller for use by software and hardware developers. The SPC57EM80xx is built on Power Architecture® technology and integrates technologies that are important for today's and tomorrow's automotive applications. SPC57EM80xx applications include automotive powertrain controllers for six to eight cylinder gasoline and diesel engines, transmission control, chassis control, steering and braking, as well as high end hybrid and advanced combustion systems, electric power steering, and safety applications that require a high level of safety integrity.

The information in this book is subject to change without notice, as described in the disclaimers on the title page. As with any technical documentation, it is the reader's responsibility to be sure he or she is using the most recent version of the documentation.

To locate any published errata or updates for this document, visit the ST Web site at www.st.com.

Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products with the SPC57EM80xx device. It is assumed that the reader understands operating systems, microprocessor system design, basic principles of software and hardware, and basic details of the Power Architecture.

Document organization

This document includes chapters that are divided into parts:

- Part I includes chapters that describe the device as a whole or provide device-specific information.
- Part II includes chapters that describe the functionality of the individual modules on the device.
- Part III includes chapters that describe the functionality of the Emulation and Debug Device (ED).

Contents

1	Register conventions	154
1.1	Acronyms and abbreviations	155
1.2	References	156
2	Introduction	157
2.1	SPC57EM80xx microcontroller	157
2.1.1	Target applications	157
2.1.2	Overall architecture	157
2.1.3	Core features	158
2.1.4	I/O Processor	158
2.1.5	Memory hierarchy	159
2.2	Features summary	160
2.3	Feature list	161
2.4	Packaging	163
2.5	Software debug and calibration	163
2.6	Block diagrams	164
3	Embedded memories	166
3.1	Overview	166
3.2	SRAM	166
3.2.1	System SRAM	166
3.2.2	Standby SRAM Regulator	166
3.2.3	Overlay SRAM	168
3.2.4	Processor core local SRAM	169
3.3	Embedded flash memory	169
3.3.1	Flash memory controller	170
3.3.2	Flash memory array	170
3.4	End-to-end Error Correction Code (e2eECC)	172
3.5	Security features	174
4	Signal Description	176
4.1	Production packages	176
4.2	Emulation package	176

4.3	Package pinouts and ballouts	176
4.4	Pin/ball descriptions	176
4.4.1	Pin/ball startup and reset states	177
4.4.2	Power supply and reference voltage pins/balls	177
4.4.3	System pins/balls	179
4.4.4	LVDS pins/balls	179
4.4.5	Generic pins/balls	184
5	Memory Map	185
6	Functional Safety	202
6.1	Introduction	202
6.2	Safety overview	202
6.3	Module categorization	202
6.4	System implementation	205
6.4.1	General concept	205
6.4.2	Dual-core lockstep	226
6.4.3	Common Cause Failure measures	229
6.4.4	ECC	229
7	Device Configuration	233
7.1	Introduction	233
7.2	Core modules	233
7.2.1	Core Reset Settings	233
7.2.2	Special Purpose Register Summary	236
7.3	System modules	238
7.3.1	SIUL2 configuration	238
7.3.2	Semaphores2 (SEMA42)	238
7.3.3	Crossbar switch configuration	239
7.3.4	System Memory Protection Unit (SMPU) configuration	243
7.3.5	Peripheral bridge configuration	248
7.3.6	Platform Configuration Module (PCM)	248
7.3.7	Interrupt Controller (INTC) configuration	253
7.3.8	DMA Controller configuration	295
7.3.9	DMACHMUX configuration	295
7.4	Clocking	300

7.5	Memories and memory interfaces	301
7.5.1	Flash memory controller (PFLASH) configuration	301
7.6	Analog modules	303
7.6.1	Temperature sensor configuration	304
7.6.2	Analog to Digital Converters (ADC) configuration	304
7.7	Timers	305
7.7.1	System Timer Module (STM) configuration	305
7.7.2	Software Watchdog Timer (SWT) configuration	306
7.7.3	PIT configuration	308
7.7.4	GTM 103 Integration Module (GTMINT103) configuration	310
7.8	Communication interfaces	311
7.8.1	Fast Ethernet Controller (FEC) configuration	311
7.8.2	FEC interface selection	311
7.8.3	CAN subsystem configuration	311
7.8.4	LFASST and SIPI	311
7.8.5	DSPI configuration	313
7.8.6	FlexRay Configuration	316
7.8.7	PSI5 Controller Configuration	317
7.8.8	SENT receiver (SRX) configuration	317
7.8.9	LINFlexD — Configurations	320
7.9	Reset and boot modules	321
7.9.1	System Status and Configuration Module (SSCM) configuration	321
7.10	Safety modules	322
7.10.1	CRC – Number Of Contexts	322
7.10.2	MEMU configuration	323
7.10.3	Indirect Memory Access (IMA) configuration	331
7.10.4	FCCU configuration	335
7.10.5	Register protection (REG_PROT) configuration	336
7.11	Security modules	343
7.11.1	Password and Device Security Module (PASS) configuration	344
7.11.2	Tamper Detection Module (TDM) configuration	350
7.12	Production device vs. emulation device	356
8	Reset and Boot	359
8.1	Introduction	359
8.1.1	Boot Assist Flash	359

8.1.2	TEST flash memory block	359
8.1.3	UTEST flash memory block	360
8.1.4	Boot header	360
8.2	Modules used in reset sequence	360
8.2.1	Power Management Controller	360
8.2.2	Reset Generation Module	360
8.2.3	Mode Entry module	361
8.2.4	System Status and Configuration Module	361
8.2.5	Self-Test Control Unit	362
8.3	Reset sequence	362
8.3.1	Power-on and the Reset Generation Module	362
8.3.2	Power-up phase: power stabilization	364
8.3.3	PHASE0 Phase: analog supply initial configuration	366
8.3.4	PHASE1[DEST] Phase: temporization and monitoring setup	366
8.3.5	PHASE2[DEST] Phase: flash initial configuration	366
8.3.6	PHASE3[DEST] Phase: device configuration	367
8.3.7	IDLE[DEST] Phase: self test execution	368
8.3.8	PHASE1[FUNC] Phase: temporization and monitoring setup	369
8.3.9	PHASE2[FUNC] Phase: flash initial configuration	369
8.3.10	PHASE3[FUNC] Phase: device configuration monitoring	370
8.3.11	IDLE[FUNC] Phase	370
8.4	MC_RGM passes boot sequence control to the System Status and Control Module	370
8.4.1	Reset sequence flow based on initial device condition	371
8.4.2	Possible boot-up sequences	371
8.4.3	Sequence from MC_RGM IDLE to IOP, HSM, and boot CPU running code	372
8.4.4	Sequence from MC_RGM IDLE to IOP and Boot CPU running code (HSM disabled)	376
8.4.5	Path from MC_RGM IDLE to serial boot mode	379
8.4.6	Path from MC_RGM IDLE with IOP and HSM enabled to watchdog timer timeout	383
9	Device Configuration Format (DCF) Records	392
9.1	Introduction	392
9.2	DCF clients	392
9.3	DCF records	393

9.3.1	UTEST DCF records	396
9.4	DCF client table	397
10	Power management	419
10.1	Overview	419
10.1.1	Power management framework	421
10.1.2	Power management supply description	422
10.1.3	SPC57EM80xx power management controller overview	423
10.2	Low power mode support	424
10.2.1	Low power support and STOP mode implementation	424
10.3	Flash power requirements	426
10.4	Device trimming	426
10.5	Supply monitoring (POR and LVDs)	426
10.5.1	Power-on reset (POR)	426
10.5.2	Behavior of device LVD / HVD	426
10.5.3	Low Voltage Detection (LVD) and High Voltage Detection (HVD)	427
10.6	Power sequence	434
10.6.1	Power-up sequence	435
10.6.2	Power-down sequence	441
10.6.3	Brown-out management	441
10.6.4	Low voltage requirement during crank	442
11	Security	443
11.1	Basic security	443
11.2	Advanced security	443
11.3	Detailed security information	444
12	Calibration and Debug	445
12.1	Core debug support	445
12.2	Run control and memory access	445
12.2.1	Debug and Calibration Interface (DCI)	446
12.2.2	JTAG Data Communication (JDC)	449
12.2.3	Sequence Processing Unit (SPU)	449
12.3	Calibration interface	461
12.3.1	JTAG Master (JTAGM)	462
12.3.2	Debug LFAST	462

12.3.3	Development Trigger Semaphore (DTS)	462
12.4	Debug over CAN	463
12.5	Nexus Trace Aurora interface	463
12.5.1	Nexus Aurora overview	466
12.5.2	Nexus Aurora Router (NAR)	467
12.5.3	Nexus Aurora Link (NAL)	470
12.5.4	Nexus Aurora PHY (NAP)	470
12.6	Nexus clients	471
12.6.1	e200z4 Nexus 3	471
12.6.2	GTM Development Interface (GTMDI)	472
12.6.3	Nexus Crossbar Multi-master Client (NXMC)	472
12.7	Data trace filtering	474
13	Core Complex Overview	475
13.1	Overview of the e200z420n3, e200z419, and e200z425n3 cores	475
13.2	Features	476
13.3	Microarchitecture summary	477
13.3.1	Instruction unit features	479
13.3.2	Integer unit features	479
13.3.3	Load/Store unit features	479
13.3.4	EFPU2 Floating-Point Unit features	480
13.3.5	LSP Lightweight Signal Processing Unit features	480
13.3.6	MPU features	481
13.3.7	Cache features	481
13.3.8	Local memory features	481
13.3.9	Performance Monitor Unit Features	482
13.3.10	e200z420n3 and e200z425n3 system bus features	482
13.3.11	e200z419 system features	482
13.4	Availability of detailed documentation	483
14	Core e200z420n3 description	484
14.1	Overview of the e200z420n3 core	484
14.2	Register model	484

25.3	Memory map/register definition	739
25.3.1	Control Register (DMA_CR)	783
25.3.2	Error Status Register (DMA_ES)	785
25.3.3	Enable Request Register High (DMA_ERQH)	787
25.3.4	Enable Request Register Low (DMA_ERQL)	790
25.3.5	Enable Error Interrupt Register High (DMA_EEIH)	793
25.3.6	Enable Error Interrupt Register Low (DMA_EEIL)	796
25.3.7	Set Enable Request Register (DMA_SERQ)	799
25.3.8	Clear Enable Request Register (DMA_CERQ)	800
25.3.9	Set Enable Error Interrupt Register (DMA_SEEI)	801
25.3.10	Clear Enable Error Interrupt Register (DMA_CEEI)	801
25.3.11	Clear Interrupt Request Register (DMA_CINT)	802
25.3.12	Clear Error Register (DMA_CERR)	803
25.3.13	Set START Bit Register (DMA_SSRT)	803
25.3.14	Clear DONE Status Bit Register (DMA_CDNE)	804
25.3.15	Interrupt Request Register High (DMA_INTH)	805
25.3.16	Interrupt Request Register Low (DMA_INTL)	808
25.3.17	Error Register High (DMA_ERRH)	811
25.3.18	Error Register Low (DMA_ERRL)	814
25.3.19	Hardware Request Status Register High (DMA_HRSH)	817
25.3.20	Hardware Request Status Register Low (DMA_HRSL)	820
25.3.21	Channel <i>n</i> Priority Register (DMA_DCHPRIn)	823
25.3.22	Channel <i>n</i> Master ID Register (DMA_DCHMIDn)	824

25.3.23	TCD Source Address (DMA_TCDn_SADDR)	825
25.3.24	TCD Transfer Attributes (DMA_TCDn_ATTR)	826
25.3.25	TCD Signed Source Address Offset (DMA_TCDn_SOFF)	827
25.3.26	TCD Minor Byte Count (Minor Loop Disabled) (DMA_TCDn_NBYTES_MLNO)	827
25.3.27	TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (DMA_TCDn_NBYTES_MLOFFNO)	828
25.3.28	TCD Signed Minor Loop Offset (Minor Loop and Offset Enabled) (DMA_TCDn_NBYTES_MLOFFYES)	829
25.3.29	TCD Last Source Address Adjustment (DMA_TCDn_SLAST)	830
25.3.30	TCD Destination Address (DMA_TCDn_DADDR)	831
25.3.31	TCD Current Minor Loop Link, Major Loop Count (Channel Linking Enabled) (DMA_TCDn_CITER_ELINKYES)	831

50.4.20	FIFO Receive Start Register (FRSR)	1838
50.4.21	Receive Descriptor Ring Start Register (ERDSR)	1838
50.4.22	Transmit Buffer Descriptor Ring Start Register (ETSDR)	1839
50.4.23	Receive Buffer Size Register (EMRBR)	1839
50.4.24	Count of frames not counted correctly (RMON_T_DROP)	1840
50.4.25	RMON Tx packet count (RMON_T_PACKETS)	1840
50.4.26	RMON Tx broadcast packets (RMON_T_BC_PKT)	1841
50.4.27	RMON Tx multicast packets (RMON_T_MC_PKT)	1841
50.4.28	RMON Tx packets with CRC/align error (RMON_T_CRC_ALIGN) ..	1842
50.4.29	RMON Tx packets < 64 bytes, good CRC (RMON_T_UNDERSIZE)	1842
50.4.30	RMON Tx packets > MAX_FL bytes, good CRC (RMON_T_OVERSIZE)	1842
50.4.31	RMON Tx packets < 64 bytes, bad CRC (RMON_T_FRAG)	1843
50.4.32	RMON Tx packets > MAX_FL bytes, bad CRC (RMON_T_JAB) ...	1843
50.4.33	RMON Tx collision count (RMON_T_COL)	1843
50.4.34	RMON Tx 64 byte packets (RMON_T_P64)	1844
50.4.35	RMON Tx 65 to 127 byte packets (RMON_T_P65TO127)	1844
50.4.36	RMON Tx 128 to 255 byte packets (RMON_T_P128TO255)	1844
50.4.37	RMON Tx 256 to 511 byte packets (RMON_T_P256TO511)	1845
50.4.38	RMON Tx 512 to 1023 byte packets (RMON_T_P512TO1023)	1845
50.4.39	RMON Tx 1024 to 2047 byte packets (RMON_T_P1024TO2047) ..	1845

50.4.40	RMON Tx packets with > 2048 bytes (RMON_T_P_GTE2048)	1846
50.4.41	RMON Tx Octets (RMON_T_OCTETS)	1846
50.4.42	Count of transmitted frames not counted correctly (IEEE_T_DROP)	1846
50.4.43	Frames transmitted OK (IEEE_T_FRAME_OK)	1847
50.4.44	Frames transmitted with single collision (IEEE_T_1COL)	1847
50.4.45	Frames transmitted with multiple collisions (IEEE_T_MCOL)	1847
50.4.46	Frames transmitted after deferral delay (IEEE_T_DEF)	1848
50.4.47	Frames transmitted with late collision (IEEE_T_LCOL)	1848
50.4.48	Frames transmitted with excessive collisions (IEEE_T_EXCOL) . . .	1848
50.4.49	Frames transmitted with Tx FIFO underrun (IEEE_T_MACERR) . . .	1849
50.4.50	Frames transmitted with carrier sense error (IEEE_T_CSERR) . . .	1849
50.4.51	Frames transmitted with SQE error (IEEE_T_SQE)	1849
50.4.52	Flow control pause frames transmitted (IEEE_T_FDXFC)	1850
50.4.53	Octet count for frames transmitted without error (IEEE_T_OCTETS_OK)	1850
50.4.54	Count of received frames not counted correctly (RMON_R_DROP) .	1850
50.4.55	RMON Rx packet count (RMON_R_PACKETS)	1851
50.4.56	RMON Rx broadcast packets (RMON_R_BC_PKT)	1851
50.4.57	RMON Rx multicast packets (RMON_R_MC_PKT)	1852
50.4.58	RMON Rx packets with CRC/Align error (RMON_R_CRC_ALIGN) .	1852
50.4.59	RMON Rx packets < 64 bytes, good CRC (RMON_R_UNDERSIZE)	1852
50.4.60	RMON Rx packets > MAX_FL bytes, good CRC (RMON_R_OVERSIZE)	1853
50.4.61	RMON Rx packets < 64 bytes, bad CRC (RMON_R_FRAG)	1853
50.4.62	RMON Rx packets > MAX_FL bytes, bad CRC (RMON_R_JAB) . . .	1853
50.4.63	Reserved (RMON_R_RESVD_0)	1854
50.4.64	RMON Rx 64 byte packets (RMON_R_P64)	1854
50.4.65	RMON Rx 65 to 127 byte packets (RMON_R_P65TO127)	1854
50.4.66	RMON Rx 128 to 255 byte packets (RMON_R_P128TO255)	1855
50.4.67	RMON Rx 256 to 511 byte packets (RMON_R_P256TO511)	1855
50.4.68	RMON Rx 512 to 1023 byte packets (RMON_R_P512TO1023) . . .	1855
50.4.69	RMON Rx 1024 to 2047 byte packets (RMON_R_P1024TO2047) . .	1856
50.4.70	RMON Rx packets with > 2048 bytes (RMON_R_P_GTE2048) . . .	1856
50.4.71	RMON Rx octets (RMON_R_OCTETS)	1856
50.4.72	Count of received frames not counted correctly (IEEE_R_DROP) . .	1857
50.4.73	Frames received OK (IEEE_R_FRAME_OK)	1857
50.4.74	Frames received with CRC error (IEEE_R_CRC)	1857

50.4.75	Frames received with alignment error (IEEE_R_ALIGN)	1858
50.4.76	Receive FIFO overflow count (IEEE_R_MACERR)	1858
50.4.77	Flow control pause frames received (IEEE_R_FDXFC)	1858
50.4.78	Octet count for frames received without error (IEEE_R_OCTETS_OK)	1859
50.5	Functional description	1859

1 Register conventions

Figure 1 and *Table 1* provide the register conventions used throughout this manual.

Warning: Any register bit described as "Reserved" should not be written. Reserved bits are not intended for customer use.

Table 1. Register Conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
slfclr	Self-clearing bit. Writing a one has some effect on the module, but it always reads as zero.
Reset Values	
0	Resets to zero
1	Resets to one
—	Undefined at reset
u	Unaffected by reset
[signal_name]	Reset value is determined by polarity of indicated signal

1.1 Acronyms and abbreviations

The [Table 2](#) lists some acronyms and abbreviations used in this document.

Table 2. Acronyms and abbreviations

Term	Meaning
ATX	Analog Test Module
AUTOSAR®	Automotive Open System Architecture
BAF	Boot Assist Flash
CAN	Controller Area Network
CGM	Clock Generation Module
CMU	Clock Monitoring Unit
CRC	Cyclic Redundancy Check
DMA	Direct Memory Access
DMAMUX	Direct Memory Access Controller Multiplexer
DSPI	Deserial Serial Peripheral interface
DTS	Development Trigger Semaphore
FCCU	Fault Collection and Control Unit
FEC	Fast Ethernet controller
FLEXRAY	automotive network communications protocol
GPIO	General-purpose I/O
GTM	Generic Timer module
IEEE	Institute for Electrical and Electronics Engineers
IIC	Inter-Integrated Circuit (I ² C)
IMA	Indirect Memory Access
INTC	Interrupt Controller
JDC	JTAG Data Communication
JEDEC	Joint Electron Device Engineering Council
JTAG	Joint Test Action Group
LFAST	LVDS Fast Asynchronous Serial Transmission
LINFlexD	Local Interconnect Network controller

Term	Meaning
PFLASH	Flash controller
PIT	Periodic Interrupt Timer
PMC	Power Management Controller
PRAM	RAM controller
PSI5	Peripheral Sensor Interface
RCOSC	RC Oscillator
RGM	Reset Generation Module
RTL	Register transfer language
Rx	Receive
SD ADC	Sigma Delta Analog to Digital Converter
SAG	Safety Application Guide
SAR ADC	Successive Approximation Register Analog to Digital Converter
SEMA4	Semaphore
SENT	Single Edge Nibble Transmission
SIPI	System Interprocessor Interface
SIUL	System Integration Unit Lite
SMPU	System Memory Protection Unit
SoC	System on Chip
SSCM	System Status and Configuration Module
STCU	Self-Test Control Unit
STM	System Timer module
SWT	Software Watchdog Timer
TSENS	Temperature Sensor
TTCAN	Time Triggered CAN
Tx	Transmit
UART	Universal asynchronous/synchronous receiver transmitter
WKPU	Wakeup Unit
XBAR	Crossbar

1.2 References

In addition to this reference manual, the following documents provide additional information on the operation of the SPC57EM80xx:

- IEEE-ISTO 5001-2003 Standard for a Global Embedded Processor Interface (Nexus)
- IEEE 1149.1-2001 standard - IEEE Standard Test Access Port and Boundary-Scan Architecture

2 Introduction

2.1 SPC57EM80xx microcontroller

The SPC57EM80xx microcontroller is the first in a new family of devices superseding the SPC56xx family. The SPC57EM80xx builds on the legacy of the SPC56xx family, while introducing new features coupled with higher throughput to provide a substantial reduction in cost per feature as well as significant improvements in power and performance (MIPS per mW). There are five processor cores on the SPC57EM80xx device.

Table 3. Processor cores

Computational Shell		
Core0	Main Core_0	e200z420

I/O Processor		
Core2	Peripheral Core_2	e200z425
Hardware Security Module		
e200z0 Core		

2.1.1 Target applications

This device is targeted at automotive powertrain controller and chassis control applications for six to eight cylinder gasoline and diesel engines, transmission control, steering and braking applications, as well as high-end hybrid and advanced combustion systems.

Many of these applications are considered to be functionally safe and are designed to achieve ISO 26262 ASIL D compliance. For this reason, safety measures have been added which are further described in [Chapter 6: Functional Safety](#), as well as the *SPC57EM80xx Safety Manual*.

2.1.2 Overall architecture

The architecture is split into two distinct regions, as shown in [Figure 2](#): the computational shell and the I/O subsystem. The computational shell consists of three CPUs (two in lock-step for safety), fast local memories inside the CPUs, and fast system memory. All components of the computational shell are connected through a fast crossbar switch (XBAR_0).

The I/O subsystems consists of an I/O processor (IOP), DMA, Hardware Security Module (HSM), and all the other peripherals connected through a slow crossbar switch (XBAR_1).

The computational shell is optimized for performance and the I/O subsystem is optimized for low power.

The two crossbars (XBAR_0 and XBAR_1) are connected by a pair of cross-connected master - slave ports. The result of this is that all crossbar masters on both crossbars, can directly access all crossbar slaves on both crossbars. From a software perspective, every

bus master (all CPUs, DMA, SIPI, Ethernet, FlexRay, HSM) sees every memory and peripheral (all RAMs, flash, and peripherals) in a consistent flat memory map.

2.1.3 Core features

The main computational shell consists of dual e200z4 CPUs operating at up to 200 MHz with a third, identical CPU running as a safety checker core in delayed lockstep mode with one of the dual z4 cores. The I/O subsystem includes a CPU targeted at managing the peripherals. The I/O subsystem core is also an e200z4 CPU running at up to 200 MHz and including enhancements to implement Digital Signal Processing (DSP) algorithms. The fifth programmable CPU is an e200z0 running at up to 100 MHz and embedded in the HSM. All CPUs are compatible with the Power Architecture® VLE instruction set, which supports code size reduction. The Power Architecture has enhancements that improve the architecture's fit in embedded applications.

2.1.4 I/O Processor

The I/O Processor (IOP), also referred to as Peripheral Core_2, is one of five processor cores on the SPC57EM80xx device as shown in [Figure 2](#). In general, the intended use of the IOP is to initially configure the machine and then control various peripheral elements of the device. However, the IOP is not limited to any particular duty.

Note: The e200z0 core is embedded in the Hardware Security Module.

The data bus structure of the IOP, which consists of a 32-bit address bus and a 64-bit data bus, is connected to the slow crossbar switch, which operates at 100 MHz. The instruction bus structure of the IOP, which consists of a 32-bit address bus and a 64-bit data bus, is connected to the fast crossbar switch, which operates at 200 MHz. The address bus structure and the data bus structure of Main Core_0 and Main Core_1 are also connected to the fast crossbar switch. The data bus structure of the IOP is connected to the slow crossbar switch, which operates at 100 MHz. Thus, data fetches run at only one-half the speed of instruction fetches.

It is possible to fetch data from memory elements connected to the fast crossbar switch and it is also possible to fetch instructions from memory elements connected to the slow crossbar switch. In both cases, the instruction and data paths would have to go through both the slow and fast crossbar switches and would be relatively slow. When the IOP first starts, it will start executing from memory elements on the fast crossbar switch. However, good programming techniques will cause the IOP to fill its internal instruction cache so that accesses through the fast crossbar switch occur less often.

The I/O Processor is automatically started during the boot-up sequence after the release of reset. This process is fully described in [Chapter 8: Reset and Boot](#). During the boot sequence the System Status and Configuration Module (SSCM) reads and interprets a set of device configuration records located in the TEST flash area. One of these records is the start address of the code where the IOP will begin program execution. This vector will always point to a location in the Boot Assist Flash (BAF). Once the SSCM finds and interprets this particular device configuration record, it will write the start address for the IOP to the appropriate location in the Mode Entry Module (MC_ME). When the internal reset signal is released, the MC_ME transfers the IOP start address to the IOP and code execution begins at that address.

The code for the Boot Assist Flash, the TEST Device Configuration records and some of the UTEST Device Configuration records are written by the device manufacturer and are programmed into the device during production testing. All SPC57EM80xx devices are

shipped with startup code programmed into the BAF. Also, the SPC57EM80xx is configured such that code execution by the IOP must begin with a start address located in the BAF.

If there is no user application code for the IOP to execute, the IOP, executing preprogrammed code in the BAF, will attempt to download user application code through the LINFlexD port using a specific data transfer protocol. This downloaded code is installed into program memory and code execution will begin at the start address embedded in the downloaded code.

As previously stated, the IOP's data bus structure is connected to the slow crossbar switch, which provides access to many of the peripheral devices on the device. The instruction bus of the IOP is connected to the fast crossbar switch, which gives the IOP access to the BAF, as well as all of the other memory elements. When the IOP begins code execution, a considerable amount of traffic through the fast crossbar switch will be required. The IOP has internal instruction cache. Once the IOP gets started and the internal instruction cache begins to fill, significantly less traffic will be required by the IOP through the fast crossbar switch. Accesses to the peripheral elements on the slow crossbar switch is transparent to activity occurring on the fast crossbar switch.

The IOP is placed in the SPC57EM80xx architecture in such a way that enables it to access many of the peripheral elements without affecting the processing speed of Main Core_0 and Main Core_1. On the SPC57EM80xx device, there are several analog-to-digital channels taking data that must be analyzed for various spectral components.

The IOP has an integrated DSP processor which has special hardware to execute multiply and accumulate operations. Because the DSP unit functions as a coprocessor integrated into the e200z425 core, data fetched by the z425 core can be evaluated with much greater speed than if the data had to reside in a memory element outside the z425 core.

One intended purpose for the IOP is to manage a system of analog-to-digital converters and fetch the digital data that is generated. The integrated DSP unit uses a signal processing algorithm to digest the incoming data. The results of this signal processing algorithm are used in other engine control algorithms. Using the IOP to manage the analog-to-digital converters and do the initial signal processing of the data allows Main Core_0 and Main Core_1 to focus on other compute intensive applications instead of managing relatively slow peripheral elements.

Once the IOP has performed its initialization duties (as determined by preloaded instruction code in the BAF) and downloaded any needed applications code, the IOP can essentially be programmed to perform any duty or access any memory element. When executing instructions from its internal instruction cache and fetching data from peripherals connected to the slow crossbar switch, the IOP operates autonomously from Main Core_0 and Main Core_1.

2.1.5 Memory hierarchy

The SPC57EM80xx computational shell has three levels of memory hierarchy. At the top level is a combination of instruction cache, data cache, local instruction RAM, and local data RAM, depending on the specific CPU. The local RAM arrays are embedded into the CPU's pipeline to provide the fastest possible access time. The second level of memory is system RAM and flash memory. These are connected by a 200 MHz, 64-bit wide crossbar. The third level of memory system is the I/O subsystem. All of the I/O peripherals are connected together by a 100 MHz, 64-bit wide crossbar switch, while peripherals are connected at either 100 or 50 MHz, depending on their need. The reduced speed for the peripherals helps to reduce power.

2.2 Features summary

On-chip modules within SPC57EM80xx include the following features:

- Three main CPUs, 32-bit CPU core complexes (e200z4), two of which run in lockstep
 - Power Architecture embedded specification compliance
 - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
 - Single-precision floating point operations
 - 16 KB Local instruction RAM and 64 KB local data RAM
 - 8 KB I-Cache and 4 KB D-Cache
- I/O Processor, 32-bit CPU core complexes (e200z4), with:
 - Power Architecture embedded specification compliance
 - Instruction set enhancement allowing variable length encoding (VLE), encoding a mix of 16-bit and 32-bit instructions, for code size footprint reduction
 - Single-precision floating point operations
 - Lightweight Signal Processing Auxiliary Processing Unit (LSP APU) instruction support for digital signal processing (DSP)
 - 16 KB Local instruction RAM and 64 KB local data RAM
 - 8 KB I-Cache
- 4304 KB on-chip flash (4000 KB code flash, 288 KB data flash, and 16 KB UTest flash: supports read during program and erase operations, and multiple blocks allowing EEPROM emulation)
- Up to 450 KB of total on-chip SRAM (128 KB general purpose SRAM, 192 KB data RAM, 48 KB instruction RAM, 35 KB GTM RAM, 16 KB overlay RAM and 32 KB peripheral RAM)
- 64-channel direct memory access controller (eDMA)
- 4 Interrupt controllers (INTC) (one INTC per user programmable CPU)
- Dual Phase-locked loops with stable clock domain for peripherals and FM modulation domain for computational shell
- Dual Crossbar switch architecture for concurrent access to peripherals, flash, or RAM from multiple bus masters with end-to-end ECC
- Hardware Security Module (HSM) to provide robust integrity checking of flash memory
- System Integration Unit Lite (SIUL2)
- Boot Assist Module (BAM) supports factory programming using serial bootloader through 'UART Serial Boot Mode Protocol'. Physical interface (PHY) can be:
 - UART/LIN
 - CAN
 - FlexRay
- GTM103 – generic timer module
 - Intelligent complex timer module
 - 120 channels (32 input and 88 output)
 - 4 programmable fine grain multi-threaded cores
 - 34 KB of RAM
 - 24-bit wide channels

- Hardware support for engine control, motor control and safety related applications
- Enhanced analog-to-digital converter system with
 - Eight separate 12-bit SAR analog converters
 - Six separate 16-bit Sigma-Delta analog converters
- Seven deserial serial peripheral interface (DSPI) modules
- Five LIN and UART communication interface (LINFlexD) modules
 - LINFlexD_0 is a Master/Slave
 - LINFlexD_1, LINFlexD_2, LINFlexD_14 and LINFlexD_15 are Masters
- Three modular controller area network (M_CAN) modules, and one time-triggered controller area network (M_TTCAN)
- Dual-channel FlexRay controller
- Nexus development interface (NDI) per IEEE-ISTO 5001-2003 standard, with some support for 2010 standard.
- Device and board test support per Joint Test Action Group (JTAG) (IEEE 1149.1 and 1149.7)

2.3 Feature list

[Table 4](#) lists a summary of major features for the SPC57EM80xx device. The feature column represents a combination of module names and capabilities of certain modules. A detailed description of the functionality provided by each on chip module is given later in this document.

Table 4. Features List

Feature	Description
SPC57xxfamily	55 nm
Main Cores	
Main Core	e200z4
Number of Main Cores	2
Number of checker cores	1
Local RAM (per main core)	16 KB Instruction 64 KB Data
Single Precision Floating Point	Yes
VLE	Yes
Cache	8 KB Instruction 4 KB Data
Peripheral Core	
Peripheral Core	e200z4
Local RAM	16 KB Instruction 64 KB Data
Single Precision Floating Point	Yes
SIMD	Yes

Table 4. Features List (continued)

Feature	Description
VLE	Yes
Cache	8 KB Instruction
Other	
MMU Entries	0
MPU	Yes
Semaphores	Yes
CRC Channels	2
Software Watchdog Timer (SWaT)	4
Core Nexus Class	3+
Sequence Processing Unit (SPU)	16
Debug and Calibration Interface (DCI) / Run control Module	Yes
System SRAM	128 KB
Flash	Code Flash: 4000 KB Data Flash: 288 KB UTest Flash: 16 KB
Flash fetch accelerator	Two 64-bit AHB ports, 256-bit read data interface. Each AHB port contains 4-entry, 2-way set-associative mini-cache.
Flash Overlay RAM	16 KB
Calibration Interface	64-bit IPS Slave
DMA channels	64
DMA Nexus Class	3
LINFlexD	5
M_CAN	3
M_TTCAN	1
DSPI	7
Microsecond channel downlink	Yes
SENT bus	10
I ² C	1
PSI5 bus	3
FlexRay	1 × Dual channel
Ethernet	Yes
SIPI / LFAST Interprocessor bus	High-Speed
System Timers	8 PIT chan 4 AUTOSAR [®] (STM)
GTM Timer	32 Input Channels, 88 Output Channels

Table 4. Features List (continued)

Feature	Description
GTM RAM	34 KB
Interrupt controller	446 sources
ADC (SAR)	8
ADC (SD)	6
Temp. sensor	Yes
PLL	Dual PLL with FM
External Power Supplies	5 V, 3.3 V, 1.2 V
Low Power Modes	Stop Mode Slow Mode

2.4 Packaging

The SPC57EM80xx is available in the following production packages: eLQFP176 and LFBGA292. The SPC57EM80xx is also available in a 256-pin Fusion Quad package for emulation and debug devices, which provides a eLQFP176 pin-compatible package with additional signals for development. The LFBGA292 package supports production and emulation and debug devices with compatibility for an emulation package in a production device footprint.

2.5 Software debug and calibration

The Production Device (PD) includes many features to facilitate software development and calibration of constant data. These features include:

- Nexus code execution trace on all CPUs
- Nexus data trace on all bus masters (DMA, Interprocessor bus, CPUs, and so on)
- Performance monitors for each CPU
- Sequence Processing Unit for complex trace triggering
- 16 KB of overlay RAM

For more complex software development and calibration of constant data, a Buddy Device (BD) is packaged together with the SPC57EM80xx production device as a multi-die emulation and is referred to as an Emulation and Debug Device (ED).

The ED provides exactly the same features as the PD. The ED is available in the same package as the PD but has an additional overlay RAM and a high-speed Nexus trace output port consisting of four lanes of Aurora (LVDS) operating up to 1.25 Gbit/s.

Block diagrams

The figures below show the top-level block diagrams.

Figure 2. Block diagram

Figure 3. Periphery allocation

3 Embedded memories

3.1 Overview

The embedded memory architecture for SPC57EM80xx devices is a significant departure from previous-generation devices. Features include:

- Onboard SRAM, including system SRAM, local instruction and data memory for each processor core, and overlay SRAM
- Onboard system error correction code (ECC) flash memory
- End-to-end ECC (e2eECC) error detection and correction
- Built-in flash memory security features including censorship and a programmable Hardware Security Module (HSM)
- Embedded memories in the peripherals^(a):
 - AMU
 - CAN
 - eDMA
 - FEC
 - FlexRay
 - GTM

3.2 SRAM

3.2.1 System SRAM

SPC57EM80xx devices include 128 KB of general-purpose on-chip ECC SRAM, including 64 KB standby RAM. The SRAM can be configured for either zero- or one-wait state read operation latency using the PFCR1 register in the SRAM controller.

- See [Chapter 33: RAM controller \(PRAM\)](#) for details on configuring the SRAM controller.
- See [Table 15](#) in [Chapter 5: Memory Map](#) for the SPC57EM80xx SRAM map.

3.2.2 Standby SRAM Regulator

A total of 64 K of the system SRAM on the device can remain powered when the rest of the device is powered down. This is achieved with the dedicated VDDSTBY pin in the packages. When the standby RAM is powered by VDDSTBY, the RAM is not operational, but the contents are retained.

a. Refer to the respective module chapter for details.

The Standby RAM regulator has the following key features:

- Automatic, safe, switch between operational (VDD_LV) and standby (VDDSTBY) supplies
- Internal regulation of the high voltage VDDSTBY supply to the low voltage standby RAM supply
- Brownout detection (minimum RAM data retention voltage violation) and reporting via a S/W clearable register bit

The Standby RAM regulator block diagram is given in [Table 4](#).

There are two primary modes of operation with the standby RAM feature:

- Standby RAM feature is not required in the application - in this case, the VDDSTBY pin is connected to ground, and the standby RAM on the device is supplied by VDD_LV and will behave as normal RAM for all conditions.
- Standby RAM feature is required in the application - in this case, the VDDSTBY pin is connected to a voltage within the range given in the device data sheet. The VDDSTBY pin is assumed to be connected to a constant supply, and present before and after the power up/down of the device LV and HV supplies. When the VDD_LV supply to the RAM is above the LV operational voltage threshold, the standby RAM is fully operational and behaves exactly the same as the non-standby system RAM. When the VDD_LV supply falls below the LV Detect threshold, the RAM low voltage supply is switched to the standby supply. For voltages above 1.2V, the standby regulator is enabled. For voltages below 1.2V, the VDDSTBY pin voltage is passed through directly to the RAM. See the device data sheet for min/max VDDSTBY values, LV supply thresholds, and the operational and brownout detection voltages.

The brownout detection feature of the standby RAM regulator informs the user if any voltage dip caused a RAM retention failure in standby mode. The brownout detector monitors the supply to the RAM array, and sets a latch in the PMC digital interface, when the voltage falls below the minimum RAM retention voltage given in the device data sheet. The latch is set on power up of the device. S/W then clears the latch by writing a '1' to the SBRAM_BRDET bit in the VD_UTST register of the PMC digital interface. If the minimum RAM retention voltage is violated, the latch will be set again. The latch is set on every power-up of VDD_LV unless VDDSTBY is present and within the specified ranges in the data sheet. See chapter [Section 60.6: Standby RAM Regulator Interface Logic](#), for more information on the VDDSTBY pin and the standby RAM regulator.

Figure 4. Standby RAM Regulator Block Diagram

3.2.3 Overlay SRAM

Overlay SRAM is included in the SPC57EM80xx family of devices as part of a comprehensive set of calibration and debug features. Overlay SRAM can be mapped over specific regions of on-chip flash memory so that any access to an overlaid flash address is routed to the overlay SRAM instead. This enables the calibration of constant data without requiring additional external RAMs and calibration memory interfaces. The SPC57EM80xx has two 8 KB banks of ECC-protected RAM, for a total of 16 KB.

Note: *Overlay SRAM is normally used for system development purposes only. Code can be executed from internal overlay RAM and extended overlay RAM where available. Execution from overlay RAM remapped over Flash can be enabled or disabled by use of PFCRCR[IRMEM]. Code can be executed directly from Extended Overlay RAM (address range beginning 0x0C000000) on the ED device or internal Overlay RAM (address range beginning 0x0D000000) regardless of the PFCRCR[IRMEM] setting.*

Overlay memory can also be used to hold the device debug trace stream without requiring complex debug tool hardware and access to a high-speed trace port. Timing for calibration accesses to a particular overlay SRAM is the same as access to the underlying flash memory if the overlay SRAM is not being used as a destination for trace streaming at the same time.

The calibration remap function supports three different types of overlay SRAM:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is available only on special emulation and debug devices.
- A portion of the system RAM can be used as the overlay RAM.

The overlay function is implemented using registers in the flash memory controller.

1. Using PFlash Calibration Region Descriptors (PFCRDn) define one or more (up to 32) overlay regions.
2. Enable individual regions using the appropriate bits in the PFLASH Remap Descriptor Enable Register (PFDCRDE).
3. Enable overlay using the PFCRCR[GRMEN] field.

See [Section 34.5.14: PFlash calibration remap support](#), for details on memory overlay (remapping).

3.2.4 Processor core local SRAM

SPC57EM80xx devices include local instruction and data SRAM (I-MEM and D-MEM) for each processor core to provide enhanced performance.

- Each main processor core has 16 KB of instruction SRAM and 64 KB of data SRAM.
- The peripheral processor core has 16 KB of instruction SRAM and 64 KB data SRAM.

The core SRAM supports zero wait-state, single-cycle latency on processor local accesses.

Each area of core SRAM is accessible by other processor cores and bus mastering peripheral devices. See [Table 15](#) in [Chapter 5: Memory Map](#) for details.

3.3 Embedded flash memory

Flash memory on SPC57EM80xx devices consists of a flash memory controller and a flash memory array module. The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the device crossbar switch. [Figure 5](#) shows the memory architecture.

Figure 5. SPC57EM80xx flash memory block diagram

The remaining sections give the functional details of the flash controller and flash array, followed by the memory maps.

3.3.1 Flash memory controller

The SPC57EM80xx flash memory controller acts as an interface between the system bus and the flash memory array and serves as the interface to the on-chip overlay RAM and off-chip Buddy Device.^(b)

The flash memory controller contains a four-entry, two-way set-associative mini-cache that delivers flash read data with a zero-wait state response on lines that reside in the cache. Each entry contains one flash page, a 256-bit (32-byte) memory value. Read requests that miss the cache generate the needed flash memory array access.

The flash memory controller contains configuration registers that manage flash functionality such as read buffering in the mini-cache, access control, calibration RAM overlay remapping, and read wait state management of the flash memory.

See [Chapter 33: RAM controller \(PRAM\)](#), for details.

3.3.2 Flash memory array

SPC57EM80xx devices include a single 4 MB flash memory array, referred to as “main space,” plus an independent 16 KB block of one-time-programmable (OTP) flash memory included to support systems that require non-volatile memory for security features or system initialization information. The independent 16 KB block is referred to as “UTEST space.”

b. The Buddy Device is an optional companion chip with additional memory and debug features. A Buddy Device is combined with a Production Device to form an Emulation and Debug Device (ED) for use during system development. It is not used in production systems.

Reads of the embedded flash memory return a 256-bit page of data that may be buffered in the mini-cache in the flash memory controller. Programming of the flash may be done by double word (64-bits), page (256-bits), or quad-page (1024-bits). Flash memory is erased on a block by block basis.

3.3.2.1 Features

- Flash segmentation
 - 16 KB, 32 KB, 64 KB, and 256 KB blocks provided for code or data
 - Four 64 KB blocks provided for EEPROM emulation
 - One 16 KB block and two 64 KB block provided for secure code
 - Two 16 KB blocks provided for secure data
 - Support for reading-while-writing when the accesses are to different partitions
- Flash memory protection: write protection and OTP function available for each block
- Test and initialization data stored in a non-volatile 16 KB OTP UTEST block
- ECC with double bit detection, single bit correction
- Erase suspend, program suspend, and erase-suspended program all supported

3.3.2.2 Flash organization

The embedded flash memory consists of six address spaces in four groupings:

- 16 KB low address space, 32 KB low address space, and 64 KB low address space
- 16 KB mid address space
- 64 KB high address space
- 256 KB address space

Address space group (low-, mid-, or high-address space) determines which registers/fields are used to select blocks for modify operations or lock them from modify operations. Each address space is independent.

The flash module is further divided into eight partitions that determine locations for valid read-while-write (RWW) operations. While the embedded flash memory is performing a “write” (program or erase) to a given partition, it can simultaneously read from any other partition.

- For program operations, only the address specified by an interlock write determines the partition being written (block locking and block select registers do not determine the RWW partitions being written).
- For erase operations, only blocks that are selected and unlocked determine the RWW partitions being written.

[Figure 6](#) shows the flash block segmentation and read-while-write partitioning for SPC57EM80xx devices.

Figure 6. Flash memory segmentation and read-while-write partitioning

Note: See [Table 13](#) in [Chapter 5: Memory Map](#) for the SPC57EM80xx flash memory map.

3.3.2.3 UTEST memory space

Devices in the SPC57EM80xx family contain a 16 KB area of One-Time Programmable (OTP) flash memory for storing test information and device configuration data. See [Table 16](#) in [Chapter 5: Memory Map](#) for the SPC57EM80xx UTEST flash memory map.

3.4 End-to-end Error Correction Code (e2eECC)

To support market requirements related to improved functional and transient fault detection capabilities, this family of automotive microcontrollers includes end-to-end ECC (e2eECC) support. This e2eECC is structurally different to traditional “ECC at memory” functionality because it provides robust error detection capabilities from one endpoint of an information transfer to another endpoint, with temporary information storage in one or more intermediate components.

Memory protected by ECC/EDC traditionally generates and checks additional error parity information local to the memory unit to detect and/or correct errors that have occurred on data stored in the memory. On the other hand, e2eECC generates error protection codes at the source of data generation. It sends the encoded data and error protection codes to intermediate storage when a memory write is initiated by a bus master and performs a data integrity check using the previously stored error protection codes at a data memory when a

read of stored information is requested by a bus master. The intermediate storage may transform the generated error protection codes into another format for storage and then regenerate the codes for provision when a request is made to read the stored information or it may simply store the original protection codes unaltered, depending on the particular unit.

Additionally, the error protection codes are generated on the basis of more than just the data associated with a storage location to protect additional information associated with an access. In particular, address information corresponding to the access location of the stored information is combined with the stored data at the data source to generate error protection codes that cover certain types of addressing errors in the system interconnect or in the memory unit. The error protection codes may be checked at the memory unit on a store to ensure that no address information or data has been corrupted while the request has transitioned through the device from the bus master source. The error protection codes may also be checked to ensure that address decoding within the storage memory was performed properly (although not all address decoding errors can be detected this way) or it may simply store the received data and protection codes at the address it receives.

On a read request from a bus master, the memory unit retrieves the data information and error protection codes corresponding to the received address from the storage location or locations and supplies the data along with the error protection codes to the requesting device. The requesting device uses a locally stored address value corresponding to the read request to check the returning data and error protection codes to ensure that no errors have occurred in either addressing the memory or in the retrieved data. This ensures that the address sent for the request was not corrupted, the addressed location was actually accessed (to the extent it is possible to ensure) and the stored data was error free, to the extent the ECC coding scheme is able to detect. As a result, the fault coverage provided by the end-to-end check is considerably more robust than the previous implementation of locally generated and checked/corrected error protection at each memory unit.

A comparison of the traditional and e2eECC approaches is shown in [Table 5](#).

Table 5. ECC comparison of data write-then-read sequence

Traditional ECC	End-to-End ECC (e2eECC)
Bus master initiates data write	Bus master initiates data write and generates ECC checkbits based on 29-bit address and 64-bit data fields
Data write transfer routed from bus master to appropriate bus slave	Data write transfer (including checkbits) routed from bus master to appropriate bus slave
For a bus memory slave, generate the ECC checkbits based on the data value and store data + checkbits into the memory	For a bus memory slave, store data and checkbits into the memory
Bus master initiates data read of previously written memory location	Bus master initiates data read of previously written memory location
Data read transfer routed from bus master to appropriate bus slave	Data read transfer routed from bus master to appropriate bus slave

Table 5. ECC comparison of data write-then-read sequence (continued)

Traditional ECC	End-to-End ECC (e2eECC)
For a bus memory slave, the memory array is accessed, the controller performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and drives the read data onto the system bus interconnect	For a bus memory slave, the memory array is accessed, and the controller passes the read data and associated checkbits onto the system bus interconnection
The bus master captures the read data and continues	The bus master captures the read data and associated checkbits, performs the ECC checkbit decode and syndrome generation, performs any needed single-bit correction and continues

The scope of differences in the operations “covered” by the ECC checks is readily apparent with the e2eECC concept providing improved fault detection capabilities in two important aspects:

- The entire data transaction; from the initiating bus master, through the entire platform crossbar steering mechanism, to the destination slave target is covered during write accesses. Likewise, a read is checked from the initiating bus master, through the crossbar steering mechanism, through the actual memory read and transmission of the data plus checkbits back to the bus master, where the integrity and correctness of the entire transaction is checked.
- The selected ECC provides protection of both the address field as well as the data field, again for improved fault coverage.

Additionally, this particular structure also provides a significant implementation improvement. The traditional ECC at the memory approach places the checkbit decode and error syndrome generation with the error/no_error state, affecting whether the system bus transfer must be stalled (to correct a single bit error or report a noncorrectable event) or is allowed to complete (for error-free transfers) in a critical timing arc which often sets the upper limit of the operating frequency of the microcontroller. With the e2eECC scheme, the checkbit decode and error syndrome logic is located in the requesting bus master where there are generally more degrees of implementation freedom and the error/no_error state determination is removed from the system bus cycle termination logic; producing an improved timing arc and generally higher operating speeds.

Errors that occur within the system interconnect are typically manifested as an incorrect address, incorrect write data, or incorrect read data to be presented to the slave or back to the master. Errors occurring within the storage typically manifest themselves eventually in corrupted read data or checkbits being returned to a requester. While not all possible errors can be detected this way, this approach provides a substantial improvement versus traditional methods. Additional on-line diagnostics, or additional hardware, or both should be able to catch a majority of the errors not covered directly by the e2eECC scheme.

3.5 Security features

The SPC57EM80xx architecture uses a combination of device life cycle monitoring and password protection to limit the conditions under which debugging interfaces can access certain areas of flash memory.

Note: Detailed information on the SPC57EM80xx security architecture is published in a separate document and is available on a limited basis to customers who have a non-disclosure agreement (NDA) with STMicroelectronics.

4 Signal Description

4.1 Production packages

The following production packages are for the SPC57EM80xx device:

- eLQFP176 Exposed Pad
- LFBGA292

The BGA292 is a superset of the eLQFP176 pins. The LFBGA292 adds only:

- Additional GPIO
- More analog inputs
- Added muxing options for the eLQFP176 I/O

There are no I/O interfaces defined for the LFBGA292 that are not included in the eLQFP176 (external bus, etc.).

Case number and outline drawings for each package are provided in the *SPC57EM80xx Microcontroller Data Sheet*.

4.2 Emulation package

A 216-pin FusionQuad QFP package is used for application debug and calibration support with the LQFP package for the SPC57EM80xx. The emulation and debug device also comes in a LFBGA292 package. This package has 20 pins on the inner top/bottom rows that allow the ED signals to be placed there, and therefore not affect the outer row pinout. These ED signals are connected from the inner row pins of the FusionQuad package to bond sites in the pad ring of the production device. Those bond sites are connected to the emulation and debug device I/O pads with routing on the die.

4.3 Package pinouts and ballouts

For pin package pinouts and ballouts refer to the SPC57EM80xx Microcontroller Data Sheet.

4.4 Pin/ball descriptions

The complete Signal Description of the SPC57EM80xx device is provided the following sections:

- [Section 4.4.1, Pin/ball startup and reset states](#)
- [Section 4.4.2, Power supply and reference voltage pins/balls](#)
- [Section 4.4.3, System pins/balls](#)
- [Section 4.4.4, LVDS pins/balls](#)
- [Section 4.4.5, Generic pins/balls](#)

The signal multiplexing options appear in the I/O Signal Description and Input Multiplexing Table^(c)

4.4.1 Pin/ball startup and reset states

This table provides startup state and reset state information for device pins/balls.

Table 6. Pin/ball startup and reset states

Pin	Startup state ⁽¹⁾	State during reset	State after reset
I/O pins ⁽²⁾	Weak pullup	Input, weak pullup	Input, weak pullup
Analog Inputs ⁽³⁾	High-impedance	High-impedance	High-impedance
F0 (ERROR0, FIO) ⁽⁴⁾	High-impedance	Input, high-impedance	Input, high-impedance
ESR0	Output	Output, strong pulldown	Input, weak pullup
ESR1	Weak pullup	Input, weak pullup	Input, weak pullup
PORST	Weak pulldown	Input, weak pulldown	Input, weak pulldown
TESTMODE ⁽⁵⁾	Weak pulldown	Input, weak pulldown	Input, weak pulldown
JCOMP (TRST)	High-impedance	Input, weak pulldown	Input, weak pulldown
TDI	High-impedance	Input, weak pullup	Input, weak pullup
TDO	High-impedance	Weak pullup	High-impedance
TMS	High-impedance	Input, weak pullup	Input, weak pullup
TCK	High-impedance	Input, weak pulldown	Input, weak pulldown
XTAL/EXTAL ⁽⁶⁾	High-impedance	High-impedance	High-impedance

1. Startup state is exited when the core and high-voltage supplies reach minimum levels as defined in the Power Management chapter.
2. Pins on the device that are not supply or reference are not explicitly defined in this table.
3. Analog input without output function—weak pull-up/weak pull-down can be activated only after reset sequence completion
4. F0 is also referred to as ERROR0 and FIO.
5. The SPC57EM80xx MCU does not implement a system configuration pin—TESTMODE is the only pin that affects device configuration. It is latched on the PORST rising edge and internally pulled-down.
6. Function of XTAL/EXTAL pins defined by the enable bit in the flash user test row. If enabled, the pins are analog inputs to the oscillator. If disabled, the XTAL/EXTAL pins default to TBD.

4.4.2 Power supply and reference voltage pins/balls

[Table 7](#) contains information on power supply and reference pin functions for the devices.

- c. The I/O Signal Description and Input Multiplexing Tables is located in a Microsoft Excel[®] workbook attached to this document.

Table 7. Power supply and reference pins

Supply			QFP pin		BGA ball	
Symbol	Type	Description	176	FQ216	292PD	292ED
V _{SS_HV}	Ground	High voltage ground	—	A1, A4, A8, A11, A14, A17, A20, A26, A29, A40	A1, B2, D4, E5, A20, B19, D17, E16, T16, U17, W19, Y20	
V _{SS_LV}	Ground	Low voltage ground	—	—	P12, P9, N9-N12, M7, M8, M10, M11, M13, M14, L8-L13, K8-K13, J13, J14, J10, J11, J7, J8, H9-H12, G12, G9	
V _{SS_HV_OSC}	Ground	Ground supply for the oscillator	101		L20	
V _{SS_HV_ADV}	Ground	Ground supply for ADC	53		Y4	
V _{DD_LV}	Power	Low voltage power supply for production device (PLL is also powered by this pin.)	24, 68, 100, 123		P13, P8, N14, N7, H14, G13	
V _{DDSTBY}	Power	Standby RAM Supply	—		T11	
V _{DD_LV_BD}	Power	Low voltage power supply for buddy die	10	10, A12	—	H7, G8
V _{DD_HV_PMC}	Power	High voltage power supply for internal power management unit	153		—	
V _{DD_HV_PMC_BYP}	Power		—		A19, B18	
V _{DD_HV_IO_MAIN}	Power	High voltage power supply for I/O	25, 69, 99, 139, 171	25, 69, 99, 139, 171, A23, A30	W20, V19, B3, A2	
V _{DD_HV_IO_BD}	Power	High voltage power supply for buddy die I/O	—	A7	—	K14
V _{DD_HV_IO_JTAG}	Power	Oscillator and JTAG pin supply	104		N20	
V _{DD_HV_IO_FLEX}	Power	FlexRay/Ethernet 3.3 V I/O supply	164		D5	
V _{DD_HV_FLA}	Power	Decoupling supply pin for flash	155		D16, E15	
V _{DD_HV_ADV}	Power	High voltage supply for ADC	54		Y5	
V _{SS_HV_ADR_S}	Reference	Ground reference of ADC SAR	51		Y7	
V _{DD_HV_ADR_S}	Reference	Voltage reference of ADC SAR	52		Y6	
V _{SS_HV_ADR_D}	Reference	Ground reference of ADC Σ/Δ	27		T2	
V _{DD_HV_ADR_D}	Reference	Voltage reference of ADC Σ/Δ	26		T1	

4.4.3 System pins/balls

Table 8 contains information on system pin functions for the devices.

Table 8. System pins

Symbol	Description	Direction	QFP pin		BGA ball	
			176	FQ216	292PD	292ED
PORST	Power on reset with Schmitt trigger characteristics and noise filter. PORST is active low	Bidirectional	121		G17	
ESR0	External functional reset with Schmitt trigger characteristics and noise filter. ESR0 is active low	Bidirectional	122		F16	
TESTMODE	Pin for testing purpose only. An internal pull-down is implemented on the TESTMODE pin to prevent the device from entering TESTMODE. It is recommended to connect the TESTMODE pin to V _{SS_HV_IO} on the board. The value of the TESTMODE pin is latched at the negation of reset and has no affect afterward. The device will not exit reset with the TESTMODE pin asserted during power-up.	Input only	118		H19	
XTAL	Analog output of the oscillator amplifier circuit needs to be grounded if oscillator is used in bypass mode.	Output	103		M19	
EXTAL	Analog input of the oscillator amplifier circuit when oscillator is not in bypass mode Analog input for the clock generator when oscillator is in bypass mode	Input	102		M20	

4.4.4 LVDS pins/balls

The following table contains information on LVDS pin functions for the devices.

Table 9. LVDS pin descriptions

Functional block	Port pin	Signal	Signal description	Direction	QFP pin (176, FQ216)	BGA ball (292 PD, 292 ED)
SIPI / LFAST ⁽¹⁾	PF[13]	SIPI_RXN	Interprocessor Bus LFAST, LVDS Receive Negative Terminal	I	107	K19
	PD[7]	SIPI_RXP	Interprocessor Bus LFAST, LVDS Receive Positive Terminal	I	108	J19
	PD[6]	SIPI_TXN	Interprocessor Bus LFAST, LVDS Transmit Negative Terminal	O	109	K20
	PA[14]	SIPI_TXP	Interprocessor Bus LFAST, LVDS Transmit Positive Terminal	O	110	J20

Table 9. LVDS pin descriptions (continued)

Functional block	Port pin	Signal	Signal description	Direction	QFP pin (176, FQ216)	BGA ball (292 PD, 292 ED)
High-Speed Debug (HSD) / LFAST ^{(1),(2)}	PA[8]	DEBUG_TXN	Debug LFAST, LVDS Transmit Negative Terminal	O	111	H17
	PA[7]	DEBUG_TXP	Debug LFAST, LVDS Transmit Positive Terminal	O	112	K16

1. DRCLK and TCK/DRCLK usage for SIPI LFAST and Debug LFAST are described in the *SPC57EM80xx Microcontroller Reference Manual* SIPI LFAST and Debug LFAST chapters.
2. Pads use special enable signal from DCI block: DCI driven enable for Debug LFAST pads is transparent to user.

Table 10. Aurora pin descriptions

Functional Block	PAD	Signal	Signal Description	Direction	QFP		BGA	
					176	FQ216	292PD	292ED
Nexus Aurora High Speed Trace	—	TX0P	Nexus Aurora High Speed Trace Lane 0, LVDS Positive Terminal	O	—	A16	—	U14
	—	TX0N	Nexus Aurora High Speed Trace Lane 0, LVDS Negative Terminal	O	—	A15	—	U13
	—	TX1P	Nexus Aurora High Speed Trace Lane 1, LVDS Positive Terminal	O	—	A10	—	U12
	—	TX1N	Nexus Aurora High Speed Trace Lane 1, LVDS Negative Terminal	O	—	A9	—	U11
	—	TX2P	Nexus Aurora High Speed Trace Lane 2, LVDS Positive Terminal	O	—	A6	—	P11
	—	TX2N	Nexus Aurora High Speed Trace Lane 2, LVDS Negative Terminal	O	—	A5	—	P10
	—	TX3P	Nexus Aurora High Speed Trace Lane 3, LVDS Positive Terminal	O	—	A3	—	K7
	—	TX3N	Nexus Aurora High Speed Trace Lane 3, LVDS Negative Terminal	O	—	A2	—	L7

	—	CLKN (BD-AGBTCL KN)	Nexus Aurora High Speed Trace Clock, LVDS Negative Terminal	I	—	A18	—	U15

4.4.5 Generic pins/balls

The I/O Signal Description Table contains information on generic pins/balls, including the port pin, SIUL MSCR number, MSCR SSS, function, module, signal description, direction, pad type, and package pin/ball numbers for each I/O pin on the device.

Note: The SPC57EM80xx I/O Signal Description and Input Multiplexing Tables are contained in a Microsoft Excel® workbook file attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

Multi-function pins are programmable via their respective Multiplexed Signal Configuration Register (MSCR) Source Signal Select (SSS) values. The SSS value selects which source signal is connected to the associated destination.

For additional information, refer to [Chapter 16: System Integration Unit Lite2 \(SIUL2\)](#).

5 Memory Map

[Table 11](#) shows the device memory map for the SPC57EM80xx.

All addresses on the SPC57EM80xx, including those that are reserved, are identified in the table. The addresses represent the physical addresses assigned to each region or module name.

[Table 11](#) Summarizes the complete 32-bit address map. A memory access, either read or write, to any region marked as 'Reserved' will result in a Transfer Error. This error can generate an interrupt request in the CPU.

[Table 12](#) lists the memory map of the peripheral region. This region is sub-divided into 16 KB byte regions or 'slots'. A peripheral occupies 1 or more slots. A memory access, either read or write, to any slot marked as 'Reserved' will result in a Transfer Error. This error can generate an interrupt request in the CPU.

Within a 16 KB byte peripheral slot, it is normal for the peripheral registers to only occupy part of that 16 KB byte slot - normally from the lowest address upwards. The individual chapters for each block, define all the registers within that contiguous group of registers.

Any memory access outside the range of the defined register map will result in a transfer error. This error can generate an interrupt request in the CPU.

Tables [Table 13](#), [Table 14](#), and [Table 15](#) define the embedded memory maps and the buddy memory map. A memory access, either read or write, to any region marked as 'Reserved' in these tables, will result in a Transfer Error. This error can generate an interrupt request in the CPU.

Table 11. Overview Memory Map

Start Address	End Address	Allocated Size	Used Size	Description

0x004001C0	0x004001FF	64	Reserved	
0x00400200	0x0040020F	16	Lifecycle Slot 0 - JDP_PROD	"JDP Production" Lifecycle slot. Programmed by JDP during test
0x00400210	0x0040021F	16	Lifecycle Slot 1 - CUST_DEL	"Customer Delivery" Lifecycle slot. Programmed by JDP during test
0x00400220	0x0040022F	16	Lifecycle Slot 2 - OEM_PROD	"OEM Production" Lifecycle slot. Programmed by customer during ECO module production/test
0x00400230	0x0040023F	16	Lifecycle Slot 3 - IN_FIELD	"In Field" Lifecycle slot. Programmed by customer during ECO module production/test
0x00400240	0x0040024F	16	Lifecycle Slot 4 - FA	Failure Analysis Lifecycle slot. Programmed by the customer on returned modules
0x00400250	0x004002FF	176	Reserved	
0x00400300	0x00400307	8	DCF Start Record	DCF start Record. Programmed by JDP during Test. Contiguous list of DCF records starts at this address
0x00400308	0x00400347	64	DCF HSM 'ROM' key Records	Space for 8 DCF records used to load the HSM 'ROM' keys. <i>Note: This region is only fully readable while Lifecycle = JDP_PROD. When Lifecycle has reached CUST_DEL, this region is read protected by the flash memory flash controller (PFLASH). Reads to this region return dummy DCF records, allowing software to parse the complete DCF record list, from start record to stop record</i>

Table 16. UTest flash memory map (continued)

Start Address	End Address	Allocated Size [bytes]	Description	Comments
0x00400348	0x00400FFF	3584	DCF Records	Contiguous list of DCF Records beginning at 0x00400200. Initial records are programmed at the factory. Subsequent records are added to the end of the list by the customer
0x00401000	0x00403FFF	12288	Reserved for customer OTP data	Programmed by the customer
0x00404000	0x00407FFF	16384	BAF code	Reserved for Boot Assist Flash (BAF). This is factory code that executes every reset to implement boot features. It is programmed at the factory and is OTP

6 Functional Safety

6.1 Introduction

The SPC57EM80xx offers a set of features to support applications that need to fulfill functional safety requirements as defined by automotive safety integrity level ASIL D of ISO 26262. This chapter gives an overview of the safety implementation for the SPC57EM80xx, and discusses the operation of the safety mechanisms.

6.2 Safety overview

The SPC57EM80xx has been designed for automotive applications executing safety-relevant tasks that require a fail-silent or fail-indicate MCU. The SPC57EM80xx supports a Fault Tolerant Time Interval (FTTI) of at least 10 ms. Shorter intervals are possible depending on the actual combination of failure detection and signaling mechanisms as documented in the Safety Manual (SM), but the SPC57EM80xx generally supports an FTTI of 10 ms.

6.3 Module categorization

The definition of the SPC57EM80xx safety concept and its validation (particularly the computation of Probabilistic Metric for Random Hardware Failures (PMHF)) has been done by splitting system modules into four categories as shown in [Table 17](#).

Table 17. PMHF module categories

Module category	Category abbreviation	Description
Vital system modules	ViMo	All modules that can directly influence the correct operation of the software execution (by influence of the correct function of CPU, RAM, flash, and the bus interconnect). Examples of ViMo are the core, the cache, the crossbar, and the interrupt controller (INTC), as well as clock or power generation.
Peripheral modules	PeMo	All microcontroller modules involved in I/O operation, specifically including the I/O bridge.
Non-safety modules	NoSaMo	Modules that belong in one of the above categories but that do not require hardware-level safety measures. Examples include the DMA, the performance core, and the I/O core. Only their non-interference with modules from the other categories is ensured by hardware. In case they are used in a safety-relevant way, application measures are necessary to ensure their safe operation.
Other support modules	SuMo	These are modules that, although safety-relevant and in principle potential members of the ViMo category, cannot lead to a violation of the safety goal on their own. Typically, these will only have multiple point faults, but not single point faults. Example SuMo's are the RCCU and Clock Monitoring Unit (CMU).

[Table 18](#) shows module classifications for the SPC57EM80xx.

Table 18. Module classification

Classification	Modules
ViMos	Master Safety Core, Master Safety Core D-Cache controller, Master Safety Core I-Cache controller, Local Memory Controllers Master Core, Safety Core D-Cache array, Safety Core I-Cache array, Safety Core Local D-Mem array, Safety Core Local I-Mem array, INTC, XBAR_0 (Computational), SRAM controller, system RAM array, flash memory controller, flash memory array, overlay RAM, system timer, MC_RGM, Dual PLL Digital, XOSC, MC_CGM, MC_ME, voltage regulator, MC_PMC, STCU2, SSCM, PIT
PeMos	SAR ADC, PSI5, SENT, LINFlexD, DSPI, M_CAN/TT_CAN, FlexRay, FEC, SIUL2, XBAR_1 (Peripheral), Concentrator FEC, FlexRay, and LFAST, Sigma-Delta ADC PBRIDGE n

Table 18. Module classification (continued)

Classification	Modules
SuMos	RCCU, Checker Safety Core, System RAM/local memory controllers of Checker Safety Core (overall 4), Checker Safety Core D-Cache controller, Checker Safety Core I-Cache controller, CRC units, Temperature Sensors, IRCOSC, CMUs, HVDs, LVDs, Bandgap reference, LBIST controllers, IMA, REG_PROT, SWT, FCCU, MEMU
NoSaMos	[SCG18.016][Covers: ASaf1061]Performance Core (Core_1)[end], Peripheral Core (Core_2), D-Cache Performance Core (Core_1), I- Cache Performance Core (Core_1), I-Cache Peripheral Core (Core_2), other local memories of Performance Core (Core_1) and Peripheral Core (Core_2), EBI (LFAST, SIPI), eDMA, DMACHMUX, GTM, Nexus, JTAG, Concentrator HSM and DMA, I2C, SEMA4, WKPU SPU

The SPC57EM80xx implements no specific protection of NoSaMos against Common Cause Failures between them.

6.4 System implementation

6.4.1 General concept

In general, safety integrity is achieved in the following ways:

- For the Safety Core and its closely related periphery, safety is ensured by a delayed lockstep approach (see [Section 6.4.2, Dual-core lockstep](#)).
- The safety of storage and of the data path to storage and periphery is ensured by End-to-End ECC (E2E ECC) with address encoding and selected additional measures for individual modules. For the periphery, end-to-end ends at the I/O bridges (see [Section 6.4.1.1, End-to-End protection on data path](#)).
- Clock and power, generation and distribution, are supervised by dedicated monitors (see [Section 6.4.1.2, Clock and power monitoring](#)).
- The safety of the periphery is ensured by application-level measures (such as connecting one sensor to different I/O modules, sensor validation by sensor fusion, and so on). Hardware supports this application-level redundancy by providing redundant I/O modules connected to different peripheral bridges (PBRIDGE) to maximize the independence between the monitored and monitoring resources (see [Section 6.4.1.3, I/O peripherals](#), and [Section 6.4.1.4, Communication controllers](#)).
- MBIST and LBIST are provided to avoid the accumulation of latent faults in the functional logic as well as the safety integrity mechanisms (see [Section 6.4.1.5, Built-In Self-Tests \(BIST\)](#)). Dedicated mechanisms are provided to check the availability of safety mechanisms and the functionality of each error reaction path (such as by fake fault injection). The *SPC57EM80xx Safety Manual*, [Table 19 \(LBIST partitions\)](#) and [Table 20 \(Not in LBIST partitions\)](#) contain details about the available LBIST partitions.
- The Fault Collection and Control Unit (see “Fault Collection and Control Unit (FCCU)” chapter for FCCU details) is responsible for collecting and reacting to failure notifications (see [Section 6.4.1.7, FCCU and failure monitoring](#)). MEMU (see [Section 6.4.4.4, Memory Error Management Unit \(MEMU\)](#)) is responsible for the collection and reporting (to the FCCU) of error events in system memories, and flash memory, as well as E2E ECC errors caused by the XBAR, or RAM or flash memory controllers. Error events include ECC corrections and detections as well as faults detected by memory BISTs.
- Common Cause Failures (CCF) are dealt with by a set of measures for both control and avoidance of CCFs spanning system-level approaches (such as temperature and nonfunctional signal monitoring) and back-end techniques (such as isolated silicon areas and routing constraints) (see [Section 6.4.3, Common Cause Failure measures](#)).

6.4.1.1 End-to-End protection on data path

Connections between XBAR masters and slaves (clients) are denoted as data paths. Data corruption on all data paths between the Safety Core and any client is detected with at least 99% coverage via two main safety mechanisms: data from the replicated cores is encoded using Error Correcting Code (ECC), which is implemented with a single-error correction, double-error detection (SEDED) code with a Hamming distance of 4 and includes coverage of addressing information; control signals and address decoding are monitored to verify the data reaches all of the intended clients, from all possible connections to these clients and the intended operation is performed on the target address. [Figure 7](#) shows a general view of ECC schema.

Figure 7. General view of E2E ECC

Note: Specific implementation for the SPC57EM80xx vary depending on the special requirements of RAM and flash memory concerning ECC handling.

ECC bits are generated on writes by XBAR masters (including, but not limited to the Safety Core) and checked on reads. The ECC correction bits are stored alongside the data in flash memory and RAM so, in principle, no ECC logic is necessary at the memories themselves. For this reason the ECC schema is referred to as End-to-End ECC (E2E ECC) in the following sections. For XBAR slaves, apart from memories, new ECC logic is added as these clients cannot store or produce the ECC correction bits. This resolves the problem where ECC needs to be calculated in real time before entering or exiting the ECC-protected data path. This setup leaves the data path downstream of the ECC units (for example, starting at, and downstream of, the peripheral bridges) unprotected by ECC. To detect corruptions introduced on those unprotected data paths, the PBRIDGES and peripherals can be used redundantly (see [Section 6.4.1.3, I/O peripherals](#)), or other mechanisms may be used to validate peripheral operation.

The E2E ECC schema provides high detection capabilities against failures affecting the data content of the transaction. The inclusion of the target address in the computation of the redundancy bits (8 ECC bits) does allow the partial detection of addressing faults as well. To reach the desired integrity level, additional dedicated safety mechanisms are implemented in the data path particularly to:

- Improve the detection capability over addressing failures (no/multiple/wrong address selected), considering faults affecting address transmission (from master to client) as well as the decoding of the address;
- Provide coverage for control failures affecting, for example, the type (read vs. write) or size of a transaction.

Though safety mechanisms protecting the XBAR, the RAM controller, or the flash memory controller are different, they are all based on the feedback of address and control information from the target to the source of the transaction, which is responsible for checking for consistency with respect to the intended transaction. Depending on the portion of the data path covered by the specific safety mechanism, the source can be an XBAR master port rather than the XBAR interface of the RAM or Flash controllers; the target is respectively an XBAR slave port, the RAM array, or the Flash module (see “Crossbar Switch (XBAR)”, “Flash memory controller”, and “RAM controller (PRAM)” chapters).

6.4.1.2 Clock and power monitoring

6.4.1.2.1 Clock

Clocks in the SPC57EM80xx are supervised by Clock Monitor Units (CMUs). The CMUs are driven by the IRCOSC (16 MHz internal oscillator) for independent operation from the monitored clocks. CMUs flag errors associated with conditions due to loss of clock, clock out of a programmable bound (over and under frequency), and loss of reference. If a supervised clock leaves the specified range for the device, a signal is sent to the FCCU.

The clock tree for Core_0 and Core_0 – Checker (the two lockstep cores comprising the Safety Core) consists of separate clock branches that are not shared with any other module. One CMU (CMU_1) is connected to the Main Core clock path, downstream from the common part of the clock tree for the Main and Checker Cores. In this way any frequency failure affecting the Main Core clock or the common clock (SYS_CLK) is detected by the CMU, and any frequency failure affecting the Checker Core clock is detected by the Redundancy Control and Checker Units (RCCUs) (see [27, Clocking](#), for MCU clocking details).

6.4.1.2.2 Power

There are two types of voltage supervisors on the SPC57EM80xx, Low Voltage Detect (LVD) and High Voltage Detect (HVD) monitors. Safety-relevant voltages are supervised for voltages that are out of these ranges. Since safety relevant voltages have the potential to disable the failure indication mechanisms of the MCU (such as FCCU, pads, and so on) the indication of these errors can be used to cause a direct transition of the MCU into the safe state (reset assertion) (see “Power management” and “Power Control Unit (MC_PCU)” chapters for details on power monitoring).

6.4.1.3 I/O peripherals

To allow a safety application to make redundant use of all I/O peripherals, each peripheral has at least two instances (except for the GTM), and each instance is connected to a different PBRIDGE. This means, for example, that if DSPI is provided by the MCU, two DSPI modules (DSPI_n, DSPI_m) are included and connected externally through different pins. Internally, DSPI_n would then be connected to PBRIDGE_A and DSPI_m to PBRIDGE_B and be accessible via different addresses.

The arrangement of I/O peripherals onto two PBRIDGES, as well as further CCF prevention measures, allow redundant use of peripherals while limiting possible causes of CCFs. Redundant usage includes usage of equivalent peripherals in a replicated way as well as usage of functionally different peripherals in, for example, feedback measurement loops. Comparison of redundant operation is the responsibility of the application software, not the safety hardware mechanism. Details on proper I/O peripheral usage can be found in the *SPC57EM80xx Safety Manual*, and the split of peripherals on the two PBRIDGES is shown in [Figure 2 \(Block diagram\)](#) and [Figure 3 \(Periphery allocation\)](#)

6.4.1.4 Communication controllers

Communication controllers provide the ability to exchange information with external components and therefore fall under the same safety reasoning as I/O peripherals. Yet we assume that for high bandwidth communication controllers additional software measures are employed that do not require redundant communication peripherals.

The following communication controllers do not contain special safety mechanisms (above what is included in them by their protocol specifications) nor are they duplicated or spread over the PBRIDGE (in contrast to other I/Os, see [Section 6.4.1.3, I/O peripherals](#)):

- FlexRay
- FEC
- M_CAN
- TT_CAN

Typically, software measures for the communication controllers (also called fault-tolerant communication layer) could contain E2E CRC data protection, sender identification, sequence numbering, and an acknowledgement mechanism.

PSI5 represents an exception to the replication of low bandwidth communications controllers. The module itself is replicated, but the two PSI5 modules share a single synchronization bit needed for staggered sync mode. This single bit is a single source of failures for both PSI5 modules if it triggers spurious synchronizations. The failure mode has to be covered by application level countermeasures, which are in any case needed to cover the single transceiver used in such a configuration.

6.4.1.4.1 Disabling of communication controllers

In the event of a dangerous failure, the MCU offers the capability of disabling transmission of individual channels of communication controllers (such as CAN modules and FlexRay). This prevents the transmission of erroneous messages while preserving the capability of communicating over the diagnostic bus. Disabling outputs is controlled by resetting the SIUL2_MSCRn[SMC] for the pins that are associated with communication controllers where this feature is needed (see the “System Integration Unit Lite2 (SIUL2)” chapter for details on disabling communication signals).

It is understood that FCCU can drive a fault state on FI[0] with either of the following two mechanisms:

- Error pin reaction due to a fault
- Software writing FCCU_CFG[FCCU_SET_CLEAR] = 01b

When the FCCU drives FI[0] to a fault state, the SIUL2 disables the output drivers of all pins whose SIUL2_MSCRn[SMC] = 0. This disables the possible transmission of erroneous messages. As long as the FCCU drives FI[0] to faulty state, the communication controllers' Tx pins are disabled and internal pull-up are enabled. As soon as FI[0] is driven to non-faulty state, the communication controllers' Tx pins are automatically enabled and state of internal pull-up/down restored.

The application should configure SIUL2_MSCRn[SMC] for pins that have active mapping of CAN modules (M_CAN, TT_CAN) or FlexRay functionality and ensure that pin does not stay in undriven state.

Note: The FCCU uses an internal signal to disable the communication controller transmission, so transmission is disabled even when the FCCU cannot drive the FI[0] pin because the pin is

configured as GPIO. Also, if FI[0] is used as error input, externally pulling it down will disable the communication controller transmission if this event drives FCCU to a fault state.

Note: Disabling of communication controllers occurs on the Tx pins of the communication controller (for example, TT_CAN, M_CAN, FlexRay) of the MCU even while the communication controller continues operating. Failed transmissions, when detected by the communication controller, may lead to additional error events.

6.4.1.5 Built-In Self-Tests (BIST)

The term BIST indicates the set of built-in hardware mechanisms that can be used (typically at startup) to avoid the accumulation of latent faults. BIST is a mechanism that permits a device to test itself. On the SPC57EM80xx, BIST is the principal means of meeting the requirement on latent faults as defined by the ISO 26262 standard. Different “flavors” of BIST are implemented in the SPC57EM80xx: LBIST for digital logic, MBIST for memories, and the MCU’s built-in mechanisms for testing analog peripherals. LBIST and MBIST execution are managed by the STCU2, while the testing of analog peripherals requires software intervention to be triggered (see “Self-Test Control Unit (STCU2)” chapter).

6.4.1.5.1 BIST during boot

A device BIST is performed every time the device boots. BIST is performed transparently for the application while the device is still under reset. BIST failure will hold the device in reset, but the BIST will continue running where possible, and inform the system of the failure. Application software can start executing when the BIST finishes successfully without detecting a fault. The boot time BIST comprises:

- Memory BIST for all RAMs and ROM
- Scan-based Logic BIST for digital logic, which is divided into multiple partitions that can be configured to be tested in parallel or sequentially to find the best time versus power consumption trade off.

6.4.1.5.2 Online Logical BIST (LBIST)

Though LBIST and MBIST are primarily intended to be run at startup under STCU2 control, the MCU allows software to trigger a memory self-test or LBIST of one partition during runtime. Since LBIST and MBIST are destructive, a reset is performed for the tested module (memory or partition) before going into operation again. This leads to a reset of the MCU or of those LBIST partitions. If a runtime LBIST requires a reset of the whole device (and not just the LBIST partition), the LBIST result is accessible to software after the reset. If a reset occurs during LBIST, the LBIST will be aborted. [Table 19](#) and [Table 20](#) below show the module groupings for each LBIST partition.

Note: Testing LBIST functionality is ongoing as of this writing. This information is preliminary and will be updated as more data is received.

6.4.1.6 Redundancy Control and Checker Units (RCCUs)

The RCCU compares a set of equivalent input signals provided by different sources and issues an alarm in case of a mismatch. For example, an RCCU compares the output of the checker core against the output of the main core and issues an alarm if they do not match. In case of a compare mismatch the fault stays stable until it is explicitly cleared.

6.4.1.7 FCCU and failure monitoring

The FCCU offers a hardware mechanism to aggregate error notifications and a configurable means to bring the device to a safe state. No CPU intervention is required for collection and control operation. Error indications are passed from the individual hardware components to the FCCU where the appropriate action is decided (according to the FCCU configuration).

6.4.1.7.1 External error indication

Failure of the MCU is signaled to one or two pins, FI[0] (ERROR0) and FI[1] (ERROR1). FI[0] can also serve as an error input mechanism (see “Fault Collection and Control Unit (FCCU)” chapter, and “FCCU configuration” section of the “Device configuration” chapter, for details on the fault output signals). Both pins can be multiplexed with other functions with different defaults.

The error indication on pins FI[0] and FI[1] is controlled by SIUL2 and FCCU. The mapping of the FCCU output signals on the relevant pins and the associated electrical characteristics are enabled by the SIUL2_MSCR[n] register (see table “SIUL2_MSCR0 - SIUL2_MSCR511 field description” in the “System Integration Unit Lite2 (SIUL2)” chapter for signal mapping details). Once the FCCU is mapped onto the pin, the logic level is driven by the FCCU.

FI[0] is controlled by the FCCU at startup by default, but the state of FI[1] is like other I/O signals (see table “Pin/ball startup and reset states” in chapter “Signal Description” for default states of FI[0] and FI[1]).

Since it is possible to reset FCCU and SIUL2 independently, the behavior of FI[0] and FI[1] is the result of the combined state of SIUL2_MSCR[n] and the FCCU. (see section “Reset interface” in chapter “Fault Collection and Control Unit (FCCU)” for FCCU reset details, and chapter “Reset and Boot” for the state of the FCCU relative to the system during different reset phases).

The FCCU_STAT[ESTAT] error status flag can be read to show whether the FCCU is in an error state. This flag can be written by software to either a 1 (fault) or 0 (operational) when the FCCU is in operational state. Another flag, FCCU_STAT[PSTAT], is accessible through the register interface (which mirrors the physical state of the *Fn* external pin's value, though this may differ from the logical state if a toggling protocol is used).

6.4.1.7.2 Failure handling

The FCCU is an autonomous module that is responsible for reacting to failure indicators. A different reaction can be configured for each failure source. Overall failure reaction time requires time for detecting, processing, and indicating the error. During this time, the SPC57EM80xx could provide wrong results to the system.

Failure sources include:

- All failure indication signals from modules within the MCU
- Control logic and signals monitored by the FCCU itself (see chapter “Fault Collection and Control Unit (FCCU)”)
- Software-initiated failure indications. For example, software signals the FCCU that it has evidence of a failure. Keep in mind that software can also directly influence the state of the *Fn* pins.
- External failure input.

Available failure reactions are:

- Assertion of an interrupt (maskable or non-maskable)
- Resetting the MCU
- Changing the state of the failure indication pins, ERROR_n
- Disabling the transmission capabilities of communication controllers (FlexRay, CAN, FEC) (Note: only possible in conjunction with changing the state of the failure indication pins)
- No reaction

Software can read the failure source that caused a fault, either before or after a functional reset (the condition indicators are not volatile). Software can also reset the failure, but the external failure indication will stay in failure mode for a configurable minimum time. If necessary, software can also reset the MCU.

6.4.1.7.3 FCCU failure inputs from other modules

[Table 35](#) shows the different failure input signals of the FCCU, how they can be tested, and their default configuration after reset.

Table 21. FCCU failure inputs⁽¹⁾

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
0	TEMP_ERROR	Event indication from temperature sensor. The fault is cleared by clearing the status in PMC_dig_EPR_TD, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	PMC_dig_EPR_TD Section 60.3.1.44
1	LVD_ERROR	Voltage out of range indication from LVDs. The fault is cleared by clearing the status in PMC_dig_EPR_VDn, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LVD assertion test by tap point manipulation	No reaction	PMC_dig_EPR_VD3 PMC_dig_EPR_VD4 PMC_dig_EPR_VD9 PMC_dig_EPR_VD10 PMC_dig_EPR_VD13 PMC_dig_EPR_VD14 Section 60.3, Memory Map/Register Definition
2	HVD_ERROR	Voltage out of range indication from HVDs. The fault is cleared by clearing the status in PMC_dig_EPR_VDn, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Self-test by TAP point manipulation	No reaction	PMC_dig_EPR_VD7 PMC_dig_EPR_VD8 PMC_dig_EPR_VD12 Section 60.3, Memory Map/Register Definition
3	DPMC_DCF_SAFETY_ERR	Digital PMC initialization error during DCF data load. The fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]. The status gets cleared if the fault is not persistent.	LBIST	No reaction	Section 60.9

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
4	MEMORY_DCF_SAFETY_ERR	Indication of fault during timing/repair configuration initialization by SSCM of different memories. The status is cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]. The status gets cleared if the fault is not persistent. Additionally, this error will cause a MBIST failure.	LBIST	No reaction	Section 59.3.1.1
5	SSCM_XFER_ERR	SSCM transfer error (during the SSCM and STCU DCF loading). The fault is cleared by clearing SSCM_STATUS[CER], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	Not testable (but wrong configuration can trigger other detection)	No reaction	Section 59.3.1.1
6	STCU_UF	STCU2 unrecoverable fault indication during self-test. It is simultaneously reported to the MC_RGM which will initiate a destructive reset, if enabled. In the STCU2, self-test failures can be configured as recoverable or unrecoverable faults which would then lead to assertion of the corresponding fault line to the FCCU. Fault is cleared by clearing STCU2_ERR_STAT[UFSF] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	SW check of BIST MISR or Feedback loop via FCCU Fake bit	Long Reset	Section 82.5.11 Section 57.1.3
7	STCU_RF	STCU2 recoverable fault indication during self-test. In the STCU2, self-test failures can be configured as recoverable or unrecoverable faults which would then lead to assertion of the corresponding fault line to the FCCU. Fault is cleared by clearing STCU2_ERR_STAT[RFSF] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	SW check of BIST MISR or Feedback loop via FCCU Fake bit	No reaction	Section 82.5.11

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
8	STCU_LMBIST_USR_ERR	Activation of LBIST or MBIST control during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]. The status will clear if the fault is not persistent.	Feedback loop via FCCU Fake bit.	No reaction	—
9	SPURIOUS_DEBUG_SSCM_ACTIVATION	JTAG, NPC or Debug functionality moved out of reset or SSCM activation during application mode. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Feedback loop via FCCU Fake bit	No reaction	—
10	RCCU_0	Safety cores out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input	No reaction	Section 6.4.1.6
11	RCCU_1	Safety cores out of sync during lockstep. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Feedback loop via FCCU Fake bit connected to additional RCCU input	No reaction	Section 6.4.1.6
12	SWT2_ResetReq	Reset request from Software Watchdog of Peripheral Core_2 domain. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT2.	LBIST + SW test by not triggering SWT during startup	Long Reset	Chapter 44: Software Watchdog Timer (SWT)
13	SWT1_ResetReq	Reset request from Software Watchdog of Main Core_1 domain. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT1.	LBIST + SW test by not triggering SWT during startup	No reaction	Chapter 44: Software Watchdog Timer (SWT)

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
14	SWT0_InterrupReq	First timeout interrupt request from Software Watchdog of Safety Core (Main Core_0). Fault is cleared by clearing SWT0_SWT_IR[TIF], followed by clearing the FCCU channel status FCCU_RF_Sn[RFSm].	LBIST + SW test by not triggering SWT during startup	No reaction	Chapter 44: Software Watchdog Timer (SWT)
15	SWT0_ResetReq	Second timeout (reset) request from Software Watchdog of Safety Core (Main Core_0). The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared inside SWT0.	LBIST + SW test by not triggering SWT during startup	No reaction	Chapter 44: Software Watchdog Timer (SWT)
16	MEMU_RAM_CE	Indication by MEMU of occurrence of correctable errors in system RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[SR_CE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Injection of RAM ECC error via ECC bit access and later reading	No reaction	Section 79.6.2.2
17	MEMU_RAM_UCE	Indication by MEMU of occurrence of uncorrectable errors in system RAMs. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_UCE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Injection of RAM ECC error via ECC bit access and later reading	No reaction	Section 79.6.2.2
18	MEMU_RAM_BOV ⁽³⁾	Indication of overflow of system RAM ECC buffer in MEMU. The fault is cleared by the clearing MEMU_ERR_FLAG[SR_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Feedback loop via FCCU Fake bit and MEMU output	No reaction	Section 79.6.2.2

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
19	MEMU_PER_CE ⁽³⁾	Indication by MEMU of the occurrence of correctable errors in peripheral RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[PR_CE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	LBIST + Feedback loop via FCCU Fake bit and MEMU output	No reaction	Section 79.6.2.2
20	MEMU_PER_UCE ⁽³⁾	Indication by MEMU of the occurrence of uncorrectable errors in peripheral RAMs. The fault is cleared by clearing MEMU_ERR_FLAG[PR_UCE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	LBIST + Feedback loop via FCCU Fake bit and MEMU output	No reaction	Section 79.6.2.2
21	MEMU_PER_BOV ⁽³⁾	Indication of overflow of system RAM ECC buffer in MEMU. The fault is cleared by clearing MEMU_ERR_FLAG[PR_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	LBIST + Feedback loop via FCCU Fake bit and MEMU output	No reaction	Section 79.6.2.2
22	MEMU_FLS_CE	Indication by MEMU of occurrence of correctable errors in flash memory. The fault is cleared by the clearing MEMU_ERR_FLAG[F_CE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Reading preprogrammed correctable ECC error from UTEST flash memory	No reaction	Section 79.6.2.2
23	MEMU_FLS_UCE	Indication by MEMU of occurrence of uncorrectable errors in flash memory. The fault is cleared by the clearing MEMU_ERR_FLAG[F_UCE], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Reading preprogrammed uncorrectable ECC error from UTEST flash memory	No reaction	Section 79.6.2.2

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
24	MEMU_FLS_BOV ⁽³⁾	Indication of overflow of flash memory ECC buffer in MEMU. The fault is cleared by the clearing MEMU_ERR_FLAG[F_EBO], followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Feedback loop via FCCU Fake bit and MEMU output	No reaction	Section 79.6.2.2
25	IMA_SOC	MCU IMA active	LBIST + IMA read	No reaction	—
26	IMA_HSM	HSM IMA active	LBIST + IMA write	No reaction	—
27	SARB_WDG	Reference-SAR ADC watchdog is triggered. Fault is cleared by clearing the asserted bits [WDGnL, WDGnH] in SARB_WTISR, followed by clearing FCCU_RF_Sn[RFSm].	LBIST + ADC conversion outside the watchdog range	No reaction	Section 40.4.7
28	SARn_WDG	OR'd outputs of watchdogs, SAR_ADC[0:7]. Fault is cleared by clearing any asserted bits [WDGnL, WDGnH] in WTISR register of any functional SAR ADC, followed by clearing FCCU_RF_Sn[RFSm].	LBIST + ADC conversion outside the watchdog range	No reaction	Section 40.4.7
29	FM_PLL_0	PLL0 loss of lock. In order for this fault source to be asserted in the event of loss of lock, the Loss of Lock Interrupt needs to be enabled by writing (PLLDIG_PLL0CR[LOLIE]) = 1. Fault is cleared by clearing PLLDIG_PLL0SR[LOLF], followed by clearing FCCU_RF_Sn[RFSm].	LBIST + Forced loss by PLL reconfiguration	No reaction	—
30	FM_PLL_1	PLL1 loss of lock. In order for this fault source to be asserted, the Loss of Lock Interrupt needs to be enabled by writing PLLDIG_PLL1CR[LOLIE] = 1. Fault is cleared by clearing PLLDIG_PLL1SR[LOLF], followed by clearing FCCU_RF_Sn[RFSm].	LBIST + Forced loss by PLL reconfiguration	No reaction	—

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
31	CMU_0_OSC ^{(4),(5)}	Loss of XOSC clock. The fault is cleared by clearing CMU_ISR[OLRI] of CMU_0, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	Section 29.4.1.5
32	CMU_0_PLL ^{(4),(6)}	SYSCLK frequency out of range. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_0, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	LBIST + Test by misconfiguration ⁽⁶⁾	No reaction	Section 29.4.1.5
33	CMU_comp_subsys ^{(4),(7)}	Exception from monitoring internal clocks of comp_subsys. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_n, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	LBIST + Test by misconfiguration ⁽⁶⁾	No reaction	Section 29.4.1.5
34	CMU_other ^{(4),(8)}	Exception from monitoring internal clocks of other subsystems. The fault is cleared by clearing either CMU_ISR[FHHI] or CMU_ISR[FLLI] (or both) of CMU_n, followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm]	LBIST + Test by misconfiguration ⁽⁶⁾	No reaction	Section 29.4.1.5
35	PERIPH XBAR Transaction Monitor	Indication of a hardware fault resulting in corrupted transaction through the peripheral XBAR. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	Chapter 18: Crossbar Integrity Checker (XBIC)
36	EDC_ECC_FLASH	Indication of a hardware fault in the ECC of the flash memory resulting in corrupted ECC detection/correction. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
37	EDC_ECC_FLASH_C	Indication of hardware fault in the flash memory controller resulting in corrupted ECC detection / correction. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
38	ENC_ERR_FLASH	Indication of hardware fault resulting in corrupted flash memory access. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
39	ADDR_FDBK_ERR_FLASH_C	Indication of an addressing error in the flash memory controller resulting in corrupted flash memory access. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
40	COMP XBAR Transaction Monitor	Indication of an addressing or control fault resulting in corrupted transaction through the computational XBAR. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	Chapter 18: Crossbar Integrity Checker (XBIC)
41	ON_CAL_RAM_ERR	Indication of an addressing error in the on-chip overlay RAM resulting in corrupted access to on-chip overlay RAM. Status should be cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
42	SAFE_CAL_ERR	Indication of hardware fault in the flash memory controller resulting in corrupted overlay remap evaluation. Status should be cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
43	ADDR_FDBK_ERR_PRAM + RAM_LWB_ERR	Indication of an addressing error in system RAM or a write error in the RAM controller resulting in corrupted RAM access. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
44	MPU_ERROR	Indication of the SMPU that it prevented an unauthorized access. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
45	EDC_ERR_PRAM	Indication of a fault in the RMW logic of the system RAM resulting in an incorrect RMW access and a potentially corrupted RAM word. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Feedback loop via FCCU Fake bit	No reaction	—
46	DFT1	Test circuitry Group 1 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
47	DFT2	Test circuitry Group 2 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
48	DFT3	Test circuitry Group 3 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—
49	DFT4	Test circuitry Group 4 activation. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST	No reaction	—

Table 21. FCCU failure inputs⁽¹⁾ (continued)

FCCU channel (2)	Failure	Failure description	Error reaction path check	Default reaction configuration after POR or destructive reset	Reference Manual related information
50	Safety Core Machine Check Exception ⁽⁹⁾	Safety Core exception indication. The fault is cleared by clearing the status in MCSR register of the Safety core followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Willfully cause an appropriate exception (for example, access a non-existing address)	No reaction	—
51	Lockstep mode	Indication of disabled Checker Core or RCCUs. Fault is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + Feedback loop via FCCU Fake bit	No reaction	Section 6.4.2
52	Safe_Mode	Indication of safe mode request assertion from MC_RGM. The event is also captured in MC_ME and available as status for crosscheck. Status should be cleared first in the MC_RGM_FES, then followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	LBIST + (in principle requesting an RGM "safe mode" though that is not typical, and should be avoided)	No reaction	Section 57.3.1.5
53	Compensation Disable	Pad compensation disabled fault which potentially results in distorted transmissions on various I/Os. The indication is cleared by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	—	No reaction	—
54	EIN_ERR ⁽¹⁰⁾	Error input pin (FI[0], external of the MCU) signalling an error condition. The fault is cleared by clearing the fault driving FI[0] followed by clearing the FCCU channel status, FCCU_RF_Sn[RFSm].	External activation of EIN. External entity has to pull the error input low.	No reaction	—
55	SWT3_ResetReq	Reset request from Security Watchdog. The fault is cleared by clearing FCCU_RF_Sn[RFSm] after the status has been cleared in the SWT3.	LBIST+ SW test by not triggering SWT during startup	No Reaction	Section 7.7.2.1

1. All of these faults require a long functional reset.

2. See "Fault Collection and Control Unit (FCCU)" chapter for channel mapping details.

3. Error reaction path check contents subject to change.
4. See Clock generation figure ([Figure 258 \(Clock generation \(part 1 of 2\)\)](#)) in the Clocking chapter ([27, Clocking](#)).
5. CMU_0 OLR event + XTAL pin floating + EXTAL Pin Floating.
6. CMU_0 FLL and FHH events.
7. CMU_1, CMU_2, CMU_3, FLL, and FHH events.
8. CMU_4, CMU_5, CMU_6, CMU_7, CMU_8, CMU_9, CMU_10, CMU_11, FLL and FHH events.
9. See “Exceptions and Conditions” table in the *e200z4 Core Reference Manual* for all exceptions which can occur in the core and table “Error report machine check exceptions” for errors indicated by a machine check exception. Note that the following do not cause a machine check and thus do not signal to the FCCU: access blocked by MPU, wrongly aligned access, execution of a privileged or trap instruction, FPU exceptions. Such errors will have to be handled by the respective exception handler if they are safety-relevant.
10. EIN_ERR can be used only when bistable protocol is selected for external error indication, and the FI[0] pin is configured as open drain.

6.4.1.8 Operational interference protection

Being a multi-master system, SPC57EM80xx provides safety mechanisms to prevent non-safety masters from interfering with the operation of the Safety Core, as well as mechanisms to handle the concurrent execution of software with different (lower) ASIL. Interference freedom is guaranteed via a hierarchical memory protection schema including:

- MPUs
- PBRIDGES
- Register protection.

There are two Memory Protection Unit levels included in the SPC57EM80xx. The Core Memory Protection Unit (CMPU) is a mechanism included in each core (except HSM core) to protect address ranges against access by software developed according to lower ASIL. The CMPU is typically used by the operating system to ensure inter-task interference protection.

The second MPU level is provided by the System MPUs (SMPU) located in each XBAR. The MPUs prevent access of different bus masters to address ranges and are typically used by the safety application to prevent NoSaMos (such as the DMA or the Performance Core) to access the application's safety-relevant resources.

Furthermore, the PBRIDGE can restrict read and write access to individual I/O modules based on the origin of the access and its state (user mode/supervisor mode).

Finally, the register protection included allows individual register to be locked against any manipulation without unlocking.

These safety mechanisms are further described in the "System Memory Protection Unit (SMPU)" chapter.

6.4.1.9 FCCU supervision (FOSU)

As the FCCU is a central component in reacting to errors, it is itself supervised even though an error in it can only cause a latent failure. This supervision is provided by the FCCU Output Supervision Unit (FOSU). The FOSU receives failure indications at the same time as the FCCU. Unless the respective failure is switched off, the FOSU will observe the outputs of the FCCU (IRQ, RESET, F_n). If the FCCU does not react within a predefined interval as specified in the "FCCU configuration" section of the "Device configuration" chapter, on one of those outputs to the incoming failure indication, the FOSU assumes the FCCU has failed, and causes a destructive reset.

The FOSU does not require any configuration by software.

6.4.2 Dual-core lockstep

The SPC57EM80xx duplicates its safety-relevant processing elements and compares their operation in Lockstep mode (LSM). This Safety core consists of two cores, Checker Core_0 and Main Core_0, and as far as software is concerned they behave as one core.

Main Core_0 is the main execution core of the pair, where Checker Core_0 follows the execution of the Main Core in lockstep.

The replicated processing elements contain:

- Core
- Cache control
- Local memory control
- Core MPU
- Core System Bus Interface, including e2eECC logic

Together each set of replicated elements forms a channel (for example, the Main channel and the Checker channel).

Elements that are not replicated are:

- Performance or I/O cores
- Cache and local memory arrays
- INTC
- Interconnect (XBAR)
- RAM controller
- Flash memory controller
- eDMA controller

Note: This is not a complete list of all non-replicated elements. But the elements listed are sometimes replicated in similar lockstep architectures.

Equivalent operation of replicated resources is supervised by comparators on all functional signals leaving the channels for the rest of the MCU. Any operational deviations between the supervised signals will cause the FCCU to be notified of the discrepancy.

The Checker Core does not have a direct connection to the XBAR. All of the outputs of Checker Core_0 that target the XBAR (as well as any other non-duplicated resource, like local memories) will end in an RCCU for verification, and all the inputs to Checker Core_0 from the XBAR will be split off from the Main Core_0 XBAR inputs.

An abstract view of the implementation including delays and RCCUs is shown in [Figure 8](#), but does not show local memory.

Figure 8. Dual core concept

A delay of two clock cycles exists between the Main and Checker channel to reduce their susceptibility to CCFs caused by power and clock disturbances. Outputs of the Main Core (such as XBAR addresses) are registered and delayed before being forwarded to the RCCUs, while inputs signals (such as XBAR read data) are registered and delayed before being fed to the Checker channel.

LSM can be disabled during boot by reprogramming the flash memory or on-line by disabling the checker core but not the master core^(d). LSM is also automatically disabled when Core_0 enters debug mode and automatically reenabled when it leaves it. If LSM is disabled, the RCCUs are disabled, and a signal is sent to the FCCU. If SW enables the checker core by writing in MC_ME - MC_ME_CCTL register while LSM is disabled (not recommended), this does not enable LSM and the RCCUs will not generate any error, in case of mismatch. Thus no user-initiated dynamic enabling of LSM is possible. A reset is needed to reestablish LSM. Also, in contrast to the SPC560ELx, no Decoupled Parallel Mode (DPM) is available (Main Core_0 and Checker Core_0 cannot operate as two

d. Disabling both cores in a single mode transition will not disable LSM.

independent cores running different software). Main Core_0 is able to operate as an independent core if Checker Core_0 is disabled. The status of LSM for the Safety core can be verified by checking the appropriate FCCU register.

6.4.3 Common Cause Failure measures

Various measures are included to prevent CCFs from endangering the effectiveness of the replication of the Safety Core or of the peripherals. These measures include physical separation of the components on the die, routing restrictions and supervision of clock, power, temperature, test and debug signals. In general these measures are independent from the software.

There are also configuration registers that, on change, can affect the execution of the MCU's safety function and, simultaneously, disable the respective safety mechanism. These are either protected against bit flips or those flips are detected by independent measures. These same registers are also protected against accidental software writes by employing the register protection described above.

6.4.4 ECC

Error correcting codes are used for end-to-end protection from cores to system storage as well as for individual protection of peripheral RAMs.

6.4.4.1 ECC for storage

All storage (system RAM, local memory, flash memory, peripheral RAM) used in normal operation is protected by ECC with SECDED (Single Error Correct and Double Error Detect). Exceptions to this are noted below:

- The caches in the cores are protected by EDC (Error Detection Code), only detecting, but not correcting errors.
- FlexRay's schedule information RAM is protected by EDC only.
- The HSM's AES program extension RAM are not protected by ECC.

A list showing the implementation of RAMs with ECC (including address protection) and for the SPC57EM80xx is shown in [Table 22](#).

Table 22. ECC RAM implementations

Location	Memory	Memory classification	ECC	Address in ECC	Reacts to uncorrectable error
Core_0 (Safety Core) (Master and Checker cores)	I-Mem	System RAM	SEC/DED	Y	Y
	D-Mem	System RAM	SEC/DED	Y	Y
	I-Cache	System RAM	EDC	Y	Y
	D-Cache	System RAM	EDC	Y	Y
	ITAG	System RAM	SEC/DED	Y	Y
	DTAG	System RAM	SEC/DED	Y	Y

Table 22. ECC RAM implementations (continued)

Location	Memory	Memory classification	ECC	Address in ECC	Reacts to uncorrectable error

Platform	AMU	Peripheral	SEC/DED	N	N
Platform	FEC/FIFO	Peripheral	SEC/DED	N	N
Platform	FEC/MIB	Peripheral	SEC/DED	N	N

As shown in [Table 22](#), some memories, particularly system storage, use an ECC computed over data and address to detect data and addressing faults (no/wrong/multiple selection). In addition, these same memories include dedicated measures against addressing and control faults (such as address/control feedback). This is different for storage related to PeMos.

PeMos, in general, use an ECC without address error protections and do not include additional measures to detect them. All ECC calculations for RAMs in PeMos are accomplished by logic outside of the RAM, not in the RAM block.

An exception to this is the GTM's RAMs. They include addressing failure detection measures in the ECC. In addition, the individual RAM ports of the GTM do not share common parts and connect to individual (non-interfering) RAM arrays.

6.4.4.2 All-x words and ECC

There is a special case for legal ECC values in the SPC57EM80xx. Memory entries that are all zeros (All-0) or all ones (All-1), including the ECC parity bits, are not legal for memory that is checked by ECC. The flash memory allows All-1, corresponding to the status of an erase block, as a valid codeword.

Memories that include addresses in the ECC calculation do not specifically protect against All-0 or All-1. This means that for some addresses All-0 or All-1 may be legal.

All-0 and All-1 memory content is indicated in different ways. For memories that do not include address into the ECC calculation, All-0 and All-1 will be uncorrectable errors. For all memories that include address into the ECC code-bit calculation, since the ECC checkbits depend on the address, it is not possible to generate an uncorrectable error indication for all the possible addresses. Therefore, an All-x content may result in a correctable error.

Note: For flash memory, additional dedicated safety mechanisms exist to detect failures that have the potential of leading to an All-1 word (see "Embedded Flash Memory" chapter, for more details on flash memory safety mechanisms).

6.4.4.3 ECC failure handling

Single-bit and double-bit errors (correctable and uncorrectable errors) are signaled to the FCCU unless filtered by the MEMU. The MEMU (see [Section 6.4.4.4, Memory Error Management Unit \(MEMU\)](#)) may filter ECC error notification for known ECC error addresses (known permanent correctable errors). Actual implementation will signal errors, not to the FCCU, but to the MEMU, which filters and then forwards unfiltered notifications in an aggregated manner to the FCCU.

6.4.4.4 Memory Error Management Unit (MEMU)

The MEMU is responsible for the collection and reporting of error events associated with ECC logic used on SRAM (system RAMs in this context are those RAMs with "System RAM" memory classification as in [Table 22](#)), peripheral RAM, and flash memory. When ECC error events occur, the MEMU receives an error signal that causes an event to be recorded, and possibly sets corresponding error flags that are reported to the FCCU.

The MEMU stores the addresses of ECC errors that have occurred in a table as follows:

- Uniqueness of the addresses in the table is ensured. For example, if an address is already stored in the MEMU's table, correctable errors at that address will no longer be reported to the FCCU.
- Software can read and modify the MEMU table and remove individual entries (by marking them as invalid). For example, this allows software to invalidate a new entry in the MEMU table and wait for a repeat occurrence of the ECC error indicating a permanent error in memory.
- If the MEMU table overflows, an additional signal (instead of the ECC error signal) is sent to the FCCU.

As the MEMU aggregates address information from several sources, it might not be able to process all simultaneously arriving reports. This is called a simultaneous overflow and is signaled to the FCCU as a buffer overflow (see “Memory Error Management Unit (MEMU)” chapter for more information).

6.4.4.4.1 Interface to ECC units

The MEMU receives data according to the following interface per ECC unit connected:

- Whether the error is a Single-Bit-Error (SBE) or Uncorrectable Error (UCE) type
- Address of the memory where the error occurred
- A configuration specifying whether the ECC unit is attached to a vital memory (SRAM, local memory, and system RAM of Safety Core), to flash memory, or to a peripheral RAM

If an error is signaled, it is compared against all errors known for that storage:

Note: If a previously known error has been marked invalid by software, no comparison against the address will occur.

- If no entry of that address is already in the buffer, it is to be added into the appropriate table depending on the SBE versus UCE indicator

Note: For this comparison the bit position will not be taken into account. This is in contrast to MBIST reporting.

- If there is no free entry left in that buffer, the overflow flag is set.

If a valid entry of that address is in the buffer, the following occurs:

- If the entry indicates an SBE in that address, and the error indicated is uncorrectable, a new entry is added in the MEMU buffer.
- In all other cases, nothing is changed in the entry.

7 Device Configuration

7.1 Introduction

This chapter provides details on the individual modules of the microcontroller. It includes:

- Module block diagrams showing immediate connections within the device
- Specific module-to-module interactions not necessarily discussed in the individual Module chapters
- Links for more information

7.2 Core modules

The SPC57EM80xx has cores in three distinct modules:- HSM (described in the HSM chapter of the *SPC57EM80xx Microcontroller Security Reference Manual*); GTM (described in the *GTM Reference Manual*; and the main platform (described below).

The main platform has four separate cores that perform various computational and control functions

- The main computational shell consists of Main Core_0 and Main Core_1, both of which use an e200z420n3 core. These two cores are used for general computational functions.
- A third core, referred to as Checker Core_0s, uses an e200z419 core which is a true subset of the e200z420n3 core. When enabled, Checker Core_0s operates in lock step mode with Main Core_0 executing exactly the same instructions as Main Core_0. Thus, Checker Core_0s checks to insure that Main Core_0 is executing correctly. There is no lock step function associated with Main Core_1.
- The fourth processor, Peripheral Core_2, employs an e200z425n3 core and is generally used to control various I/O modules.

For more information, please see [Chapter 13: Core Complex Overview](#).

7.2.1 Core Reset Settings

[Table 23](#) shows the state of the *PowerISA 2.06* architected registers and other optional resources immediately following a system reset.

- Undefined on **POR** assertion, unchanged on **external PORESET** assertion.
- Reset by processor reset **external PORESET** if DBCR0[EDM]=0, as well as unconditionally by **POR**.
- Read-only registers.

7.2.2 Special Purpose Register Summary

PowerISA 2.06 and implementation-specific SPRs for the e200z420n3, e200z419, and e200z425n3 cores are listed in [Table 24](#). All registers are 32 bits in size. Register bits are numbered from bit 0 to bit 31 (most-significant to least-significant). Shaded entries represent optional registers. An SPR register may be read or written with the **mfscr** and **mtscr** instructions. In the instruction syntax, compilers should recognize the mnemonic name given in [Table 24](#).

Table 24. Special Purpose Registers (SPRs)

Mnemonic	Name	SPR Number	Access	Privileged	e200z Specific
XER	Integer Exception Register	1	R/W	No	No
LR	Link Register	8	R/W	No	No
CTR	Count Register	9	R/W	No	No
SRR0	Save/Restore Register 0	26	R/W	Yes	No
SRR1	Save/Restore Register 1	27	R/W	Yes	No
PID0	Process ID Register	48	R/W	Yes	No
CSRR0	Critical Save/Restore Register 0	58	R/W	Yes	No
CSRR1	Critical Save/Restore Register 1	59	R/W	Yes	No
DEAR	Data Exception Address Register	61	R/W	Yes	No
ESR	Exception Syndrome Register	62	R/W	Yes	No
IVPR	Interrupt Vector Prefix Register	63	R/W	Yes	No
SPRG0	SPR General 0	272	R/W	Yes	No
SPRG1	SPR General 1	273	R/W	Yes	No
SPRG2	SPR General 2	274	R/W	Yes	No
SPRG3	SPR General 3	275	R/W	Yes	No
PIR	Processor ID Register	286	R/W	Yes	No
PVR	Processor Version Register	287	Read-only	Yes	No
DBSR	Debug Status Register	304	Read/Clear ⁽¹⁾	Yes	No

MPU0CSR0	MPU0 configuration register	1014	R/W	Yes	Yes
MMUCFG	MMU/MPU configuration register	1015	Read-only	Yes	Yes
L1FINV0	L1 cache flush and invalidate control register 0	1016	R/W	Yes	Yes
SVR	System Version Register	1023	Read-only	Yes	Yes

1. The Debug Status Register can be read using *mfscr RT,DBSR*. The Debug Status Register cannot be directly written to. Instead, bits in the Debug Status Register corresponding to '1' bits in GPR(RS) can be cleared using *mtscr DBSR,RS*.
2. Undefined on **POR** assertion, unchanged on **external PORESET** assertion.
3. The Machine Check Syndrome Register can be read using *mfscr RT,MCSR*. The Machine Check Syndrome Register cannot be directly written to. Instead, bits in the Machine Check Syndrome Register corresponding to '1' bits in GPR(RS) can be cleared using *mtscr MCSR,RS*.
4. The 64-bit DVC registers are accessed by using the DVC1,2 spr #s for the lower 32 bits, and the DVC1,2U spr #s for the upper 32 bits.

7.3 System modules

7.3.1 SIUL2 configuration

The System Integration Unit Lite 2 (SIUL2) controls:

- MCU pad configuration
- Ports
- General-purpose input and output (GPIO) signals
- External interrupts with trigger event configuration

For details please refer [Chapter 16: System Integration Unit Lite2 \(SIUL2\)](#).

7.3.2 Semaphores2 (SEMA42)

The peripheral platform shell includes a memory-mapped module (SEMA42) that provides

- Robust hardware support needed in multi-core systems for implementing semaphores
- A simple mechanism to achieve "lock/unlock" operations via a single write access

The hardware semaphore module is an architecture-neutral solution that provides sixteen hardware-enforced gates for SPC57EM80xx as well as other useful system functions related to the gating mechanisms. The capabilities provided by the hardware semaphore module are currently utilized in dual-core AUTOSAR® implementations and its use is expected to continue in future multi-core ports. The result is a second-generation module implementation known as Semaphores2 or SEMA42.

For details refer to [Chapter 23: Semaphores2 \(SEMA42\)](#).

7.3.3 Crossbar switch configuration

This device contains two crossbar switch modules. [Figure 9](#) illustrates that they are connected via a Cross-lake, which is comprised of intelligent bridging bus gaskets. These bus gaskets handle the traffic which crosses between the shells and do not require any interaction with the user. This dual-crossbar architecture allows all masters to access all slaves across the computational shell and peripheral shell.

Figure 9. Crossbar switch diagram

The following sections explain how each crossbar switch is configured on this device.

7.3.3.1 Computational shell crossbar switch (XBAR_0) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

Figure 10. Computational shell's crossbar switch integration

Table 25. Reference links to related information

Topic	Related module	Reference

Crossbar switch master	Cores	Section 7.2, Core modules
Crossbar switch slave	Flash memory controller	Section 3.3.1, Flash memory controller
Crossbar switch slave	Processor core local memory	Section 3.2.4, Processor core local SRAM
Crossbar switch slave	System RAM	Section 3.2.1, System SRAM

7.3.3.1.1 Computational shell crossbar switch master assignments

This device contains six masters connected to the computational shell's crossbar switch. The master assignment is shown in [Table 26](#).

Table 26. Computational shell crossbar switch master assignments

Master module	Physical master port number
Core 0 instruction bus	0
Core 0 data bus	1
Core 1 instruction bus	2
Core 1 data bus	3
Peripheral shell crossbar switch	4
Core 2 instruction bus	5

7.3.3.1.2 Computational shell crossbar switch slave assignments

This device contains six slaves connected to the computational shell's crossbar switch.

The slave assignment is shown in [Table 27](#).

Table 27. Computational shell crossbar switch slave assignments

Slave module	Physical slave port number
Flash memory controller port 0	0
Flash memory controller port 1	1
Backdoor port to Core 0's xMEM	2
Backdoor port to Core 1's xMEM	3
System RAM	4
Peripheral shell crossbar switch	7

Access to the flash memory via slave ports 0 and 1 is routed based on the master. The master-to-flash memory port routing have been assigned in a way to balance data traffic, with attention paid to facilitate core instruction fetches. The following table shows the flash memory port assignments.

Table 28. Flash memory port assignments

Flash memory slave port 0	Flash memory slave port 1
Core 0 instruction bus (M0)	Core 0 data bus (M1)
Core 1 data bus (M3)	Core 1 instruction bus (M2)
Peripheral shell crossbar switch (M4)	Core 2 instruction bus (M5)

7.3.3.1.3 PRS register reset values

The computational shell's XBAR_0 PRS_n registers reset to 0x0030_1425. Note that these registers are read-only.

7.3.3.2 Peripheral shell crossbar switch (XBAR_1) configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

7.3.3.2.1 Peripheral shell crossbar switch master assignments

This device contains four masters connected to the peripheral shell's crossbar switch.

The master assignment is shown in [Table 30](#).

Table 30. Peripheral shell crossbar switch master assignments

Master module	Physical master port number
Core 2 data bus	0
DMA and Hardware Security Module (HSM)	1
FEC, LFAST, and FlexRay	2
Cross-lake (computational shell crossbar switch)	3

7.3.3.2.2 Peripheral shell crossbar switch slave assignments

This device contains four slaves connected to the peripheral shell's crossbar switch.

The slave assignment is shown in [Table 31](#).

Table 31. Peripheral shell crossbar switch slave assignments

Slave module	Physical slave port number
Computational shell crossbar switch	0
Backdoor port to Core 2's xMEM	1
Peripheral bridge 1	2
Peripheral bridge 0	3

7.3.3.2.3 PRS register reset values

The peripheral shell's XBAR_1 PRS_n registers reset to 0000_3102h.

7.3.4 System Memory Protection Unit (SMPU) configuration

This chip contains three instances of the System Memory Protection Unit (SMPU):

- SMPU_HSM for the Hardware Security Module
- SMPU_0 for the Computational Shell
- SMPU_1 for the Peripheral Shell

The following sections explain how SMPU_0 and SMPU_1 are configured on this chip. See the *SPC57EM80xx Microcontroller Security Reference Manual* for configuration details of SMPU_HSM.

7.3.4.1 SMPU0 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

Figure 12. SMPU0 configuration

13	Reserved
14	HSM
15	Reserved

7.3.4.1.2 Number of region descriptors supported by SMPU0

This instance of the SMPU module supports a maximum of twelve region descriptors.

7.3.4.1.3 RGD_WORD2 formats supported by SMPU0

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.4.1.4 Master Access permissions for SMPU0

The only masters allowed to access the SMPU0 registers are HSM, Core 2, Core 1, and Core 0. It is also required that the core be in supervisor mode.

7.3.4.2 SMPU1 configuration

This section summarizes how the module instance has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

Figure 13. SMPU1 configuration

15	Reserved

7.3.4.2.2 Number of region descriptors supported by SMPU1

This instance of the SMPU module supports a maximum of eight region descriptors.

7.3.4.2.3 RGD_WORD2 formats supported by SMPU1

For RGD_WORD2, this instance of the SMPU module supports only the FMT0 format. The RGD_WORD3[FMT] field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.

7.3.4.2.4 Master Access permissions for SMPU1

The only masters allowed to access the SMPU1 registers are HSM, Core 2, Core 1, and Core 0. It is also required that the core be in supervisor mode.

7.3.5 Peripheral bridge configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the chapter for that module.

Figure 14. Peripheral bridge configuration

System memory map	—	Chapter 5: Memory Map
Clocking	—	Chapter 27: Clocking
Crossbar switch	Crossbar switch	Section 7.3.3, Crossbar switch configuration

7.3.5.1 Number of peripheral bridges

This device contains two identical peripheral bridges.

7.3.5.2 Memory maps

The peripheral bridges are used to access the registers of most of the modules on this device. See [Chapter 5: Memory Map](#) for the memory slot assignment for each module.

7.3.5.3 MPR registers

Each of the two peripheral bridges supports a maximum of sixteen crossbar switch masters, each assigned to a MPROT n field in the MPRA-B registers. However, fewer are supported on this device. See [Section 7.3.3, Crossbar switch configuration](#) for details of the master port assignments for this device.

7.3.5.4 PACR/OPACR registers

The peripherals attached to the peripheral bridges each are assigned to a PACR n or OPACR n field within the PACRA-H/OPACRA-AF registers. See [Chapter 5: Memory Map](#) for details of the peripheral slot assignments for this device. Unused PACR n fields are reserved.

7.3.6 Platform Configuration Module (PCM)

The Platform Configuration Module contains three miscellaneous configuration registers for the device. Currently, the configuration registers are related to the operation of the FEC and

intelligent bus bridging gasket. The module is mapped to PBRIDGE on-platform slot 10 with a base address of 0xFC02_8000.

7.3.6.1 FEC Burst Optimization Master Control Register (FBOMCR)

Figure 15. FEC Burst Optimization Master Control Register (FBOMCR)

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Figure 16. FBOMCR field description

Field	Description
0–20	Reserved
21 ACCERR	Accumulate error This bit determines whether an error response for the first half of the write burst is accumulated to the second half of the write burst or discarded. In order to complete the burst, the FEC interface to the system bus responds by indicating that the first half of the burst completed without error before it actually writes the data so that it can fetch the second half of the write data from the FIFO. When actually written onto the system bus, the first half of the write burst can have an error. Because this half initially responded without an error to the FIFO, the error is discarded or accumulated with the error response for the second half of the burst. 0 Any error to the first half of the write burst is discarded. 1 Any actual error response to the first half of the write burst is accumulated in the second half's response. In other words, an error response to the first half will be seen in the response to the second half, even if the second half does not contain an error.
22 WBEN	Global write burst enable to XBAR slave port designated by FXSBE_n 0 Write bursting to all XBAR slave ports is disabled. 1 Write bursting is enabled to any XBAR slave port whose FXSBE_n bit is asserted.

Figure 16. FBOMCR field description (continued)

Field	Description
23 RBEN	Global read burst enable from XBAR slave port designated by FXSBE _n 0 Read bursting from all XBAR slave ports is disabled. 1 Read bursting is enabled from any XBAR slave port whose FXSBE _n bit is asserted.
24-31 FXSBE[7:0]	The FEC burst optimization master control register (FBOMCR) controls FEC burst optimization behavior on the system bus. FXSBE — FEC XBAR slave burst enable. FXSBE_n enables bursting by the FEC interface to the XBAR slave port controlled by that respective FXSBE_n bit. If FXSBE_n is asserted, then that XBAR slave port enabled by the bit can accept the bursts allowed by RBEN and WBEN. Otherwise, the FEC interface will not burst to the XBAR slave port controlled by that respective FXSBE_n bit. Read bursts from that XBAR slave port are enabled by RBEN. Write bursts to that XBAR slave port are enabled by WBEN. FXSBE_n assignments to XBAR slave ports: FXSBE0 = Flash FXSBE1 = reserved FXSBE2 = RAM, TCMA, TCMB, TCMC FXSBE3 = reserved FXSBE4 = reserved FXSBE5 = reserved FXSBE6 = reserved FXSBE7 = PBRIDGE0 and PBRIDGE1

5–7 RSV	Reserved, undefined.
8–12	Reserved
13 PRE_SIPI	Pending read enable (PRE) SIPI This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
14 BRE_SIPI	Burst read enable (BRE) SIPI This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
15 BWE_SIPI	Burst write enable (BWE) SIPI This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
16–20	Reserved
21 PRE_Flexray	Pending read enable (PRE) Flexray This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.

Table 38. IAHB_BE2 field description (continued)

Field	Description
22 BRE_Flexray	Burst read enable (BRE) Flexray This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
23 BWE_Flexray	Burst write enable (BWE) Flexray This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.
24–28	Reserved
29 PRE_FEC	Pending read enable (PRE) FEC This bit controls the bus gasket's handling of pending read transactions. 0 Pending reads are disabled. 1 Pending reads are enabled.
30 BRE_FEC	Burst read enable (BRE) FEC This bit controls the bus gasket's handling of burst read transactions. 0 Burst reads are converted into a series of single transactions on the slave side of the gasket. 1 Burst reads are optimized for best system performance.
31 BWE_FEC	Burst write enable (BWE) FEC This bit controls the bus gasket's handling of burst write transactions. 0 Burst writes are converted into a series of single transactions on the slave side of the gasket. 1 Burst writes are optimized for best system performance. Note this setting treats writes as "imprecise" such that an error response on any beat of the burst is reported on the last beat.

7.3.7 Interrupt Controller (INTC) configuration

7.3.7.1 INTC configurable parameters

The INTC on this chip supports three processors—the safety core, the computational core, and the I/O processor (IOP).

7.3.7.2 INTC implemented registers

[Table 39](#) shows the registers implemented on the INTC on this chip.

Table 39. INTC implemented registers

Address offset	Register
000h	INTC Block Configuration Register (INTC_BCR)
010h	INTC Current Priority Register for Processor 0 (INTC_CPR0)
014h	INTC Current Priority Register for Processor 1 (INTC_CPR1)
018h	INTC Current Priority Register for Processor 2 (INTC_CPR2)
020h	INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)
024h	INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)

Table 39. INTC implemented registers (continued)

Address offset	Register
028h	INTC Interrupt Acknowledge Register for Processor 2 (INTC_IACKR2)
030h	INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)
034h	INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)
038h	INTC End Of Interrupt Register for Processor 2 (INTC_EOIR2)
040h–05Ch	INTC Software Set/Clear Interrupt Register 0–3 (INTC_SSCIR0_3) – INTC Software Set/Clear Interrupt Register 28–31 (INTC_SSCIR28_31)
05Ch–85Ch	INTC Priority Select Register 0–1 (INTC_PSR0_1) – INTC Priority Select Register 1022–1023 (INTC_PSR1022_1023)

7.3.7.3 Interrupt sources

Table 40 defines the interrupt sources for the INTC on this chip. All IRQ numbers not specifically listed are not used.

Table 40. Interrupt sources

IRQ #	Offset	Source description	Source name
0	1000h	Software settable flag 0	SSCIR0_3[CLR0]
1	1004h	Software settable flag 1	SSCIR0_3[CLR1]
2	1008h	Software settable flag 2	SSCIR0_3[CLR2]
3	100Ch	Software settable flag 3	SSCIR0_3[CLR3]
4	1010h	Software settable flag 4	SSCIR4_7[CLR4]
5	1014h	Software settable flag 5	SSCIR4_7[CLR5]
6	1018h	Software settable flag 6	SSCIR4_7[CLR6]
7	101Ch	Software settable flag 7	SSCIR4_7[CLR7]
8	1020h	Software settable flag 8	SSCIR8_11[CLR8]
9	1024h	Software settable flag 9	SSCIR8_11[CLR9]
10	1028h	Software settable flag 10	SSCIR8_11[CLR10]
11	102Ch	Software settable flag 11	SSCIR8_11[CLR11]
12	1030h	Software settable flag 12	SSCIR12_15[CLR12]
13	1034h	Software settable flag 13	SSCIR12_15[CLR13]
14	1038h	Software settable flag 14	SSCIR12_15[CLR14]
15	103Ch	Software settable flag 15	SSCIR12_15[CLR15]
16	1040h	Software settable flag 16	SSCIR16_19[CLR16]
17	1044h	Software settable flag 17	SSCIR16_19[CLR17]
18	1048h	Software settable flag 18	SSCIR16_19[CLR18]
19	104Ch	Software settable flag 19	SSCIR16_19[CLR19]
20	1050h	Software settable flag 20	SSCIR20_23[CLR20]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
21	1054h	Software settable flag 21	SSCIR20_23[CLR21]
22	1058h	Software settable flag 22	SSCIR20_23[CLR22]
23	105Ch	Software settable flag 23	SSCIR20_23[CLR23]
24	1060h	Software settable flag 24	SSCIR24_27[CLR24]
25	1064h	Software settable flag 25	SSCIR24_27[CLR25]
26	1068h	Software settable flag 26	SSCIR24_27[CLR26]
27	106Ch	Software settable flag 27	SSCIR24_27[CLR27]
28	1070h	Software settable flag 28	SSCIR28_31[CLR28]
29	1074h	Software settable flag 29	SSCIR28_31[CLR29]
30	1078h	Software settable flag 30	SSCIR28_31[CLR30]
31	107Ch	Software settable flag 31	SSCIR28_31[CLR31]
32	1080h	Software watchdog timer 0 (SWT_0) Time-out	SWT_0_IR[TIF]
33	1084h	Software watchdog timer 1 (SWT_1) Time-out	SWT_1_IR[TIF]
34	1088h	Software watchdog timer 2 (SWT_2) Time-out	SWT_2_IR[TIF]
36	1090h	System Timer 0 Channel 0 match	STM_0_CIR0[CIF]
37	1094h	System Timer 0 Channel 1 match	STM_0_CIR1[CIF]
38	1098h	System Timer 0 Channel 2 match	STM_0_CIR2[CIF]
39	109Ch	System Timer 0 Channel 3 match	STM_0_CIR3[CIF]
40	10A0h	System Timer 1 Channel 0 match	STM_1_CIR0[CIF]
41	10A4h	System Timer 1 Channel 1 match	STM_1_CIR1[CIF]
42	10A8h	System Timer 1 Channel 2 match	STM_1_CIR2[CIF]
43	10ACh	System Timer 1 Channel 3 match	STM_1_CIR3[CIF]
44	10B0h	System Timer 2 Channel 0 match	STM_2_CIR0[CIF]
45	10B4h	System Timer 2 Channel 1 match	STM_2_CIR1[CIF]
46	10B8h	System Timer 2 Channel 2 match	STM_2_CIR2[CIF]
47	10BCh	System Timer 2 Channel 3 match	STM_2_CIR3[CIF]
52	10D0h	eDMA Combined Channel Error Flags 63-0	eDMA Channel Error Flags 63-0
53	10D4h	eDMA Channel interrupt 0	DMA_INTL[INT0]
54	10D8h	eDMA Channel interrupt 1	DMA_INTL[INT1]
55	10DCh	eDMA Channel interrupt 2	DMA_INTL[INT2]
56	10E0h	eDMA Channel interrupt 3	DMA_INTL[INT3]
57	10E4h	eDMA Channel interrupt 4	DMA_INTL[INT4]
58	10E8h	eDMA Channel interrupt 5	DMA_INTL[INT5]
59	10ECh	eDMA Channel interrupt 6	DMA_INTL[INT6]
60	10F0h	eDMA Channel interrupt 7	DMA_INTL[INT7]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
61	10F4h	eDMA Channel interrupt 8	DMA_INTL[INT8]

240	13C0h	PIT1 Channel 0	PIT_1_TFLG0[TIF]
241	13C4h	PIT1 Channel 1	PIT_1_TFLG1[TIF]
242	13C8h	Crystal oscillator (XOSC) clock interrupt	XOSC_CTL[I_OSC]
243	13CCh	SIUL2 Combined External Interrupt 0 (= OR of REQ5, REQ4, REQ2, REQ1, REQ0)	SIUL2_DISR0[EIF5] SIUL2_DISR0[EIF4] SIUL2_DISR0[EIF2] SIUL2_DISR0[EIF1] SIUL2_DISR0[EIF0]
244	13D0h	SIUL2 Combined External Interrupt 1 (= OR of REQ10, REQ9, REQ8)	SIUL2_DISR0[EIF10] SIUL2_DISR0[EIF9] SIUL2_DISR0[EIF8]
251	13ECh	MC_ME Safe Mode interrupt	ME_IS[I_SAFE]
252	13F0h	MC_ME Mode Transition Interrupt	ME_IS[I_MTC]
253	13F4h	MC_ME Invalid Mode interrupt	ME_IS[I_IMODE]
254	13F8h	MC_ME Invalid Mode Config	ME_IS[I_ICONF]
255	13FCh	MC_RGM 0	MC_RGM Functional and destructive reset alternate event interrupt
259	140Ch	DSPI_0 combined overrun interrupt requests: – Transmit FIFO underflow – Receive FIFO overflow	DSPI_0_SR[TFUF] DSPI_0_SR[RFOF]
260	1410h	DSPI_0 transmit FIFO end-of-queue flag	DSPI_0_SR[EOQF]
261	1414h	DSPI_0 Tx FIFO fill request flag	DSPI_0_SR[TFFF]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
262	1418h	DSPI_0 transfer complete flag	DSPI_0_SR[TCF]
263	141Ch	DSPI_0 Rx FIFO drain request flag	DSPI_0_SR[RDFD]
266	1428h	DSPI_0 combined DSI and SPI Parity Error Flags	DSPI_0_SR[SPEF]
268	1430h	DSPI_1 combined overrun interrupt requests: – Transmit FIFO underflow – Receive FIFO overflow	DSPI_1_SR[TFUF] DSPI_1_SR[RFOF]
269	1434h	DSPI_1 transmit FIFO end-of-queue flag	DSPI_1_SR[EOQF]
270	1438h	DSPI_1 Tx FIFO fill request flag	DSPI_1_SR[TFFF]
271	143Ch	DSPI_1 transfer complete flag	DSPI_1_SR[TCF]
272	1440h	DSPI_1 Rx FIFO drain request flag	DSPI_1_SR[RDFD]
275	144Ch	DSPI_1 combined DSI and SPI Parity Error Flags	DSPI_1_SR[SPEF]
277	1454h	DSPI_2 combined overrun interrupt requests: – Transmit FIFO underflow – Receive FIFO overflow	DSPI_2_SR[TFUF] DSPI_2_SR[RFOF]
278	1458h	DSPI_2 transmit FIFO end-of-queue flag	DSPI_2_SR[EOQF]
279	145Ch	DSPI_2 Tx FIFO fill request flag	DSPI_2_SR[TFFF]
280	1460h	DSPI_2 transfer complete flag	DSPI_2_SR[TCF]
281	1464h	DSPI_2 Rx FIFO drain request flag	DSPI_2_SR[RDFD]
284	1470h	DSPI_2 combined DSI and SPI Parity Error Flags	DSPI_2_SR[SPEF]
286	1478h	DSPI_3 combined overrun interrupt requests: – Transmit FIFO underflow – Receive FIFO overflow	DSPI_3_SR[TFUF] DSPI_3_SR[RFOF]
287	147Ch	DSPI_3 transmit FIFO end-of-queue flag	DSPI_3_SR[EOQF]
288	1480h	DSPI_3 Tx FIFO fill request flag	DSPI_3_SR[TFFF]
289	1484h	DSPI_3 transfer complete flag	DSPI_3_SR[TCF]
290	1488h	DSPI_3 Rx FIFO drain request flag	DSPI_3_SR[RDFD]
293	1494h	DSPI_3 combined DSI and SPI Parity Error Flags	DSPI_3_SR[SPEF]
295	149Ch	DSPI_4 combined overrun interrupt requests: – Transmit FIFO underflow – Receive FIFO overflow	DSPI_4_SR[TFUF] DSPI_4_SR[RFOF]
296	14A0h	DSPI_4 transmit FIFO end-of-queue flag	DSPI_4_SR[EOQF]
297	14A4h	DSPI_4 Tx FIFO fill request flag	DSPI_4_SR[TFFF]
298	14A8h	DSPI_4 transfer complete flag	DSPI_4_SR[TCF]
299	14ACh	DSPI_4 Rx FIFO drain request flag	DSPI_4_SR[RDFD]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
300	14B0h	DSPI_4 SPI Frame Transfer Complete Flag	DSPI_4_SR[SPITCF]
301	14B4h	DSPI_4 DSI Frame Transfer Complete Flag	DSPI_4_SR[DSITCF]
302	14B8h	DSPI_4 combined DSI and SPI Parity Error Flags	DSPI_4_SR[SPEF] DSPI_4_SR[DPEF]
303	14BCh	DSPI_4 DSI Data Received with Active Bits	DSPI_4_SR[DDIF]
304	14C0h	DSPI_5 combined overrun interrupt requests: – Transmit FIFO underflow – Receive FIFO overflow	DSPI_5_SR[TFUF] DSPI_5_SR[RFOF]
305	14C4h	DSPI_5 transmit FIFO end-of-queue flag	DSPI_5_SR[EOQF]
306	14C8h	DSPI_5 Tx FIFO fill request flag	DSPI_5_SR[TFFF]
307	14CCh	DSPI_5 transfer complete flag	DSPI_5_SR[TCF]
308	14D0h	DSPI_5 Rx FIFO drain request flag	DSPI_5_SR[RFDF]
309	14D4h	DSPI_5 SPI Frame Transfer Complete Flag	DSPI_5_SR[SPITCF]
310	14D8h	DSPI_5 DSI Frame Transfer Complete Flag	DSPI_5_SR[DSITCF]
311	14DCh	DSPI_5 combined DSI and SPI Parity Error Flags	DSPI_5_SR[SPEF] DSPI_5_SR[DPEF]
312	14E0h	DSPI_5 DSI Data Received with Active Bits	DSPI_5_SR[DDIF]
367	15BCh	DSPI_12 combined overrun interrupt requests: – Transmit FIFO underflow – Receive FIFO overflow	DSPI_12_SR[TFUF] DSPI_12_SR[RFOF]
368	15C0h	DSPI_12 transmit FIFO end-of-queue flag	DSPI_12_SR[EOQF]
369	15C4h	DSPI_12 Tx FIFO fill request flag	DSPI_12_SR[TFFF]
370	15C8h	DSPI_12 transfer complete flag	DSPI_12_SR[TCF]
371	15CCh	DSPI_12 Rx FIFO drain request flag	DSPI_12_SR[RFDF]
374	15D8h	DSPI_12 combined DSI and SPI Parity Error Flags	DSPI_12_SR[SPEF]
376	15E0h	LINFlexD_0 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wake-up – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_0_LINIER[HRIE] LINFlexD_0_LINIER[DRIE] LINFlexD_0_LINIER[DBFIE] LINFlexD_0_LINIER[WUIE] LINFlexD_0_LINIER[LSIE]
377	15E4h	LINFlexD_0 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_0_LINIER[HRIE] LINFlexD_0_LINIER[DTIE] LINFlexD_0_LINIER[DBEIE]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
378	15E8h	LINFlexD_0 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_0_LINIER[SZIE] LINFlexD_0_LINIER[OCIE] LINFlexD_0_LINIER[BEIE] LINFlexD_0_LINIER[CEIE] LINFlexD_0_LINIER[HEIE] LINFlexD_0_LINIER[FEIE] LINFlexD_0_LINIER[BOIE] LINFlexD_0_LINIER[TOIE]
380	15F0h	LINFlexD_1 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wake-up – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_1_LINIER[HRIE] LINFlexD_1_LINIER[DRIE] LINFlexD_1_LINIER[DBFIE] LINFlexD_1_LINIER[WUIE] LINFlexD_1_LINIER[LSIE]
381	15F4h	LINFlexD_1 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_1_LINIER[HRIE] LINFlexD_1_LINIER[DTIE] LINFlexD_1_LINIER[DBEIE]
382	15F8h	LINFlexD_1 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_1_LINIER[SZIE] LINFlexD_1_LINIER[OCIE] LINFlexD_1_LINIER[BEIE] LINFlexD_1_LINIER[CEIE] LINFlexD_1_LINIER[HEIE] LINFlexD_1_LINIER[FEIE] LINFlexD_1_LINIER[BOIE] LINFlexD_1_LINIER[TOIE]
384	1600h	LINFlexD_2 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wake-up – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_2_LINIER[HRIE] LINFlexD_2_LINIER[DRIE] LINFlexD_2_LINIER[DBFIE] LINFlexD_2_LINIER[WUIE] LINFlexD_2_LINIER[LSIE]
385	1604h	LINFlexD_2 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_2_LINIER[HRIE] LINFlexD_2_LINIER[DTIE] LINFlexD_2_LINIER[DBEIE]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
386	1608h	LINFlexD_2 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_2_LINIER[SZIE] LINFlexD_2_LINIER[OCIE] LINFlexD_2_LINIER[BEIE] LINFlexD_2_LINIER[CEIE] LINFlexD_2_LINIER[HEIE] LINFlexD_2_LINIER[FEIE] LINFlexD_2_LINIER[BOIE] LINFlexD_2_LINIER[TOIE]
432	16C0h	LINFlexD_14 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wake-up – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_14_LINIER[HRIE] LINFlexD_14_LINIER[DRIE] LINFlexD_14_LINIER[DBFIE] LINFlexD_14_LINIER[WUIE] LINFlexD_14_LINIER[LSIE]
433	16C4h	LINFlexD_14 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_14_LINIER[HRIE] LINFlexD_14_LINIER[DTIE] LINFlexD_14_LINIER[DBEIE]
434	16C8h	LINFlexD_14 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_14_LINIER[SZIE] LINFlexD_14_LINIER[OCIE] LINFlexD_14_LINIER[BEIE] LINFlexD_14_LINIER[CEIE] LINFlexD_14_LINIER[HEIE] LINFlexD_14_LINIER[FEIE] LINFlexD_14_LINIER[BOIE] LINFlexD_14_LINIER[TOIE]
436	16D0h	LINFlexD_15 Reception combined interrupt: – Header Received – Data Reception complete – Data Buffer Full – Wake-up – LIN State (Sync Del, Sync Field, Identifier Field or Checksum Field)	LINFlexD_15_LINIER[HRIE] LINFlexD_15_LINIER[DRIE] LINFlexD_15_LINIER[DBFIE] LINFlexD_15_LINIER[WUIE] LINFlexD_15_LINIER[LSIE]
437	16D4h	LINFlexD_15 Transmission combined interrupt: – Header Received – Data Transmitted – Data Buffer Empty	LINFlexD_15_LINIER[HRIE] LINFlexD_15_LINIER[DTIE] LINFlexD_15_LINIER[DBEIE]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
438	16D8h	LINFlexD_15 Error combined interrupt: – Stuck at zero – Output Compare – Bit Error – Checksum Error – Header Error – Frame Error – Buffer Overrun – UART Timeout Error	LINFlexD_15_LINIER[SZIE] LINFlexD_15_LINIER[OCIE] LINFlexD_15_LINIER[BEIE] LINFlexD_15_LINIER[CEIE] LINFlexD_15_LINIER[HEIE] LINFlexD_15_LINIER[FEIE] LINFlexD_15_LINIER[BOIE] LINFlexD_15_LINIER[TOIE]
440	16E0h	I2C Combined interrupt: – Byte transfer complete – Addressed as slave – Arbitration Lost – No Acknowledge from Slave – I2C Bus going idle	I2C_0_IBSR[IBIF] I2C_0_IBSR[IAAS] I2C_0_IBSR[IBAL]
453	1714h	FlexRay LRAM Non-Corrected errors combined interrupt: – LRAM Non-Corrected Error Overflow – LRAM Non-Corrected Error	FR_0_EEIFER[LRNE_OF] FR_0_EEIFER[LRNE_IF]
454	1718h	FlexRay LRAM Corrected errors combined interrupt: – LRAM Corrected Error Overflow – LRAM Corrected Error	FR_0_EEIFER[LRCE_OF] FR_0_EEIFER[LRCE_IF]
455	171Ch	FlexRay Receive FIFO Channel A Almost Full Interrupt	FR_0_GIFER[FAFAIF]
456	1720h	FlexRay Receive FIFO Channel B Almost Full Interrupt	FR_0_GIFER[FAFBIF]
457	1724h	FlexRay Wakeup Interrupt	FR_0_GIFER[WUPIF]
458	1728h	FlexRay Protocol global interrupt	FR_0_GIFER[PRIF]
459	172Ch	FlexRay Controller Host Interface global interrupt	FR_0_GIFER[CHIF]
460	1730h	FlexRay Transmit Message Buffer global Interrupt	FR_0_GIFER[TBIF]
461	1734h	FlexRay Receive Message Buffer global Interrupt	FR_0_GIFER[RBIF]
462	1738h	FlexRay Module global Interrupt	FR_0_GIFER[MIF]
477	1774h	Power Management Controller Supply Gauge Low Voltage Detect and High Voltage Detect Interrupts	GR_S[VD15] GR_S[VD14] GR_S[VD13] GR_S[VD12] GR_S[VD10] GR_S[VD9] GR_S[VD7] GR_S[VD4] GR_S[VD3]
478	1778h	Power Management Controller Temperature Sensor interrupts	EPR_TD[TEMP_3] EPR_TD[TEMP_2] EPR_TD[TEMP_0]
480	1780h	Loss-of-lock interrupt request for PLL0	PLL0SR[LOLF]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
482	1788h	Loss-of-lock interrupt request for PLL1	PLL1SR[LOLF]
484	1790h	PLL0 External Power Down Cycle Complete indication interrupt	PLL0SR[EXTPDF]
485	1794h	PLL1 External Power Down Cycle Complete indication interrupt	PLL1SR[EXTPDF]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
624	19C0h	PSI5_1 Channel 0 DMA Combined interrupt: – DMA transfer complete – DMA SENT frame transfer complete – Fifo full or underflow of the RAM register – Underflow in the PSI5 SENT message area	PSI5_1_CH_0_DSR[IS_DMA_TF_PM_DS] PSI5_1_CH_0_DSR[IS_DMA_TF_SF] PSI5_1_CH_0_DSR[IS_DMA_PM_DS_FIFO_FULL] PSI5_1_CH_0_DSR[IS_DMA_SFUF] PSI5_1_CH_0_DSR[IS_DMA_PM_DS_UF]
625	19C4h	PSI5_1 Channel 0 combined General interrupt: – New SENT message reception – CRC error – Overwrite of unread message in corresponding SENT location (in PSI5_SFR) – DPR is ready for receiving a new data – DBR is ready for receiving a new data – DSR is ready for receiving a new data – Write to DPR while it is NOT ready – Write to DBR while it is NOT ready – Write to DSR while it is NOT ready – New value in data time stamp register – New value in sync time stamp read register	PSI5_1_CH_0_GISR[IS_CESM[6:1]] PSI5_1_CH_0_GISR[IS_STS] PSI5_1_CH_0_GISR[IS_DTS] PSI5_1_CH_0_GISR[IS_DSROW] PSI5_1_CH_0_GISR[IS_BROW] PSI5_1_CH_0_GISR[DSR_RDY] PSI5_1_CH_0_GISR[DBR_RDY] PSI5_1_CH_0_GISR[DPR_RDY] PSI5_1_CH_0_GISR[IS_OWSM[6:1]] PSI5_1_CH_0_GISR[IS_NVSM[6:1]]
626	19C8h	PSI5_1 Channel 0 New message combined interrupt: New data received in any enabled PSI5_1 Channel 0 message buffer	PSI5_1_CH_0_NDSR[NDS31] PSI5_1_CH_0_NDSR[NDS30] ... PSI5_1_CH_0_NDSR[NDS1] PSI5_1_CH_0_NDSR[NDS0]
627	19CCh	PSI5_1 Channel 0 Message Overwrite combined interrupt: Overwrite of any PSI5_1 Channel 0 message buffer	PSI5_1_CH_0_OWSR[NDS31] PSI5_1_CH_0_OWSR[NDS30] ... PSI5_1_CH_0_OWSR[NDS1] PSI5_1_CH_0_OWSR[NDS0]
628	19D0h	PSI5_1 Channel 0 Error combined interrupt: error in any enabled PSI5_1 Channel 0 message buffer	PSI5_1_CH_0_EISR[NDS31] PSI5_1_CH_0_EISR[NDS30] ... PSI5_1_CH_0_EISR[NDS1] PSI5_1_CH_0_EISR[NDS0]
629	19D4h	PSI5_1 Channel 0 Global interrupt: global OR of all the previous PSI5_1 Channel 0 sources	PSI5_1_CH_0_DSR[*] PSI5_1_CH_0_GISR[*] PSI5_1_CH_0_NDSR[31:0] PSI5_1_CH_0_OWSR[31:0] PSI5_1_CH_0_EISR[31:0]
654	1A38h	SIPI combined Error Interrupt: – Channels 0 to 3 Timeout error – Channels 0 to 3 transaction ID error – Channels 0 to 3 acknowledge error	SIPI_ERR[TOEn] SIPI_ERR[TIDEn] SIPI_ERR[ACKEn] n = [0..3]
655	1A3Ch	SIPI CRC Error interrupt	SIPI_SR[GCRCE]
656	1A40h	SIPI Channel 0 Reception combined interrupt: – Read answer received – Acknowledge received	SIPI_CSR0[RAR] SIPI_CSR0[ACKR]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
657	1A44h	SIPI Channel 1 Reception combined interrupt: – Read answer received – Acknowledge received	SIPI_CSR1[RAR] SIPI_CSR1[ACKR]
658	1A48h	SIPI Channel 2 Reception combined interrupt: – Read answer received – Acknowledge received	SIPI_CSR2[RAR] SIPI_CSR2[ACKR]
659	1A4Ch	SIPI Channel 3 Reception combined interrupt: – Read answer received – Acknowledge received	SIPI_CSR3[RAR] SIPI_CSR3[ACKR]
660	1A50h	SIPI combined Event Interrupt: – Channel 0 to 3 trigger events – Maximum count reached (streaming mode) event	SIPI_SR[TE0] SIPI_SR[TE1] SIPI_SR[TE2] SIPI_SR[TE3] SIPI_SR[MCR]
661	1A54h	LFAST_0 Transmit Complete combined interrupt: – Ping response frame transmitted – Unsolicited Frame transmitted – ICLC Frame transmitted – Data frame transmitted	LFAST_0_TISR[TXPNGF] LFAST_0_TISR[TXUNSF] LFAST_0_TISR[TXICLCF] LFAST_0_TISR[TXDTF]
662	1A58h	LFAST_0 Transmit Error combined interrupt: – Transmit interface not enabled error – Transmit data FIFO overflow error	LFAST_0_TISR[TXIEF] LFAST_0_TISR[TXOVF]
663	1A5Ch	LFAST_0 Receive combine interrupt: – Frame with CTS bit low received – Data frame received – Unsolicited Frame received	LFAST_0_RISR[RXCTSF] LFAST_0_RISR[RXDF] LFAST_0_RISR[RXUNSF]
664	1A60h	LFAST_0 Receive Error combined interrupt: – Unsolicited frame register overflow – Rx Data FIFO Minimum Threshold reached – Rx Data FIFO Max Threshold reached – Rx Data FIFO Underflow – Rx Data FIFO Overflow – Frame with unsupported frame size received – Invalid ICLC code Received – Invalid Logical Channel Type	LFAST_0_RISR[RXUOF] LFAST_0_RISR[RXMNF] LFAST_0_RISR[RXMXF] LFAST_0_RISR[RXUFF] LFAST_0_RISR[RXOFF] LFAST_0_RISR[RXSZF] LFAST_0_RISR[RXICF] LFAST_0_RISR[RXLCEF]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
665	1A64h	LFAST_0 ICLC receive combined interrupt: – Ping Frame Response failed – Ping Frame Response successful – ICLC Ping Frame Request received – ICLC frame for Test mode off received – ICLC frame for Loopback On received – ICLC frame for Clk Test mode received – ICLC frame for LFAST Slaves Tx Interface Disable received – ICLC frame for LFAST Slaves Tx Interface Enable received – ICLC frame for LFAST Slaves Rx Interface fast mode switch received – ICLC frame for LFAST Slaves Rx Interface slow mode switch received – ICLC frame for LFAST Slaves Tx Interface fast mode switch received – ICLC frame for LFAST Slaves Tx Interface slow mode switch received – ICLC frame for PLL OFF received – ICLC frame for PLL ON received	LFAST_0_RIISR[ICPFF] LFAST_0_RIISR[ICPSF] LFAST_0_RIISR[ICPRF] LFAST_0_RIISR[ICTOF] LFAST_0_RIISR[ICLPF] LFAST_0_RIISR[ICCTF] LFAST_0_RIISR[ICTDF] LFAST_0_RIISR[ICTEF] LFAST_0_RIISR[ICRFF] LFAST_0_RIISR[ICRSF] LFAST_0_RIISR[ICTFF] LFAST_0_RIISR[ICTSF] LFAST_0_RIISR[ICPOFF] LFAST_0_RIISR[ICPONF]
674	1A88h	JTAG Master combined interrupt: – Idle interrupt – Sequence Processing Unit interrupt	JTAGM_SR[SPU_INT] JTAGM_SR[Idle]
675	1A8Ch	JTAG Data Communication combined interrupt: – JDC Input data received – JDC output data sent	JDC_MSR[JIN_INT] JDC_MSR[JOUT_INT]

Table 40. Interrupt sources (continued)

IRQ #	Offset	Source description	Source name
677	1A94h	M_TTCAN_0 Line0 combined interrupt: Stuff Error, Format Error, Acknowledge Error, Bit Error, CRC Error, Watchdog, Bus_Off Status, Warning Status, Error Passive Status, Error Logging Overflow, Bit Error Uncorrected, Bit Error Corrected, Timeout Occurred, Unprocessed Message Discarded, Timestamp Wraparound, Tx Event FIFO Event Lost, Tx Event FIFO Full, Tx Event FIFO Watermark Reached, Tx Event FIFO New Entry, Tx FIFO Empty, Transmission Cancellation Finished, Transmission Completed, High Priority Message, Rx FIFO 1 Message Lost, Rx FIFO 1 Full, Rx FIFO 1 Watermark Reached, Rx FIFO 1 New Message, Rx FIFO 0 Message Lost, Rx FIFO 0 Full, Rx FIFO 0 Watermark Reached, Rx FIFO 0 New Message	(M_TTCAN_0_IR[0] & ~M_TTCAN_0_ILS[0]) ... 1. This character is used to denote the OR operator throughout this table.

7.3.7.4 Interrupt Latency

The Interrupt systems is designed to provide a very short latency between the assertion of an interrupt request from a peripheral and the first instruction of the Interrupt Service Routine.

The latency time is difficult to define exactly because it depends what interrupts the INTC is processing and what the CPU is doing.

But in general, the latency time is divided into 3 sub-sections:

- INTC Latency
 - 3 clock cycles (INTC clock domain) from the assertion of the interrupt request from the peripheral to assertion of the interrupt request to the CPU
- CPU Latency
 - 4 clock cycles (CPU clock domain) from the assertion of the interrupt request from the INTC to the execution of the first instruction
- Software Latency
 - 7 clock cycles (CPU clock domain) to execute the 3 instructions needed to save essential registers and enable interrupts

Figure 19. Interrupt timing

7.3.7.5 INTC (hsm_z0_platform) configuration

For interrupts specific to the Hardware Security Module (HSM) please refer to the *SPC57EM80xx Security Reference Manual*.

7.3.8 DMA Controller configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 20. DMA controller configuration

Transfers	Crossbar switch	Chapter 17: Crossbar Switch (XBAR)

7.3.9 DMACHMUX configuration

The peripheral DMA requests are serviced by a DMA controller. A static multiplexing scheme allows the support of more peripheral requests than available DMA channels.

7.3.9.1 DMA channel assignment

SPC57EM80xx has six multiplexers. [Table 42](#) lists which channels apply to each multiplexer.

Table 42. SPC57EM80xx multiplexer and channel list

DMAMUX instance	DMA channel
0	0–7
1	8–15
2	16–23
3	24–31

5	48–63

7.3.9.2 DMA channel multiplexing block diagram

The connections of the DMA channel multiplexors to the eDMA are shown in [Figure 21](#). For the lower thirty-two channels, One DMAMUX is instantiated for every eight DMA channels. For the upper thirty-two channels, one DMAMUX is instantiated for every sixteen DMA channels.

Figure 21. DMA channel multiplexing

7.3.9.3 DMA request mapping

The mapping of the peripheral DMA requests to the DMA_CH_MUX input sources is shown in [Table 43](#).

Table 43. DMAMUX peripheral DMA request to input source mapping

Note: Just as multiple CHCONFIG registers within the same instance must not select the same source value, CHCONFIG registers among multiple instances must not select the same source value.

The mapping of the PIT periodic triggers to the DMA channel sources is shown in [Table 44](#).

Table 44. PIT_0 periodic trigger to DMA channel mapping

PIT_0 periodic trigger	DMA channel
0	8
1	9
2	10
3	11
4	12
5	16
6	32
7	48

7.3.9.4 DMAMUX Memory map

The 6 instances of DMAMUX (0–5) share one PBRIDGE slot. Each instance is allocated 512 bytes of memory space. The DMAMUX address offsets are shown in [Table 45](#).

Table 45. DMAMUX memory map

Offset ⁽¹⁾	Register ⁽²⁾	Access
0x0000	DMAMUX_0 CHCONFIG0–CHCONFIG7 — Channel configuration registers	R/W
0x0200	DMAMUX_1 CHCONFIG0–CHCONFIG7 — Channel configuration registers	R/W
0x0400	DMAMUX_2 CHCONFIG0–CHCONFIG7 — Channel configuration registers	R/W
0x0600	DMAMUX_3 CHCONFIG0–CHCONFIG7 — Channel configuration registers	R/W
0x0800	DMAMUX_4 CHCONFIG0–CHCONFIG15 — Channel configuration registers	R/W
0x0A00	DMAMUX_5 CHCONFIG0–CHCONFIG15 — Channel configuration registers	R/W

1. Offsets are from DMAMUX base address (0xFFF6_C000), shown in [Chapter 5: Memory Map](#).
2. Each channel must be configured separately via settings in a dedicated configuration channel. There is one configuration register per channel for each DMAMUX. See the DMACHMUX chapter for details.

7.5.1 Flash memory controller (PFLASH) configuration

The flash controller provides flash configuration and control functions and manages the interface between the flash memory array and the crossbar switch. The configuration and control functions are accessed via control registers, which are read/write accessible only in supervisor mode.

Three of the registers, PFCR1, PFCR2, and PFAPR, control the interaction of master modules with the flash array by enabling/disabling prefetch or by controlling access to the flash array on a per-master basis. Use of the fields in these registers requires knowledge of the number assigned to each master. For example, the PFAPR[M2AP] field controls flash array access by master 2, the PFAPR[M3AP] field controls flash array access by master 3, and so on. See [Table 28 \(Flash memory port assignments\)](#) in the crossbar switch configuration section for details. See the PFCR3 register details in the flash memory controller chapter for more details on configuring the flash controller.

7.5.1.1 Calibration remapping support

The PFLASH_C55FM flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM or on-chip system RAM that can be used as overlay RAM. The relationship between flash access latency and remapped overlay RAM latency is contingent upon operating frequency and intrinsic memory access times. [Table 49](#) describes the intrinsic cycle latency on a random, initial access for each supported overlay RAM target.

(See [Section 34.5.14, PFlash calibration remap support](#) for more details on the relationship between flash access latency and overlay RAM access latency.

Note: Cycle times measured based on the PFLASH_C55FM clock. See [Chapter 27: Clocking](#) for more details on clocking.

Table 50. Calibration memory access times

Calibration memory	Burst access time (cycles)
On-chip overlay RAM	5
Buddy device overlay RAM	8
System RAM	9

7.5.1.2 Wait state settings for overlay flash latency matching

A remapped calibration load access has a fixed, intrinsic 4-beat latency, where the access time of each individual beat depends on the overlay target - system RAM, on-chip overlay RAM or buddy device. Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time for a flash access as well as the required access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. [Table 51](#) describes the minimum supported flash wait state setting to guarantee a remapped access matches the response latency of a flash access.

Table 51. Minimum wait state settings for overlay flash latency match

Overlay Target	PFCR1[RWSC] Minimum Value
BD RAM	6
On-Chip Overlay RAM	3
System RAM	6

If PFCR1[RWSC] is set sufficiently high such that the remapped burst access completes before flash read data is expected to be returned, the flash controller stalls the return of overlay data the appropriate number of additional cycles to ensure the access time matches the response latency of a flash access. Once the overlay access is stored in the flash controller mini-cache, subsequent requests that hit in the mini-cache are returned with zero wait state latency.

7.6 Analog modules

This section highlights the following analog modules that are implemented on SPC57EM80xx:

Table 52. Analog modules

Module or Subsystem	Device-specific information	Block details
Temperature sensor	Section 7.6.1, Temperature sensor configuration	Chapter 41: Temperature Sensor
ADC subsystem	Section 38.1, ADC overview	See individual modules.
Sigma-Delta Analog-to-Digital Converters (SDADCs)	Section 38.2.1, Sigma-Delta Analog-to-Digital Converter (SDADC)	Chapter 39: Sigma-Delta Analog-to-Digital Converter (SDADC) Digital Interface
Successive Approximation Register Analog-to-Digital Converters (SARADCs)	Section 38.2.2, Successive Approximation Register Analog-to-Digital Converter (SARADC)	Chapter 40: Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface

7.6.1 Temperature sensor configuration

The temperature sensor is used to measure the temperature of the SPC57EM80xx device. The temperature sensor has the following outputs:

- An analog voltage that is linearly proportional to temperature.
- Three digital outputs that signal under- or over-temperature operating conditions.

During production testing of the device, the output of the temperature sensor is sampled by SARB input channel 120 of the onboard ADC module at a predefined high temperature and also at a predefined low temperature. These two temperature sensor readings are used to calculate two constants, TSCA and TSCB, according to the formulas in [Chapter 41: Temperature Sensor](#).

Once calculated, the values for TSCA and TSCB are programmed during production test into the UTEST flash memory at locations 0x0040_0000 and 0x0040_0002, respectively.

The ADC bandgap voltage, used in the temperature calculation, is sampled by SARB input channel 121 of the onboard ADC module.

Software must perform the following steps in order to calculate device temperature.

1. Measure the bandgap voltage, $V_{BG}(T)$, using SARB input channel 121 of the onboard ADC module.
2. Calculate $V_{BG_CODE}(T)$ according to the formula in [Chapter 41: Temperature Sensor](#).
3. Measure the temperature sensor output voltage, $V_{TSENS}(T)$, using SARB input channel 120 of the onboard ADC module.
4. Calculate $T_{TSENS_CODE}(T)$ according to the formula in [Chapter 41: Temperature Sensor](#).
5. Retrieve parameters TSCA and TSCB from flash memory.
6. Calculate T according to the formula in [Chapter 41: Temperature Sensor](#).

7.6.2 Analog to Digital Converters (ADC) configuration

See [Chapter 38: Analog-to-Digital Converters \(ADC\) Configuration](#), for an overview of the ADC subsystem, including a block diagram and a summary of analog input pin multiplexing. The chapter also provides configuration details for the SARADCs and SDADCs.

7.6.2.1 SDADC configuration

The Sigma-Delta Analog-to-Digital Converter (SDADC) digital interface block controls the on-chip SDADC and holds control and status registers accessible for application. It provides the accurate conversion data for a wide range of applications.

SPC57EM80xx includes six independent 16-bit SDADCs.

For details, see [Chapter 38: Analog-to-Digital Converters \(ADC\) Configuration](#).

7.6.2.2 SARADC configuration

The Successive Approximation Register Analog-to-Digital Converter (SARADC) digital interface block controls the on-chip SARADC analog block and holds control and status registers accessible for an application. The SARADC provides accurate and fast conversion data for a wide range of applications. Each SARADC analog block has a corresponding digital interface.

SPC57EM80xx includes eight (8) independent 12-bit SARADCs. SAR ADCB has access to all external analog input pins, access to the external multiplexed inputs, and has special safety features.

For details, see [Chapter 38: Analog-to-Digital Converters \(ADC\) Configuration](#).

7.7 Timers

Three types of timers are implemented on SPC57EM80xx and a complex timer subsystem.

Table 53. Timers

Timer	Device-specific information	Block details
System Timer Module (STM)	Section 7.7.1, System Timer Module (STM) configuration	Chapter 43: System Timer Module (STM)
Software Watchdog Timer (SWT)	Section 7.7.2, Software Watchdog Timer (SWT) configuration	Chapter 44: Software Watchdog Timer (SWT)
Periodic Interrupt Timer (PIT)	Section 7.7.3, PIT configuration	Chapter 45: Periodic Interrupt Timer (PIT)
GTM103 Wrapper Module Configuration	Section 7.7.4, GTM 103 Integration Module (GTMINT103) configuration	Chapter 88: GTM103 Integration (GTMINT) Module

Each core will have a dedicated System Timer Module (STM) and a dedicated Software Watchdog Timer (SWT). The checker core does not have a dedicated STM.

The Secure SWT is on the Hardware Security Module (HSM). It is an enhanced version of the SWT that has the ability to trigger an interrupt not only based on some number of clock cycles, but also based on code executing at some user-defined address. For more information, refer to the *SPC57EM80xx Security Manual*.

Two Periodic Interrupt Timer (PIT) module instances are implemented. One PIT module is for 64-bit timer implementation by way of two 32-bit timer channels (0 and 1) with chaining mode; the timer value is unchanged by a non-destructive reset. The other PIT module is for general use and has eight 32-bit timer channels with no chaining mode.

The GTM103 is an implementation of the Robert Bosch GmbH GTM timer subsystem. It is not a single module; it is a complex timer subsystem that consists of many modules. It can be used to implement highly complex timer functions.

7.7.1 System Timer Module (STM) configuration

The System Timer Module (STM) is a 32-bit timer designed to support commonly required system and application software timing functions. The STM includes a 32-bit up counter and four 32-bit compare channels with a separate interrupt source for each channel. The counter is driven by the appropriate system clock divided by an 8-bit prescale value (1 to 256).

SPC57EM80xx includes three STMs, one for each core, with four 32-bit compare channels in each STM.

Table 54. System Timer Module (STM) instances

Instance	Description	Number of Channels	Number of Registers (32-bit)
STM0	Intended for Main Core_0 in the high-speed computational clock domain.	4	14
STM1	Intended for Main Core_1 in the high-speed computational clock domain.	4	14
STM2	Intended for Peripheral Core_2 in the peripheral clock domain.	4	14

7.7.2 Software Watchdog Timer (SWT) configuration

SPC57EM80xx includes four SWTs.

Table 55. Software Watchdog Timer (SWT) instances

Instance	Description
SWT0	Intended for Main Core_0 in the high-speed computational clock domain.
SWT1	Intended for Main Core_1 in the high-speed computational clock domain.
SWT2	Intended for Peripheral Core_2 in the peripheral clock domain. Elapsed times recorded in timeout register are different from SWT0 and SWT1.
SWT3	Intended as security watchdog timer in the peripheral clock domain. Elapsed times recorded in timeout registers are different from SWT0 and SWT1

The SWT has the following features:

- 32-bit time-out register to set the time-out period
- Internal 16 MHz RC oscillator clock that is used for timer operation
- Programmable selection of system or internal oscillator clock for timer operation
- Programmable selection of window mode or regular servicing
- Programmable selection of reset or interrupt on an initial time-out
- Programmable selection of the servicing mode
- Master access protection
- Hard and soft configuration lock bits

7.7.2.1 Security watchdog

SWT (SWT3 Security) is identical to the other SWT modules except the Instruction Address Compare feature is NOT instantiated. It is anticipated that each CPU would use an SWT to ensure software tasks continue to execute correctly.

If a CPU malfunctions (either software or hardware) the SWT is no longer serviced and a reset occurs. This is referred to as a Task Watchdog. The Security Watchdog is slightly different from the Task Watchdog.

The Security watchdog is intended to be serviced when the CPU executes an instruction at a specific address location. This address location would be an address within some fundamental section of security code. If this address location is not executed regularly, it implies that a malicious security attach has occurred and the device should be reset.

Additionally, the Security watchdog is deactivated by a device Power-On-Reset.

This security code could be executed on any of the CPUs. The SWT for that CPU would perform the Security Watchdog (SWT0, SWT1 or SWT2) because it includes the IAC feature. The Task Watchdog for that CPU would need to use SWT3 (Security), which does NOT include the IAC feature.

As a result the SWT3 (Security) is never used to perform the Security Watchdog; but is used for Task Watchdog to replace the SWT that IS being used for Security Watchdog

7.7.2.2 Reset assertion

The SWT can assert a reset when the watchdog timer expires. This reset causes a system reset equivalent to assertion of the RESET pin.

7.7.2.3 Default configuration

On SPC57EM80xx, the SWTs come out of reset with the following default values. [Table 56](#) summarizes the reset values. Minimum timeout value is 256 cycles for SWT0, SWT1, SWT2, and SWT3.

Table 56. Register reset values

SWT instance	Register	Reset value
SWT0	SWT Control Register (SWT_CR)	0xFF00_010A
SWT0	SWT Time-out (SWT_TO)	0x0005_FCD0
SWT1	SWT Control Register (SWT_CR)	0xFF00_010A
SWT1	SWT Time-out (SWT_TO)	0x0005_FCD0
SWT2	SWT Control Register (SWT_CR) ⁽¹⁾	0xFF00_011B
SWT2	SWT Time-out (SWT_TO)	0x0003_FDE0
SWT3	SWT Control Register (SWT_CR)	0xFF00_010A
SWT3	SWT Time-out (SWT_TO)	0x0005_FCD0

1. The SWT can be disabled by accepting a DCI-driven signal to clear the SWT_CR[WEN] bit. For SWT2, the default reset value for that bit is '1', but the DCI can override that default value by setting it to '0'. If the signal is de-asserted, there is no change to the SWT_CR[WEN] value. (The DCI can only disable the SWT, it cannot enable it.) See the DCI chapter for details on the system watchdog control.

The Security Watchdog (SWT3) is enabled using DCF Records in conjunction with the BAF. Please see [Section 58.3.6.2, Security watchdog configuration](#) for details.

For SWT[0,1,3], the SWT_CR register reset value of 0xFF00_011B selects:

- All masters allowed access
- Reset on invalid access
- Oscillator clock selected
- Counter stops in debug mode
- Watchdog is disabled

For SWT[2], the SWT_CR register reset value of 0xFF00_010A selects:

- All masters allowed access
- Reset on invalid access
- Oscillator clock selected
- Counter stops in debug mode
- Soft locked
- Watchdog is enabled

7.7.2.4 Service mode watchpoint input

Each SWT comes out of reset in 'Fixed Service Sequence' mode (SWT_CR[SMD] = 2'b00), but the Instruction Address Compare 8 (IAC8) register (SPR 568) can be used for servicing by using the SWT jd_watchpt input.

To use SWT address execution modes for this purpose, the e200z4 core IAC8 register signal jd_watchpt[15] is connected to the SWT jd_watchpt input. (See [Section 63.6, Watchpoint support](#) for details.) The jd_watchpt[15] signal tells the SWT that an IAC8 compare occurred.

Set SWT_CR[SMD] to one of the following so the SWT is serviced by executing code at the address loaded into the IAC8 register:

- 2'b10 for Fixed Address Execution; the IAC8 register cannot be updated while the watchdog is enabled. If the SWT is in 'Fixed Address Execution' mode, an SWT output signal tells the core; this 'freezes' changes to the IAC8 register when the SWT is enabled.
- 2'b11 for Incremental Address Execution; the IAC8 register can be updated.

7.7.3 PIT configuration

This section summarizes how the module has been configured in the chip. For a comprehensive description of the module itself, see the module's dedicated chapter.

Figure 22. PIT configuration

Table 57. Reference links to related information

Topic	Related module	Reference

7.7.3.0.1 PIT Instantiation

Table 58. PIT Information

PIT Module	No of Channels	Description
PIT0	8 + RTI	PIT0 has 8 standard channels and 1 RTI channel. In PIT0, all registers are cleared by any reset.
PIT1	2	PIT1 has chaining mode to implement a 64-bit timer and the timer value is unchanged by a functional reset.

7.7.3.0.2 PIT/DMA Periodic Trigger Assignments

In PIT1, DMA is not supported. The PIT0 generates periodic trigger events to the DMA Mux as shown in the table below.

Table 59. PIT0 channel assignments for periodic DMA triggering

DMA Channel	PIT0 Channel
DMA Channel 8	PIT0 Channel 0
DMA Channel 9	PIT0 Channel 1
DMA Channel 10	PIT0 Channel 2
DMA Channel 11	PIT0 Channel 3
DMA Channel 12	PIT0 Channel 4
DMA Channel 16	PIT0 Channel 5
DMA Channel 32	PIT0 Channel 6
DMA Channel 48	PIT0 Channel 7

7.7.3.0.3 PIT Registers

The following tables show the implementation of PIT registers in this MCU.

Table 60. PIT0 memory map

Absolute address (hex)	Register name
FFF8_4000	PIT Module Control Register (PIT0_MCR) ⁽¹⁾
FFF8_40E0 - FFF8_40E4	Reserved
FFF8_40F0 - FFF8_40FC	RTI Timer Channel Registers (PIT0_RTI_LDVAL, PIT0_RTI_CVAL, PIT0_RTI_TCTRL, PIT0_RTI_TFLG)
FFF8_4100 - FFF8_417C	Timer Channel [0:7] Registers (PIT0_LDVALn, PIT0_CVALn, PIT0_TCTRLn, PIT0_TFLGn)
FFF8_4180 - FFF8_7FFF	Reserved

1. The reset value of MCR is 0x06.

Table 61. PIT1 memory map

Absolute address (hex)	Register name
FFF8_0000	PIT Module Control Register (PIT1_MCR) ⁽¹⁾
FFF8_00E0	PIT Upper Lifetime Timer Register (PIT1_LTMR64H)
FFF8_00E4	PIT Lower Lifetime Timer Register (PIT1_LTMR64L)
FFF8_00F0 - FFF8_00F8	Reserved
FFF8_0100 - FFF8_011C	Timer Channel [0:1] Registers (PIT1_LDVALn, PIT1_CVALn, PIT1_TCTRLn, PIT1_TFLGn)
FFF8_0120 - FFF8_3FFF	Reserved

1. The reset value of MCR is 0x02.

7.7.3.1 PIT clocking

The PIT0 standard channels are clocked with the peripheral clock (PER_CLK).

The PIT0 RTI channel clock source is selectable between XOSC and RCOSC via the auxiliary clock selector 9.

The PIT 1 channels are clocked with the peripheral clock (PER_CLK).

7.7.4 GTM 103 Integration Module (GTMINT103) configuration

The GTM103 integration module (GTMINT) is an interface to the General Timer Module 103 (GTM103) that adds ECC functionality and a Nexus-based system debugger interface (GTMDI). It has two control registers and provides access to the GTM103's memory-mapped registers. The GTM103 is detailed separately in the *GTM-IP_103_Specification*. See [Chapter 88: GTM103 Integration \(GTMINT\) Module](#), for more information.

7.8 Communication interfaces

7.8.1 Fast Ethernet Controller (FEC) configuration

The Fast Ethernet Controller (FEC) is a communication controller supports 10 and 100 Mbps Ethernet/IEEE 802.3 networks.

7.8.2 FEC interface selection

On this chip, the FEC interface depends on the settings of the RCR (in the FEC) and SIUL2_SCR0 (in the SIUL2), as shown in [Table 62](#).

Table 62. FEC interface selection

RCR[MII_MODE]	SIUL2_SCR0[FEC_MODE]	Interface used by the FEC
0	0 or 1	7-wire
1	0	RMII
	1	MII ⁽¹⁾

1. MII supported only on BGA packages.

7.8.3 CAN subsystem configuration

7.8.3.1 CAN nodes

The number of CAN nodes are listed below:

Table 63. CAN bus controllers

Types	Instances	CAN FD support	Debug on CAN Support
M_CAN	M_CAN_1	Yes	Yes
	M_CAN_2	Yes	Yes
	M_CAN_3	Yes	No
M_CAN with TTCAN	M_TTCAN_0	Yes	No

7.8.4 LFAST and SIPI

This section summarizes the module configuration in the controller. For a comprehensive description of SIPI and LFAST, please reference the specific dedicated chapters for SIPI and LFAST.

7.8.4.1 Instantiation

The SIPI and LFAST are connected to one another and appear as a single unit. The LFAST portion of the two modules allows for high speed inter-device communications. The SIPI allows memory to be shared between devices which have SIPI and LFAST communication modules (see [Figure 23](#)).

Figure 23. LFAST and SIPI block diagram

7.8.4.2 Device-specific features

The LFAST can operate in either slave or master mode configurations. The node running in master mode controls the serial link, but SIPI, in both master and slave modes, can act as both initiator and target for SIPI commands simultaneously. Please see the SIPI and LFAST chapters for detailed information on module configuration and functionality. The SIPI CHIP ID = 0AF0A01Dh for the SPC57EM80xx.

7.8.5.1 DSPI instantiation

This device contains seven DSPI modules. [Table 66](#) shows the instantiation information for each module.

Table 66. DSPI instantiation

DSPI Module	CTARs	TX FIFO Depth	RX FIFO Depth	PCS Signals	LVDS Support	Data Serialization Support
DSPI0	8	4	4	PCS[7:0]	Not Available	—
DSPI1	8	4	4	PCS[7:0]	Not Available	—
DSPI2	8	4	4	PCS[7], PCS[4:0]	Available ⁽¹⁾	—
DSPI3	8	4	4	PCS[7:0]	Not Available	—
DSPI4	8	4	4	PCS[7:0]	Available ⁽²⁾	32
DSPI5	8	4	4	PCS[7:0]	Available ⁽³⁾	32
DSPI12 ⁽⁴⁾	8	4	4	—	Not Available	—

1. Does not support Microsecond Bus.
2. Supports Microsecond Bus SCK and SOUT LVDS signal pairs.
3. Supports Microsecond Bus SCK and SOUT LVDS signal pairs; supports Differential DSPI with SCK, SIN and SOUT LVDS signal pairs.
4. Available in half duplex mode.

7.8.5.2 DSPI half duplex operation

Half duplex operation is not supported within the DSPI module, but it is configured by connecting the SIN and SOUT together within the SIUL2 and operating the combined pad in open drain mode. Software must ensure that the SOUT signal is passive (high) during SIN reception. This can be done by reconfiguring the SIUL2 to disconnect the SOUT or by writing a data frame that is all '1's.

7.8.5.3 Serialized timed I/O

The timer sources and injection pin inputs to be DSPI serialized downstream outputs are selected through the SIUL2 and selected through the MSCR registers. Inversion of these signals is also handled in the SIUL2. Refer to [Chapter 16: System Integration Unit Lite2 \(SIUL2\)](#), for details.

7.8.5.4 High Speed and MicroSecond Channel (MSC) Support

The baud rate generator in the DSPI is clocked from the peripheral clock. The DSPI module can operate at a baud rate of up to half the peripheral clock. The peripheral clock frequency specification is 16 MHz to a maximum of 100 MHz. As long as the peripheral clock is 100 MHz, 50 MHz baud rate is achievable.

To support microsecond channel functionality, pairs of LVDS signals are implemented for the appropriate DSPI signals. Therefore, SOUT4, SOUT_5, SOUT_6, SCK_4, SCK_5, SCK_6, have LDVS capability. In addition, SIUL2 MSCR muxing is implemented to mux the SOUT and CLK onto these LVDS signals well as standard CMOS signals. Finally, in the SIUL2 MSCR pin muxing, 4 input pins can be routed to 32 possible serialization inputs, each selectable for a specific DSPI.

The following four external pins can be inserted into the MSC data stream:

- 0000_0010 IO_PAD PC[2]
- 0000_0011 IO_PAD PD[8]
- 0000_0100 IO_PAD PF[3]
- 0000_0101 IO_PAD PJ[4]

Details of these pin assignments can be found in the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the Input Multiplexing Table tab.

7.8.5.5 DSPI HT external trigger

External hardware triggers are not supported.

7.8.5.6 DSPI ITSB mode

For the ITSB trigger, the internal DSPI trigger (TRGPRD in DSICR1) is used. Use of external trigger is not supported.

7.8.5.7 DSPI registers

The following table shows the absolute addresses of DSPI module registers in this MCU.

Table 67. DSPI registers memory map

Absolute address (hex)	Module
FBE7_0000	DSPI2 registers
FBE7_4000	DSPI3 registers
FBE7_8000	DSPI5 registers
FFE7_0000	DSPI0 registers
FFE7_4000	DSPI1 registers
FFE7_8000	DSPI4 registers
FFE8_8000	DSPI12 registers

7.8.5.7.1 DSPIx_MCR implementation

The following figure shows the implementation of DSPIx_MCR register in this MCU.

Figure 25. DSPI Module Configuration Register (DSPIx_MCR)

Address : Base + 0x0000

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	MSTR	CONT_SCKE	DCONF		FRZ	MTFE	PCSSE	ROOE	PCISIS[7:0]

R	DOZE ⁽¹⁾	MDIS	DIS_TXF	DIS_RXF	0	0	SMPL_PT		0	0	0	0	XSPI	FCPCS	PES	HALT
W					CLR_TXF	CLR_RXF										
Reset	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	1

1. Doze mode is not implemented on SPC57EM80xx.

7.8.6 FlexRay Configuration

The FlexRay communications system is designed to provide high-speed deterministic distributed control for advanced automotive applications. Its dual-channel architecture supporting data rates up to 10 Mbit/s per channel offers system-wide redundancy that supports the reliability requirements of safety system.

7.8.6.1 FlexRay signals pin assignment

This table lists the pin names for the FlexRay signals that are connected to pins on the boundary of the chip.

Table 68. Flexray pin names

Signal description	Pin name
FR_A_RX (Receive Data Channel A)	RXDA
FR_A_TX (Transmit Data Channel A)	CA_TX
FR_A_TX_EN (Transmit Enable Channel A)	CA_TR_EN
FR_B_RX (Receive Data Channel B)	RXDB
FR_B_TX (Transmit Data Channel B)	CB_TX
FR_B_TX_EN (Transmit Enable Channel B)	CB_TR_EN
FR_DBG[0] (Debug Strobe Signal 0)	DBG[0]
FR_DBG[1] (Debug Strobe Signal 1)	DBG[1]
FR_DBG[2] (Debug Strobe Signal 2)	DBG[2]
FR_DBG[3] (Debug Strobe Signal 3)	DBG[3]

7.8.6.2 Stopwatch timer input

Stopwatch timer input is routed to FlexRay module (selected by SIUL MSCR register) via:

- STM0_CMP0
- STM1_CMP0
- STM2_CMP0
- PIT1_CH0

Figure 26. Stopwatch timer source muxing

7.8.7 PSI5 Controller Configuration

The PSI5 chapter has 2 instances. Parameters for the 2 instances are listed below:

Table 69. PSI5 controller generics.

Signal name	Description	Value - PSI5_0	Value - PSI5_1
PSI5_NUM_CH	Number of channels	2	1
PSI5_PDIS_RST	Default State of the IP after reset	1	1

7.8.8 SENT receiver (SRX) configuration

7.8.8.1 SRX channels

The following table shows the SENT receiver channels for each instance configured on this chip. SPC57EM80xx has two SENT modules.

7.8.8.2 SRX channels

The following table shows the SENT receiver channels for each instance configured on this chip.

Table 70. SENT channel configuration

Instance	Channels (CH)
SENT 0	5 Channels: SENT_0_CH0 SENT_0_CH1 SENT_0_CH2 SENT_0_CH3 SENT_0_CH4
SENT 1	5 Channels: SENT_1_CH0 SENT_1_CH1 SENT_1_CH2 SENT_1_CH3 SENT_1_CH4

7.8.8.3 SRX registers

The following table lists the address offset and memory map for both SENT receiver (SRX) instances for this chip.

Table 71. SENT Receiver memory map

Offset	Register Name
0x0000	GBL_CTRL—Global Control Register
0x0004	CHNL_EN—Channel Enable Register
0x0008	GBL_STATUS—Global Status Register
0x000C	FMSG_RDY—Fast Message Ready Register

7.8.9 LINFlexD — Configurations

The LINFlexD chapter has 5 instances. Configuration for the 5 instances are listed below:

Table 72. LINFlexD configurations

Description	linflex_0	linflex_1	linflex_2	linflex_14	linflex_15
Number of filters implemented	16	16	16	16	16
Number of Tx DMA channels	1	1	1	1	1
Number of Rx DMA channels	1	1	1	1	1
LIN operation mode	master/slave	master	master	master	master
Autosynchronization	yes	no	no	no	no

7.9 Reset and boot modules

7.9.1 System Status and Configuration Module (SSCM) configuration

This section summarizes the System Status and Configuration Module (SSCM) configuration in the SPC57EM80xx. For a comprehensive description of the SSCM, please reference the SSCM's dedicated chapter.

7.9.1.1 SSCM instantiation

There is one SSCM instance in the SPC57EM80xx device. The SSCM is part of the reset and boot sub-system.

7.9.1.2 Device specific features

The SSCM allows Boot Assist from Flash (BAF), LINFlexD search at boot and utilizes PASS security concept. It also allows for external booting from the LINFlex port, but with no autobaud feature. The device specific resets value for the SSCM_MEMCONFIG register are shown in [Table 73](#).

Table 73. SSCM_MEMCONFIG Reset Values

Field	Field Definition	Value
MREV	Minor Revision	0000b ⁽¹⁾
JPIN	JTAG Part ID	30Ah ⁽²⁾

1. This value will change for each minor revision of the device.
2. This value will change for each major revision of the device.

[Table 74](#) shows the address locations that the SSCM uses to search for startup information.

Table 74. SSCM startup information addresses

Description	Value
The location at which the SSCM will look for the UTEST DCF records (UTEST_OFFSET).	0040_0000h
Location of the Boot Assist code in Flash (BAF)	0040_4000h
Specify the locations which are searched for a valid HSM boot header. (starting from the lowest address)	60_C000h 61_0000h 62_0000h

7.9.1.3 Protected registers

The SSCM module has a built-in register protection mechanism that affects the behavior of write operations to one or more registers. After software has activated the protection for a register, writes can only be performed in supervisor mode until the protection is either deactivated by software or the device undergoes reset.

See the Register protection section of this chapter for a list of affected registers.

See the Register protection chapter for a detailed description of the register protection mechanism.

7.10 Safety modules

7.10.1 CRC – Number Of Contexts

The number of contexts available for the current CRC computation of multiple data streams of CRC are listed below:

Table 76. CRC Contexts

Signal name	Description	Value
CRC_CNTX_NUM (N)	Number of contexts available for the current CRC computation of multiple data streams	1

7.10.2 MEMU configuration

7.10.2.1 MEMU system connections

Figure 27. MEMU system connections

7.10.2.2 MEMU error sources

The following table shows the MEMU error sources for each instance configured on this chip.

Table 77. MEMU error sources

Instance	Value
Number of System RAM unique error sources	93
Number of Peripheral RAM unique error sources	25
Number of FLASH unique error sources	3

7.10.2.3 Reporting tables implementation

There are 3 categories of error reporting for the MEMU:

- Flash error reporting
- System RAM error reporting—Any RAM that is CPU accessible falls into this category.
- Peripheral RAM error reporting—Any RAM that is not CPU accessible falls into this category.

Each category of error reporting has two tables associated with it, these are:

- Correctable Error Reporting Table
- Uncorrectable Error Reporting Table

Each entry in a reporting table corresponds to a unique error event. The number of entries supported by each table depends upon the error source.

The table below describes the number of entries in each reporting table for the different error sources.

Table 78. Number of entries in each reporting table

Error Source	Number of entries in correctable error reporting table	Number of entries in un-correctable error reporting table
Flash	20	1
System RAM	10	1
Peripheral RAM	2	1

7.10.2.4 Concurrent overflow register (OFLW) implementation

Errors are reported to the MEMU from one of three categories:

- Flash
- System RAM
- Peripheral RAM

In an overflow condition, it is possible to identify the unique error source that caused the overflow. Corresponding error sources for the OFLW register details the corresponding error source to the respective bit-field in the Concurrent Overflow registers.

Table 79. Corresponding error sources for System RAM OFLW0 register

OFLW0 bit-field position (bit)	Error sources
0	z4a Data AHB

0x0CC8	Flash memory concurrent overflow register (FLASH_OFLW0)

7.10.3 Indirect Memory Access (IMA) configuration

The IMA refers to the alteration of memory data values during system development and test activities. This section provides details about what memory locations can be accessed—

either via processor core access or via the IMA module—and how they are configured. For details on IMA see [Chapter 80: Indirect Memory Access \(IMA\)](#).

Note: See the *SPC57EM80xx Microcontroller Security Reference Manual for the HSM IMA details*.

7.10.3.1 SRAM Arrays accessible by processor cores

All the SRAM arrays in [Table 85](#) can be accessed by the main CPUs (CPU0 & CPU1) and the IOP (CPU2).

7.10.4.2 FOSU parameters

The FOSU_COUNT, or FOSU time out response time, is 1000 IRCOSC clock cycles.

7.10.5 Register protection (REG_PROT) configuration

Some modules on this device include a built-in register protection mechanism that can be used to override the normal write permissions associated with individual registers in the module. This mechanism is software-controlled and can be dynamically reconfigured at runtime or made effective until device reset. For a detailed explanation, see the [Chapter 83: Register Protection \(REG_PROT\)](#).

7.11 Security modules

The modules described in this section provide a basic set of customer-configurable security features designed to protect code and data from unauthorized access and to provide a way implement an audit trail to identify accesses to specific blocks of flash memory.

Table 104. Reference links to related information

Topic	Related module	Reference
Security overview	—	Chapter 11: Security
Password protection of flash memory blocks	PASS	Chapter 37: Flash Memory Programming and Configuration
	PASS	Chapter 84: Password and Device Security Module (PASS)
Tamper Detection	TDM	Chapter 85: Tamper Detection Module (TDM)
Detailed information on advanced security features	—	See the <i>SPC57EM80xx Microcontroller Security Reference Manual</i>

7.11.1 Password and Device Security Module (PASS) configuration

The PASS module is used to implement password-based read and write protection for flash blocks on the SPC57EM80xx MCU. Up to 4 levels of password protection can be implemented for each flash block.

Note: The registers discussed in this section are initialized via DCF records, so the reset values depend on user settings.

See the Password and Device Security Module (PASS) chapter for further details.

7.11.1.1 PASS_LOCKn_PGn register bit mapping

As described in [Chapter 37: Flash Memory Programming and Configuration](#), each password group defined in the DCF records has a set of 4 LOCKn registers association with it—PASS_LOCKn_PGn. The bits of these registers are associated with specific flash blocks. The mapping is shown in the following figures.

Note: The mapping of various LOCK register bits to flash blocks in the SPC57EM80xx microcontroller is very similar, but not identical. The PASS module has additional mapping in the LOCK3 register and defines read locking regions. See the PASS chapter for details.

Figure 28. PASS_LOCK0_PGn Register⁽¹⁾

7.11.1.2 PASS Module DCF Records (includes life cycle state and censorship)

The records required to configure the initial values for the PASS module password group registers is shown in [Table 105](#). These values provide the following capabilities:

- Set the current life cycle state
- Set flash memory to censored/uncensored state (censorship also depends on lifecycle)
- Override the basic flash write protection for flash memory blocks
- Set levels of password-based write protection (up to four 256-bit passwords can be required) for individual blocks of flash memory
- Set levels of password-based read protection (up to four 256-bit passwords can be required) for up to five flash memory Read Locking Regions
- Set levels of password-based protection (up to four 256-bit passwords can be required) for the debug part.

Table 105. PASS DCF records

000_0000_0000_1000	00000000	01001100–11111111	Reserved		

1. See [Section 84.3.1.1, Life Cycle Status register \(LCSTAT\)](#) for values.
2. See [Section 84.5.4, Censoring/uncensoring the device](#) for values.
3. See [Section 7.11.1.1, PASS_LOCKn_PGn register bit mapping](#) for values.

7.11.2 Tamper Detection Module (TDM) configuration

The Tamper Detection Module provides a type of flash memory write protection mechanism that forces software to write a record associated with one or more blocks in a Tamper Detection Region (TDR) before the block(s) can be erased. An additional feature is provided to enable customers to override the protection mechanism for any TDR so that no record is required to be written before a block within the TDR can be erased.

Additionally, the TDM provides a mechanism for configuring individual flash memory blocks as One Time Programmable (OTP), i.e., write once, blocks.

The following sections provide details on the TDM configuration registers and DCF clients.

Warning: The TDM configuration registers detailed in this section are DCF clients. In general, DCF clients can only be written once—their intended values must be carefully selected beforehand.

See the Tamper Detection Module (TDM) chapter for further details on the TDM, including the DCF clients and two additional memory-mapped registers.

7.11.2.1 Diary Base Address (DBA) DCF client

DBA DCF client holds the base address of the diary, which is the region of flash that contains records corresponding to erase operations. This DCF client is more fully described in the TDM chapter.

7.11.2.2 Tamper Region Override (TO) DCF client

Tamper detection can be overridden by writing to enable bits (one per region) in the Tamper Region Override (TO) DCF client. This DCF client is more fully described in the TDM chapter. The mapping is shown below.

Figure 32. Tamper Region Override (TO) DCF client

The mapping of the Tamper Region Override Enable (TOEn) DCF client is as follows:

Table 106. TO[TOEn] field mapping

Field	TDR
TOE0	0
TOE1	1
TOE2	2
TOE3	3
TOE4	4
TOE5	5

This DCF client is more fully described in the TDM chapter

7.11.2.3 OTPENn DCF clients

Configuring individual flash blocks as OTP blocks is accomplished by setting the appropriate values in the TDM_OTPENn DCF clients. Each mapped bit is associated with a specific flash block. A “1” bit value indicates a block is OTP.

The mapping is shown in [Figure 28](#) - [Figure 36](#).

7.11.2.4 TDRx_LOCKn DCF clients

Configuration of the 6 tamper regions is accomplished by setting field values in LOCK DCF clients (4 for each TDR).

Each set of 4 LOCKn DCF clients acts as a map of the MCU's flash memory blocks. A "1" in a LOCKn bit indicates that software must write a record before the corresponding block can be modified. The mapping of TDM_LOCKn DCF client bits to flash blocks is identical to the OTPENn mapping and is shown in [Figure 28](#) - [Figure 36](#). Any available flash block can be mapped to any tamper protection region.

7.11.2.5 DCF client details

[Table 107](#) contains the DCF client information.

Table 107. Tamper Detection Module (TDM) DCF clients

DCF CS[14:0]	DCF Address [16:10]	DCF Address [9:2] (Binary)	DCF Client Description	No. of Valid Bits	No. of DCF Records

1. OTP DCF clients have the same structure and mapping as the write-protect bits of the flash and PASS module LOCK DCF clients. A value of '1' in an OTP bit indicates a block is programmable only once. Note that a block cannot be reconfigured as non-OTP after it has been configured as OTP.
2. There are no flash memory blocks mapped to the OTPEN3 DCF client.

7.12 Production device vs. emulation device

SPC57EM80xx microcontrollers have a comprehensive feature set to assist debug and calibration. Specialized variants, referred to as Emulation and Debug Devices (EDs), include additional calibration and debug features. An ED consists of the normal production die plus an additional die, called a Buddy die or Buddy Device (BD), bonded together in the same package. A Production Device (PD) includes a production die only and no buddy die.

Note: All features and modules included in the PD are also included in the ED.

The following table lists the key differences between the ED and PD of the SPC57EM80xx microcontroller.

Table 108. Debug and calibration features per SPC57EM80xx type

Debug or calibration feature	SPC57EM80xx PD	SPC57EM80xx ED
Internal Overlay Memory	16 KB	16 KB
Extended Overlay Memory	—	1 MB
Debug Interface	JTAG / LFAST	JTAG / LFAST
Trace Interface	—	Aurora (1.25 GHz, 4 Lane)
Trace Sources	Data trace on all bus accesses initiated from PD, Program trace on main CPUs, DMA and GTM	Data trace on all bus accesses initiated from PD, Program trace on main CPUs, DMA and GTM

Table 108. Debug and calibration features per SPC57EM80xx type (continued)

Debug or calibration feature	SPC57EM80xx PD	SPC57EM80xx ED
Trace Destination	Internal Overlay	Internal Overlay, Extended Overlay, Aurora Trace Port
Calibration Remap capabilities	32 Region	32 Region
System Level Performance Monitor Counters ⁽¹⁾	16 × 32 bits	16 × 32 bits
CPU Level Performance Monitor Counters	12 × 32 bits (4 × 32 bits per z4 CPU)	12 × 32 bits (4 × 32 bits per e200z4 CPU)

1. All system level PMCs can also be configured for use as debug timers.

The following figure shows the top-level block diagram of the SPC57EM80xx ED, which consists of the production die packaged together with the 1 MB Buddy die (BD1M). The figure shows the general interconnection of functional debug modules including interconnections between the two devices. All functional blocks are shown for the BD, but for clarity only blocks relevant to the debug and calibration system are shown for the PD.

Acronyms used in the block diagram include:

- BD_SIU — BD System Integration logic
- BD_XBS_RAM — Buddy Device RAM Crossbar
- DCI — Debug and Calibration Interface
 - JTAGC — JTAG Controller
 - M.JTAG — Mastered JTAG
 - P.JTAG — Peripheral JTAG
 - I.JTAG — Inter-die JTAG
 - DCU — Debug Control Unit
- DTS — Development Trigger Semaphore
- JTAGM — JTAG Master
- SPU — Sequence Processing Unit
- NAR — Nexus Aurora Router
- NAL — Nexus Aurora Link
- Nexus RWA — Nexus Read/Write Access client

On ED devices, the device packaging routes the tool interface to the interface logic on the BD. On standard production devices packages the device packaging routes the tool interface to the interface logic on the PD.

Figure 37. Debug and calibration architecture for SPC57EM80xx ED

8 Reset and Boot

8.1 Introduction

Resetting the SPC57EM80xx involves an entire process starting with the application of power to actually fetching the first instruction of the user's application code. In general, the SPC57EM80xx is much more than a microcontroller with some selected group of peripheral elements and bus interfaces. It is an entire system containing multiple processing elements with their own associated local memory systems as well as memory elements that can be accessed by any of the processor cores.

To properly understand reset, some knowledge of the chip architecture is needed. There are five processor cores on the SPC57EM80xx. There are Core_0 and Core_1, both based on the e200_z420 architecture. These cores are used, in general, to execute user application code. Associated with Core_0 is Checker Core_0. This core executes the same instruction stream as Core_0. The results of each instruction execution are compared between the two cores and are flagged if a mismatch occurs. Peripheral Core_2, generally referred to as the IOP (or I/O Processor), is implemented using an e200_z425 core. Its intended purpose is to control the various peripheral elements on the SPC57EM80xx; however, there are no limitations to the types of programs that it can execute. Also included on the SPC57EM80xx is a Hardware Security Module (HSM) that has an embedded e200_z0 core. The HSM can execute code written by the factory and stored in a special Secure Flash that can only be accessed by the HSM. However, like the other processor cores, the HSM can access other memory elements on the SPC57EM80xx as well.

There are several memory elements that are also involved in the boot-up process. These are the UTEST flash memory area, the TEST flash memory area, and the Boot Assist Flash (BAF).

8.1.1 Boot Assist Flash

The Boot Assist Flash (BAF) contains code written by the manufacturer that facilitates the boot-up procedure of the SPC57EM80xx. Two important features of the BAF code are that it searches for a valid boot header and if none is found, the BAF code starts and runs the Serial Boot Loader. If there is no valid boot header loaded into the program memory when the SPC57EM80xx device is powered on, the Serial Boot Loader software can receive files from an external serial link controlled by the internal LINFlexD module. The received file is put into RAM and then program execution begins at the start address specified in the received file. The serial boot loader is only an option in the early stages of the device life cycle. In later life cycle stages (for example "field") the device simply waits for the watchdog to reset the device if no boot header is found.

8.1.2 TEST flash memory block

The TEST flash memory block contains Device Configuration Format (DCF) records used to hold trim values and other variables that are calculated during production test as well as general device configuration information. These trim values are for such things as adjusting low-voltage and high-voltage detect circuit trip points, temperature sensor adjustments, power-on reset voltage trip point, analog-to-digital adjustments and internal RC oscillator (IRCOSC) trim values. These values are determined during production testing and written into the TEST flash memory area. The ability to further program the TEST flash area is

disabled at the end of the factory test cycle. The DCF records are written by the device manufacturer and programmed into the TEST flash memory area during production testing.

8.1.3 UTEST flash memory block

The UTEST flash memory block also contains DCF records. Some UTEST DCF records are written by the factory and programmed during production testing. Others are written by the end user and programmed at the same time application code is programmed into the flash memory. UTEST DCF records are used to set up various control and configuration registers, including the Self-Test Control Unit (STCU2) and default memory configuration. UTEST DCF records, written by the device manufacturer, are programmed into the UTEST flash memory area during factory testing.

8.1.4 Boot header

A boot header is also needed in addition to the Device Configuration Records. A boot header is used to supply the start address for code execution for Core_0, Core_1 and Checker Core_0s. The boot header is written by the application programmer and loaded into specific locations in flash memory. The boot header contains the reset vectors for the various cores. The Boot Header also specifies the BOOT CPU that will eventually execute application code.

8.2 Modules used in reset sequence

There are several modules used to step through the sequence needed to properly reset the SPC57EM80xx and prepare it to fetch the first instruction of the user application code. These are the Power Management Controller (PMC), the Reset Generation Module (MC_RGM), the Mode Entry Module (MC_ME), the System Status and Configuration Module (SSCM) and the Self-Test Control Unit (STCU2).

8.2.1 Power Management Controller

The Power Management Controller (PMC) controls and monitors various voltage levels around the chip. Specifically, the PMC monitors its own supply voltage, the supply voltages to all the high- and low-voltage detect circuits, the trip points for all the high- and low-voltage detect circuits, the power supplies and reference voltages to the Analog-to-Digital Converter as well as the major power supplies to the SPC57EM80xx.

8.2.2 Reset Generation Module

The Reset Generation Module (MC_RGM) is a complex state machine that begins sequencing the SPC57EM80xx through the initial part of the reset process (see [Figure 38](#)). Reset sources are organized into two categories: destructive and functional. The MC_RGM is simply a state machine; it does not execute program code. In general, the reset generation module centralizes the different reset sources and manages the reset sequence.

8.2.2.1 Destructive resets

A destructive reset source is associated with an event related to a critical error or dysfunction, usually caused by a hardware malfunction. When a destructive reset event occurs, a software solution for recovery is not possible and the contents of memory are assumed to be unknown. Therefore, a full reset sequence is applied to the device starting

with PHASE0 in response to a destructive reset. This resets the full device ensuring a safe startup state for both digital and analog modules. See [Figure 38](#) for more information on the MC_RGM reset sequence.

Examples of destructive resets are:

- Power-on reset
- Low voltage detection
- Reset escalation (occurs when too many functional resets occur simultaneously)

8.2.2.2 Functional resets

A functional reset source is associated with an event related to a less critical error or dysfunction. These events are usually not associated with a hardware malfunction. When a functional reset event occurs, a partial reset sequence is applied to the device starting with PHASE1[FUNC]. See [Figure 38](#) for more information on the MC_RGM reset sequence. In this case, most digital modules are reset normally. The state of analog modules, specific digital modules (for example, debug and flash memory modules) and system memory content is preserved.

Examples of functional resets are:

- external reset
- machine check
- software reset from mode entry
- boundary scan instructions

8.2.3 Mode Entry module

The Mode Entry module (MC_ME) is responsible for delivering initial values to many registers in SPC57EM80xx. Among other things, the MC_ME supplies the reset vectors to all the SPC57EM80xx cores. During the power-up sequence, the System Status and Configuration Module (SSCM) searches for a boot header at defined locations in the flash memory, derives the necessary reset vectors from the boot header and then writes these vectors to their respective locations in the Mode Entry module. The SSCM also interprets the DCF records, which contain other information that is written to the MC_ME. As the boot-up sequence progresses, the SSCM instructs the MC_ME to transfer the reset vectors to the respective processor cores.

Even though the reset vectors are in the boot header located in flash memory, the Mode Entry module always provides them to the CPU cores.

8.2.4 System Status and Configuration Module

The System Status and Configuration Module (SSCM) is a state machine. During the reset sequence, the Reset Generation Module (MC_RGM) enables the SSCM, which reads the DCF records in both the TEST and UTEST flash memory areas. The DCF records contain device setup information that the SSCM uses to write data to various registers in the SPC57EM80xx. The DCF records are primarily concerned with setting up the memory, configuring the Self-Test Control Unit (STCU2), and providing initial device configuration values.

The SSCM continues with the reset or boot-up sequence by locating boot vectors for the various cores. Once the SSCM locates the boot header, the SSCM writes the start address information for the CPU cores to special locations in the Mode Entry Module (MC_ME). For

all cores enabled by the boot header, the MC_ME feeds a reset vector to each enabled core and the respective cores begin program execution at the specified address. The SSCM starts up the IOP and the HSM in different ways depending on whether there is valid code in the Boot Assist Flash (BAF). The boot-up sequence ends when the SSCM starts up the boot CPU, which can be either Core_0 or Core_1.

8.2.5 Self-Test Control Unit

The Self-Test Control Unit (STCU2) is a self-contained module that runs a Logic Built-In Self Test (LBIST) and a Memory Built-In Self Test (MBIST). The DCF record can be used to select which individual tests are run for LBIST and MBIST and disable tests for modules and memory elements that are not going to be used in user applications, thus shortening device boot-up time.

8.3 Reset sequence

The power-up reset sequence always begins with the application of power and follows different sequences depending on the condition of the SPC57EM80xx device and whether various modes are enabled from settings in the DCF records. For instance, the SPC57EM80xx device enters serial boot mode if a valid boot header file is not found. In this case, the device uses the serial boot loader to receive startup code and begin program execution. If an emulation and debug device is detected during the reset sequence, the device enters the calibration sequence. The calibration sequence is not a user mode and is only used for code development. Another reset outcome is that the Hardware Security Module, the IO Processor, and the boot CPU are all properly started and begin executing their respective program code.

8.3.1 Power-on and the Reset Generation Module

The initial power-up sequence starts with power being applied to the SPC57EM80xx. The Reset Generation Module (MC_RGM) then advances the device through a series of steps shown in [Figure 38](#). The remainder of the power-up sequence is detailed in [Figure 39](#) through to [Figure 43](#). The Reset Generation Module (MC_RGM) starts the System Status and Control Module (SSCM), which continues the boot-up process after the MC_RGM enters the IDLE state.

Figure 38. Reset Generation Module Reset Sequence

Table 109. Module status during reset phases

Module	PHASE								
	P0	P1 [DEST]	P2 [DEST]	P3 [DEST]	IDLE [DEST]	P1 [FUNC]	P2 [FUNC]	P3 [FUNC]	IDLE [FUNC]

								Short functional reset	
								functional reset	
						destructive reset			

1. RESET only during POR
2. STCU time-out monitoring LBIST/MBIST execution
3. Depending on flash configuration
4. FCCU remains ON during functional reset; it is instead reset in PHASE1[FUNC] if coming from IDLE[DEST]
5. Can be triggered by SW. Please refer to [Chapter 82: Self-Test Control Unit \(STCU2\)](#).
6. LBIST is optionally triggered depending on safety execution directives
7. LBIST is optionally triggered depending on safety execution directives after enabling from IOP. Please refer to [Chapter 58: Boot Assist Flash \(BAF\)](#).

8.3.2 Power-up phase: power stabilization

When a power-on reset event occurs (initial application of power), the reset generation module (MC_RGM) causes the device to enter the power-up phase of the reset sequence (See [Figure 38](#)). The only method to enter the power-up phase is from a power-on reset event.

The device remains in the power-up phase until the power management controller module (PMC) determines that all power supplies are in their respective operational ranges.

The supplies for initial configuration are:

- VDD_HV_CORE: high voltage supply for core module, including power management unit, internal RC oscillator (IRCOSC), external oscillator (XOSC) driver
- VDD_LV_CORE: low voltage supply for digital module
- VDD_HV_FLA: high voltage supply for flash module
- VDD_LV_FLA: low voltage supply for flash module
- VDD_HV_IO_IM: high voltage supply associated with system pins (PORST, ESR0, TEST Mode)

Peripheral supplies, such as VDD_HV_IO_JTAG, VDD_HV_IO_FLEX or VDD_HV_ADC, do not gate the power-up process. The low- and high-voltage detect circuits for these and other power supplies are managed by the PMC, which provides enable and status bits for these voltage detection circuits.

The PMC sends a signal to the Reset Generation Module when power stabilization has been achieved. The Reset Generation Module then advances to the PHASE0 state (see [Figure 38](#)). During the power-up phase, the PMC does the following:

- Drives to a logic 0 all LVDxx (low-voltage detect) and HVDxx (high-voltage detect) signals monitored by the Power Management Control (PMC) module.
- Monitors its own power supply voltage (VDD_HV_PMC) to determine that the applied voltage is within a specified range.
- Monitors the core power supply voltage (VDD_LV_CORE) to determine that the applied voltage is within a specified range.
- Monitors the low- and high-voltage detect circuit power supply voltage to determine that the applied voltage is within a specified range.
- Holds the outputs of the internal low- and high-voltage detect circuits at a ground state until the PMC determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Determines that all power supplies needed for correct device initialization and configuration are within their respective functional voltage ranges.
- Enables all low- and high-voltage detect circuits once all power supplies are at their functional levels.
- Begins to monitor the various power supplies using the high- and low-voltage detect circuits.
- Provides status information to the Reset Generation Module (MC_RGM) indicating whether or not power is properly applied.

To exit power-up and enter PHASE0:

- All enabled “destructive” resets must be processed.
- All power supplies must be at their functional voltages.
- The PMC must signal the MC_RGM that all power supplies are at the required levels.

8.3.3 **PHASE0 Phase: analog supply initial configuration**

This phase is entered:

- On exit from power-up phase.
- On PORST pin falling edge detection except for the initial power-up sequence.
- Immediately from PHASE2[DEST], PHASE3[DEST], IDLE[DEST], PHASE1[FUNC], PHASE2[FUNC], PHASE3[FUNC] or IDLE[FUNC], on the occurrence of a PORST falling edge event other than power-on reset.

During PHASE0:

- All digital modules are reset, including safety, security, and test modules.
- All trimming bits for analog modules are reset.
- Startup of the internal analog modules (PMC, IRCOSC, and I/Os) begins:
 - PMC determines that proper voltages are applied.
 - I/O pins are ensured correctly configured: outputs are driven to known levels, inputs ignored.

To exit PHASE0 and enter PHASE1[DEST]:

- All enabled destructive resets must be processed.
- Core Low Voltage Detect must be released.
- All processes initiated in **PHASE0** must be completed. This generally includes startup of the internal analog modules: PMC, IRCOSC, and I/Os.

This phase is completed in about 20 μ s.

Note: The core voltage must rise above LVD112 upper threshold to exit PHASE0. This ensures significant hysteresis on low voltage supply avoiding spurious low voltage detection during the power-up process.

8.3.4 **PHASE1[DEST] Phase: temporization and monitoring setup**

This phase is entered on exit from **PHASE0**.

During PHASE1[DEST]:

- Initial configuration of the watchdog to monitor the reset sequence
- Temporization for reset signal propagation in case of reset

This phase is completed in less than 1 μ s and corresponds to eight IRCOSC clock cycles.

During PHASE1[DEST], test modules are available. However, their actual test functionality is limited by the security module (no security waiver granted at this phase).

To exit PHASE1[DEST] and enter PHASE2[DEST], all PHASE1[DEST] tasks must be completed.

8.3.5 **PHASE2[DEST] Phase: flash initial configuration**

This phase is entered on exit from **PHASE1[DEST]**.

During PHASE2[DEST]:

- Reset is released to the flash memory module by the Reset Generation Module.
- The flash memory module starts its initial configuration process.
- The flash memory initialization is performed by a state machine internal to the flash module.
- The system watchdog starts monitoring flash memory configuration execution so that a reset occurs in the event of configuration failure.

Note: System Watchdog is configured to generate destructive reset in case of flash memory failure during boot process. If, on boot completion, the watchdog event is converted to generate an FCCU fault only, application software should re-configure the MC_RGM watchdog register bit to prevent destructive reset from being triggered.

To exit **PHASE2[DEST]** and enter **PHASE3[DEST]**, all processes started in **PHASE2[DEST]** must be completed.

This phase is completed in less than 200 μ s.

8.3.6 **PHASE3[DEST] Phase: device configuration**

This phase is entered on exit from **PHASE2[DEST]**.

During PHASE3[DEST]:

The System Status and Configuration Module (SSCM) is started. Configuration and initialization information in the Device Configuration Format (DCF) record is retrieved from the TEST and UTEST flash memory areas by the System Status and Configuration Module (SSCM) and used to configure the Self-Test Control Unit (STCU2) and the initial memory map of the device. It also transfers reset vectors for the various cores to the Mode Entry Module (MC_ME). This information enables tests that the STCU runs and also provides the memory map setup information so that the STCU can test memory. Trim values for the analog modules, such as the Analog-to-Digital Converter, low- and high-voltage detect circuits, and the temperature sensor, are written to their respective registers by the SSCM. The DCF record programmed into the TEST flash memory area is generally written by the manufacturer. The portion of the DCF record that is programmed into the UTEST flash memory is generally written by the customer although there is a default DCF record programmed into both the TEST and the UTEST flash memory areas during device production testing. In general, you write your own DCF record for the UTEST area to replace the default DCF.

The DCF record also provides configuration information for the following:

- Trimming of the analog modules (for example, voltage regulator, voltage detectors, I/Os, and oscillator)
 - Trim values are in DCF records in the TEST flash memory area.
 - Trim values are determined during production test and programmed into the TEST flash memory area.
- Device life cycle information:
 - Censorship configuration
 - Debug security configuration
 - Functional security configuration
- Application configuration bits:
 - Watchdog configuration
 - Safety execution directives (self test, LBIST/MBIST)
 - Boot Assist Flash options
 - Oscillator startup during reset sequence configuration

To exit **PHASE3[DEST]**: All processes that need to be completed in **PHASE3[DEST]** must be finished.

This phase is dependant on actual trim values, especially those used for safety execution directives. This device configuration is maintained until the next internal power-on reset. Each time a destructive reset event occurs, the SSCM takes values from the DCF record and write these values to the applicable registers.

If the configuration information from the DCF record requests that self test execution be performed, the device moves to **IDLE[DEST]** and the STCU2 begins self test execution. At the end of the self test execution, the STCU2 asserts a functional interrupt causing the Reset Generation Module to move to **PHASE1[FUNC]**. If self test execution is not requested, the device moves directly to **IDLE[FUNC]**. The reset generation module determines whether self test execution is enabled or not by examining an entry in the DCF record stored in the UTEST flash memory.

*Note: When self test execution is not requested, it is possible to maintain the device within **PHASE3[DEST]** by forcing either the PORST or ESR0 pin low. This can be used for debugging purposes by allowing external test/development equipment to connect through JTAG to the internal debugger.*

8.3.7 **IDLE[DEST] Phase: self test execution**

This phase is entered upon exit from **PHASE3[DEST]** if the execution of self test is enabled.

During the **IDLE[DEST]** phase:

- Dedicated watchdog is configured to monitor self test execution completion within expected time. The length of this phase is variable depending on the self-test requirements.
- The Self-Test Control Unit (STCU2) executes all tests specified by the DCF information retrieved in **PHASE3[DEST]**.
- The self test engine updates the self test completion flag and triggers an associated functional reset on completion of self test.

The length of this phase is variable depending on the self test requirements.

Note: When the SSCM is decoding the Device Configuration field, it sets and clears various flags in STCU registers and memory that can later be examined by the SSCM to determine which self test directives must be run.

Exiting IDLE[DEST] and moving to PHASE1[FUNC]

- The IDLE[DEST] phase is automatically exited at completion of self test when the self test code generates a functional reset.
- The functional reset causes the reset generation module to move to the **PHASE1[FUNC]** phase.

Note: In case of unrecoverable fault detection during STCU execution, unrecoverable fault reset are triggered and device re-enters **PHASE1[DEST]**.

8.3.8 **PHASE1[FUNC] Phase: temporization and monitoring setup**

This phase is entered either:

- On exit from **IDLE[DEST]**
- Immediately from **PHASE2[FUNC]**, **PHASE3[FUNC]**, or on **IDLE[FUNC]** when a non-masked external or “functional” reset event occurs, providing the source of the reset event has not been configured to trigger a ‘short’ reset sequence

During PHASE1[FUNC]:

- Initial configuration of the watchdog to monitor reset process
- Temporization for reset signal propagation in case of reset

To exit **PHASE1[FUNC]** and enter **PHASE2 [FUNC]**:

- All enabled, non-shortened “functional” resets must be processed.
- All processes started in **PHASE1[FUNC]** must be completed.
 - Initial configuration of the watchdog to monitor reset process
 - Temporization for reset signal propagation in case of reset

This phase is completed in ~1 µs or less. During this phase, test modules are available.

8.3.9 **PHASE2[FUNC] Phase: flash initial configuration**

This phase is entered on exit from **PHASE1[FUNC]**.

During the PHASE2[FUNC] phase:

- The reset signal is released to the flash memory.
- Flash initialization and configuration begins using a state machine that is internal to the flash memory module.
- A watchdog monitors flash initialization to ensure a reset in case of flash memory configuration failure.

The reset state machine exits **PHASE2[FUNC]** and enters **PHASE3[FUNC]** on verification that all processes started in **PHASE2[FUNC]** are completed.

This phase is completed in ~200 µs.

8.3.10 **PHASE3[FUNC] Phase: device configuration monitoring**

PHASE3[FUNC] is entered either:

- On exit from **PHASE2[FUNC]**
- Immediately from **IDLE[FUNC]** when an enabled, shortened functional reset event occurs

During **PHASE3[FUNC]**, configuration information contained within the UTEST flash memory sector is checked against information extracted during **PHASE3[DEST]** and written to the Self-Test Control Unit (STCU2). In case of mismatches, a dedicated boot fault is triggered within the FCCU which, if enabled, can cause a system reset. The purpose of **PHASE3[FUNC]** is to verify that the DCF information transferred to the STCU, MC_ME and other modules, in **PHASE3[DEST]**, was performed correctly and has not been corrupted.

The Reset Generation Module exits **PHASE3[FUNC]** and enters the **IDLE[FUNC]** on verification of the following:

- All processes started in **PHASE3[FUNC]** are completed.
- PORST and ESR0 pin are not forced low externally.
- A minimum number of cycles have elapsed since the last enabled, shortened “functional” reset event.

After all **PHASE3[FUNC]** internal actions have been completed, it is possible to maintain the device within **PHASE3[FUNC]** by forcing either the PORST or ESR0 pin low. This can be used for debugging purposes in order to connect through the JTAG port to the internal debugger. In the case of a secured device, it is possible to submit the debug password to access device and/or HSM debug through the JTAG module. The HSM responds by performing certification of the provided password and eventually may enable debug access to the different cores.

8.3.11 **IDLE[FUNC] Phase**

This is the Reset Generation Module's final phase of the reset sequence. It is entered either on exit from **PHASE3[DEST]**, if the execution of self test was not enabled, or at the completion of **PHASE3[FUNC]**. When the **IDLE[FUNC]** phase is reached, the MC_RGM releases control of the system to the System Status and Control Module. At this point, the SSCM which is stated in **PHASE3[FUNC]**, runs and waits for a signal from the MC_RGM indicating that the MC_RGM is now in the IDLE state. The MC_RGM then waits for new reset events that can trigger a reset sequence. The SSCM continues with the system boot-up sequence.

8.4 **MC_RGM passes boot sequence control to the System Status and Control Module**

The SSCM continues the boot-up sequence after the Self-Test Control Unit (STCU2) finishes executing the MBIST and LBIST functions that were initiated by the MC_RGM during the **IDLE[DEST]** state.

A flow chart of the boot-up sequence is shown in [Figure 39](#), [Figure 40](#), [Figure 41](#), [Figure 42](#), and [Figure 43](#).

8.4.1 Reset sequence flow based on initial device condition

The SPC57EM80xx is highly configurable. The flow through the boot-up sequence takes different paths depending on which modules are enabled and which header files are present. For instance, a device shipped from the factory has pre-installed programs in the Boot Assist Flash and the Boot Assist ROM. Also DCF records are programmed into the TEST flash memory area and the UTEST flash memory area.

- Boot Assist Flash
 - Contains code written by factory.
 - Cannot be modified by user.
- Boot Assist ROM
 - Contains code written by factory.
 - Cannot be modified by user.
- TEST DCF record cannot be modified by user
- UTEST DCF record
 - UTEST flash memory contains a default DCF record.
 - User-supplied UTEST DCF file can replace default UTEST DCF record.

After the SPC57EM80xx flash memory has been programmed, it contains the CPU boot header file, and, if required, an HSM boot header file, together with the user application. This boot header is used by the boot-up sequence flow which is managed by the SSCM module.

8.4.2 Possible boot-up sequences

8.4.2.1 Enter JTAG test mode

- Used for JTAG testing (non-user mode)
- Interface to JTAG port Development Equipment for Code Development

8.4.2.2 Enable IOP and enable the Boot CPU (CPU_0 or CPU_1)

- Normal operation for I/O Processor (IOP)
- Normal operation for the selected boot CPU

8.4.2.3 Enable IOP, HSM and enable the Boot CPU (CPU_0 or CPU_1)

- Normal operation for I/O Processor (IOP)
- Normal operation for selected boot CPU
- Normal Hardware Security Module (HSM) operation

8.4.2.4 Enable IOP and/or HSM and enter serial boot mode if no application code is present

- Mode used to download program code and place in RAM
- Mode used to start downloaded application program

The following sections detail the exact flow through the reset sequence to achieve the various outcomes.

8.4.3 Sequence from MC_RGM IDLE to IOP, HSM, and boot CPU running code

This path is taken when operation of both the IOP and HSM is desired. In this scenario, a boot CPU is selected and starts executing application code. Also, this is the scenario that is used to start all of the processor cores: CPU_0, CPU_1, Checker Core_0s, the HSM, and the IOP.

8.4.3.1 Initial conditions

- Boot Assist Flash bypass mode is NOT enabled (execute BAF code).
- HSM is enabled.
- Application code for the IOP is programmed into Boot Assist Flash memory.
- Application code for the HSM is programmed into flash memory.
- Application code for the boot CPU is programmed into flash memory.
- A valid boot header for CPU_0, CPU_1, and the Checker Core_0s has been programmed into flash memory.
 - Boot Header_ID
 - Boot CPU selection
 - Boot CPU start address (address of first instruction in application code)
 - CPU_0 reset vector
 - CPU_1 reset vector
 - Checker Core_0s reset vector
- A valid boot header for HSM has been written into flash memory
 - HSM_Boot_Header_ID
 - Start address of HSM application code
- The Reset Generation Module (MC_RGM) has passed control to the System Status and Control Module during the IDLE[FUNC] state.

8.4.3.2 Reset Generation Module has entered idle state

The MC_RGM enters the IDLE[FUNC] state. The MC_RGM completes all the tasks in defined the IDLE[FUNC] state. Then, the MC_RGM signals the SSCM that the MC_RGM has become idle and that the SSCM is to take over control of the boot-up sequence.

8.4.3.3 LBIST and MBIST start execution (state 1 and 2)

The MC_RGM enters the IDLE[FUNC] state and completes all tasks. Then, the MC_RGM signals the SSCM that the MC_RGM has become idle and that the SSCM is to take over control of the boot-up sequence. At this point, LBIST and MBIST have completed their test cycles, the data in the DCF record has been written to the appropriate registers, and all the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.3.4 Is a JTAG request pending? (state A)

The SSCM is now in charge of the boot-up sequence. It begins by determining if a JTAG request is pending. The JTAG test circuitry is for production test and use by software development systems. The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.3.5 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether or not the Boot Assist Flash bypass mode is enabled. If this mode is enabled, any eventual code in the BAF is not executed. If the Boot Assist Flash bypass mode is not enabled, the code in the BAF is executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the BAF bypass mode. Therefore, this mode is not available for customer use. With the BAF bypass mode disabled, code in the Boot Assist Flash is always be executed during a boot-up sequence.

The Boot Assist Flash code is written by the device manufacturer. Among other things, the BAF code runs the Serial Boot Loader. This involves setting up pins on the device to act as a UART, receiving a file using a defined format and transferring the program portion of the file to RAM. Once the program is installed, the SSCM causes the IOP (I/O Processor) to begin execution at the start address specified in the header portion of the program file.

8.4.3.6 Is the Hardware Security Module enabled? (state C)

The SSCM examines a status bit to determine if the Hardware Security Module (HSM) is enabled. A DCF record in the TEST area is responsible for enabling/disabling the HSM. In the present example, it is assumed that the HSM is enabled.

8.4.3.7 Locate HSM Boot Header (state 44)

The SSCM is responsible for locating the HSM boot header. The SSCM reads several memory locations in flash memory to determine whether a valid HSM boot header is present. Specifically, the SSCM reads locations 0x60_C000, 0x61_0000, and 0x62_0000. A valid HSM boot header consists of three words: an HSM_Boot_Header_ID, a start address for the HSM application code, and a third word that is reserved for future use. By definition a valid HSM_Boot_Header_ID is 0xFFFF_0000_FFFF_0000.

If a valid HSM_Boot_Header_ID is found, the SSCM transfers the start address to the Mode Entry Module (MC_ME). When reset is released to the HSM, the HSM start address is transferred from the MC_ME to the HSM and HSM code execution begins at that point.

8.4.3.8 Valid Hardware Security Module header file? (state D)

In the present scenario, a valid HSM boot header is present as determined in state 44.

8.4.3.9 Provide reset vectors to IOP and HSM (state 25—go to state 22 and 26)

Under the control of the SSCM, the HSM start address obtained from the HSM boot header is transferred to the MC_ME.

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address of the BAF code loaded into the Boot Assist Flash is transferred to the MC_ME. The SSCM releases reset to the IOP and HSM and then turns on the clock to both modules. The BAF code start address is transferred from the MC_ME to the IOP. At this time, the HSM code start address is also transferred from the MC_ME to the HSM under the control of the SSCM.

8.4.3.10 HSM code and BAF code execution begins (state 26)

After the reset signal is released and the respective clock is turned on to the HSM and the IOP, code execution begins. The HSM begins executing its application code and the IOP begins execution of code in the Boot Assist Flash.

8.4.3.11 Verification of HSM host boot block (state 27)

HSM applications code can optionally be written to confirm that the correct start address for the HSM applications code was obtained from the HSM boot header file. This step is optional and requires that the HSM applications code and the HSM boot header file match.

If a new revision of the HSM code is created with a start address that is different from the prior revision, the HSM applications code must be modified to take into account that there is a different start address. The HSM Boot Header must also be appropriately modified.

8.4.3.12 Set HSM Boot Ready flag (state 28)

The HSM hardware sets the HSM Boot Ready flag when the HSM becomes fully initialized.

8.4.3.13 Execution of HSM application code begins (state 29)

The HSM has been properly enabled, a valid start address for code execution has been supplied and the HSM begins normal code execution.

8.4.3.14 IOP begins BAF code execution (state 22)

The BAF code begins by initializing registers and applying device settings. The BAF code is written by the device manufacturer and changes from device to device.

8.4.3.15 IOP applies device settings (state 23)

The IO Processor, executing code in the Boot Assist Flash, configures the SPC57EM80xx with various initialization parameters. The System Status and Configuration Module (SSCM) has already applied some configuration information from the DCF record.

8.4.3.16 Calibration Sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production SPC57EM80xx (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The emulation and debug device (ED) consists of a regular production SPC57EM80xx (PO) and a special Buddy Device (BD) in a single package.

The I/O Processor (IOP) executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is detected, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of SPC57EM80xx reset.

In this example, it is assumed that an emulation and debug device (ED) is not being used in place of a regular production SPC57EM80xx.

8.4.3.17 Is HSM enabled? (decision point E)

The IOP, executing BAF code, checks to see if the HSM is enabled. In this example, it is assumed that the HSM is enabled.

8.4.3.18 Wait for HSM to set HSM_Boot_Ready flag? (decision point F)

The IOP determines whether it must wait until the HSM becomes ready before the IOP begins a search for the boot header file. If the IOP is directed to wait for the HSM to set its

HSM_Boot_Ready flag, the IOP goes to state 30 until the “HSM_Boot_Ready” flag is set. Afterwards, the IOP begins a search for the Boot Header file in state 31.

If the IOP is not directed to wait for the HSM to set its HSM_Boot_Ready flag, the IOP immediately begins a search for the boot header file in state 31.

8.4.3.19 Wait until HSM_Boot_Ready flag sets (state 30)

The IOP waits until the HSM_Boot_Ready flag is set.

8.4.3.20 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. This is the header file for the CPU that starts executing the your application code. Generally, the BOOT CPU is either Core_0 or Core_1.

The Boot CPU header is programmed into flash memory at the same time your application program is programmed into flash memory. The IOP searches for the boot header file which can be located at one of eight addresses:

Note: Addresses are searched in the following order.

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid boot header begins with the value 0x005A.

The boot header structure consists of seven words:

- Boot Header_ID/Boot_CPU
- Start address
- Configuration bits
- Configuration bits
- CPU_0 reset vector
- CPU_1 reset vector
- Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

Only four bits in the 16-bit Boot_CPU field are used. Bit 0 selects the I/O Processor, bit 1 selects CPU_0, bit 2 selects CPU_1, and bit 3 selects the Checker Core_0s. Bits 4–15 are not implemented.

Note: Checker Core_0s can only be used if CPU_0 is also used. Both cores must have the same reset vector.

8.4.3.21 Valid boot header is found (state N)

In the present example, a valid boot header is assumed to be present in flash memory.

8.4.3.22 Decode boot CPU (state 32)

The IOP decodes the boot header and then writes the reset vectors for CPU_0, CPU_1, and the Checker Core_0s to the Mode Entry Module.

8.4.3.23 Lock BAF access (state 33)

Further access to the BAF is locked against further code execution, but it is readable.

8.4.3.24 Boot From Internal flash (state 34)

The MC_ME transfers the reset vectors to the respective CPUs and code execution for each of the cores begins at their respective reset vector address.

8.4.4 Sequence from MC_RGM IDLE to IOP and Boot CPU running code (HSM disabled)

This path is taken when operation of the IOP, but not the HSM, is desired. In this scenario, a Boot CPU is selected and starts executing application code. Also, this is the scenario that is used to start all of the processor cores except the HSM: CPU_0, CPU_1, Checker Core_0s, and the IOP.

8.4.4.1 Assumptions

- Boot Assist Flash bypass mode is not enabled (execute BAF code).
- HSM is not enabled.
- Application code for the IOP is programmed into Boot Assist Flash memory.
- Application code for the Boot CPU is programmed into flash memory.
- A valid boot header for CPU_0, CPU_1 and Checker Core_0s has been programmed into flash memory.
 - Boot Header_ID
 - Boot CPU selection
 - Boot CPU start address (address of first instruction in application code)
 - CPU_0 reset vector
 - CPU_1 reset vector
 - Checker Core_0s reset vector
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.4.2 Reset Generation Module has entered idle state (state 1 and 2)

The Reset Generation Module (MC_RGM) enters the IDLE[FUNC] state and completes all tasks. Then, the MC_RGM signals the System Status and Control Module (SSCM) that the MC_RGM has become idle and that the SSCM is to take over control of the boot-up sequence. At this point, LBIST and MBIST have completed their test cycles, the data in the DCF record has been written to the appropriate registers and all the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.4.3 Is a JTAG request pending? (state A)

The SSCM is now in charge of the boot-up sequence. It begins by determining whether a JTAG request is pending. The JTAG test circuitry is for production test and used by software development systems. The JTAG mode has no user functions and should never be used in

a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.4.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether the Boot Assist Flash bypass mode is enabled. If this mode is enabled, any eventual code in the BAF is not executed. If the Boot Assist Flash bypass mode is not enabled, the code in the BAF is executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. Therefore, this mode is not available for customer use. This means that the code in the Boot Assist Flash is always executed during a boot-up sequence.

The Boot Assist Flash code is written by the device manufacturer. Among other things, the BAF code runs the serial boot loader. This involves setting up pins on the device to act as a UART, receiving a file, using a defined format, and transferring the program portion of the file to RAM. Once the program is installed, the SSCM causes the IOP to begin execution at the start address specified in the header portion of the program file.

8.4.4.5 Is the Hardware Security Module enabled? (state C)

The SSCM examines a status bit to determine if the HSM is enabled. A DCF record in the TEST area is responsible for enabling/disabling the HSM. In the present example, it is assumed that the HSM is not enabled.

8.4.4.6 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code loaded into the Boot Assist Flash is transferred to the MC_ME.

The SSCM releases reset to the I/O Processor (IOP) and then turns on the clock to the IOP. The BAF code start address is transferred to the IOP at this time under the control of the SSCM. Execution of the Boot Assist Flash code begins.

8.4.4.7 BAF code execution begins (state 22)

After the reset signal is released to the IOP, BAF code execution begins.

8.4.4.8 The IOP executes code to apply device setting (state 23)

The IOP executes BAF code, written by the manufacturer, to apply specific device settings to the SPC57EM80xx.

The BAF code begins by initializing registers and applying device settings. The BAF code, written by the device manufacturer, changes from device to device.

8.4.4.9 Calibration sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production SPC57EM80xx (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of SPC57EM80xx reset.

In this example, it is assumed that an ED is not being used in place of a regular SPC57EM80xx production device.

8.4.4.10 Is HSM enabled? (decision point E)

The IOP determines whether the HSM is enabled by examining a status bit in the HSM. In the present example, it is assumed that the HSM is not enabled.

8.4.4.11 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that a valid Boot Header is present.

This is the header file that specifies which Boot CPU starts executing the user application code. Generally, the Boot CPU is either Core_0 or Core_1. The boot header file also contains the reset vector addresses for Core_0, Core_1, and the Checker Core_0s.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of seven words:

- Boot Header_ID/Boot_CPU
- Start address
- Configuration bits
- Configuration bits
- CPU_0 reset vector
- CPU_1 reset vector
- Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

Only four bits in the 16-bit Boot_CPU field are used. Bit 0 selects the I/O Processor, bit 1 selects CPU_0, bit 2 selects CPU_1, and bit 3 selects the Checker Core_0s. Bits 4–15 are not implemented.

8.4.4.12 Is a valid boot header present? (decision point N)

In the present example, a valid boot header is assumed to be present in flash memory.

8.4.4.13 Decode boot CPU (state 32)

The I/O Processor decodes the boot header and then writes the reset vectors for CPU_0, CPU_1, and the Checker Core_0s to the Mode Entry Module (MC_ME).

8.4.4.14 Lock BAF access (state 33)

Further access to the Boot Assist Flash is locked.

8.4.4.15 Boot from internal flash (state 34)

The MC_ME transfers the reset vectors to the respective CPUs and code execution for each of the cores begins at their respective reset vector.

8.4.5 Path from MC_RGM IDLE to serial boot mode

This path is taken when no application program or valid boot headers for the HSM or CPU_0, CPU_1, or Checker Core_0s is programmed into flash memory. This case is taken when a device has not been programmed with a user application. This is an unusual case in that it describes an improperly programmed device. It is shown here for illustration.

8.4.5.1 Initial conditions

- No valid boot header for CPU_0, CPU_1, and Checker Core_0s has been programmed into flash memory.
- BAF bypass mode is NOT enabled (execute BAF code).
- The HSM is enabled.
- Application code for the IOP is programmed into the BAF.
- Application code for the HSM is not programmed into secure flash memory.
- Application code for the Boot CPU is not programmed into flash memory.
- A valid boot header for the HSM has not been written into flash memory.
- The Life Cycle variable is set to FACTORY, indicating an unprogrammed device.
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.5.2 Reset Generation Module has entered idle state (state 1 and 2)

The MC_RGM enters the IDLE[FUNC] state and completes all tasks. Then, the MC_RGM signals the SSCM that the MC_RGM has become idle and that the SSCM is to take over control of the boot-up sequence. At this point, LBIST and MBIST have completed their test cycles, the data in the DCF record has been written to the appropriate registers and all the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.5.3 Is a JTAG request pending? (state A)

The SSCM is now in charge of the boot-up sequence. It begins by determining if a JTAG request is pending. The JTAG test circuitry is for production test and use by software development systems. The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.5.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether the BAF bypass mode is enabled. If this mode is enabled, any eventual code in the BAF is not executed. If the BAF bypass mode is not enabled, the code in the BAF is executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. Therefore, this mode is not available for use. This means that the code in the BAF is always executed during a boot-up sequence.

The Boot Assist Flash code is written by the device manufacturer. Among other things, the BAF code runs the serial boot loader. This involves setting up pins on the device to act as a UART, receiving a file, using a defined format, and transferring the program portion of the file to RAM. Once the program is installed, the SSCM causes the IOP to begin execution at the start address specified in the header portion of the program file.

8.4.5.5 Is the Hardware Security Module enabled? (state C)

The SSCM examines a status bit to determine if the HSM is enabled. A DCF record in the TEST area is responsible for enabling/disabling the HSM. In the present example, it is assumed that the HSM is enabled.

8.4.5.6 Locate HSM boot header (state 44)

The SSCM is responsible for locating the HSM boot header. The SSCM reads several memory locations in flash memory to determine whether a valid HSM boot header is present. Specifically, the SSCM reads locations 0x60_0000, 0x60_4000, and 0x61_4000. A valid HSM boot header consists of three words: an HSM_Boot_Header_ID, a Start Address for the HSM application code, and a third word that is reserved for future use. By definition, a valid HSM_Boot_Header_ID is 0xFFFF_0000_FFFF_0000.

8.4.5.7 Valid Hardware Security Module header file? (state D)

In the present scenario, no valid HSM boot header is present. In this case, the System Status and Control Module takes the same path as if the HSM was not enabled at decision point C.

8.4.5.8 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code in the Boot Assist Flash is transferred from the DCF record to the MC_ME by the SSCM.

The SSCM releases reset to the IOP and then turns on the clock to the IOP. The clock to the HSM is turned off in this state even though the HSM was originally enabled. Because no valid header file for the HSM is found, the IOP goes to state 21 from decision point D, which turns the HSM clock off. The start address is transferred to the IOP at this time under the control of the SSCM and the IOP begins execution of the BAF code.

8.4.5.9 IOP begins BAF code execution (state 22)

After the reset signal is released and the respective clocks are turned on to the IOP, the IOP begins execution of code in the Boot Assist Flash.

8.4.5.10 IOP continues BAF code execution (state 23)

The BAF code begins by initializing registers and applying device settings. The BAF code is written by the device manufacturer and changes from device to device.

8.4.5.11 Calibration Sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production SPC57EM80xx (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of SPC57EM80xx Reset.

In this example, it is assumed that an ED is not being used in place of a regular SPC57EM80xx production device.

8.4.5.12 IOP checks to determine if HSM is enabled (state E)

The IOP, executing BAF code, checks to see if the HSM is enabled. In the present case, the SSCM has already disabled the clock to the HSM. Therefore, the HSM is not enabled.

8.4.5.13 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that no boot header file is present.

This is the header file for the CPU that starts executing the user application code. Generally, the BOOT CPU is either Core_0 or Core_1.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of seven words:

- Boot Header_ID/Boot_CPU
- Start address
- Configuration bits
- Configuration bits
- CPU_0 reset vector
- CPU_1 reset vector
- Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

Only four bits in the 16-bit Boot_CPU field are used. Bit 0 selects the I/O Processor, bit 1 selects CPU_0, bit 2 selects CPU_1, and bit 3 selects the Checker Core_0s. Bits 4–15 are not implemented.

8.4.5.14 Valid boot header is not found (decision point N)

The IOP, executing code in the Boot Assist Flash, does not find a valid boot header file in flash memory. Because there is no valid boot header, serial boot mode must be entered to obtain an application program.

Note: This mode receives a program to be executed over a serial port implemented using the LINFlexD port. Once the program is received, using a defined format, the IOP jumps to the start address of the program and begins execution.

8.4.5.15 Initialize RAM (state 35)

The IOP, executing code in the Boot Assist Flash, initializes RAM in preparation for entering serial boot mode. Serial boot mode configures the LINFlexD port to receive code from an external source. The LINFlexD port comes in a number of hardware configurations. The SPC57EM80xx uses LINFlexD, which implements a basic UART. Code in the BAF operates the LINFlexD module and implements the protocol.

8.4.5.16 Enter serial boot mode (state 14)

[Figure 43 \(Boot-up sequence, part E\)](#) shows the boot loader flow.

8.4.5.17 Life Cycle check indicates FACTORY (decision point G)

There are two possible settings for the Life Cycle parameter—FIELD and FACTORY. A setting of FIELD indicates that application code has been programmed into the flash memory of the device. In this case, serial boot mode is exited. The IOP enters a “wait mode” and remains there until a watchdog reset occurs. A setting of FACTORY means that there is no application code programmed into the flash memory. For the present example a setting of FACTORY is assumed so there is no application code present.

8.4.5.18 Receive and install application code

In general, a serial link is implemented using the LINFlexD port and a particular protocol for data transmission has been defined and implemented in the Boot Assist Flash code. Once the LINFlexD port is configured, the serial boot loader waits to receive the code.

Note: There is a software watchdog timer that is started by the BAF code. If a program is not received before the watchdog timer timeout, a reset occurs.

- Configure LINFlexD module and external pins (state 37).
- Wait for START WORD (state 38).
- Receive START WORD (state 39).
- Receive START ADDRESS (state 40).
- Receive DOWNLOAD SIZE (state 41).
- Receive CODE (state 42).
- Branch to START ADDRESS (state 43).

Application code, using the IOP, begins at the received START ADDRESS.

8.4.6 Path from MC_RGM IDLE with IOP and HSM enabled to watchdog timer timeout

This path is taken when the operation of the IOP and the HSM is desired but there is no valid boot header file or HSM header file and the Life Cycle variable is set to FIELD.

The Life Cycle variable of FIELD indicates that the device was programmed with application code and the appropriate boot header files. This particular path is taken only if a catastrophic event has occurred or the device is improperly programmed.

8.4.6.1 Initial conditions

- Boot Assist Flash bypass mode is not enabled (execute BAF code).
- The HSM is enabled.
- A valid boot header for the HSM has not been programmed into flash memory.
- A valid boot header for CPU_0, CPU_1 and Checker Core_0s has not been programmed into flash memory.
 - Boot Header_ID
 - Boot CPU selection
 - Boot CPU start address (address of first instruction in application code)
 - CPU_0 reset vector
 - CPU_1 reset vector
 - Checker Core_0s reset vector
- The Life Cycle variable is set to FIELD, indicating a programmed device.
- The MC_RGM has passed control to the SSCM during the IDLE[FUNC] state.

8.4.6.2 Reset Generation Module has entered idle state (state 1 and 2)

The MC_RGM enters the IDLE[FUNC] state and completes all tasks. Then, the MC_RGM signals the SSCM that the MC_RGM has become idle and that the SSCM is to take over control of the boot-up sequence. At this point, LBIST and MBIST have completed their test cycles, the data in the DCF record has been written to the appropriate registers, and all the trim values for the analog portions of the chip have been installed in their proper locations.

8.4.6.3 Is a JTAG request pending? (state A)

The SSCM is now in charge of the boot-up sequence. It begins by determining if a JTAG request is pending. The JTAG test circuitry is for production test and use by software

development systems. The JTAG mode has no user functions and should never be used in a user application. System designers must ensure that the external JTAG request pins cannot inadvertently cause a JTAG test request.

8.4.6.4 Is the Boot Assist Flash bypass mode enabled? (state B)

The SSCM examines a status bit to determine whether or not the boot assist flash bypass mode is enabled. If this mode is enabled, any eventual code in the Boot Assist Flash is not executed. If the Boot Assist Flash bypass mode is not enabled, the code in the BAF is executed. The BAF bypass mode is enabled/disabled using a DCF record.

The DCF record supplied by the factory disables the bypass mode. Therefore, this mode is not available for use. This means that the code in the BAF is always executed during a boot-up sequence.

The BAF code is written by the device manufacturer. Among other things, the BAF code runs the serial boot loader. This involves setting up pins on the device to act as a UART, receiving a file, using a defined format, and transferring the program portion of the file to RAM. Once the program is installed, the SSCM causes the IOP to begin execution at the start address specified in the header portion of the program file.

8.4.6.5 Is the Hardware Security Module enabled? (state C)

The SSCM examines a status bit to determine if the HSM is enabled. A DCF record in the TEST area is responsible for enabling/disabling the HSM. In the present example, it is assumed that the HSM is enabled.

8.4.6.6 Locate HSM boot header (state 44)

The SSCM is responsible for locating the HSM boot header. The SSCM reads several memory locations in flash memory to determine whether a valid HSM boot header is present. Specifically, the SSCM reads locations 0x60_0000, 0x60_4000 and 0x61_4000. A valid HSM boot header consists of three words: an HSM_Boot_Header_ID, a Start Address for the HSM application code, and a third word which is reserved for future use. By definition, a valid HSM_Boot_Header_ID is 0xFFFF_0000_FFFF_0000.

8.4.6.7 Valid Hardware Security Module header file? (state D)

In the present scenario, no valid HSM boot header is present. In this case, the SSCM takes the same path as if the HSM was not enabled at decision point C.

8.4.6.8 Provide reset vectors to IOP (state 21)

During PHASE3[DEST] of the Reset Generation Module's sequence, the start address for execution of the BAF code in the Boot Assist Flash is transferred from the DCF record to the MC_ME.

The SSCM releases reset to the IOP and then turns on the clock to the IOP. The clock to the HSM is turned off in this state even though the HSM was originally enabled. Because no valid header file for the HSM is found, the IOP goes to state 21 from decision point D, which turns the HSM clock off. The start address is transferred to the IOP at this time under the control of the SSCM and the IOP begins execution of the Boot Assist Flash code.

8.4.6.9 IOP begins BAF code execution (state 22)

After the reset signal is released and the respective clocks are turned on to the IOP, the IOP begins execution of code in the Boot Assist Flash.

8.4.6.10 IOP continues BAF code execution (state 23)

The BAF code begins by initializing registers and applying device settings. The BAF code is written by the device manufacturer and changes from device to device.

8.4.6.11 Calibration sequence (state 24)

This state is used to detect the presence of an emulation and debug device (ED) normally used in place of a regular production SPC57EM80xx (PO). The purpose of the emulation and debug device is to facilitate the use of external software development tools, such as CodeWarrior. The ED consists of a PO and a special Buddy Device (BD) in a single package.

The IOP executing BAF code writes a special sequence to the emulation and debug device. If no emulation and debug device is present, the IOP steps to decision point E.

A discussion of software development and software emulation tools is beyond the scope of this explanation of SPC57EM80xx reset.

In this example, it is assumed that an ED is not being used in place of a regular SPC57EM80xx production device.

8.4.6.12 IOP checks to determine if HSM is enabled (state E)

The IOP, executing BAF code, checks to see if the HSM is enabled. In the present case, the SSCM has already disabled the clock to the HSM. Therefore, the HSM is not enabled.

8.4.6.13 IOP searches for boot header (state 31)

The IOP continues code execution by searching for the boot header. In the present example, it is assumed that no boot header file is present.

This is the header file for the CPU that starts executing the user application code. Generally, the BOOT CPU is either Core_0 or Core_1.

The Boot CPU header is programmed into flash memory at the same time the user application program is programmed into flash memory. The IOP searches for the boot header, which can be located at one of eight addresses:

- 0xFC_0000
- 0xFC_4000
- 0xFC_8000
- 0xFC_C000
- 0x100_0000
- 0x104_0000
- 0x108_0000
- 0x10C_0000

A valid Boot Header_ID begins with the value 0x005A.

The boot header structure consists of seven words:

- Boot Header_ID/Boot_CPU
- Start address
- Configuration bits
- Configuration bits
- CPU_0 reset vector
- CPU_1 reset vector
- Checker Core_0s reset vector

To indicate a valid boot header, the 16-bit Boot_Header_ID field is written with the value 0x005A.

Only four bits in the 16-bit Boot_CPU field are used. Bit 0 selects the I/O Processor, bit 1 selects CPU_0, bit 2 selects CPU_1, and bit 3 selects the Checker Core_0s. Bits 4–15 are not implemented.

8.4.6.14 Valid boot header is not found (decision point N)

The IOP, executing code in the Boot Assist Flash, does not find a valid boot header file in flash memory. Because there is no valid boot header, the serial boot mode must be entered to obtain an application program.

Note: This mode receives a program to be executed over a serial port implemented using the LINFlexD port. Once the program is received, using a defined format, the IOP jumps to the start address of the program and begins execution.

8.4.6.15 Initialize RAM (state 35)

The IOP, executing code in the Boot Assist Flash, initializes RAM areas in preparation for entering the serial boot mode. The serial boot mode configures the LINFlexD port to receive code from an external source. The LINFlexD port comes in a number of hardware configurations. The SPC57EM80xx uses LINFlexD, which implements a basic UART. Code in the BAF operates the LINFlexD module and implements the protocol.

8.4.6.16 Enter serial boot mode (state 14)

[Figure 43 \(Boot-up sequence, part E\)](#) shows the boot loader flow.

8.4.6.17 Life Cycle check indicates FIELD (decision point G)

There are two possible settings for the Life Cycle parameter—FIELD and FACTORY. A setting of FIELD indicates that application code has been programmed into the flash memory of the device. In this case, the IOP enters a “wait mode” and remain there until a watchdog reset occurs.

8.4.6.18 Stop—wait for watchdog (state 36)

The present example would only be encountered when the SPC57EM80xx's program flash memory is incorrectly programmed.

9 Device Configuration Format (DCF) Records

9.1 Introduction

Device Configuration Format (DCF) records are used to configure certain registers in the device during system boot while the reset signal is asserted. An individual DCF record consists of a pointer to the location of a register internal to the device and the data to be written to that register.

There are two broad categories of DCF records, TEST DCF Records and UTEST DCF Records. TEST DCF records are developed by the factory and are used mainly to program registers involved in trimming trip points for voltage comparators, adjusting analog to digital voltage supplies, trimming oscillator frequencies, and enabling RAM repair. However these records can also be used to write any DCF client. The TEST DCF Records are programmed into TEST flash during production and cannot be modified. TEST flash is not visible to the user.

The second set of DCF records are UTEST DCF records. Some UTEST DCF records are written by the factory and programmed during production testing (see [Table 16](#) in [Chapter 5: Memory Map](#)). Others are written by the end user and programmed at the same time application code is programmed into the flash memory. User-supplied UTEST DCF records start at the next location in the UTEST memory map following the UTEST DCF records programmed into the flash memory during factory production. The user-defined DCF records set up the initial memory map, define which tests the Self-Test Control Unit (STCU2) runs during the boot sequence, enable the HSM, assign memory blocks as OTP, assign flash blocks to be associated with specific password groups and assign flash memory blocks to specific tamper detect regions.

System boot is a complex process requiring a considerable amount of initialization to take place before releasing reset. Before the device can be used in an application, the user application code, reset vectors for all of the CPUs and the DCF records must be properly programmed into their respective flash memories.

When power is applied to a properly programmed device, the Power Management Controller (PMC) takes control of the device. After the system power supplies have reached predefined levels, the Power Management Controller signals the Reset Generation Module (RGM) to begin the boot sequence. During the boot sequence, the RGM enables another internal module, the System Status and Control Module (SSCM), to read the device configuration records and then write the configuration information to the specified registers. After registers are initialized, the SSCM starts the (STCU2), which begins running the tasks enabled by the DCF record information.

9.2 DCF clients

DCF clients are 32-bit wide hardware registers inside a module, that receive and store the data from a DCF record. This stored data is used to initialize registers and to configure features. DCF Clients have a default value before any DCF Records are written, and may have special writing constraints, such as, 'Write Once' or allowing bits to be written from '1' to '0' only or vice versa. DCF clients need not implement all 32 bits. DCF clients maybe designated 'TEST DCF record only', which means that only DCF Records stored in TEST flash can write to the DCF Client.

A list of DCF clients is shown in [Table 112](#). (TEST DCF Record Only Clients are not shown as these are not accessible by the user).

The DCF Records select the 'target' DCF client by a 30-bit field in the DCF Record consisting of a 15-bit 'Chip Select' field and a 15-bit Address field. Each module that includes DCF clients is assigned a Chip Select during chip definition. The address field is only relevant to the address decoding within that module and may not necessarily relate to the address of a register visible to software.

9.3 DCF records

DCF records appear as contiguous double-word (64-bit) entries programmed in a reserved area of OTP UTEST flash memory beginning at 0x0040_0200.

The structure of a DCF Record is shown in [Figure 44](#).

Figure 44. DCF record structure

Table 110. DCF record field description

Field	Description
0–31 Data[0:31]	32 bits of data that is to be written to the DCF Client
32–46 CSn	Chip Select n One Chip select is asserted ('1') per DCF record to select the target module for the DCF client. All other Chip Selects should be negated ('0')
47–61 Address[16:2]	Address of the DCF client within the selected module Note: Address decoding for DCF clients may not match the standard software address map decoding. Details of DCF Client addresses are defined in each module chapter

Table 110. DCF record field description

Field	Description
62 Parity	Parity Bit for the DCF Record Note: This bit is NOT implemented for DCF Client written from UTEST
63 Stop	Stop bit This bit indicates the end the list of DCF Records. Stop = '0' - NOT the end of the list Stop = '1' - End of the list Note: The Erased state of flash is 0xFFFF_FFFF_FFFF_FFFF. Therefore the list ends with the first unprogrammed double word. This location can be programmed with a new record to extend the list

The following structure must be present:

- The first record must be a start record.
- DCF records containing configuration data must immediately follow the start record with no blank records between—an unprogrammed record is interpreted as a stop record and no DCF records following that record are processed.
- The end of the configuration records are indicated by the presence of a stop record.

Each record is 64 bits in length. [Figure 45](#) shows the DCF start record.

Warning: The start record must be placed at the beginning of the DCF area in UTEST flash memory to indicate to the device that the following data records must be processed.

Figure 45. DCF start record

0x00 0:31	0x04 32:63
0x05AA55AF	0x00000000

The stop bit designates the last device configuration record in a set of records. Normally, the stop bit is never set in a valid UTEST DCF record programmed during production, since this would prevent additional UTEST records from being appended to the factory programmed UTEST DCF records. However, the flash memory location following the last UTEST DCF record programmed at the factory is an unprogrammed location. Therefore, that location's contents is 0xFFFF_FFFF_FFFF_FFFF. Thus, the stop bit location in this unprogrammed flash memory location is a logic 1, signifying that this is the last DCF record and it is not to be acted upon.

During the boot sequence, the SSCM uses the DCF records to program various registers before reset is released. Some device configuration records are calculated during production testing and programmed into the TEST flash memory area. Other DCF records are developed by the end user and programmed into the UTEST flash area. A device configuration record simply consists of an internal register address and a data field. During system boot, while the reset signal is asserted, the SSCM reads the device configuration

records and writes the data to the appropriate internal module registers. Thus, many operational aspects of the device are properly configured when the reset signal is released and normal device operation begins.

The stop record indicates the end of DCF records to be processed. The general format of the stop record is shown in [Figure 46](#). Only the stop bit needs to be 1 in order to form a stop record—all other bits are ignored. An unprogrammed location in UTEST flash is interpreted as a stop record.

Figure 46. DCF stop record

0:31	32:62	63
Reserved	Reserved	1

If n data records are to be stored in UTEST, the data structure must be as shown in [Table 111](#).

Table 111. Series of DCF records in UTEST flash memory

ADDR offset	DATA			
0x00	0x05AA55AF			
0x04	0x00000000			STOP=0
0x08	WDATA[31:0]			
0x0C	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
0x10	WDATA[31:0]			
0x14	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
$8n-1 + 0x0$	Reserved			
$8n-1 + 0x4$	Reserved			1
$8n + 0x0$				
$8n + 0x4$				

Warning: There must never be an unprogrammed record in the DCF data structure, as it is interpreted as a stop record and subsequent records are ignored. This allows one to program the records in several sessions, each time appending new records at the end of the list, as shown in [Figure 47](#).

It is possible for more than one DCF Record to write to the same DCF client. In this case, as shown in the “Extension” part of [Figure 47 \(Appending DCF records\)](#), the later record usually overrides a DCF client value set by a previous record. However, not all DCF clients allow overwrites; this depends on the DCF client implementation.

Figure 47. Appending DCF records

9.3.1 UTEST DCF records

UTEST DCF records are located in the UTEST flash memory area (refer to UTEST flash memory map in the Memory map chapter). Some UTEST DCF records are programmed at the factory. The user may add additional USER DCF records beginning with the first unprogrammed location following the factory programmed UTEST DCF records. An unprogrammed location in flash memory contains 0xFFFF_FFFF.

When programming UTEST DCF records at the factory, the records must start at the first address in the UTEST flash memory area and be continuous; that is, one UTEST DCF record must immediately follow the previous UTEST DCF record. An unprogrammed location in the UTEST flash memory area is interpreted by the SSCM as the end of the UTEST DCF records. When this happens, the SSCM passes control of the boot sequence to the Reset Generation Module, which directs the STCU to begin memory built in self test (MBIST) and logic built in self test (LBIST) execution.

9.4 DCF client table

A list of DCF clients is shown in [Table 112](#). Various attributes of the DCF clients are listed in these tables. The following list explains the meaning of the columns and give a description of the attributes of these DCF clients.

- **DCF Chip Select**
The CS field is a 15-bit field with each bit in the field assigned to a particular module. These bits act as module select signals for the internal modules. Only one bit in this field should be set in a DCF record.
- **DCF address**
The ADDR field is a 15-bit field that specifies an internal address for a DCF client. These addresses are used only by the SSCM when interpreting DCF records and writing the data to specified modules.
- **DCF Client Description**
This field contains the name of the DCF clients.
- **Reset value of DCF client**
This field contains the reset value of DCF client before being written by the SSCM with the associated DCF record.
- **Typical value of DCF client**
This field contains a typical value that you might program into the various DCF clients. This field is for information only.
- **IPS read**
This column specifies whether or not a DCF client can be read by user software after the release of reset.
- **DCF client special strategy**
Though all DCF records have the same format, they can be used in different ways. As the device is being designed, registers must be designated as Device Configuration Format clients if they need to be written with a DCF record. There are other features that must be designated for DCF clients. For instance, DCF clients can have several different write strategies—Parity, Write Once, Triple Voted + Parity + Check with second write, Triple voted + Check with second write, or no strategy at all. The SSCM examines the DCF client to determine the correct special strategy to use and then appropriately write a DCF record to that client. The following list defines the special strategies.
 - **None**
No special DCF strategy is used.
 - **Parity**
Not implemented for DCF clients. Only used for TEST only DCF clients not accessible by the user.
 - **Write Once**
A register using the Write Once strategy can only be written once. The DCF client ignores subsequent writes.
 - **Triple Voted**
DCF clients that use the Triple Voted strategy have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value.

Triple voting allows for a 'bit-flip' error to occur without changing the DCF client output data.

- Triple Voted with second write

DCF clients that use the Triple Voted with 2nd write strategy have three copies of the register. The SSCM writes to all three registers in a single write cycle. The outputs of the three registers are majority voted together to determine the correct data value. During the second execution of Phase 3 of the reset sequence, the SSCM attempts to write the DCF client again. At this time, the DCF client checks to see that the register contains the same data that is being written again.

- Write 0 only

A bit in a DCF client can only be written from a logic 1 to a logic 0. An attempt to write a bit with this attribute to a logic 1 is ignored.

- Write 1 only

A bit in a DCF client can only be written from a logic 0 to a logic 1. An attempt to write a bit with this attribute to a logic 0 is ignored.

- DCF order dependency in flash memory

This column details whether or not there are special conditions on the location of a particular DCF record in flash memory.

10 Power management

10.1 Overview

SPC57EM80xx microcontrollers include a robust power management infrastructure that enables applications to select among various operational and low-power modes and to monitor internal voltages for high- and low-voltage conditions. The monitoring capability is also used to ensure supply voltages and internal voltages are within the required ranges before the microcontroller can leave reset. This chapter gives an overview of the built-in power management features.

The power management infrastructure comprises the following modules:

- Power Control Unit (MC_PCU)
- Clock Generation Module (MC_CGM)
- Mode Entry Module (MC_ME)

This chapter describes these modules in brief. For complete details, see the respective module chapters.

The MC_CGM generates reference clocks for all the chip blocks. It works in conjunction with internal clock gating logic to implement low power modes.

The MC_PCU provides a status register and a submodule, the PMC_dig (Power Management Control Digital Interface), provides an interface to configure and control internal voltages.

The MC_ME module controls chip operational modes and mode transition sequences. It also contains configuration, control and status registers accessible for the application.

The SPC57EM80xx has two types of modes, SYSTEM modes and USER modes.

SYSTEM modes:

- SYSTEM modes are entered automatically on system events or on application request.
- The SYSTEM modes are: RESET, SAFE, TEST and DRUN.

Table 115. SYSTEM modes

Mode	Description	Entry	Exit
RESET	System remains in this mode until all resources are available for S/W to take device control. RESET manages H/W initialization of chip configuration, voltage regulators, oscillators, PLLs, and flash.	System reset assertion from RGM	System reset deassertion from RGM
SAFE	May be entered on detection of a recoverable error. Forces system into predefined safe configuration from which the system may try to recover.	H/W fail, S/W request from DRUN, TEST and RUNx	System reset assertion, DRUN through S/W
TEST	Control environment for device self-test. Allows application to run its own self-test like flash checksum and RAM BIST.	Software request from DRUN	System reset asserted, DRUN through S/W
DRUN	Entry mode for the embedded software. Provides full system accessibility and enables system configuration. Provides gate to enter USER modes. BAF, when present, is executed in DRUN mode.	Reset removed, from SAFE, TEST and RUNx through S/W, STANDBY wakeup	Reset applied, RUNx, TEST through S/W, SAFE through S/W or H/W fail

USER modes:

- USER modes control performance and consumption during normal application operation. The modes are organized according to the performance provided.
- The USER modes are RUNx, HALT, and STOP.
- Each mode is entered by writing a dedicated register protected by a key, to avoid unwanted transition.
- [Figure 50](#) shows the mode relationships.

Table 116. USER modes

Mode	Description	Entry	Exit
RUNx	These are software running modes where most of the processing activity is done. These run modes allow the user to enable different clock and power configurations of the system with respect to each other.	Software request from DRUN, interrupt event from HALT, wakeup request from STOP	Reset asserted, SAFE through S/W or H/W fail, RUNx, HALT, STOP, STANDBY through S/W
HALT	Reduced-activity low-power mode during which the core clock is disabled. It can be configured to switch off analog peripherals like PLL, flash, main voltage regulator, etc., for efficient power management at the cost of higher wakeup latency.	Software request from RUNx	Reset asserted, SAFE on hardware failure, RUNx on interrupt event
STOP	Advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including the oscillator for efficient power management at the cost of higher wakeup latency.	Software request from RUNx	Reset asserted, SAFE on hardware failure, RUNx on wakeup event

Figure 50. Mode relationships

10.1.1 Power management framework

The power management framework supports a variety of configuration options. See [Figure 51](#) for more details. SPC57EM80xx implements a unique core voltage power domain. There are no separate functional power domains.

Figure 51. Device power management framework

10.1.2 Power management supply description

Table 117 provides an overview of the PMC supply signals.

Table 117. Device power management controller external signals

Name	Type	Description
VDD_HV_ADR_D	Reference	Voltage reference of ADC Σ/Δ module
VDD_HV_ADR_S	Reference	Voltage reference of ADC SAR module
VDD_HV_ADV	Supply	High voltage supply for the ADC modules
VDD_HV_FLA	Decoupling	Decoupling supply pin for Flash
VDD_HV_IO	Supply	High voltage power supply for the I/Os
VDD_HV_IO_FLEX	Supply	FlexRay/Ethernet 3.3 V I/O supply
VDD_HV_IO_JTAG	Supply	Oscillator and JTAG pin supply
VDD_HV_PMC	Supply	High voltage power supply for internal power management unit
VDD_LV	Supply	Low voltage power supply for the core area
VDD_LV_BD	Supply	Low voltage power supply for the buddy device
VSS	Ground	Ground supply for the device / I/O. This is covering both VSS_LV and VSS_HV in case of exposed pad device.
VSS_HV_ADR_D	Reference	Ground reference of ADC Σ/Δ module
VSS_HV_ADR_S	Reference	Ground reference of ADC SAR module
VSS_HV_ADV	Supply	Ground supply for the ADC modules

Warning: There are constraints on some input voltages relative to other input voltages. Please refer to the device data sheet for detailed information.

10.1.3 SPC57EM80xx power management controller overview

Figure 52. SPC57EM80xx PMU overview

VDD_HV_IO is redundant, ensuring that single pin failure does not prevent device from functioning correctly. Full specification may not be guaranteed.

VDD_LV is redundant, ensuring that single pin failure does not prevent the device from functioning correctly.

10.1.3.1 1.2 V safety/spike regulator specification

SPC57EM80xx implements a 1.2 V safety/spike regulator. This regulator can be used to handle fast application current variation that cannot be fully handled by external regulator.

10.2 Low power mode support

The SPC57EM80xx microcontroller supports low power modes.

Dedicated logic prevents uncontrolled activation of low-power mode. This is implemented using protected sequence from ME.

Any register leading to low power entry is triple-voted.

10.2.1 Low power support and STOP mode implementation

Low power mode may be used to control the engine during the power-up phase, as in a Start-Stop system or when the key has been turned off.

The device implements the equivalent of an idle or power-down mode through STOP and HALT mode configuration.

The microcontroller application code can be used to put the device or modules into STOP mode.

A combination of mode control and clock control allows the user to configure the STOP mode.

In Afterrun mode, peripheral modules can be enabled/disabled in STOP using the control described in the ME section. For alternate configurations, other modules can be enabled/disabled in STOP using the control described in the ME section. External interrupt request channels and external wake-up channels can be made active to wake-up the device in alternative to peripherals interrupts.

All pins associated to the active modules are functional.

Control of the pins is defined by user during run time. A wake-up line is associated to each selectable module.

One of the available modules can be configured to perform the wake-up task. For example, with four CAN modules on the chip, three modules are set completely to power down mode and only one is configured for wake-up message receive (any of the four modules can be configured to perform this task).

All CAN modules can be independently configured to receive messages and respond to wake-up messages. Control of the pins is defined by user during run time.

In idle mode these modules can also be idle, but able to wake-up as soon as activity is detected and wake the core.

All these modules can be configured to a low power state. Wake-up recovery is programmable, for instance depending on state or activity of associated pin.

All parts of the device can be disabled. Following modules are configurable:

- There is one CAN module, selectable from any of the CAN modules on the device. The others can be disabled.
 - The maximum CAN baud rate is 1 MBaud.
 - One CAN module is able to receive messages from the CAN bus and wake-up the controller if the received message contains the correct message identifier.
- One LIN/UART module is able to recognize special wake-up messages on the receive line and then wake up the controller.
- Some “request” pins are able to initiate a wake-up. Refer to the pinout chapter for more information.
- The system timer is able to initiate a wake-up.

Configurable modules (ASC, three CANs, timer) can all be off in STOP mode.

The CAN module recovers from wake-up instantaneously but its ability to capture the message depends on settings of certain peripherals such as the CAN protocol clock. Depending on recovery time this impacts whether the first message can be captured, hence software must be used as a workaround.

Device implements all three mechanisms to exit from stop mode: pin wakeup, CAN wake-up and timed wake-up.

10.2.1.1 After-run implementation

After-run mode is implemented mainly making use of clock gating, module disabling, reduced frequency, mode switching.

Assuming that the selected CAN is kept enabled (clocked and active) then it can maintain its synchronization with the CAN network. Assuming also that the supplied CAN module can buffer the received (first) message, the CAN is then able to interrupt the IOP. The IOP would execute from TCM (i.e., Flash is disabled) and use the internal RC oscillator (IRCOSC) or the external oscillator (XOSC). To support this would keep the PMC, LVD, temperature sensor, internal FIRC, XOSC and pads active. The PLL, Flash, and ADC would be disabled, with rest of part static and clock gated off.

10.2.1.2 Checker core disabling

The checker core is always in lock step with the main core — hence if the main core is clocked, the checker core is clocked. Also if the main core is gated off, then the checker core is also gated off.

It is possible to disable the safety checker core to reduce current consumption.

The checker core can be placed in idle mode throughout the afterrun mode. By default the checker core mimics the main core, but it can be clock gated off during afterrun mode whilst continuing to clock the main core.

The checker core is implemented in such a way that its entire clock tree can be gated off while the core logic remains supplied.

The checker core (part of the Checker Logic) and the corresponding ‘checked main’ core share the same cache SRAM arrays and local SRAM arrays. Once the checker logic is disabled (i.e., its clock is gated) the SRAM array of the cache and the local memory of the main core are still usable by the main core.

10.3 Flash power requirements

During start-up operation, the flash module operates from an untrimmed regulator, which has a slightly larger variation than the ideal case. During this start-up phase, the flash can still be read, but it must be read at a slower rate. For SPC57EM80xx, read is performed differentially, i.e., the data is duplicated / inverted across two locations. While operating in this slower read mode, the flash can operate at a much reduced voltage, and hence the untrimmed regulator should default to a < 3.3V average. This will help guarantee that the maximum value is not exceeded.

Following completion of the start-up phase the regulator is in its trimmed condition, and subsequently the flash module reference current has also been trimmed. Therefore when entering normal operation the flash can be read in the normal access manner and support the full flash specification.

For SPC57EM80xx, the flash is using the externally supplied 1.25 V for the low voltage supply, while high voltage (3.3 V) is generated by a dedicated internal regulator.

10.4 Device trimming

During the initialization phase the device defaults to a pre-determined state for each of the LVDs, HVDs and the internal regulators. As the flash becomes available the differential read process allows the trimmed data to be available for trimming the internal LVDs, HVDs and regulators.

Please refer to [Section 10.6, Power sequence](#) for further details.

10.5 Supply monitoring (POR and LVDs)

The function of the POR and LVD circuits is to hold the device in reset regardless of how slow the supply voltage rise is, until the point at which the POR and LVDs are released.

The POR and LVD circuits function correctly even if the input voltage is non monotonic.

10.5.1 Power-on reset (POR)

The PMC implements two internal power-on reset circuits:

- VPORUPLV monitors the voltage on the 1.2 V input supply. It is monitoring the VDD_LV_CORE pin. The VPORUPLV asserts a reset when the input supply is below defined values.
- VPORUPHV monitors the voltage on the 5.0 V input supply. It is monitoring the VDD_HV_PMC pin. The POR trip point is high enough to make sure all the LVD circuits are functional.

See [Chapter 8: Reset and Boot](#) for PORST/ESR0 pin functionality.

10.5.2 Behavior of device LVD / HVD

Although there is an option to disable the LVD and HVD following reset (see section [Section 10.5.3, Low Voltage Detection \(LVD\) and High Voltage Detection \(HVD\)](#)), they are capable of being used in a 'monitor' only mode and also capable of generating a safe / interrupt event. The diagram in [Figure 53](#) illustrates the behavior of these internal LVD /

HVD circuits during the power on phase, through into device initialization and subsequently in 'normal' run / operating mode.

The LVDs/HVDs can also be configured after device initialization preventing reset to happen when supply crosses the LVD threshold, effectively providing a higher voltage operating range. It is the responsibility of the application to ensure that the device remains in the functional range.

Figure 53. Internal LVD and HVD in configuration example during power-up

10.5.3 Low Voltage Detection (LVD) and High Voltage Detection (HVD)

The internal LVD circuits monitor when the voltage on the corresponding supply is below defined values and either assert a reset or an interrupt. The LVDs also support hysteresis in the falling and rising trip points.

10.5.3.1 LVD and HVD implementation

- All LVDs and HVDs are capable of generating either an RGM and/or FCCU event, with the following exceptions:
 - The LVD270 (that is, the LVD monitoring the high voltage supply input) can be disabled only for test purpose and should otherwise always generate a reset when triggered.

Warning: In case LVD270 are disabled, the device may not detect through internal monitor that VDD_HV voltage is outside

functional range. If this event occurs, reset state must be ensured by assertion of external PORST pin from the user.

- It is not possible to disable the LVD096 (that is, the LVD monitoring the internal core voltage) and they always generate a reset when triggered. This LVD096 is integral to the POR management.
- All LVDs and HVD configured for reset generation can cause functional or destructive reset. MC_RGM PHASE0 is not exited until all destructive reset conditions are cleared.
- The appropriate bits in the PMC registers are set by LVD and HVD events.
- The LVDs and HVDs control is protected by the SoC wide register protection scheme. Therefore it is configurable as long as the scheme is followed. Please refer to [Chapter 83: Register Protection \(REG_PROT\)](#).
- SPC57EM80xx implements REE DCF records to allow to associate “configurable” LVDs/HVDs to a RESET event. This is a write once mechanism managed by SSCM during device initialization. When RESET event is selected through REE DCF record, it cannot be changed until next RESET event. When RESET event is not selected through REE DCF record, LVDs/HVDs trigger event default to FCCU event.

Note: The list of the “configurable” LVDs/HVDs is provided in [Table 118](#), in which the “User configurability” columns provide the possible user configuration.

- When the LVD or the HVD is enabled for destructive reset generation and a subsequent trigger event is detected, the external PORST pin is driven low.

Note: LVD096 and LVD270 (low range LVDs) cannot be disabled by the user during boot sequence. These modules are used during power-up phase and must ensure that an absolute lowest threshold of operation is never crossed. This is not a guarantee that the device will function down to this level. It is rather a guarantee that the device will recover if this level is crossed.

Warning: The LVD270 can be disabled for test purpose through software accessing PMC_REE register. In case LVD270 are disabled, the device may not detect through internal monitor that VDD_HV voltage is outside functional range (below LVD270 threshold). If this event occurs, reset state must be ensure by assertion of external PORST pin from the user. When supply goes below the threshold of the POR240 (internal power-on state detector), device will be forced into reset and LVD270 is automatically re-enabled.

Table 118. POR and voltage monitors description

Monitor name	Register bit	Description	Monitor/ sensing	POWERUP- PHASE0	PHASE1-2-3	User configurability	
						DCF (PHASE3)	REE/FEE / IE ⁽¹⁾ (RUN)

10.6 Power sequence

The following sections describe the power sequence and the relation between the different supplies during power-up and power-down.

The device is considered to be in a power sequence (or POWERUP state) when it is either not supplied or partially supplied. An internal power-on signal is used to identify POWERUP

state. This signal is released high on exit of power sequence. The power-on signal is a combination of the LVDs monitoring the following supplies:

- VDD_LV
- VDD_HV_PMC
- VDD_HV_IO
- VDD_HV_FLA

The actual threshold use for each LVD is dependent on the configuration of the device. This is configurable by hardware (flash option bits content) or by software (LVD event configuration through register interface). Once power-on signal has been asserted, device configuration is reset to default power-up configuration.

10.6.1 Power-up sequence

In this section it is assumed that all supplies are low when entering the power-up sequence. Brown-out and power down sequences are managed in specific sections.

10.6.1.1 POWERUP state

At the beginning of power-up, the internal power-on signal remains low due to internal parasitics diodes. As soon as minimum threshold is reached on VDD_LV and VDD_HV supply, the internal power-on signal is forced low until power-up LVDs reach upper not trimmed threshold (refer to datasheet).

The different supplies can rise independently as long as the constraints described in the datasheet are met.

During power-up, all functional terminals are maintained into a known state as described in [Table 120](#).

Table 120. Functional terminal state during power-up and reset

Terminal type ⁽¹⁾	POWERUP ⁽²⁾ pad state	RESET pad state	DEFAULT pad state ⁽³⁾	Comments
PORST	strong pull-down	weak pull-down	weak pull-down	Power-on reset pad
ESR0	strong pull-down	strong pull-down	weak pull-up ⁽⁴⁾	Functional reset pad
ESR1	weak pull-up	weak pull-up	weak pull-up	Functional NMI/reset pad
TEST_MODE	weak pull-down	weak pull-down	weak pull-down	—
GPIO	weak pull-up	weak pull-up	weak pull-up	—
ANALOG	high impedance	high impedance	high impedance	—
ERROR	high impedance	high impedance	high impedance	During functional reset, pad state can be overridden by FCCU
JCOMP ⁽⁵⁾	high impedance	weak pull-down	weak pull-down	—
TCK ⁽⁵⁾	high impedance	weak pull-down	weak pull-down	—
TMS ⁽⁵⁾	weak pull-up	weak pull-up	weak pull-up	—

Table 120. Functional terminal state during power-up and reset (continued)

Terminal type ⁽¹⁾	POWERUP ⁽²⁾ pad state	RESET pad state	DEFAULT pad state ⁽³⁾	Comments
TDI ⁽⁵⁾	weak pull-up	weak pull-up	weak pull-up	—
TDO	high impedance	high impedance	high impedance	—

1. Refer to pinout information for terminal type
2. POWERUP state is maintained until supply cross the power-on reset threshold: V_{PORUP_LV} for LV supply, V_{PORUP_HV} for high voltage supply.
3. Before software configuration
4. ESR0 configuration move from strong pull-down to weak pull-up on completion of internal reset sequence (PHASE3[FUNC]).
5. JTAG interface implements build-in pull-up/pull-down configuration to ensure noise immunity. Worst case is boundary scan activation, requiring JCOMP to pulse high and following events to occur during JCOMP pulse high:
 - 23 TCK events corresponding to 12 clock cycles.
 - 3 TMS events synchronous with TCK: sequence 0,1,1,0,0,0,0,0,0,0,1
 - 2 TDI events synchronous with TCK: sequence x,x,x,x,x,0,0,0,1,0,0,x
 TCK, TMS, TDI are implementing hysteresis requiring minimum variation

Digital reset is asserted, ensuring that all modules registers are reset to power-on value.

10.6.1.2 POWERUP exit

The POWERUP state can be exited when both VDD_LV and VDD_HV are above the internal LVD thresholds.

10.6.1.2.1 VDD_LV conditions and LVD trimming/enabling sequence

During POWERUP, only the following low voltage LVDs are enabled:

- LVD112_C
- LVD096_C, LVD096_F

The VDD_LV conditions to exit POWERUP are the following:

- LVD096_C, LVD096_F upper threshold is crossed
- LVD112_C upper threshold is crossed

Figure 54. VDD_LV monitored voltages during power-up

After the POWERUP exit conditions (low voltage, high voltage conditions) have been verified, the internal power-on signal is released to all analog modules.

The internal RC oscillator module (IRCOSC) starts initialization and provides clock to the system after $t_{RCSTARTUP}$. PMC digital interface reset is released after two RC clock cycles and LVD112_C is masked. Only LVD096_C remains active.

LVD096_C and LVD112_C share the same reference. $LVD112_C - LVD096_C > 90\text{ mV} \pm 5\%$. This difference provides margin with respect to maximum internal resistive drop (40 mV at I_{max}) and 50 mV hysteresis addressing external supply drop.

The device proceeds through the reset sequence through RGM phase PHASE0, PHASE1[DEST], PHASE2[DEST] and PHASE3[DEST].

Voltage detector (LVD/HVD) modules are trimmed at the beginning of PHASE3[DEST]. Trimming of LVDs/HVDs are stored as internal DCF records. They are read by SSCM at low voltage, using the differential flash read accesses and applied to each LVDs/HVDs module. After analog delay ($t_{LVDTRIM}$) has elapsed, the PMC acknowledges that all LVDs/HVDs have been trimmed and supply is above threshold, the SSCM proceeds with the reset sequence, eventually running full speed accesses to the flash to read the option bits required to complete device configuration.

The configurable LVD/HVD modules can optionally be unmasked at the end of PHASE3[DEST]. Mask information is read as DCF record from the flash UTEST option bits.

When LVD108_C and LVD360_IM are masked by the application using the flash user option bits, the device should rely on PORST signal to detect a voltage failure during power-up. The device must wait for PORST to be released high before proceeding with the power-up sequence. This may increase the amount of time necessary to complete the reset sequence.

[Figure 55](#) provides an example of VDD_LV power-up sequence from POWERUP to PHASE3[DEST].

[Figure 56](#) illustrates threshold variation of VDD_LV LVD monitor during power-up sequence from POWERUP to PHASE3[DEST]. Internal LVD108_C LVD and internal HVD140_C HVD are *enabled* during PHASE3[DEST].

[Figure 57](#) illustrates threshold variation of VDD_LV LVD monitor during power-up sequence from POWERUP to PHASE3[DEST]. Internal LVD108_C LVD and internal HVD140_C HVD are *disabled* during PHASE3[DEST]. The device relies on external voltage monitors.

Figure 55. Example of VDD_LV power-up sequencing

Figure 56. Threshold variation during power-up sequence: hot point LVD enabled

Figure 57. Threshold variation during power-up sequence: hot point LVD disabled

10.6.1.2.2 VDD_HV conditions and LVD trimming/enabling sequence

During POWERUP, the following high voltage LVDs are enabled:

- LVD400_IM
- LVD360_IM
- LVD295_F
- LVD270_xx

The VDD_HV conditions to exit POWERUP are the following:

- LVD400_IM upper threshold is crossed.
- LVD360_IM upper threshold is crossed.
- LVD300_F upper threshold is crossed.
- LVD270_xx upper threshold is crossed.

Figure 58. VDD_HV monitored voltages during power-up

After both LV and HV POWERUP exit conditions have been verified, ipp_por_en_b signal is released to all analog modules.

The IRCOSC module starts initialization and provides the clock to the system after $t_{RCSTARTUP}$. PMC digital interface reset is released after two RC clock cycles and LVD400_IM is masked. All other HV LVDs remain active.

LVD360_IM and LVD400_IM share the same reference. LVD400_IM - LVD360_IM difference is implementing margin with respect to maximum internal resistive drop and hysteresis addressing external supply drop.

Device proceeds through the reset sequence through RGM phase PHASE0, PHASE1[DEST], PHASE2[DEST], PHASE3[DEST].

LVD/HVD modules are trimmed at the beginning of PHASE3[DEST]. Trimming is done by SSCM at low voltage, using the differential flash read accesses. After LVD is completed, SSCM waits for PMC acknowledgement before proceeding with reset sequence.

Configurable LVD/HVD modules are optionally enabled at the end of PHASE3[DEST].

[Figure 59](#) provides the threshold variation of VDD_HV LVDs monitor during power-up sequence from POWERUP to PHASE3[DEST]. Internal LVD360_IM LVDs and internal HVD600_IM HVD are *enabled* during PHASE3[DEST].

Figure 59. Threshold variation during power-up sequence — 2.7V–5.5V hot point LVD disabled, 4.5V–5.5V range

The device needs to fulfill all conditions described on [Section 10.6.1, Power-up sequence](#) to recover.

10.6.2 Power-down sequence

In case the threshold of the higher ranges LVDs that are configured to generate destructive reset is crossed but neither LVD096 nor LVD270 threshold is crossed, the device enters PHASE0 phase.

Power-down sequence is actually entered as soon as the threshold of one of the LVD096 or LVD270 is crossed. The device enters the POWERUP state. The internal power-on signal `ipp_por_en_b` is asserted.

On `ipp_por_en_b` assertion, all analog modules reach their safe state.

Device supplies may then proceed to drop down to ground either through device leakage or external pull-down. During power-down, all supplies should comply with supply constraints.

10.6.3 Brown-out management

During brown-out, the device re-enters the POWERUP phase as soon as the threshold of either LVD096 or LVD270 is crossed. The internal power-on signal `ipp_por_en_b` is asserted.

Note: The device will correctly start independently from any residual voltage. Below LVD270 threshold the device is under POWERUP state. Above the LVD270 threshold, the device is

into a RESET state as defined by Voltage monitor or external PORST pin or active state when all have been released.

Warning: This mechanism is ensured when LVD270 are not disabled by the user. In case LVD270 are disabled, reset state must be ensured by assertion of external PORST pin from the user. When supply goes below the threshold of the POR240 (internal power-on state detector), device will be forced into reset and LVD270 is automatically re-enabled.

On internal power-on signal assertion, all analog modules reach their safe state.

10.6.4 Low voltage requirement during crank

The device can continue operation to the minimum input voltage during crank.

In order to proceed with execution during cranking and prevent device reset, it is important to correctly configure the high voltage LVDs.

Internal LVDs that monitor the supply ensure that the flash content is protected.

11 Security

All SPC57xx family devices have a comprehensive set of customer-configurable security features designed to protect code and data from unauthorized access. Some security features are available in all device configurations while other more advanced security features are not available in all device configurations. These more advanced features require more than simply being turned on or off; they require significant involvement for implementation. Consequently, they provide an important opportunity to define the security level of the device.

11.1 Basic security

All SPC57EM80xx devices have the following basic set of security features.

- Device censorship based on the life cycle model with code and data access progressively more restricted as device matures through defined life cycle steps
- Memory security features:
 - NVM censorship support, password protection, one-time-programmable (OTP) flash memory areas, Flash erase counter and tamper detection
 - SRAM and caches initialized to a constant value after reset (power-on reset, when in a test mode, when not booting from internal flash memory); MBIST functionality used in case of power-on and destructive resets to initialize RAMs selected via configuration in UTEST flash; BAM software routines to initialize RAMs when not booting from internal flash memory
- Monitoring of operating conditions
- Unique ID for each device: each SPC57EM80xx device has a unique identification number stored in an OTP flash memory area which can be read by any of the cores on the device
- Secure watchdog timer
- Basic debugger restrictions (on/off via censorship mode)

11.2 Advanced security

Depending on the device configuration, the following features are available:

- Customer programmable Hardware Security Module (HSM): a dedicated security subsystem that includes a processor core, dedicated SRAM, an encryption module, and exclusive access to secure areas of device flash memory; HSM runs code independently from the main device processor cores and can be used to implement advanced security and monitoring functions
- Secure debugger interface
- Boot modes:
 - Trusted/secure boot support
 - Handshake with Boot Assist Module (BAM) supported

11.3 Detailed security information

Details of most of the SPC57EM80xx security features are published in a separate *SPC57EM80xx Microcontroller Security Reference Manual*, which is only available to qualified customers.

12 Calibration and Debug

This chapter discusses the device-specific information for the debug and calibration modules. This device implements a high-speed serial Nexus trace auxiliary port. The Aurora interface allows the Nexus protocol information to be transmitted serially at high speed over four Aurora lanes. The Aurora protocol handles the encoding of the data and striping the information across the four Aurora lanes available on the device. In addition, the LFAST module, a high speed calibration interface, is supported for run control and memory access. The LFAST signals are alternate functions on the device's JTAG pins. The device starts up in JTAG mode and the tool can request that the JTAG interface be converted to the LFAST high-speed interface. All standards used have freely available specifications for tool developers.

The debug and calibration features for this device are provided in two separate dies: the Production die and the Buddy die, or Buddy Device (BD). The Production die is packaged alone in the Production Device (PD) package. The PD is also assembled into an Emulation and Debug Device (ED) package that consists of the Production die along with the Buddy die. The Buddy device supports additional debug capability. The Nexus Aurora interface is only available on the ED. The PD only supports trace to the internal trace/calibration memory.

The Event Out ($\overline{\text{EVTO}}[0,1]$) signals are connected to the external TGOUT[0,1] device pins and the Event In (EVTI) signals are connected to the external TGIN[0,1] device pins.

12.1 Core debug support

Internal debug support in the e200z420n3 and e200z425n3 cores allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. The cores have the capability of exiting reset halted in debug mode, such that no code runs. This allows debuggers to perform operations such as configuration of calibration remap or edit of overlay memory prior to user code execution.

For details, see [Chapter 63: e200z420n3 Core Debug Support](#) and [Chapter 64: e200z425n3 Core Debug Support](#).

12.2 Run control and memory access

Run control is any operation required to control device operation. Run control includes starting and stopping the processor's execution of code, as well as accessing memory while the device is stopped to download code. The Debug and Calibration Interface (DCI) provides the central run control including cross-triggering of breakpoint conditions. This DCI provides support for the IEEE 1149.1 JTAG standard with the JTAG Controller (JTAGC) as well as the IEEE 1149.7 standard with the Compact JTAG (CJTAG) module. The JTAG interface supports both Boundary Scan and Debug modes. It is based on the IEEE 1149.1 and IEEE 1149.7 standards. The JTAG Controller (JTAGC) operates in the standard IEEE 1149.1 5-wire interface. The JTAGC can either be fed directly from the JTAG pins or the CJTAG module, which supports the IEEE 1149.7 standard.

The Sequence Processing Unit (SPU) provides cross-triggering of events from the device. The SPU can access some of the DCU run control features since it can control the $\overline{\text{EVTO}}$ pins and monitor the EVTI pins. Furthermore, the SPU can use system triggers to cause

many different types of actions, including triggering a breakpoint cross-trigger (managed by the DCI).

12.2.1 Debug and Calibration Interface (DCI)

The Debug and Calibration Interface (DCI) module provides debug and calibration features. The DCI module includes the device JTAG Controller and the IEEE 1149.7 interface. The DCI provides the following features:

- Debug mode enable control for connected tools or software
- Port-sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- IEEE 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control

Simultaneous operation for debug and calibration featuresThe DCI sends and receives the EVTI[1:0] and EVTO[1:0] signals to/from the cores and other modules. The tables below summarize the source and destination of EVTI, EVTO, and related signals for the PD and the BD. For example, for the PD, EVTI[0] are outputs of the JTAGM and SPU and inputs to the Cores, HSM, GTM, and NXMC.

Table 122. PD DCI signals

Signal	Cores	HSM	GTM	NXMC	NAR	JTAGM	SPU	DTS
EVTI[0]	I	I	I	I	—	O	I/O	—
EVTI[1]	—	—	—	—	—	O	I/O	—
EVTO[0]	O	O	O	O	—	I	I/O	—
EVTO[1]	—	—	—	—	—	I	I/O	O
Core debug event	I	—	—	—	—	—	—	—
DCI cross triggering	O	—	O	—	—	—	—	—

Table 123. BD DCI signals

Signal	RWA	NAR	NAL	JTAGM
$\overline{\text{EVTI}}[0]$	—	I	—	O
$\overline{\text{EVTI}}[1]$	—	—	—	O
$\overline{\text{EVTO}}[0]$	—	—	—	I
$\overline{\text{EVTO}}[1]$	—	—	—	I

The DCI sends the system debug signal, `ipg_debug`, to the following modules. For details regarding module functionality during system debug, refer to the individual module chapter.

- AMU
- CAN
- LFAST (Interprocessor Communications instance only)
- DSPI
- eDMA
- FCCU
- GTMINT
- I2C
- NXMC
- PIT
- PSI5
- SARADC
- SDADC
- SRX
- SSCM
- STM
- SWT

DCI $\overline{\text{EVTx}}$ Pin Multiplexing Control Register (DCI_PINCR)

The DCI $\overline{\text{EVTx}}$ pin multiplexing control register (DCI_PINCR) is described below. The $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ functions share the same set of possible pins. If this register is written to enable both $\overline{\text{EVTI}}$ and $\overline{\text{EVTO}}$ on the same pin, the $\overline{\text{EVTI}}$ function is selected, although this type of programming should be avoided. Programming the $\overline{\text{EVTI}}$ fields to select $\overline{\text{EVTI}}[0]$ or $\overline{\text{EVTI}}[1]$ inputs to come from more than one pin is considered a programming error and no pin is enabled.

Field	Description
7	Reserved
6 EVTI1C	Enables $\overline{\text{EVTI}}[1]$ function on pin PM[6]
5 EVTI1B	Enables $\overline{\text{EVTI}}[1]$ function on pin PK[14]
4 EVTI1A	Enables $\overline{\text{EVTI}}[1]$ function on pin PH[11]
3 EVTI0D	Enables $\overline{\text{EVTI}}[0]$ function on pin PM[5]
2 EVTI0C	Enables $\overline{\text{EVTI}}[0]$ function on pin PM[4]
1 EVTI0B	Enables $\overline{\text{EVTI}}[0]$ function on pin PF[15]
0 EVTI0A	Enables $\overline{\text{EVTI}}[0]$ function on pin PF[14]

12.2.1.1 JTAG Controller (JTAGC)

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format. All Nexus debug registers are accessed and configured via the JTAG Controller.

12.2.1.2 Compact JTAG (CJTAG)

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities.

12.2.2 JTAG Data Communication (JDC)

The JTAG Data Communication (JDC) module allows both JTAG and software access to two registers. These two registers are the challenge/response password authorization registers used by the Hardware Security Module (HSM).

12.2.3 Sequence Processing Unit (SPU)

The Sequence Processing Unit (SPU) provides on-device logic analyzer trigger functions, such as performance monitoring, by using internal device signals as trigger sources. Performance monitor functions are available at both the system and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System-level performance monitor functions are integrated into the SPU complex trigger logic, thus allowing the counting and timing of any debug trigger combinations supported by the SPU.

Various clients generate watchpoints and other triggers when operating in Debug mode. The SPU collects these triggers and uses them as conditions for programmable sequences

of states and resultant actions. The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, it achieves complex logic-analyzer-like behavior, providing vital real-time visibility and the ability to debug system activities.

12.2.3.1 SPU Level1 Input Mux Configuration registers

The SPU Level1 Mux inputs for the L1SELn registers (where n = 0–7) are described in the following tables. The L1SEL0 register fields are described in the following table.

Table 125. L1SEL0 register field descriptions

12.3 Calibration interface

This device includes an alternate calibration interface for high-speed run control and advanced software control. This calibration interface is based on the LFAST interface. The LFAST based calibration has the ability to perform all of the functions that JTAG supports, only at a faster speed. The MCU implements the slave module, and the pins for the LFAST interface are multiplexed onto the same pins as the JTAG pins. Initially, the device powers up with the JTAG module in control of the pins. Under tool commands, the LFAST interface

can be enabled and the pins become LFAST signals. Once the LFAST interface has been activated, all run control and other JTAG operations are converted in the MCU from LFAST messages into JTAG control operations of the JTAG Controller. The interface is supported entirely in hardware for both LFAST and JTAG modes, with no software or system overhead required to support interface traffic.

Table 133. Reference links to related information

Related module	Reference
JTAG Master (JTAGM)	Chapter 70: JTAG Master (JTAGM)
LFAST Module—JTAGM	Chapter 71: LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug
Development Tool Semaphore (DTS)	Chapter 72: Development Trigger Semaphore (DTS)

12.3.1 JTAG Master (JTAGM)

The JTAG Master (JTAGM) acts as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or through software.

The data transferred to this module is transformed to produce TCK, TMS, TDI, and TRST outputs and to accept TDO inputs. The module allows these five signals to connect to the JTAGC as if the JTAG data were coming from an external tool. The JTAGM generates all required JTAG scan chains to allow software and high-speed serial communication access to all JTAG-mapped resources.

12.3.2 Debug LFAST

The high-speed calibration interface provides up to a 320 Mbit/s interface between a calibration tool and the device. The calibration interface uses the LFAST as the physical layer between the tool and the JTAGM for access to debug resources. In addition, an LFAST switch allows direct access to read and write memory. The calibration debug LFAST module is one of two instantiations of the LFAST module on the device. The calibration LFAST is configured for slave-only operation and is meant to be used as a calibration interface to provide higher (than JTAG) speed debug and calibration operations. The calibration LFAST interface supports full duplex operation, where the available bandwidths for upstream and downstream traffic are independent.

12.3.3 Development Trigger Semaphore (DTS)

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways that this module can be used, including as a component of an external real-time data acquisition system.

Note: *When used as a component of a triggered data-acquisition system, Nexus read/write access is via the JTAG interface of the Nexus debug port and is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus auxiliary port.*

12.4 Debug over CAN

As well as supporting debug via JTAG and LFAST interfaces, the device supports the use of a CAN interface for debug. This allows debug of application hardware where access to the dedicated JTAG/LFAST interface signals is not easily available. The debug over CAN mechanism is intended to provide basic debug functionality with some reduction in bandwidth and features compared to use of the dedicated JTAG or LFAST interfaces.

Use of the CAN interface for debug purposes requires the use of some M_CAN, eDMA and JTAGM resources. Some initialization of these resources via software is required, but once this initialization has completed, debug over CAN is possible without any further software overhead.

As the debug over CAN scheme generates internal JTAG messages based on received CAN data, all JTAG clients and included debug resources are accessible. Basic device trace capability is also possible by configuring the device trace hardware to stream to a device overlay/trace RAM, which can be read later using debug over CAN.

The debug over CAN scheme supports the following features:

- Supports operation through M_CAN_0 or M_CAN_1 interfaces
 - Makes use of M_CAN debug enhancements
 - Debug message selected by filter configuration SFEC/EFEC=111
- Allows debug of hardware where JTAG access is not available
- Debug traffic carried over application CAN bus
- Debug traffic on CAN coexists with application traffic
- No software overhead after initialization
- flexible selection of CAN identifiers for debug use
- Access to all JTAG debug facilities, includes CPU run control

12.5 Nexus Trace Aurora interface

The Aurora interface allows Nexus protocol information to be transmitted serially at high speed over multiple Aurora lanes to provide advanced trace information from the device. The Aurora protocol handles the encoding of the data and the striping of information across the lanes. The Aurora interface is only available on the Emulation and Debug Device. Trace information is transferred to the Buddy Device for transmission via the Aurora interface.

The Aurora information can be used to reconstruct events or operations that occurred inside the microcontroller. Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the MCU. Each Nexus message is tagged with the source client identifier and the type of message. The actual trace information that is available depends on the Nexus client; generally, it can be individually enabled (both the type of message and the client). [Table 134](#) shows a few examples of Nexus messages. All messages can be enabled to include a timestamp.

Table 134. Nexus message types

Message Type	Description
Program trace	Nexus program trace messages transmit any discontinuities in the program flow, such as branches and interrupts. Multiple types of messages can be generated.
Ownership trace	Ownership trace provides information on process identification changes.

Table 134. Nexus message types (continued)

Message Type	Description
Watchpoint trace	Watchpoint messages are generated any time a watchpoint match occurs in the program or data flow, or as a result of SPU actions. These can be programmed for many types of events within the MCU.
Device identification	The device identification message allows information about the MCU to be transmitted upon startup to allow tools to identify the target system MCU type.
Debug status	Debug status messages provide additional information that may be needed to reconstruct software execution, such as whether the device has entered Debug or Low-power mode.
Data acquisition	Data acquisition messages are an optional feature that allows software control of information to be transmitted.
error	Error messages are transmitted when an error condition occurs, such as internal buffer overflows.

The Nexus trace information can be output to internal memory, or the parallel information can be serialized for transmission over a serial interface through the Nexus Aurora interface. Nexus trace information can also be routed through the Data Write Processing Unit (DWPU) as described in [Section 12.7, Data trace filtering](#).

The Nexus blocks do not have memory-mapped registers. The Nexus registers are accessed by the development tool via the JTAG port using a two step process. First, the specific block is selected by loading the corresponding ACCESS_AUX instruction as described in the JTAGC chapter. Next, after the block is selected, the Nexus registers are enabled by loading the enable instruction to the JTAGC Instruction Register (IR). The enable instructions for the different Nexus clients are shown in the following table. After the enable instruction is received, the development tool has access to the Nexus registers of the selected client.

Table 135. Nexus client JTAG enable instructions

Module	Enable instruction	Opcode
Production Die		
Cores	CORE_ENABLE	0x7C (10 bits)
NXMC	NEXUS_ENABLE	0x0 (4 bits)
GTM		
NAR		
SPU		
Buddy Die		
RWA	CORE_ENABLE	0x7C (10 bits)
NAR	NEXUS_ENABLE	0x0 (4 bits)
NAL		
DWPU		

All of the internal JTAG modules are accessed through a single JTAG connection to the device. In the case of the ED, all JTAG communication is performed through the JTAG

interface located in the BD. In the production package configuration, access is performed through the JTAG interface located in the PD.

With the hierarchical JTAG configuration, the BD JTAGC is considered the master JTAG TAP controller. The PD JTAGC TAP controller is selected via an AUX_ACCESS instruction. Other TAP controllers residing on the BD are also selected via AUX_ACCESS instructions (NAR, RWA, BD_DCI). Once control is transferred from the BD JTAGC to the PD JTAGC via the AUX_ACCESS instruction, all other PD TAP controllers are then selected via AUX_ACCESS instructions executed by the PD JTAGC. This is also referenced as TAP-sharing and is shown in the following figure.

Note: *On the Emulation device, when the PAUSE-DR/UPDATE-DR state is executed to pass control of the JTAG TAP controller, control is always passed to the top level JTAG TAP controller, in other words, the DCI of the BD. For this reason, it is recommended that all JTAG operations, except when the BD clients need to be accessed, that all PD JTAG access be preceded with ACCESS_PD_JTAGC command. If the device is not an ED, the access is ignored.*

12.5.1 Nexus Aurora overview

The IEEE-ISTO 5001-2011 standard adds a new type of auxiliary trace port that supports a higher bandwidth. This new interface type uses the Aurora protocol to reformat the parallel Nexus messages into one or more output serial lanes of data, where a lane is defined as a 2-pin Low Voltage Differential Signals (LVDS) interface. The protocol handles striping the data onto the multiple lanes. Each lane uses an 8b/10b encoded LVDS driver. The encoding allows the receiver to recover clocking information.

The Aurora physical interface is based on the XAUI (10 Gigabit Attachment Unit Interface) standard used in communication protocols, which covers the jitter, differential skew, inter-lane skew, and bit error rate requirements.

The Aurora protocol covers lane initialization and channel bonding for both simplex and duplex implementations. The current implementation uses a simplex output-only connection from the MCU to the external tool.

The Aurora interface connects Nexus parallel trace output to an Aurora Protocol Engine (APE), the Aurora Lane Control (ALC), and the Nexus Aurora Physical interface (NAP). [Figure 62](#) shows the Aurora interface block diagram, where the number of lanes, n , is 4.

Figure 62. Aurora interface block diagram

12.5.2 Nexus Aurora Router (NAR)

The Nexus Aurora Router (NAR) manages the Nexus trace information from each of the Nexus clients. The NAR takes the parallel trace information from each of the clients, buffers it to avoid overruns, and routes it to either the internal overlay RAM or the Buddy Device, where it is stored in on-chip SRAM or transmitted out of the device through the Aurora interface.

16 KB of trace SRAM is available on the PD (located in the flash module), and 1 MB of trace SRAM is available in the ED. (Some of this SRAM may be used for calibration overlay content as well as trace content.) Similarly, a smaller NAR output queue is located on the PD (2 KB), and a much larger NAR output queue is located in the ED (8 KB). The physical Aurora pins are only available on the ED. [Figure 63](#) shows the NAR block diagram.

Figure 63. NAR block diagram

The PD NAR module has seven clients, with client index 1–7. Clients 8–16 are not connected. The client connections and the corresponding NAR client index are shown in the following table. The NAR client index is used in the NAR_STCR, NAR_CSSR, and NAR_CDR registers. The source trace ID is used in the NAR_SFR.

Table 137. PD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
—	NAR	0b1111 (0xF)	—
1	GTM	0b0111 (0x7)	3
2	HSM	0b0011 (0x3)	1
3	Core 0	0b0000 (0x0)	1
4	NXMC Client 0 Concentrator	0b1100 (0xC)	1

Table 137. PD NAR clients (continued)

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
5	Core 1	0b0001 (0x1)	1
6	NXMC Client 1 Concentrator	0b1101 (0xD)	1
7	Core 2	0b0010 (0x2)	1
8	—	—	—
9	—	—	—
10	—	—	—
11	—	—	—
12	—	—	—
13	—	—	—
14	—	—	—
15	—	—	—
16	—	—	—

The BD NAR module has one client and the client connections and the corresponding NAR client index are shown in the following table.

Table 138. BD NAR clients

Client index	Client	Nexus source trace ID (SRC)	Beats per client (Bn)
1	PD NAR	0b1110 (0xE)	2

The NAR is limited writing trace information to the overlay RAM. The PD NAR only has access to the 16 KB internal overlay RAM. Therefore, the PD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0D000000–0x0D003FFF. The BD NAR also has access to 1 MB of extended overlay RAM. Therefore, the BD NAR trace memory bus base address registers (NAR_TBALO and NAR_TBAHI) must specify a base address in the range 0x0C000000–0x0C1FFFFFF.

The NUM_LANES field of the NAR_NAPCR is described in the following table.

Table 139. NAR_NAPCR field descriptions

Field	Description
19–16 NUM_LANE	TX Lane Configuration. Number of enabled TX lanes. 0000 Disable NAP and NAL 0001 Reserved 0010 Enable 2 lanes (Lane 0–1) 0011 Reserved 0100 Enable 4 lanes (Lanes 0–3) 0101 Reserved 0110 Reserved 0111 Reserved 1000 Reserved 1001–1111 Reserved

12.5.3 Nexus Aurora Link (NAL)

The Nexus Aurora Link (NAL) is only included in the Emulation and Debug Device. The Nexus Aurora Link (NAL) consists of all the logic on the MCU needed to implement the connection up to the physical-layer serializer and transmitter (no receiver). It includes Aurora control and data multiplexing, data-encoding and striping, and the Physical Coding Sublayer (PCS) portion of the protocol.

Debug data in the Nexus format from multiple clients is packetized into a 32-bit format by the clients and then collected by the NAR. The NAL encodes the message data (8b/10b), stripes it across the lanes, and inserts Aurora control characters (such as start of message, end of message, idle, clock compensation characters, and so on) around the payload. The NAL PCS drives the Nexus Aurora Physical (NAP) interface.

12.5.4 Nexus Aurora PHY (NAP)

The Nexus Aurora PHY (NAP) is only included in the Emulation and Debug Device. The NAP, in conjunction with the Nexus Aurora Link (NAL), supports one-way simplex high-speed serial communication with an external debugger. The NAP receives 8b/10b encoded data from the ALC block in the NAL and transmits this data onto a given PHY lane's LVDS pads. The NAP performs lane striping with settings in the NAL and NAR specifying lane configuration. Each NAP lane consists of a Data Symbol Character Accumulator that registers the 10-bit character for that lane from the ALC on the rising edge of the NAL clock. A serializer takes the 10-bit character and serializes it into the individual transmit data bits at the PHY clock rate to be transmitted via the LVDS output drivers to the external debugger receive channel.

Note: The NAL performs static link training for an attached debugger's PHY. The NAP is not directly aware of the link training operation, since it merely transmits the data presented to it by the NAL.

On the receive data side of the external debugger, it is the responsibility of the external debugger to perform elastic buffering, symbol detection, symbol locking (called "lane alignment" in Aurora terminology), 10b/8b decoding, decode and disparity error tracking, and CRC checking in the received data stream.

Figure 64 shows a block diagram of the Nexus Aurora Physical (NAP) interface and the LVDS output drivers, where the number of lanes, *n*, is 4.

Figure 64. NAP block diagram

12.6 Nexus clients

Nexus supports the transmission, through a single Aurora port, of information from multiple trace clients within the device.

Nexus Crossbar Multi-Master Client (NXMC)	Chapter 77: Nexus Crossbar Multi-Master Client (NXMC)

12.6.1 e200z4 Nexus 3

The e200z420n3 and e200z425n3 Nexus 3 modules provide real-time development capabilities for e200z4d processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering and Processor Overrun Control.

12.6.2 GTM Development Interface (GTMDI)

The GTM Development Interface (GTMDI) provides real-time development capabilities for the GTM system including Multi-channel Sequencer (MCS) cores, Advanced Routing Unit (ARU) data trace, Input Channel Filters trace, Output Timer channels, DPLL and Sensor Pattern Evaluation (SPE) module submodules. The GTMDI interfaces to the GTM IP using dedicated signals. The GTMDI operates in conjunction with on-chip debug modules to implement complex debug features. Trace capability is also provided along with a global timestamp that allows real-time trace for several GTM submodule events. The GTMDI implements a Nexus client standard interface and a JTAG standard port controller to provide communication capability via the JTAG port and the on-chip NAR.

12.6.3 Nexus Crossbar Multi-master Client (NXMC)

The Nexus Crossbar Multi-master Client (NXMC) module provides real-time trace capabilities in compliance with the IEEE-ISTO Nexus 5001-2011 standard. This module provides development support capabilities for SoCs without requiring address and data pins for internal visibility. A portion of the pin interface is also compliant with the IEEE 1149.1 JTAG standard.

To provide Nexus data trace messaging from bus masters on the master ports of the crossbar (XBAR) that do not inherently have a trace client, a Nexus Crossbar Multi-Master Client (NXMC) monitors traffic into the master port of the XBAR. Two NXMCs are implemented: one for the fast masters and one for the slow masters. Trace messages transmitted over the Nexus interface (or stored in trace memory) include which NXMC generated the message as well as an identifier for the pre-concentrator source of the message. In addition to XBAR bus master trace capability, the NXMC also allows for in-circuit trace capability that can be used to trace the Sequence Processing Unit (SPU) counter values. The two external hardware watchpoint triggers of each NXMC are used to generate timestamps (four total—two from each NXMC) for events from the SPU.

The following figure shows a block diagram illustrating the NXMC integration.

Figure 65. NXMC integration block diagram

The values of the trace master ID or in-circuit client ID, along with the Nexus message source identifier for the different clients are shown in the following table.

Table 141. NXMC source and master client IDs

Client		Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
In-Circuit Trace	SPU	0b1011	0b0000
XBAR Client 0 Concentrator (fast masters)	Hardware Security Module (HSM)	0b1100	0b0000
	eDMA Controller		0b0001
	Reserved		0b0010–0b0111

Table 141. NXMC source and master client IDs (continued)

Client		Nexus trace source ID (SRC)	Trace master ID or In-circuit trace client ID (MASTER)
XBAR Client 1 Concentrator (slow masters)	System Bus	0b1101	0b1000
	FlexRay		0b1001
	Ethernet		0b1010
	Reserved		0b1011–0b1110
Data Write Processor Unit (DWPU)	e200zx core	— ⁽¹⁾	0b1111

1. The Nexus trace Source ID is the same as the original core SRC.

12.7 Data trace filtering

The Data Write Processing Unit (DWPU) supports data trace filtering as well as out of range parameter identification.

Table 142. Reference links to related information

Related module	Reference
Data Write Processing Unit (DWPU)	Chapter 98: Buddy Device—Data Write Processing Unit (DWPU)

DWPU operates in conjunction with the BD NAR and a small RAM array. DWPU receives its input trace stream from the BD NAR Nexus Out Link. The trace stream is initially decompressed (which includes conversion of relative address and data values to absolute values) to ease subsequent filtering and comparison operations. The decompression process tracks multiple contexts, with individual context tracking required for each supported Nexus client.

The processed stream then passes through an address compare block, that generates tag RAM addresses corresponding to a portion of each data write address within the trace stream. Another portion of the data write addresses is used to select a particular bit from the data word returned by the tag RAM, so that each tag RAM bit corresponds to a unique 64-bit data write address. The value of the selected bit determines whether the data write trace occurrence is passed out of the DWPU back to the BD NAR, or is removed from the trace stream. DWPU returns the data trace filtered and re-formatted stream back to a secondary Nexus client input port on the BD NAR.

13 Core Complex Overview

The SPC57EM80xx has four separate cores that perform various computational and control functions. The main computational shell consists of Main Core_0 and Main Core_1, both of which use an e200z420n3 core. These two cores are used for general computational functions. A third core, referred to as Checker Core_0s, uses an e200z419 core, which is a true subset of the e200z420n3 core. When enabled, Checker Core_0s operates in Lock Step mode with Main Core_0 executing exactly the same instructions as Main Core_0. Checker Core_0s checks to ensure that Main Core_0 is executing correctly. There is no Lock Step function associated with Main Core_1. The e200z419 core, used as Checker Core_0s, differs in hardware from the e200z420n3 in that it has no Instruction Cache, Data Cache, I-memory, or D-memory. The fourth processor, Peripheral Core_2, employs an e200z425n3 core and is generally used to control various I/O modules. The register set for these three cores is identical.

Note: The processor ID for each CPU core is contained in its Processor ID Register (PIR).

This chapter provides overviews of the e200z420n3 core, the e200z419 core and the e200z425n3 core.

13.1 Overview of the e200z420n3, e200z419, and e200z425n3 cores

The e200z processor family is a set of CPU cores that implement low-cost versions of the Power Architecture.

Each core integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

The e200z420n3, e200z419, and e200z425n3 are dual-issue, 32-bit Power VLE (variable-length-encoding) compliant designs with 32-bit general-purpose registers (GPRs) for improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document. The base *PowerISA 2.06* fixed-length 32-bit instruction set is not directly supported.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision embedded numeric operations using the general-purpose registers.

13.2 Features

The following is a list of some of the key features of the e200z420n3, e200z419, and e200z425n3 processor cores:

- Dual issue, 32-bit *PowerISA 2.06*-VLE compliant CPU
- In-order execution and retirement
- Precise exception handling
- Branch processing unit
 - Dedicated branch address calculation adder
 - Branch target prefetching using BTB allows for single cycle branches in many cases
- Load/store unit
 - 2 cycle load latency
 - Fully pipelined
 - Misaligned access support
- 32-bit General-Purpose Register (GPR) file
- Dual AHB 2.v6 64-bit system buses
- Local Instruction and Data Memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
 - e200z420n3 core—16 KB IMEM, 64 KB DMEM
 - e200z425n3 core—16 KB IMEM, 64 KB DMEM
 - e200z419 core does not contain either Instruction or Data Memories
- Memory Protection Unit (MPU) implementing a 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized instruction or data memory regions
- 2-Way Set Associative Harvard Instruction and Data Cache
 - e200z420n3 core—8 KB ICache, 4 KB DCache
 - e200z425n3 core—8 KB ICache, no DCache
 - e200z419 core does not contain either Instruction or Data Cache
- Embedded Floating-point APU (EFPU2) supporting single-precision floating-point operations
- Lightweight Signal Processing (LSP) APU (e200z425n3 core only) supporting fixed-point multiply/accumulate and integer/fixed-point operations using the 32-bit General-Purpose Register file.
- Performance Monitor APU supporting execution profiling
- Nexus Class 3+ Real-time Development Unit
- Power management
 - Low power design with extensive clock gating
 - Power saving modes: DOZE, NAP, SLEEP, WAIT
 - Dynamic power management of execution units, caches, and local memories
- Testability
 - Synthesizeable, MuxD scan design
 - ABIST/MBIST for arrays
 - Built-in LBIST unit

13.3 Microarchitecture summary

The e200z420n3, e200z419, and e200z425n3 processor cores utilize a five stage instruction pipeline with two stages for execution. The Instruction Fetch, Instruction Decode/Register File Read/ EA Calc, Execute0/Memory Access0, Execute1/Memory Access1, and Register Writeback stages operate in an overlapped fashion allowing single-clock instruction execution for most instructions. [Figure 66](#) shows a block diagram of the e200z architecture.

The integer execution units each consists of a 32-bit Arithmetic Unit (AU), a Logic Unit (LU), a 32-bit Barrel Shifter (Shifter), a Mask-Insertion Unit (MIU), a Condition Register Manipulation Unit (CRU), a Count Leading Zeros unit (CLZ), and result feed-forward hardware. Integer EU1 also supports hardware division and a 32 x 32 Hardware Multiplier array.

Most arithmetic and logical operations are executed in a single-cycle with the exception of the multiply, which is implemented with a pipelined hardware array, and divide instructions. A Count-Leading-Zeros unit operates in a single clock cycle.

The Instruction Unit contains a PC incrementer and dedicated branch address adders to minimize delays during change-of-flow operations. Sequential prefetching is performed to ensure a supply of instructions into the execution pipeline. Branch target prefetching is performed to accelerate taken branches. Prefetched instructions are placed into an instruction buffer.

Branch target addresses are calculated in parallel with branch instruction decode, resulting in an execution time of two clock cycles for correctly predicted branches. Conditional branches that are not taken execute in a single clock. Branches with successful BTB target prefetching have an effective execution time of one clock if correctly predicted.

Memory load and store operations are provided for byte, halfword, word (32-bit), and doubleword data with automatic zero or sign extension of byte and halfword load data as well as optional byte reversal. These instructions can be pipelined to allow effective single-cycle throughput. Load and store multiple word instructions allow low overhead context save and restore operations. The load/store unit contains a dedicated effective address adder to optimize effective address generation.

The CRU supports the condition register (CR) and condition register operations defined by the Power Architecture. The condition register consists of eight 4-bit fields that reflect the results of certain operations — such as move, integer and floating-point compare, arithmetic, and logical instructions, and provide a mechanism for testing and branching.

Figure 66. e200z block diagram

Vectored and autovectored interrupts are supported by the CPU. Vectored interrupt support is provided to allow multiple interrupt sources to have unique interrupt handlers invoked with no software overhead.

The LSP APU (included only on the e200z425n3 core) supports vector instructions operating on 16-bit and 32-bit fixed-point data types. The EFPU2 APU supports 32-bit IEEE-754 single-precision floating-point formats and operates in a pipelined fashion. The 32-bit

general-purpose register file is used for source and destination operands. There is a unified storage model for scalar single-precision floating-point data types of 32 bits and the normal integer type. Low latency floating-point add, subtract, mixed add/subtract, sum, diff, min, max, multiply, multiply-add, multiply-sub, divide, square root, compare, and conversion operations are provided. Most operations can be pipelined.

13.3.1 Instruction unit features

The features of the e200z420n3, e200z419, and e200z425n3 instruction units are:

- 64-bit path to cache supports fetching of two 32-bit instructions per clock
- Instruction buffer holds up to 8 32-bit instructions
- Dedicated PC incrementer supporting instruction prefetches
- Branch unit with dedicated branch address adder and branch lookahead logic (BTB) supporting single-cycle execution of successfully predicted branches

13.3.2 Integer unit features

The e200z420n3, e200z419, and e200z425n3 integer units support single-cycle execution of most integer instructions:

- 32-bit AU for arithmetic and comparison operations
- 32-bit LU for logical operations
- 32-bit priority encoder for the Count Leading Zeros function
- 32-bit single-cycle Barrel Shifter for static shifts and rotates
- 32-bit mask unit for data masking and insertion
- Divider logic for signed and unsigned divide in 4–14 clock cycles with minimized execution timing (EU1 only)
- Pipelined 32 x 32 hardware multiplier array supports 32 x 32->32 multiply with 2 clock latency, 1 clock throughput (EU1 only)

13.3.3 Load/Store unit features

The e200z420n3, e200z419, and e200z425n3 load/store units support load, store, and the load multiple / store multiple instructions:

- 32-bit effective address adder for data memory address calculations
- Pipelined operation supports throughput of one load or store operation per cycle
- Dedicated 64-bit interface to memory supports saving and restoring of up to two registers per cycle for load multiple and store multiple word instructions and context save/restore instructions

13.3.4 EFPU2 Floating-Point Unit features

The EFPU2 embedded floating-point unit supports pipelined operation of most floating-point operations, allowing a throughput of one FP operation per cycle, and supports a variety of operations:

- Supports IEEE754 single-precision data format
- Supports IEEE754 half-precision format for conversion $\leftrightarrow$ single-precision format
- EFPU2 instructions utilize the 32-bit GPRs for minimized context save/restore overhead
- Provides low latency pipelined floating-point add, subtract, add/sub, sub/add, multiply, multiply-add, min, max, absolute value, compare, and conversion instructions with single-cycle throughput
- Default results mode for real-time applications allows for exception-free operations when underflow or overflows occur
- Trap Enable controls allow for trapping of various operation exceptions and emulation of IEEE754 boundary case results
- Floating-point Divide and Square root logic operating in 13 (FP div) and 11 (FP sqrt) clock cycles

13.3.5 LSP Lightweight Signal Processing Unit features

The LSP APU is designed to accelerate signal processing applications normally suited to DSP operation.

- LSP instructions operate on the 32-bit GPRs
- Supports SIMD integer operations - arithmetic, logical, shift
- Supports SIMD rounding, saturation, pack, unpack, merge, extract, select for efficient data manipulation
- Supports SIMD multiply/multiply accumulate/ dot product operations
- 16, 32, and (limited) 64-bit signed and unsigned integer data types
- 16-bit and 32-bit signed fractional support (1.15, 1.31 representations)
- Guarded 32-bit and 64-bit signed fractional support (9.23, 33.31, and 17.47 representations)
- Single-cycle throughput for all instructions (except frac divide)
- Supports fractional divide operations (32/32 $\rightarrow$ 32)
- Specialized operations such as field manipulation, count-leading sign/zero bits
- Supports specialized load/store operations with integrated data manipulation
- Multiple addressing modes supported including circular and bit-reversed addressing
- Sustained throughput of up to 2 16x16-bit multiply/accumulate operations per cycle.

13.3.6 MPU features

The features of the MPU are as follows:

- 24-entry fully-associative Range Table
- Arbitrary range size support from 1 byte to 4 GB
- 8-bit process identifier
- Bypass capability for individual access types
- Maskable process identifier and address
- Programmable memory attributes
- Entry invalidation protection
- Write-once option
- Alternate Debug Breakpoint/Watchpoint function

13.3.7 Cache features

The features of the caches are as follows:

- 2-Way Set Associative Harvard Instruction and Data Caches
 - e200z420—8 KB ICache, 4 KB DCache
 - e200z425—8 KB ICache, No DCache
 - e200z419—No ICache, No DCache
- Writethrough support
- 8-entry Store Buffer
- Linefill Buffer
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and 64-bit write data bus
- Way locking support
- Write allocation policies
- Support for multi-bit EDC with correction/auto-invalidation capability for the instruction and data caches
- Hardware debug cache invalidate support for the data cache via DBL1CCSR0 register
- Software and hardware debug access to cache tag, status, and data storage via CDANTL and CDADATA dedicated control registers

13.3.8 Local memory features

The features of the Local Instruction and Data Memories are as follows:

- Local Instruction and Data Memories (IMEM, DMEM) with shared AHB 2.v6 64-bit slave interface
 - e200z420n3—16 KB IMEM, 64 KB DMEM
 - e200z425n3—16 KB IMEM, 64 KB DMEM
 - e200z419—No IMEM, No DMEM
- I-MEM provides RAM storage for instruction allowing the CPU to execute these instruction with 0 wait-state delay. I-MEM includes a feature to allow the memory to be relocated in the memory map as seen by the local CPU, such that it overlays MCU code flash (The memory map to other bus masters is unchanged). This relocation of the I-MEM into the flash region, allows it to be accessed directly from any location in

flash with a single short branch instruction. IMEM and DMEM are not duplicated on e200z419 core.

- Supports zero wait-state access relative to cache hit timings
- Supports multi-bit (SECCDED) ECC with correction/scrubbing capability
- 4-entry ECC RMW Store Buffer for DMEM
- 32-bit address bus plus attributes and control
- Separate uni-directional 64-bit read data bus and (for DMEM only) 64-bit write data bus

13.3.9 Performance Monitor Unit Features

The features of the e200z42x performance monitor include:

- Four configurable 32-bit performance monitor counters each capable of counting selected CPU subsystem events
- Performance Monitor interrupt
- Ability to configure performance monitor resources for debugger use
- Hardware input signals for qualification of counting by individual counters
- Hardware output signals to indicate counter overflows
- Dedicated watchpoint outputs for each counter with programmable periodicity
- Trigger On/Off control for each counter based on subsystem events
- Multiple selectable event types including # of clock cycles, CPU stall cycles, # of instructions completed, # of interrupts taken, # of memory accesses (by type), # of instruction or data cache misses, # of cycles with 0, 1, or 2 instructions issued, # of instructions in a given class completed (ldst, branch, integer, FP, etc.), cache linefills, and many other event types

13.3.10 e200z420n3 and e200z425n3 system bus features

The features of the e200z420n3 and e200z425n3 system bus interface are as follows:

- Independent instruction and data interfaces
- Advanced microcontroller bus architecture (AMBA) AHB2.v6 protocol
- 32-bit address bus, 64-bit data bus, plus attributes and control
- Data interface provides separate uni-directional 64-bit read and write data buses
- Support for HCLK running at a slower rate than CPU clock

13.3.11 e200z419 system features

Checker Core_0 is implemented using an e200z419 core. When enabled, Checker Core_0s is used in Lock Step with Main_Core_0. The e200z419 core can only be enabled or disabled by the user. For the SPC57EM80xx device, the Checker Core_0s has no system bus and cannot independently execute user code. The core is only used to execute the same instruction stream as Main Core 0.

The e200z419 core is identical to the e200z420n3 with five exceptions:

- IMEM memory array is not present
- I CACHE memory array is not present
- D MEM memory array is not present
- D CACHE memory array is not present
- The e200z419 has a pair of system bus interfaces, which are driven/sampled by the delayed Lock Step logic

13.4 Availability of detailed documentation

Detailed documentation of the e200z4xxd core is provided in a separate core reference manual (CRM). This CRM is available online at <http://www.st.com>.

14 Core e200z420n3 description

14.1 Overview of the e200z420n3 core

The e200z420n3 is a dual-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z420n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

The e200z420n3 processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

e200z420n3 contains an 8 KB Instruction Cache, and a 4 KB Data Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit that protects various instruction and data memory areas is also included.

14.2 Register model

This section describes the registers implemented in the e200z420n3 core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

e200z420n3 extends usage of the general purpose registers to support EFPU operations on the 32-bit GPR registers.

[Figure 67](#) and [Figure 68](#) show the complete e200z420n3 register set, all of which are accessible in supervisor mode. [Figure 69](#) and [Figure 70](#) show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

Figure 69. e200z420n3 User Mode Programmer's Model SPRs

Figure 70. e200z420n3 User Mode Programmer's Model PMRs

14.3 Dual-issue operation

The instruction issue unit attempts to issue a pair of instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the

operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions.

Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

[Table 143](#) shows the e200z420n3 concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue of those instructions.

Table 143. Concurrent instruction issue capabilities for e200z420n3

Class of instruction	Branch	Load/Store	Scalar integer	Scalar float	Special
Branch	—	yes	yes	yes	—
Load/Store	yes	—	yes	yes	—
Scalar integer	yes	yes	yes ⁽¹⁾	yes	—
Scalar float	yes	yes	yes	—	—
Special	—	—	—	—	—

1. Excludes multiply or divide class instructions occurring in both issue slots.

14.4 Reservation instructions and cache interactions

The CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited, and forces a cache miss. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure. The bus access will be treated as a single-beat transfer.

14.5 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the mfspr and mtspr instructions. The SPEFSCR is shown in Figure 71.

Figure 71. EFPU Status and Control Register (SPEFSCR)

0										FINXS	FINVS	FDBZS	FUNFS	FOVFS	MODE	0	0	FG	FX	FINV	FDBZ	FUNF	FOVF	0	FINXE	FINVE	FDBZE	FUNFE	FOVFE	FRMC

SPR 512; Read/Write; Reset: 0x0

The SPEFSCR bits are defined in [Table 144](#).

Table 144. EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z420n3 supports only mode 0. Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by Zen)
16 (48)	—	Reserved
17 (49)	—	Reserved
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler. FX is zeroed if a Floating-point Data Exception occurs.

Table 144. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the I dividend is a finite nonzero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact ($FG \vee FX = 1$), or if the result of a Floating-point instruction does result in overflow ($FOVF = 1$) but Floating-point Overflow exceptions are disabled ($FOVFE = 0$), or if the result of a Floating-point instruction results in underflow ($FUNF = 1$ or $FUNFH = 1$) but Floating-point Underflow exceptions are disabled ($FUNFE = 0$), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
28 (60)	FUNFE	Embedded Floating-point Underflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FUNF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

Table 144. EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
29 (61)	FOVFE	Embedded Floating-point Overflow Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FOVF bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

14.6 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

14.6.1 Cache overview

The e200z420n3 processor supports an 8 KB 2-way set-associative instruction and 4 KB 2-way set-associative data cache with a 32-byte line size.

The caches improve system performance by providing low-latency data to the e200z420n3 instruction and data pipelines, which decouples processor performance from system memory performance.

The e200z420n3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction and data addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

14.6.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of the data cache and for disabling ways in both caches. The L1CSR0 register is accessed using a **mfsprr** or **mtsprr** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in [Figure 72](#).

Figure 72. L1 Cache Control and Status Register 0 (L1CSR0)

WID		0		WDD		0						DCWA	0		DCECE	DCEI	DCLOC		0						DCEA		DCLOINV	0		DCABT	DCINV	DCE
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	

SPR 1010; Read/Write; Reset: 0x0

The L1CSR0 fields are described in [Table 145](#).

Table 145. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:3	—	Reserved ⁽¹⁾
4:5	WDD	Way Data Disable Bit 4 corresponds to way 0. Bit 5 corresponds to way 1. The WDD bits may be used for locking ways of the data cache, and also affect the replacement policy of the data cache. 0 The corresponding way in the data cache is available for replacement by data miss line fills. 1 The corresponding way in the data cache is not available for replacement by data miss line fills.
8:11	—	Reserved ⁽¹⁾
12	DCWA	Data Cache Write Allocation Policy This bit also controls merging of store data into the linefill buffer while a cache linefill is in progress. Store data will not be merged when write allocation is disabled. 0 Cache line allocation on a cacheable write miss is disabled 1 Cache line allocation on a cacheable write miss is enabled
13:14	—	Reserved ⁽¹⁾
15	DCECE	Data Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	DCEI	Data Cache Error Injection DCEI will cause injection of errors regardless of the setting of DCECE, although reporting of errors will be masked while DCECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected on each write into the cache data array by inverting the two uppermost parity check bits (p_dchk[0:1]). This includes writes due to store hits as well as writes due to cache line refills.

Table 145. L1CSR0 field descriptions (continued)

Bits	Name	Description
17:18	DCLOC	Data Cache Lockout Control <i>Note: For the dcbi and dcbf instructions, and for specialized load/store instructions, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled.</i> <i>Note: When operating in MC mode (DCEA = 00), detected errors on cache-inhibited accesses will not cause a data cache line to be locked out, instead the cache line contents are ignored.</i> 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved ⁽¹⁾
25:26	DCEA	Data Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	DCLOINV	Data Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing DCINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. When DCINV = 0: Reserved, do not set to 1 When DCINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved ⁽¹⁾
29	DCABT	Data Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.

Table 145. L1CSR0 field descriptions (continued)

Bits	Name	Description
30	DCINV	Data Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the data cache enable (DCE) value. 0 No cache invalidate 1 Cache invalidation operation
31	DCE	Data Cache Enable When disabled, cache lookups are not performed for normal load or store accesses. Other L1CSR0 cache control operations are still available. Also, operation of the store buffer is not affected by DCE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

14.6.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mfsprr** or **mtsprr** instruction. The SPR number for L1CSR1 is 1011 in decimal. The L1CSR1 register is shown in [Figure 73](#).

Figure 73. L1 Cache Control and Status Register 1 (L1CSR1)

0															ICECE	ICEI	ICLOC	0							ICEA	ICLOINV	0	ICABT	ICINV	ICE	
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR 1011; Read/Write; Reset: 0x0

The L1CSR1 fields are described in [Table 146](#).

Table 146. L1CSR1 field descriptions

Bits	Name	Description
0:14	—	Reserved ⁽¹⁾
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled
16	ICEI	Instruction Cache Error Injection Enable ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits (p_chk[0:1]).

Table 146. L1CSR1 field descriptions (continued)

Bits	Name	Description
17:18	ICLOC	Instruction Cache Lockout Control <i>Note: For the icbi instruction, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled.</i> <i>Note: When operating in MC mode (ICEA = 00), detected errors on cache-inhibited accesses will not cause an instruction cache line to be locked out, instead the cache line contents are ignored.</i> 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved ⁽¹⁾
25:26	ICEA	Instruction Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing ICINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value. Bits	Name	Description
30	ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31	ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

14.6.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z420n3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfspir** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in [Figure 74](#).

Figure 74. L1 Cache Configuration Register 0 (L1CFG0)

11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 The size of the instruction cache is 8 KB

14.6.6 Data Cache Software Coherency

Data cache coherency is supported through software operations to invalidate lines using either a **dcbi** or **dcbf** instruction, or by using the L1FINV0 control register.

Data cache misses will force the store buffer to empty prior to performing the access.

14.6.7 Data Cache Hardware Coherency

Data cache coherency is not supported in hardware. Software operations must generally be used to maintain coherency.

Debug support is provided, however, for a D-Cache line invalidation operation requested by an external hardware debugger. When requested by an external hardware debugger tool operating through the OnCE port, an individual cache line invalidation operation will be scheduled to occur at the next available D-Cache access cycle

14.6.8 Cache Invalidate by Set and Way

e200z420n3 supports cache set/way invalidation under software control. The caches may be invalidated by index and way through a **mtspr l1finv{0,1}** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV{0,1}) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when a cache is disabled. L1FINV0 is used for data cache operations, while L1FINV1 is used for instruction cache operations.

14.6.8.1 L1FINV0

The SPR number for L1FINV0 is 1016 in decimal. The L1FINV0 register is shown in [Figure 76](#).

Figure 76. L1 Flush/Invalidate Register 0 (L1FINV0)

0	CWAY	0	CSET	0	CCMD
---	------	---	------	---	------

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 1016; Read/Write; Reset: 0x0

The L1FINV0 bits are described in [Table 149](#).

Table 149. L1FINV0 field descriptions

Bits	Name	Description
0:6	—	Reserved ⁽¹⁾ for way extension
7	CWAY	Cache Way Specifies the data cache way to be selected
8:20	—	Reserved ⁽¹⁾ for set extension
21:26	CSET	Cache Set Specifies the cache set to be selected
27:28	—	Reserved ⁽¹⁾ for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV0, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

14.6.8.2 L1FINV1

The SPR number for L1FINV1 is 959 in decimal. The L1FINV1 register is shown in [Figure 77](#).

Figure 77. L1 Flush/Invalidate Register 1 (L1FINV1)

0	CWAY	0	CSET	0	CCMD

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 959; Read/Write; Reset: 0x0

The L1FINV1 bits are described in [Table 150](#).

Table 150. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved ⁽¹⁾ for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8:19	—	Reserved ⁽¹⁾ for set extension
20:26	CSET	Cache Set Specifies the instruction cache set to be selected
27:28	—	Reserved ⁽¹⁾ for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

14.6.9 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of each cache. Seven parity check bits are provided for each tag entry for the tag arrays of both caches to support error detection and correction (ECC — SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, and each word in the data arrays of the D-Cache, which are used for single- and double-bit error detection (EDC — DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the L1CSR0_{DCECE} and L1CSR1_{ICECE} control fields. When error checking is enabled, checking is performed on each cache access. Errors are not signaled by the respective cache when cache error checking is disabled for that cache (L1CSR{0,1}_{[D,I]CECE} = 0).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, normal loads, or normal stores, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch or a normal load occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Store hits to the D-Cache will be placed into one of the RMW buffers to support EDC checkbit operation. If the store is a partial-width store, the cache data word corresponding to

the address of the store is read into the next available buffer, the store data is merged, and the new EDC checkbits for the word are calculated. If the store is a full-width store, no read of the cache data is performed, since the store will overwrite the full EDC data granularity, and the EDC checkbits can be computed directly. Buffers are managed on a FIFO basis. If no buffer is available to hold the store data, a stall is incurred while a buffer (or two if possible) is written back to the cache to be freed for holding the new store. Buffers are written back to the D-Cache during otherwise idle cycles when two buffers are occupied, providing a simple form of store gathering.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

14.6.9.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the caches, each cache line in the I-Cache and D-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by $L1CSR\{0,1\}_{[D,I]CLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on normal instruction fetch, load, or store accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via $L1CSR\{0,1\}_{[D,I]CLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch or normal load or store access, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, to avoid certain exception conditions and for consistency with error reporting, specialized load/store accesses do not set LO bits; instead, cache contents are ignored for lines with those errors. Cache flush and invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable normal access will perform the lockout function if required.

14.6.10 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction and/or data cache.

Error injection into the instruction cache operates as follows:

- If L1CSR1_{ICEI} is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Error injection for the data cache operates as follows:

- If L1CSR0_{DCEI} is set, any cache line fill to the data cache data array has the associated two most significant parity check bits inverted in the data array for each word loaded. Additionally, inverted parity bits are generated for any data stored into the data cache data array on a store hit.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi/dcbi** instruction, or an L1FINV{0,1} invalidation operation.

14.7 Exceptions

Interrupts implemented in e200z420n3 and the exception conditions that cause them are listed in [Table 151](#).

Table 151. Exceptions and conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] 2'b00	Reset
Critical Input	0x00 ⁽¹⁾	p_critint_b is asserted and MSR _{CE} = 1.
Machine check	0x10	1. p_mcp_b transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40 ⁽²⁾	Interrupt Controller interrupt and MSR _{EE} = 1
Alignment	0x50	1. lmw, stmw not word aligned 2. lwarx or stwcx. not word aligned, lharx or sthcx. not halfword aligned 3. dcbz
Program	0x60	Illegal, Privileged, Trap

Table 151. Exceptions and conditions (continued)

Interrupt type	Interrupt vector offset value	Causing conditions
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/PMGC0 _{UDI} = 0
System call	0x80	Execution of the System Call (se_sc) instruction
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/PMGC0 _{UDI} = 1, MPU
EFPU Data Exception	0xA0	See section “Embedded Floating-point Data Exception” in the Power Architecture core reference manual relative to this core.
EFPU Round Exception	0xB0	See section “Embedded Floating-point Round Exception” in the Power Architecture core reference manual relative to this core.
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectored Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectored External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

14.7.1 Exception Syndrome Register (ESR)

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

Figure 78. Exception Syndrome Register (ESR)

0				PIL	PPR	PTR	FP	ST	0		0	0	BO	0	0								SPV	0	VLEMI	0			0	0

Read/ Write; Reset: 0x0

The MSR bits are defined in [Table 153](#).

Table 153. MSR field descriptions

Bit(s)	Name	Description
0:13	—	Reserved
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	—	Reserved
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	—	Reserved
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23:28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR _{PR} and MSR _{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLC _n Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

14.7.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in [Figure 80](#).

Figure 80. Machine Check Syndrome Register (MCSR)

0	MCP	1	IC_DPERR	2	0	3	DC_DPERR	4	EXCP_ERR	5	IC_TPERR	6	DC_TPERR	7	IC_LKERR	8	DC_LKERR	9	0	10		11	NMI	12	MAV	13	MEA	14	U	15	IF	16	LD	17	ST	18	G	19	0	20		21	STACK_ERR	22	IMEM_PERR	23	DMEM_RDPERR	24	DMEM_WRPERR	25	0	26		27	BUS_IRERR	28	BUS_DRERR	29	BUS_WRERR	30	BUS_WRDSI	31	0

SPR 572; Read/Clear; Reset: 0x0

[Table 154](#) describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as “write 1 to clear.” Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR_{ME} = 1.

Table 154. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type ⁽¹⁾	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise

Table 154. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type ⁽¹⁾	Recoverable
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load or linefill	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.

— “Error Report” indicates that this bit is only set for error report exceptions that cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

— “Status” indicates that this bit provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

— “NMI” indicates that this bit is only set for the non-maskable interrupt type exception, which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a ‘1’ to the bit position.

— “Async Mchk” indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any “Async Mchk” bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME} = 1. If MSR_{ME} = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

2. Note that since no address translation mechanism is present on e200z420n3, the MEA value is always set to ‘0’.

14.7.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in [Figure 81](#).

Figure 81. Zen Interrupt Vector Prefix Register (IVPR)

Vector Base																								0							
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR 63; Read/Write

The IVPR fields are defined in [Table 155](#).

Table 155. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

14.7.5 Interrupt Definitions

14.7.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE} , the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

[Table 156](#) lists register settings when a Critical Input interrupt is taken.

Table 156. Critical Input Interrupt—register settings

Register	Setting description		
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
CSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME — FE0 0 DE —/0 ⁽¹⁾	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	Unchanged		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	IVPR _{0:23} 0x00 (autovectored) IVPR _{0:15} (IVPR _{16:29} p_voffset[0:13]) 2'b00 (non-autovectored)		

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register ($HID0_{CICLRDE}$).

14.7.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register (HID0_{MCCLRDE}).

When a Machine Check interrupt is taken, registers are updated as shown in [Table 157](#).

Table 157. Machine Check Interrupt—register settings

Register	Setting description		
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.		
MCSRR1	Set to the contents of the MSR at the time of the interrupt

ESR	Unchanged		
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.		
Vector	IVPR _{0:23} 0x10		

1. Clearing of DE is optionally supported by control in HID0.

14.7.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

[Table 158](#) lists register settings when a DSI is taken.

Table 158. Data Storage Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the excepting load/store instruction.

ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	IVPR _{0:23} 0x30		

14.7.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

[Table 160](#) lists register settings when an External Input interrupt is taken.

Table 160. External Input Interrupt—register settings

Register	Setting description
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.
SRR1	Set to the contents of the MSR at the time of the interrupt

Table 160. External Input Interrupt—register settings (continued)

14.7.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.

[Table 161](#) lists register settings when an alignment interrupt is taken.

Table 161. Alignment Interrupt—register settings

SRR0	Set to the effective address of the excepting load/store/dcbz instruction.			
SRR1	Set to the contents of the MSR at the time of the interrupt			
MSR	SPV 0 WE 0 CE — EE 0 PR 0	FP 0 ME — FE0 0 DE —	FE1 0 IS 0 DS 0 PMM 0 RI —	
ESR	[ST], VLEMI. All other bits cleared.			
MCSR	Unchanged			
DEAR	Set to the effective address of a byte of the load or store access causing the violation.			
Vector	IVPR _{0:23} 0x50			

14.7.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z420n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspir** instructions with an undefined SPR specified
- **mtdcr** and **mfddcr** instructions with an undefined DCR specified

The e200z420n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when $MSR_{PR} = 1$ (user mode):

- A privileged instruction
- **mtspr** and **mfspir** instructions that specify a SPRN value with $SPRN_5 = 1$ (even if the SPR is undefined)

The e200z420n3 will invoke a Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfddcrx**, **mtddcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

[Table 162](#) lists register settings when a Program interrupt is taken.

Table 162. Program Interrupt—register settings

DEAR	Unchanged		
Vector	IVPR _{0:23} 0x80		

14.7.5.9 Debug Interrupt (offset 0x90)

There are multiple sources that can signal a Debug exception. A Debug interrupt occurs when no higher priority exception exists, a Debug exception exists in the Debug Status Register, and Debug interrupts are enabled (both DBCR0_{IDM} = 1 (internal debug mode) and MSR_{DE} = 1).

[Table 164](#) lists register settings when a Debug interrupt is taken.

Table 164. Debug Interrupt—register settings

14.7.5.10 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

[Table 165](#) lists register settings when a System Reset interrupt is taken.

Table 165. System Reset Interrupt—register settings

14.7.5.13 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMCx register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, PMGC0_{PMIE} must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

[Table 168](#) lists register settings when an performance monitor interrupt is taken.

Table 168. Performance Monitor Interrupt—Register Settings

Register	Setting description			
SRR0/ DSRR0 ⁽¹⁾	Set to the effective address of the next instruction to be executed.

3. EE is not cleared if $PMGC0_{UDI} = 1$ and $HID0_{DCLREE} = 0$
4. DE is cleared if $PMGC0_{UDI} = 1$

14.8 Memory Protection Unit (MPU)

14.8.1 MPU Overview

The e200z420n3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

14.8.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mf spr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

14.8.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure

mpu read entry

mpure

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

14.8.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe
mpu write entry

mpuwe

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

14.8.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the e200z420n3.

mpusync
MPU Synchronize

mpusync

mpusync

14.8.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z420n3 MPU design. The MMUCFG register is shown in [Figure 82](#).

Figure 82. MMU/MPU Configuration Register (MMUCFG)

0	RASIZE	0	PIDSIZE	NMPUS	NTLBS	MAVN
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31						

SPR 1015; Read-Only

The MMUCFG bits are described in [Table 169](#).

Table 169. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

14.8.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z420n3 MPU. The MPU0CFG register is shown in [Figure 83](#).

Figure 83. MPU0 Configuration Register (MPU0CFG)

FASSOC	0	MINSIZE	MAXSIZE	IPROT	0	UAMSKA	0	SHENTRY	DENTRY	IENTRY

SPR 1014; Read/ Write; Reset: 0x0⁽¹⁾

- Reset by processor reset **p_reset_b** if EDBCR0_{EDM} = 0, as well as unconditionally by **m_por**. If EDBCR0_{EDM} = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in [Table 171](#).

Table 171. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYP UW	Bypass MPU protections for User Write accesses This bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYP UX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved

Table 171. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved

Table 171. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation <i>Note: Entries that have the IPROT bit set will not be invalidated.</i>
31	MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

14.8.9 MPU Assist Registers (MAS)

The e200z420n3 uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mf spr** and **mt spr** instructions.

The MAS0 register is shown in [Figure 85](#). Fields are defined in [Table 172](#).

Figure 85. MPU Assist Register 0 (MAS0)

VALID	IPROT	SEL		0	RO	DEBUG	INST	SHD	0		ESEL				0	UAMSK				UW	SW	UX/UR	SX/SR	IOVR	GOVR ⁽¹⁾	1	1	I	0	G ⁽¹⁾	0

SPR 624; Read/ Write; Reset: Unaffected

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 172. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 This MPU entry is invalid 1 This MPU entry is valid
1	IPROT	Invalidation Protect 0 Entry is not protected from invalidation 1 Entry is protected from invalidation

Table 172. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
2:3	SEL	Selects MPU for access: 00 Reserved, no access 01 Reserved, no access 10 Select MPU 11 Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 This MPU entry is writable 1 This MPU entry is Read-only
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for mpure and mpuwe instruction operations. When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 This MPU entry is used for matching data accesses only 1 This MPU entry is used for matching instruction accesses only
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. 0 The shared portion of the region descriptor table is not accessed on a mpure or mpuwe operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 The shared portion of the region descriptor table is accessed on a mpure or mpuwe operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:11	—	Reserved
12:15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1.

14.9 Local memories

14.9.1 Local Instruction and Data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added. This provides low latency access (zero wait-states) similar to an instruction or data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity “tightly coupled” storage capability.

14.9.2 Local memory control and configuration

DMEM and IMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mf spr** instructions. DMEM and IMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that are accessed using the **mf dcr** and **mt dcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

14.9.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z420n3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mf spr** instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register

is shown in [Figure 90](#).

Figure 90. DMEM Configuration Register 0 (DMEMCFG0)

DMEM BASE ADDR																				0	DECUA	DECA	0	DMSIZE					0

DCR 496; Read/Write; Reset⁽¹⁾: 19'b0 || p_dmem_rstcfg[8,6:7,0] || 4'b0 || p_dmem_rstcfg[1:5]; Privileged

1. Reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 177. DMEMCTL0 field descriptions

Bits	Name	Description
0:15	DMEM BASE ADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit. Note: Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that no cached entries are present in the D-Cache for the memory space to be occupied by the DMEM.
16:18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (lbcbx, lhcbx, lwc bx, and stwtwx, sthwtx, stbwtx) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[8] input.</i>
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[6] input.</i>

Table 177. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[7] input.</i>
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[0] input.</i>
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port (p_dmem_baseaddr[0:n]) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port (p_dmem_baseaddr[0:n]) is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port (p_dmem_baseaddr[0:n]) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]).
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).

Table 177. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. <i>Note: This field is updated on m_por and slv_reset_b based on the values of the p_dmem_rstcfg[1:2] inputs.</i>
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[3] input.</i>
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[4] input.</i>
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[5] input.</i>

14.9.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0_{DBYPCB}, DBYPATF, DBYPDEC.

14.9.2.4 IMEM Configuration Register 0 (IMEMCFG0)

The IMEM Configuration Register 0 (IMEMCFG0) is a 32-bit read-only register. IMEMCFG0 provides information about the configuration of the e200z420n3 local instruction memory design. The contents of the IMEMCFG0 register can be read using a **mf spr** instruction. The SPR number for IMEMCFG0 is 695 in decimal. The IMEMCFG0 register is shown in [Figure 93](#).

1. Reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 180. IMEMCTL0 field descriptions

Bits	Name	Description
0:17	IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. <i>Note: Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated, and that no cached entries are present in the I-Cache for the memory space to be occupied by the IMEM.</i>
18:19	—	Reserved for Base Address extension
20:21	—	Reserved
22	IECUE	IMEM Error Correction Update Enable IECUE can be used to provide an error scrubbing function. This field is updated on m_por and slv_reset_b based on the value of the p_imem_rstcfg[0] input. 0 Error Correction Update is disabled 1 Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read cycles will cause the IMEM to be re-written with the corrected data if the corresponding error checking enable bit is set (ICPECE for CPU accesses, ISECE for slave port accesses). IECUE can be used in conjunction with ICPECE and ISECE to provide an error scrubbing function.
23	—	Reserved
24	IBAPD	IMEM Base Address Port Disable This bit controls usage of the external Base Address port (p_imem_baseaddr[0:n]) to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses. 0 The external IMEM base address port (p_imem_baseaddr[0:n]) is used to define the base address of the IMEM for CPU accesses. 1 The external IMEM base address port (p_imem_baseaddr[0:n]) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses.
25:26	—	Reserved
27:28	ISWCE	IMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 4, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. <i>Note: This field is updated on m_por and slv_reset_b based on the values of the p_imem_rstcfg[1:2] inputs.</i>

Table 180. IMEMCTL0 field descriptions (continued)

Bits	Name	Description
29	IDAUEC	IMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_imem_rstcfg[3] input.</i>
30	ICPECE	IMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_imem_rstcfg[4] input.</i>
31	ISECE	IMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_imem_rstcfg[5] input.</i>

14.9.2.6 IMEM Control Register 1 (IMEMCTL1)

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.

Figure 95. IMEM Control Register 1 (IMEMCTL1)

A single control field is used for each access based on the upper two address bits used to index into the IMEM. IUXAC0 is used when these two bits = 2'b00.</i>

14.10 End-to-End ECC support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

14.10.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

14.10.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

Figure 96. e2eECC Control Register 0 (E2ECTL0)

0																												IDAC	IECCEN	DDAC	DECCEN
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DCR 510; Read/Write; Reset: 0x0 || p_e2e_rstcfg[0:3]; Privileged

Table 182. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. <i>Note: This field is updated on p_reset_b based on the value of the p_e2e_rstcfg[0] input.</i>
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. <i>Note: This field is updated on p_reset_b based on the value of the p_e2e_rstcfg[1] input.</i>
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. <i>Note: This field is updated on p_reset_b based on the value of the p_e2e_rstcfg[2] input.</i>
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. <i>Note: This field is updated on p_reset_b based on the value of the p_e2e_rstcfg[3] input.</i>

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the

initialization, software may enable e2eECC operation by writing the appropriate values to the E2ECTLO_{[I,D]ECCEN} control bits.

The E2ECTLO_{[I,D]DAC} control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

14.10.1.2 End-to-End ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits).

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

Figure 97 shows the layout of E2EECSR0.

Table 183. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to p_hrchkbit[7:0] for external reads and to p_dchk[0:7] for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	—	Reserved

Table 183. E2EECSR0 field descriptions (continued)

Bits	Name	Description
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving p_hwchkbit[7:0] with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving p_hwchkbit[7:0] with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved <i>Note: Checkbit substitution has priority over Error injection.</i>
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved <i>Note: Checkbit substitution has priority over Error injection.</i>
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to p_hwchkbit[7:0]. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on p_hwchkbit[7:0] when error injection occurs.

15 Core e200z425n3 description

15.1 Overview of the e200z425n3 core

The e200z425n3 is a dual-issue 32-bit *PowerISA 2.06* VLE compliant design with 32-bit general-purpose registers (GPRs). The e200z425n3 core implements the VLE (variable-length encoding) ISA, providing improved code density. The VLE ISA is further documented in *PowerISA 2.06*, a separate document.

An Embedded Floating-point (EFPU2) APU is provided to support real-time single-precision floating-point embedded numerics operations using the general-purpose registers.

A Lightweight Signal Processing Extension (LSP) APU is provided to support real-time SIMD fixed-point embedded numerics operations using the general-purpose registers. All arithmetic instructions that execute in the core operate on data in the general purpose registers (GPRs). The GPRs support register pairing in order to support vector instructions defined by the LSP APU. These instructions operate on a vector pair of 16-bit or 32-bit data types, and deliver vector and scalar results. A wide variety of data manipulation, multiply, multiply/accumulate, and dot product instructions along with specialized memory access instructions allow a sustained throughput of up to two 16×16 -bit multiply/accumulate operations per cycle.

The e200z425n3 processor integrates a pair of integer execution units, a branch control unit, instruction fetch unit, load/store unit, and a multi-ported register file capable of sustaining six read and three write operations per clock cycle. Most integer instructions execute in a single clock cycle. Branch target prefetching is performed by the branch unit to allow single-cycle branches in many cases.

e200z425n3 contains an 8 KB Instruction Cache, as well as a Nexus Class 3+ real-time debug module with support for program and data trace features as well as extensive trace controls.

A Memory Protection Unit that protects various instruction and data memory areas is also included.

15.2 Register model

This section describes the registers implemented in the e200z425n3 core. The *PowerISA 2.06* architecture defines register-to-register operations for all computational instructions.

e200z425n3 extends usage of the general purpose registers to support EFPU/LSP APU operations on the 32-bit GPR registers.

[Figure 98](#) and [Figure 99](#) show the complete e200z425n3 register set, all of which are accessible in supervisor mode. [Figure 100](#) and [Figure 101](#) show the subset of registers accessible in user mode. The number to the right of the special-purpose registers (SPRs) is the decimal number used in the instruction syntax to access the register (for example, the integer exception register (XER) is SPR 1).

15.3 Dual-issue operation

The instruction issue unit attempts to issue a pair of instructions to the execution units each cycle. Source operands for each of the instructions are provided from the GPRs or from the

operand feed-forward muxes. Data or resource hazards may create stall conditions that cause instruction issue to be stalled for one or more cycles until the hazard is eliminated.

The execution units write the result of a finished instruction onto the proper result bus and into the destination registers. The writeback logic retires an instruction when the instruction has finished execution. Up to three results can be simultaneously written.

Two execution units are provided to allow dual issue of most instructions.

Only a single load/store unit is provided. Only a single integer multiply and divide unit is provided, thus a pair of multiply or divide instructions cannot issue simultaneously. In addition, the divide unit is blocking.

[Table 184](#) shows the e200z425n3 concurrent instruction issue capabilities. Note that data dependencies between instructions will generally preclude dual-issue of those instructions.

Table 184. Concurrent instruction issue capabilities for e200z425n3

Class of instruction	Branch	Load/Store	Scalar integer	Scalar float	Vector integer non-MAC	Vector integer MAC	Special
Branch	—	yes	yes	yes	yes	yes	—
Load/Store	yes	—	yes	yes	yes	yes	—
Scalar integer	yes	yes	yes ⁽¹⁾	yes	yes	yes ⁽²⁾	—
Scalar float	yes	yes	yes	—	yes	yes	—
Vector integer non-MAC	yes	yes	yes	yes	yes	yes	—
Vector integer MAC	yes	yes	yes ⁽²⁾	yes	yes	—	—
Special	—	—	—	—	—	—	—

1. Excludes multiply or divide class instructions occurring in both issue slots.

2. Excludes vector MAC/multiply class instructions occurring with scalar multiply, or divide class instructions.

15.4 Reservation instructions and cache interactions

The CPU treats reservation instruction (**lbarx**, **lharx**, **lwarx**, **stbcx**, **sthcx**, and **stwcx**) accesses as though they were cache-inhibited. A reservation access is always issued to the bus. This is done to allow external reservation logic to be built that properly signals a reservation failure.

15.5 Signal Processing Extension/Embedded Floating-point Status and Control Register (SPEFSCR)

Status and control for embedded floating-point operations use the SPEFSCR. This register is also used by the LSP APU. The SPEFSCR is implemented as special-purpose register (SPR) number 512 and is read and written by the **mf spr** and **mt spr** instructions. The SPEFSCR is shown in Figure 102.

Figure 102. LSP/EFPU Status and Control Register (SPEFSCR)

0										FINXS	FINVS	FDBZS	FUNFS	FOVFS	MODE	SOV	OV	FG	FX	FINV	FDBZ	FUNF	FOVF	0	FINXE	FINVE	FDBZE	FUNFE	FOVFE	FRMC

SPR 512: Read/Write; Reset: 0x0

The SPEFSCR bits are defined in [Table 185](#).

Table 185. LSP/EFPU Status and Control Register field descriptions

Bits	Name	Description
0:9 (32:41)	—	Reserved
10 (42)	FINXS	Embedded Floating-point Inexact Sticky Flag The FINXS bit is set to 1 whenever the execution of a floating-point instruction delivers an inexact result and no Floating-point Data exception is taken, or if the result of a Floating-point instruction results in overflow (FOVF = 1), but Floating-point Overflow exceptions are disabled (FOVFE = 0), or if the result of a Floating-point instruction results in underflow (FUNF = 1), but Floating-point Underflow exceptions are disabled (FUNFE = 0), and no Floating-point Data exception occurs. The FINXS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
11 (43)	FINVS	Embedded Floating-point Invalid Operation Sticky Flag The FINVS bit is set to a 1 when a floating-point instruction sets the FINV bit to 1. The FINVS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
12 (44)	FDBZS	Embedded Floating-point Divide by Zero Sticky Flag The FDBZS bit is set to 1 when a floating-point divide instruction sets the FDBZ bit to 1. The FDBZS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
13 (45)	FUNFS	Embedded Floating-point Underflow Sticky Flag The FUNFS bit is set to 1 when a floating-point instruction sets the FUNF bit to 1. The FUNFS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
14 (46)	FOVFS	Embedded Floating-point Overflow Sticky Flag The FOVFS bit is set to 1 when a floating-point instruction sets the FOVF bit to 1. The FOVFS bit remains set until it is cleared by a mtspr instruction specifying the SPEFSCR.
15 (47)	MODE	Embedded Floating-point Operating Mode This bit controls the operating mode of the EFPU. e200z425n3 supports only mode 0. Software should read the value of this bit after writing it to determine if the implementation supports the selected mode. Implementations will return the value written if the selected mode is a supported mode, otherwise the value read will indicate the hardware supported mode. 0 Default hardware results operating mode 1 IEEE754 hardware results operating mode (not supported by Zen)
16 (48)	SOV	Summary integer overflow Defined by LSP APU.
17 (49)	OV	Integer overflow Defined by LSP APU.

Table 185. LSP/EFPU Status and Control Register field descriptions (continued)

Bits	Name	Description
18 (50)	FG	Embedded Floating-point Guard bit FG is supplied for use by the Floating-point Round exception handler. FG is zeroed if a Floating-point Data Exception occurs.
19 (51)	FX	Embedded Floating-point Sticky bit FX is supplied for use by the Floating-point Round exception handler. FX is zeroed if a Floating-point Data Exception occurs.
20 (52)	FINV	Embedded Floating-point Invalid Operation / Input error In mode 0, the FINV bit is set to 1 if the A or B operand of a floating-point instruction is Infinity, NaN, or Denorm, or if the operation is a divide and the dividend and divisor are both 0. In mode 1, the FINV bit is set on an IEEE754 invalid operation (IEEE754-1985 sec7.1).
21 (53)	FDBZ	Embedded Floating-point Divide by Zero The FDBZ bit is set to 1 when a floating-point divide instruction executed with divisor of 0, and the I dividend is a finite nonzero number.
22 (54)	FUNF	Embedded Floating-point Underflow The FUNF bit is set to 1 when the execution of a floating-point instruction results in an underflow.
23 (55)	FOVF	Embedded Floating-point Overflow The FOVF bit is set to 1 when the execution of a floating-point instruction results in an overflow.
24 (56)	—	Reserved
25 (57)	FINXE	Embedded Floating-point Inexact Exception Enable If the exception is enabled, a Floating-point Round exception is taken if the result of a Floating-point instruction does not result in overflow or underflow, and the result is inexact ($FG \vee FX = 1$), or if the result of a Floating-point instruction does result in overflow ($FOVF = 1$) but Floating-point Overflow exceptions are disabled ($FOVFE = 0$), or if the result of a Floating-point instruction results in underflow ($FUNF = 1$ or $FUNFH = 1$) but Floating-point Underflow exceptions are disabled ($FUNFE = 0$), and no Floating-point Data exception occurs. 0 Exception disabled 1 Exception enabled
26 (58)	FINVE	Embedded Floating-point Invalid Operation / Input Error Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FINV bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled
27 (59)	FDBZE	Embedded Floating-point Divide by Zero Exception Enable If the exception is enabled, a Floating-point Data exception is taken if the FDBZ bit is set by a floating-point instruction. 0 Exception disabled 1 Exception enabled

15.6 Cache

This section describes the cache registers, cache control instructions, and various cache operations.

15.6.1 Cache overview

The e200z425n3 processor supports an 8 KB 2-way set-associative instruction cache with a 32-byte line size.

The cache improves system performance by providing low-latency data to the e200z425n3 instruction pipeline, which decouples processor performance from system memory performance.

The e200z425n3 processor also contains an 8-entry store buffer to decouple store completion to the processor from store completion on the data interface to further improve system performance.

Instruction addresses from the processor are used to index the cache arrays. If the access address matches a valid cache tag entry, the access hits in the cache.

15.6.2 L1 Cache Control and Status Register 0 (L1CSR0)

The L1 Cache Control and Status Register 0 (L1CSR0) is a 32-bit register used for general control of a data cache and for disabling ways in both caches. L1CSR0 implements the WID control field for instruction cache way disabling. The other fields are reserved. The L1CSR0 register is accessed using a **mfsp** or **mtsp** instruction. The SPR number for L1CSR0 is 1010 in decimal. The L1CSR0 register is shown in [Figure 103](#).

Figure 103. L1 Cache Control and Status Register 0 (L1CSR0)

WID	0																														
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

The L1CSR0 fields are described in [Table 186](#).

Table 186. L1CSR0 field descriptions

Bits	Name	Description
0:1	WID	Way Instruction Disable Bit 0 corresponds to way 0. Bit 1 corresponds to way 1. The WID bits may be used for locking ways of the instruction cache, and also affect the replacement policy of the instruction cache. 0 The corresponding way in the instruction cache is available for replacement by instruction miss line fills. 1 The corresponding way instruction cache is not available for replacement by instruction miss line fills.
2:31	—	Reserved ⁽¹⁾

1. These bits are not implemented and should be written with zero for future compatibility.

15.6.3 L1 Cache Control and Status Register 1 (L1CSR1)

The L1 Cache Control and Status Register 1 (L1CSR1) is a 32-bit register used for general control of the instruction cache. The L1CSR1 register is accessed using a **mf spr** or **mt spr** instruction. The SPR number for L1CSR1 is 1011 in decimal. The L1CSR1 register is shown in [Figure 104](#).

Figure 104. L1 Cache Control and Status Register 1 (L1CSR1)

0															ICECE	ICEI	ICLOC	0							ICEA	ICLOINV	0	ICABT	ICINV	ICE

SPR 1011: Read/Write: Reset: 0x0

The L1CSR1 fields are described in [Table 187](#).

Table 187. L1CSR1 field descriptions

Bits	Name	Description
0:14	—	Reserved ⁽¹⁾
15	ICECE	Instruction Cache Error Checking Enable 0 Error Checking is disabled 1 Error Checking is enabled

Table 187. L1CSR1 field descriptions (continued)

Bits	Name	Description
16	ICEI	Instruction Cache Error Injection Enable ICEI will cause injection of errors regardless of the setting of ICECE, although reporting of errors will be masked when ICECE = 0. 0 Cache Error Injection is disabled 1 A double-bit error will be injected into each doubleword written into the cache by inverting the two uppermost parity check bits (p_chk[0:1]).
17:18	ICLOC	Instruction Cache Lockout Control <i>Note: For the icbi instruction, no lockout operation is performed, regardless of the occurrence of EDC/ECC error conditions, and errors are handled in the same manner as when lockout is disabled.</i> <i>Note: When operating in MC mode (ICEA = 00), detected errors on cache-inhibited accesses will not cause an instruction cache line to be locked out, instead the cache line contents are ignored.</i> 00 Cache line lockout is disabled (and array LO indicators are ignored). 01 Cache line lockout is enabled. Cache lines with any tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. 10 Cache line lockout is enabled. Cache lines with any tag or data errors will have the corresponding lockout indicators set. A Machine check will still be generated for an error if the operation would have normally generated one. 11 Cache line lockout is enabled. Cache lines with uncorrectable tag errors or any data errors will have the corresponding lockout indicators set. A Machine check will not be generated for the error if the operation would have normally generated one unless a locked line is locked out. If a correctable tag error occurs, and is re-detected on recycling the access after a correction cycle for the tag is performed, the line is locked out regardless of detecting a single-bit or multi-bit error.
19:24	—	Reserved ⁽¹⁾
25:26	ICEA	Instruction Cache Error Action 00 Error Detection causes Machine Check exception. 01 Error Detection causes Correction/Auto-invalidation. No machine check is generated for most cases. Correction is performed for single-bit tag errors, and lines with multi-bit tag errors are invalidated. Correction is performed for single or multi-bit data errors on cache hits by reloading of the line. 10 Reserved 11 Reserved
27	ICLOINV	Instruction Cache Lockout Indicator Invalidate When written to a 1 in conjunction with writing ICINV to a 1, a cache lockout indicator invalidation operation is initiated by hardware, and the LO bits are cleared, removing all line lockout status. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache lockout bit invalidation operations require approximately 66 cycles to complete. Invalidation occurs regardless of the instruction cache enable (ICE) value. When ICINV = 0: Reserved, do not set to 1 When ICINV = 1: 0 No cache lockout bit invalidate 1 Cache lockout indicator invalidation operation
28	—	Reserved ⁽¹⁾

Table 187. L1CSR1 field descriptions (continued)

Bits	Name	Description
29	ICABT	Instruction Cache Operation Aborted Indicates a Cache Invalidate operation was aborted prior to completion. This bit is set by hardware on an aborted condition, and will remain set until cleared by software writing 0 to this bit location.
30	ICINV	Instruction Cache Invalidate When written to a 1, a cache invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. Cache invalidation operations require approximately 130 cycles to complete. Invalidation occurs regardless of the enable (ICE) value. 0 No cache invalidate 1 Cache invalidation operation
31	ICE	Instruction Cache Enable When disabled, cache lookups are not performed for instruction accesses. Other L1CSR1 cache control operations are still available and are not affected by ICE. 0 Cache is disabled 1 Cache is enabled

1. These bits are not implemented and should be written with zero for future compatibility.

15.6.4 L1 Cache Configuration Register 0 (L1CFG0)

The L1 Cache Configuration Register 0 (L1CFG0) is a 32-bit read-only register. L1CFG0 provides information about the configuration of the e200z425n3 L1 data cache design. The contents of the L1CFG0 register can be read using a **mfsprr** instruction. The SPR number for L1CFG0 is 515 in decimal. The L1CFG0 register is shown in [Figure 105](#).

Figure 105. L1 Cache Configuration Register 0 (L1CFG0)

CARCH	CWPA	CFAHA	DCFISWA	0	DCBSIZE	DCREPL	DCLA	DCECA	DCNWAY	DCSIZE

7:8	ICBSIZE	Instruction Cache Block Size 00 The instruction cache implements a block size of 32 bytes
9:10	ICREPL	Instruction Cache Replacement Policy 11 The instruction cache implements a FIFO replacement policy
11	ICLA	Instruction Cache Locking APU Available 0 The instruction cache does not implement the line locking APU
12	ICECA	Instruction Cache Error Checking Available 1 The instruction cache implements error checking
13:20	ICNWAY	Instruction Cache Number of Ways 0x01 The instruction cache is 2-way set-associative
21:31	ICSIZE	Instruction Cache Size 0x008 The size of the instruction cache is 8 KB

15.6.6 Cache Invalidate by Set and Way

e200z425n3 supports cache set/way invalidation under software control. The instruction cache may be invalidated by index and way through a **mtspr l1finv1** instruction.

The L1 Flush and Invalidate Control Registers (L1FINV1) are 32-bit SPRs used to select a cache set and way to be invalidated. This function is available even when the instruction cache is disabled.

15.6.6.1 L1FINV1

The SPR number for L1FINV1 is 959 in decimal. The L1FINV1 register is shown in [Figure 107](#).

Figure 107. L1 Flush/Invalidate Register 1 (L1FINV1)

0	CWAY	0	CSET	0	CCMD

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 959; Read/Write; Reset: 0x0

The L1FINV1 bits are described in [Table 189](#).

Table 189. L1FINV1 field descriptions

Bits	Name	Description
0:6	—	Reserved ⁽¹⁾ for way extension
7	CWAY	Cache Way Specifies the instruction cache way to be selected
8:19	—	Reserved ⁽¹⁾ for set extension
20:26	CSET	Cache Set Specifies the instruction cache set to be selected
27:28	—	Reserved ⁽¹⁾ for set/command extension
29:31	CCMD	Cache Command 000 The data contained in this entry is invalidated. LO bits are unaffected 001 Reserved 01x Reserved 100 Reserved 101 The data contained in this entry is invalidated. LO bits are cleared 11x Reserved

1. These bits are not implemented and should be written with zero for future compatibility.

For invalidation operations via L1FINV1, tag ECC errors and data EDC errors are ignored, and the selected line will be invalidated regardless of any error. Invalidations conditionally affect the state of the lockout bits (LO).

15.6.7 Cache EDC/ECC Parity Protection

Cache parity protection is supported for both the tag and data arrays of the instruction cache. Seven parity check bits are provided for each tag entry for the tag array to support error detection and correction (ECC — SECDED). Eight parity check bits are provided for each doubleword in the data arrays of the I-Cache, which are used for single- and double-bit error detection (EDC — DED, double error detection). Utilizing ECC/EDC protection, many multi-bit errors are also detected.

The error detection codes also cover the cache index address of the cache line, providing additional protection against addressing errors. If any type of error (including a single-bit error in one of the index bits) is encountered in one of the index address bits, it is treated as an uncorrectable tag ECC error to protect against internal addressing failures. No attempt will be made to correct single-bit errors where the syndrome indicates an index address bit.

Tag ECC and data EDC checking is controlled by the L1CSR1_{ICECE} control field. When error checking is enabled, checking is performed on each cache access. Errors are not

signaled by the instruction cache when cache error checking is disabled ($L1CSR1_{ICECE} = 0$).

If an uncorrectable tag ECC error is detected on any portion of a tag accessed during cache lookups performed because of instruction fetching, a tag ECC error is signaled, regardless of whether a cache hit or miss occurs. Otherwise, if a cache hit for an instruction fetch occurs and a data EDC error is detected on any portion of the accessed data, a parity error is also signaled.

Signaling of an ECC error or EDC error may cause a Machine Check exception to occur. One or more syndrome bits may be set in the Machine Check Syndrome register, or may instead result in a correction/auto-invalidation operation and not result in an exception being signaled. Both may occur, depending on the error action control setting in the appropriate cache control register.

15.6.7.1 Cache Line Lockout

In addition to the ECC/EDC protection employed for the cache, each cache line in the I-Cache has a lockout indicator composed of a redundant set of lockout bits. These lockout bits can selectively be set when certain errors occur in either the tag or the data portion of the cache line. Use of the lockout function and control over error conditions that cause a lockout to occur are controlled by $L1CSR1_{ICLOC}$. When the lockout function is enabled, lines that encounter selected tag ECC or data EDC errors on instruction fetch accesses will have their lockout bits set. When the lockout indicator is set, the line will not be replaced and will remain in an invalid state, effectively disabling it. Also, future tag ECC or data EDC errors on the line are ignored. Cache-inhibited accesses will only set lockout indicators on lines not in a locked way. In addition, no lockout indicators are set by cache-inhibited accesses when operating in machine check mode.

When operating in machine check mode, if lockout controls are enabled via $L1CSR1_{ICLOC}$, lockout bit parity errors on any line detected on a cacheable cache lookup will generate a machine check exception.

If correction/auto-invalidation is instead enabled, on each cache lookup operation for an instruction fetch, if a single- or double-bit lockout bit parity error is detected in one or more ways and lockout controls are enabled, the lockout error(s) will be corrected by rewriting all lockout bits to the asserted state, and no machine check is generated, unless the line is in a locked way. If a line in a locked way incurs a LO bit parity error, a machine check will be generated to ensure that any possible new lockout of the line is reported. For non-cacheable accesses, lockout bit parity errors will only be corrected for lines not in a locked way. Lockout bit parity errors do not generate a machine check for non-cacheable accesses in either error action mode, thus lockout bit correction is not performed for lockout bit parity errors detected on a line in a locked way.

In addition, cache contents are ignored for lines with those errors. Cache invalidate instructions do not report or correct lockout bit parity errors. For both of these cases, a future cacheable access will perform the lockout function if required.

15.6.8 Cache Error Injection

Cache error injection provides a way to test error recovery by intentionally injecting parity errors into the instruction cache.

Error injection into the instruction cache operates as follows:

- If L1CSR1_{ICEI} is set, any instruction cache line fill to the instruction cache data has the associated two most significant parity check bits inverted in the instruction cache data array for each doubleword loaded.

Cache parity error injection is not performed for cache debug write accesses, since parity bit values written can be directly controlled.

In order to clear the parity errors, a cache invalidation or an invalidation of the lines that could have had an injected parity error may be performed. Line invalidation may be performed by an **icbi** instruction, or an L1FINV1 invalidation operation.

15.7 Exceptions

Interrupts implemented in e200z425n3 and the exception conditions that cause them are listed in [Table 190](#).

Table 190. Exceptions and conditions

Interrupt type	Interrupt vector offset value	Causing conditions
System reset	none, vector to [p_rstbase[0:29]] 2'b00	Reset
Critical Input	0x00 ⁽¹⁾	p_critint_b is asserted and MSR _{CE} = 1.
Machine check	0x10	1. p_mcp_b transitions from negated to asserted 2. ISI or Bus Error on first instruction fetch for an exception handler 3. Parity Error signaled on Cache access 4. Parity Error signaled on Local Memory access 5. External bus error 6. Stack limit check failure
Machine check (NMI)	0x10	Non-Maskable Interrupt
Data Storage	0x20	Access control
Instruction Storage	0x30	Access control
External Input	0x40 ⁽²⁾	Interrupt Controller interrupt and MSR _{EE} = 1
Alignment	0x50	1. lmw, stmw not word aligned 2. lwarx or stwcx. not word aligned, lharx or sthcx. not halfword aligned 3. LSP ld and st instructions not properly aligned 4. dcbz
Program	0x60	Illegal, Privileged, Trap
Performance Monitor	0x70	Performance Monitor Enabled Condition or Event w/PMGC0 _{UDI} = 0
System call	0x80	Execution of the System Call (se_sc) instruction

Interrupt type	Interrupt vector offset value	Causing conditions
Debug	0x90	Trap, Instruction Address Compare, Data Address Compare, Instruction Complete, Branch Taken, Return from Interrupt, Interrupt Taken, Debug Counter, External Debug Event, Unconditional Debug Event, Performance Monitor Enabled Condition or Event w/PMGC0 _{UDI} = 1, MPU
EFPU Data Exception	0xA0	See section “Embedded Floating-point Data Exception” in the Power Architecture core reference manual relative to this core.
EFPU Round Exception	0xB0	See section “Embedded Floating-point Round Exception” in the Power Architecture core reference manual relative to this core.
TBD	0xC0–0xF0	Reserved for future processor use

1. Autovectorized Critical Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.
2. Autovectorized External Input interrupts use this offset value. Vectored interrupts supply an interrupt vector offset directly.

The Exception Syndrome Register (ESR) provides a *syndrome* to differentiate between exceptions that can generate the same interrupt type.

0				PIL	PpR	Ptr	FP	ST	0		0	0	BO	0	0								SPV	0	VLEMI	0		0	0		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR 62: Read/Write: Reset: 0x0

The ESR bits are defined in [Table 191](#).

Bit(s)	Name	Description	Associated interrupt type
0:3	—	Reserved	—
4	PIL	Illegal Instruction exception For core e200z425n3, PIL is used for both illegal and unimplemented instructions.	Program
5	PPR	Privileged Instruction exception	Program
6	PTR	Trap exception	Program
7	FP	Floating-point operation	Program
8	ST	Store operation	Alignment Data Storage
9:11	—	Reserved	—
12	—	Reserved	—

31	—	Reserved	—

15.7.2 Machine State Register (MSR)

The Machine State Register defines the state of the processor. The e200z425n3 MSR is shown in [Figure 109](#).

Figure 109. Machine State Register (MSR)

0														CE	0	EE	PR	0	ME	0	0	DE	0										PMM	RI	0
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31				

Read/ Write; Reset: 0x0

The MSR bits are defined in [Table 192](#).

Table 192. MSR field descriptions

Bit(s)	Name	Description
0:13	—	Reserved
14	CE	Critical Interrupt Enable 0 Critical Input interrupts are disabled. 1 Critical Input interrupts are enabled.
15	—	Reserved

Table 192. MSR field descriptions (continued)

Bit(s)	Name	Description
16	EE	External Interrupt Enable 0 External Input interrupts are disabled. 1 External Input interrupts are enabled.
17	PR	Problem State 0 The processor is in supervisor mode, can execute any instruction, and can access any resource (e.g. GPRs, SPRs, MSR, etc.). 1 The processor is in user mode, cannot execute any privileged instruction, and cannot access any privileged resource.
18	—	Reserved
19	ME	Machine Check Enable 0 Asynchronous Machine Check interrupts are disabled. 1 Asynchronous Machine Check interrupts are enabled.
20	—	Reserved
21	—	Reserved
22	DE	Debug Interrupt Enable 0 Debug interrupts are disabled. 1 Debug interrupts are enabled.
23:28	—	Reserved
29	PMM	PMM Performance monitor mark bit System software can set PMM when a marked process is running to enable statistics to be gathered only during the execution of the marked process. MSR _{PR} and MSR _{PMM} together define a state that the processor (supervisor or user) and the process (marked or unmarked) may be in at any time. If this state matches an individual state specified in the PMLC _{an} Performance Monitor registers, the state for which monitoring is enabled, counting is enabled.
30	RI	Recoverable Interrupt This bit is provided for software use to detect nested machine check exception conditions. This bit is cleared by hardware when a Machine Check interrupt is taken.
31	—	Reserved

15.7.3 Machine Check Syndrome Register (MCSR)

When the processor takes a machine check interrupt, it updates the Machine Check Syndrome Register (MCSR) to differentiate between machine check conditions. The MCSR is shown in [Figure 110](#).

Figure 110. Machine Check Syndrome Register (MCSR)

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR 572; Read/Clear; Reset: 0x0

[Table 193](#) describes MCSR fields. The MCSR indicates the source of a machine check condition.

All bits in the MCSR are implemented as “write 1 to clear.” Software in the machine check handler is expected to clear the MCSR bits it has sampled prior to re-enabling MSR_{ME} to avoid a redundant machine check exception and to prepare for updated status bit information on the next machine check interrupt.

Note that any set bit in the MCSR other than status-type bits will cause a subsequent machine check interrupt once MSR_{ME} = 1.

Table 193. Machine Check Syndrome Register (MCSR) field descriptions

Bit	Name	Description	Exception type ⁽¹⁾	Recoverable
0	MCP	Machine check input pin	Async Mchk	Maybe
1	IC_DPERR	Instruction Cache data array parity error	Async Mchk	Precise
2	—	Reserved	—	—
3	DC_DPERR ⁽²⁾	Data Cache data array parity error	Async Mchk	Maybe
4	EXCP_ERR	ISI or Bus Error on first instruction fetch for an exception handler	Async Mchk	Precise
5	IC_TPERR	Instruction Cache Tag parity error	Async Mchk	Precise
6	DC_TPERR ⁽²⁾	Data Cache Tag parity error	Async Mchk	Maybe
7	IC_LKERR	Instruction Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the I-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
8	DC_LKERR ⁽²⁾	Data Cache Lock error Indicates a cache control operation or invalidation operation invalidated one or more lines in a locked way of the D-Cache for certain situations. May also be set on locked line refill error.	Async Mchk	—
9:10	—	Reserved	—	—
11	NMI	NMI input pin	NMI	—

Table 193. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type ⁽¹⁾	Recoverable
12	MAV	MCAR Address Valid Indicates that the address contained in the MCAR was updated by hardware to correspond to the first detected Async Mchk error condition	Status	—
13	MEA	MCAR holds Effective Address If MAV = 1, MEA = 1 indicates that the MCAR contains an effective address and MEA = 0 indicates that the MCAR contains a physical address ⁽³⁾	Status	—
14	U	User Indicates the value captured in MCAR was generated in user mode.	Status	—
15	IF	Instruction Fetch Error Report An error occurred during the fetch of an instruction and the instruction attempted to execute. This could be due to an internal parity error, or an external bus error. MCSRR0 contains the instruction address.	Error Report	Precise
16	LD	Load type instruction Error Report An error occurred during the attempt to execute the load type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or an external bus error.	Error Report	Precise
17	ST	Store type instruction Error Report An error occurred during the attempt to execute the store type instruction located at the address stored in MCSRR0. This could be due to an internal parity error, stack limit check error, or on certain external bus errors.	Error Report	Precise
18	G	Guarded instruction Error Report An error occurred during the attempt to execute the load or store type instruction located at the address stored in MCSRR0 and the access was guarded and encountered an error on the external bus, or an uncorrectable DMEM error.	Error Report	Precise
19:20	—	Reserved	—	—
21	STACK_ERR	Stack Access Limit Check Error Indicates a limit check failure on a CPU data access using R1 in the <EA> calculation.	Async Mchk	Precise
22	IMEM_PERR	Instruction Mem (IMEM) Parity Error Indicates an uncorrectable error in the IMEM on a CPU port access.	Async Mchk	Precise
23	DMEM_RDPERR	Data Mem (DMEM) Parity Error Indicates an uncorrectable error in the DMEM on a CPU port read access.	Async Mchk	Precise

Table 193. Machine Check Syndrome Register (MCSR) field descriptions (continued)

Bit	Name	Description	Exception type ⁽¹⁾	Recoverable
24	DMEM_WRPERR	Data Mem (DMEM) Write Parity Error Indicates an uncorrectable error in the DMEM on a CPU port write access.	Async Mchk	Maybe
25:26	—	Reserved	—	—
27	BUS_IRERR	Read bus error on Instruction recovery linefill	Async Mchk	Precise if data used
28	BUS_DRERR	Read bus error on data load	Async Mchk	Precise if data used
29	BUS_WRERR	Write bus error on store to bus or DMEM imprecise write error	Async Mchk	Unlikely
30	BUS_WRDSI	Write bus error on buffered store to bus with DSI signaled. Set concurrently with BUS_WRERR for this case	Async Mchk	Unlikely
31	—	Reserved	—	—

1. The Exception Type indicates the exception type associated with a given syndrome bit.

— “Error Report” indicates that this bit is only set for error report exceptions that cause machine check interrupts. These bits are only updated when the machine check interrupt is actually taken. Error report exceptions are not gated by MSR_{ME}. These are synchronous exceptions. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

— “Status” indicates that this bit provides additional status information regarding the logging of a machine check exception. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

— “NMI” indicates that this bit is only set for the non-maskable interrupt type exception, which causes a machine check interrupt. This bit is only updated when the machine check interrupt is actually taken. NMI exceptions are not gated by MSR_{ME}. This is an asynchronous exception. This bit will remain set until cleared by software writing a ‘1’ to the bit position.

— “Async Mchk” indicates that this bit is set for an asynchronous machine check exception. These bits are set immediately upon detection of the error. Once any “Async Mchk” bit is set in the MCSR, a machine check interrupt will occur if MSR_{ME} = 1. If MSR_{ME} = 0, the machine check exception will remain pending. These bits will remain set until cleared by software writing a ‘1’ to the bit position(s) to be cleared.

2. Will not be set by e200z425n3 since no data cache is present.

3. Note that since no address translation mechanism is present on e200z425n3, the MEA value is always set to ‘0’.

15.7.4 Interrupt Vector Prefix Registers (IVPR)

The Interrupt Vector Prefix Register is used during interrupt processing for determining the starting address of a software handler used to handle an interrupt. The value of the Vector Offset selected for a particular interrupt type is concatenated with the Vector Base value held in the IVPR to form an instruction address from which execution is to begin. The format of IVPR is shown in [Figure 111](#).

Figure 111. Zen Interrupt Vector Prefix Register (IVPR)

Vector Base	0
-------------	---

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 63; Read/Write

The IVPR fields are defined in [Table 194](#).

Table 194. IVPR field descriptions

Bit(s)	Name	Description
0:23 (32:55)	Vector Base	Vector Base This field is used to define the base location of the vector table, aligned to a 256 byte boundary. This field provides the high-order 24 bits of the location of all interrupt handlers (unless hardware vectoring is used). The vector offset value appropriate for the type of exception being processed is concatenated with the IVPR Vector Base to form the address of the handler in memory. For hardware-vectored interrupts, the value of the supplied interrupt vector is logically OR'ed with the low order bits of the Vec Base Field to determine the interrupt handler address.
24:31 (56:63)	—	Reserved

15.7.5 Interrupt Definitions

15.7.5.1 Critical Input Interrupt (offset 0x00)

A Critical Input exception is signaled to the processor by the assertion of the critical interrupt pin. If the exception is enabled by MSR_{CE} , the Critical Input interrupt is taken.

A Critical Input interrupt may be delayed by other higher priority exceptions or if MSR_{CE} is cleared when the exception occurs.

[Table 195](#) lists register settings when a Critical Input interrupt is taken.

Table 195. Critical Input Interrupt—register settings

Register	Setting description		
CSRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
CSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME — FE0 0 DE —/0 ⁽¹⁾	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	Unchanged		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	IVPR _{0:23} 0x00 (autovectored) IVPR _{0:15} (IVPR _{16:29} p_voffset[0:13]) 2'b00 (non-autovectored)		

1. Clearing of DE is optionally supported by control in HID0.

The MSR_{DE} bit is not automatically cleared by a Critical Input interrupt, but it can be configured to be cleared via the HID0 register (HID0_{CICLRDE}).

15.7.5.2 Machine Check Interrupt (offset 0x10)

The EIS Machine Check APU defines a separate set of save/restore registers (MCSRR0/1), a Machine Check Syndrome Register (MCSR) to record the source(s) of machine checks, and a Machine Check Address Register (MCAR) to hold an address associated with a machine check for certain classes of machine checks. Return from Machine Check instructions (**se_rfmci**) are also provided to support returns using MCSRR0/1.

The MSR_{DE} bit is not automatically cleared by a Machine Check exception, but it can be configured to be cleared or left unchanged via the HID0 register (HID0_{MCCLRDE}).

When a Machine Check interrupt is taken, registers are updated as shown in [Table 196](#).

Table 196. Machine Check Interrupt—register settings

Register	Setting description			
MCSRR0	On a best-effort basis, set to the address of some instruction that was executing or about to be executing when the machine check condition occurred.			
MCSRR1	Set to the contents of the MSR at the time of the interrupt			
MSR	SPV 0 WE 0 CE 0 EE 0 PR 0	FP 0 ME 0 FE0 0 DE 0/— ⁽¹⁾	FE1 0 IS 0 DS 0 PMM 0 RI 0	
ESR	Unchanged			
MCSR	Updated to reflect the source(s) of a machine check. Hardware only sets appropriate bits, no previously set bits are cleared by hardware.			
Vector	IVPR _{0:23} 0x10			

1. Clearing of DE is optionally supported by control in HID0.

15.7.5.3 Data Storage Interrupt (offset 0x20)

A Data Storage interrupt (DSI) may occur if no higher priority exception exists and a Read or Write Access Control exception condition exists.

[Table 197](#) lists register settings when a DSI is taken.

Table 197. Data Storage Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the excepting load/store instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE — EE 0 PR 0	FP 0 ME — FE0 0 DE —	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	Access:	[ST], [SPV], VLEMI. All other bits cleared.	
MCSR	Unchanged		

Table 197. Data Storage Interrupt—register settings (continued)

Register	Setting description
DEAR	For Access Control exceptions, set to the effective address of the access that caused the violation.
Vector	IVPR _{0:23} 0x20

15.7.5.4 Instruction Storage Interrupt (offset 0x30)

An Instruction Storage interrupt (ISI) occurs when no higher priority exception exists and an Execute Access Control exception occurs.

[Table 198](#) lists register settings when an ISI is taken.

Table 198. Instruction Storage Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the excepting instruction.		
SRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE — EE 0 PR 0	FP 0 ME — FE0 0 DE —	FE1 0 IS 0 DS 0 PMM 0 RI —
ESR	VLEMI. All other bits cleared.		
MCSR	Unchanged		
DEAR	Unchanged		
Vector	IVPR _{0:23} 0x30		

15.7.5.5 External Input Interrupt (offset 0x40)

An External Input exception is signaled to the processor by the assertion of an interrupt from the interrupt controller. The input is a level-sensitive signal expected to remain asserted until the core acknowledges the external interrupt. If the input is negated early, recognition of the interrupt request is not guaranteed. When the core detects the exception, if the exception is enabled by MSR_{EE}, it takes the External Input interrupt.

An External Input interrupt may be delayed by other higher priority exceptions or if MSR_{EE} is cleared when the exception occurs.

[Table 199](#) lists register settings when an External Input interrupt is taken.

Table 199. External Input Interrupt—register settings

Register	Setting description
SRR0	Set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.
SRR1	Set to the contents of the MSR at the time of the interrupt

Table 199. External Input Interrupt—register settings (continued)

Register	Setting description			
MSR	SPV 0 WE 0 CE — EE 0 PR 0	FP 0 ME — FE0 0 DE —	FE1 0 IS 0 DS 0 PMM 0 RI —	
ESR	Unchanged			
MCSR	Unchanged			
DEAR	Unchanged			
Vector	IVPR _{0:23} 0x40 (autovectored) IVPR _{0:15} (IVPR _{16:29} p_voffset[0:13]) 2'b00 (non-autovectored)			

15.7.5.6 Alignment Interrupt (offset 0x50)

An Alignment exception is generated when any of the following occurs:

- The operand of **lmw** or **stmw** is not word aligned.
- The operand of **lwarx** or **stwcx.** is not word aligned.
- The operand of **lharx** or **sthcx.** is not halfword aligned.
- Execution of a **dcbz** instruction is attempted.
- Execution of an LSP APU load or store instruction that is not properly aligned.

[Table 200](#) lists register settings when an alignment interrupt is taken.

Table 200. Alignment Interrupt—register settings

Register	Setting description			
SRR0	Set to the effective address of the excepting load/store/dcbz instruction.			
SRR1	Set to the contents of the MSR at the time of the interrupt			
MSR	SPV 0 WE 0 CE — EE 0 PR 0	FP 0 ME — FE0 0 DE —	FE1 0 IS 0 DS 0 PMM 0 RI —	
ESR	[ST], [SPV], VLEMI. All other bits cleared.			
MCSR	Unchanged			
DEAR	Set to the effective address of a byte of the load or store access causing the violation.			
Vector	IVPR _{0:23} 0x50			

15.7.5.7 Program Interrupt (offset 0x60)

A program interrupt occurs when no higher priority exception exists and one or more of the following exception conditions occur:

- Illegal Instruction exception
- Privileged Instruction exception
- Trap exception

The e200z425n3 will invoke an Illegal Instruction program exception on attempted execution of the following instructions:

- Unimplemented instructions
- An instruction from the illegal instruction class
- **mtspr** and **mfspir** instructions with an undefined SPR specified
- **mtdcr** and **mfddcr** instructions with an undefined DCR specified

The e200z425n3 will invoke a Privileged Instruction program exception on attempted execution of the following instructions when $MSR_{PR} = 1$ (user mode):

- A privileged instruction
- **mtspr** and **mfspir** instructions that specify a SPRN value with $SPRN_5 = 1$ (even if the SPR is undefined)

The e200z425n3 will invoke a Trap exception on execution of the **tw** instruction if the trap conditions are met and the exception is not also enabled as a Debug interrupt.

The core will invoke an Illegal instruction program exception on attempted execution of the instructions **lswi**, **lswx**, **stswi**, **stswx**, **mfapidi**, **mfddcrx**, **mtddcrx**, or on any *PowerISA 2.06* floating-point instruction. All other defined or allocated instructions that are not implemented by core will cause an illegal instruction program exception.

[Table 201](#) lists register settings when a Program interrupt is taken.

Table 201. Program Interrupt—register settings

Register	Setting description		
SRR0	Set to the effective address of the excepting instruction.

DEAR	Unchanged		
Vector	IVPR _{0:23} 0x80		

15.7.5.9 Debug Interrupt (offset 0x90)

There are multiple sources that can signal a Debug exception. A Debug interrupt occurs when no higher priority exception exists, a Debug exception exists in the Debug Status Register, and Debug interrupts are enabled (both DBCR0_{IDM} = 1 (internal debug mode) and MSR_{DE} = 1).

[Table 203](#) lists register settings when a Debug interrupt is taken.

Table 203. Debug Interrupt—register settings

Register	Setting description		
DSRR0 ⁽¹⁾	Set to the effective address of the excepting instruction for IAC, BRT, RET, CRET, and TRAP. Set to the effective address of the next instruction to be executed <i>following</i> the excepting instruction for DAC (usually) and ICMP. For a UDE, IRPT, CIRPT, DCNT, or DEVT type exception, set to the effective address of the instruction that the processor would have attempted to execute next if no exception conditions were present.		
DSRR1	Set to the contents of the MSR at the time of the interrupt		
MSR	SPV 0 WE 0 CE —/0 ⁽²⁾ EE —/0 ⁽²⁾ PR 0	FP 0 ME — FE0 0 DE 0	FE1 0 IS 0 DS 0 PMM 0 RI —

15.7.5.10 System Reset Interrupt

The System Reset exception is a non-maskable, asynchronous exception signaled to the processor through the assertion of system-defined signals.

A System Reset may be initiated by either a software reset or during power-on reset.

When a reset request occurs, the processor branches to the system reset exception vector without attempting to reach a recoverable state. If reset occurs during normal operation, all operations cease and the machine state is lost.

[Table 204](#) lists register settings when a System Reset interrupt is taken.

Table 204. System Reset Interrupt—register settings

Register	Setting description

15.7.5.11 Embedded Floating-point Data Interrupt (offset 0xA0)

The Embedded Floating-point Data interrupt is taken if no higher priority exception exists and an EFPU Floating-point Data exception is generated. When a Floating-point Data exception occurs, the processor suppresses execution of the instruction causing the exception.

[Table 205](#) lists register settings when an EFPU Floating-point Data interrupt is taken.

Table 205. Embedded Floating-point Data Interrupt—register settings

15.7.5.13 Performance Monitor Interrupt (offset 0x70)

A performance monitor interrupt that may be generated by an enabled condition or event. An enabled condition or event is as follows:

A PMCx register overflow condition occurs with the following settings:

- PMLCax_{CE} = 11; that is, for the given counter the overflow condition is enabled.
- PMCx_{OV} = 11; that is, the given counter indicates an overflow.

For a performance monitor interrupt to be signaled on an enabled condition or event, PMGC0_{PMIE} must be set.

Although an exception condition may occur with MSR_{EE} = 0, the interrupt cannot be taken until MSR_{EE} = 1.

The priority of the performance monitor interrupt is below all other asynchronous interrupts.

[Table 207](#) lists register settings when an performance monitor interrupt is taken.

Table 207. Performance Monitor Interrupt—Register Settings

Register	Setting description			
SRR0/ DSRR0 ⁽¹⁾	Set to the effective address of the next instruction to be executed.

1. DSRR0/1 are used if PMGC0_{UDI} = 1

2. CE is cleared if PMGC0_{UDI} = 1 and HID0_{DCLRC} = 1

3. EE is not cleared if $PMGC0_{UDI} = 1$ and $HID0_{DCLREE} = 0$
4. DE is cleared if $PMGC0_{UDI} = 1$

15.8 Memory Protection Unit (MPU)

15.8.1 MPU Overview

The e200z425n3 Memory Protection Unit (MPU) protects regions of memory, with the following feature set:

- 24-entry region descriptor table with support for 6 arbitrary-sized instruction memory regions, 12 arbitrary-sized data memory regions, and 6 additional arbitrary-sized regions programmable as instruction or data memory regions
- Ability to set access permissions and memory attributes on a per-region basis
- Process ID aware, with per-bit masking of TID values
- Capability for masking upper address bits in the range comparison
- Capability of bypassing permissions checking for selected access types
- Per-entry write-once logic for entry protection
- Hardware flash invalidation support and per-entry invalidation protection controls
- Ability to optionally utilize region descriptors for generating debug events and watchpoints
- Software managed by **mpure** and **mpuwe** instructions

15.8.2 Software Interface and MPU Instructions

The MPU entries are accessed indirectly through several MPU Assist (MAS) registers. Software can write and read the MAS registers with **mtspr** and **mf spr** instructions. These registers contain information related to reading and writing a given entry within the MPU. Data is read from the MPU into the MAS registers with an **mpure** (MPU read entry) instruction. Data is written to the MPU from the MAS registers with an **mpuwe** (MPU write entry) instruction.

The **mpure**, **mpuwe**, and **mpusync** instructions are privileged.

15.8.3 MPU Read Entry Instruction (mpure)

The MPU read entry instruction causes the content of a single MPU entry to be placed in the MPU assist registers. The entry is specified by the INST, SHD, and ESEL fields of the MAS0 register. The entry contents are placed in the MAS0, MAS1, MAS2, and MAS3 registers.

mpure
mpu read entry

mpure

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
result = MPU(mpu_entry_id)
MAS0, MAS1, MAS2, MAS3 = result
```

15.8.4 MPU Write Entry Instruction (mpuwe)

The MPU write entry instruction causes the contents of certain fields within the MPU assist registers MAS0, MAS1, MAS2, and MAS3 to be written into a single MPU entry in the MPU. The entry written is specified by the INST, SHD, and ESEL fields of the MAS0 register.

mpuwe

mpu write entry

mpuwe

```
mpu_entry_id = MAS0(INST, SHD, ESEL)
MPU(mpu_entry_id) = MAS0, MAS1, MAS2, MAS3
```

15.8.5 MPU Synchronize Instruction (mpusync)

The MPU Synchronize instruction is treated as a privileged no-op by the e200z425n3.

mpusync

MPU Synchronize

mpusync

15.8.6 MMU/MPU Configuration Register (MMUCFG)

The MMU/MPU Configuration Register (MMUCFG) is a 32-bit read-only register. The SPR number for MMUCFG is 1015 in decimal. MMUCFG provides information about the configuration of the e200z425n3 MPU design. The MMUCFG register is shown in [Figure 112](#).

Figure 112. MMU/MPU Configuration Register (MMUCFG)

0	RASIZE	0	PIDSIZE	NMPUS	NTLBS	MAVN
---	--------	---	---------	-------	-------	------

SPR 1015; Read-Only

The MMUCFG bits are described in [Table 208](#).

Table 208. MMUCFG field descriptions

Bits	Name	Function
0:7	—	Reserved
8:14	RASIZE	Number of Bits of Real Address supported 0100000 This version of the MPU implements 32 real address bits
15:16	—	Reserved
17:20	—	Reserved
21:25	PIDSIZE	PID Register Size 00111 PID registers contain 8 bits in this version of the MPU
26:27	NMPUS	Number of MPUs 01 This version of the MMU implements one MPU structure: a fully associative MPU for MPU0
28:29	NTLBS	Number of TLBs 00 This version of the MMU implements no TLB structures
30:31	MAVN	MMU Architecture Version Number 11 This version of the MMU implements Version 3.1 of the EIS MMU Architecture

15.8.7 MPU0 Configuration Register (MPU0CFG)

The MPU0 Configuration Register (MPU0CFG) is a 32-bit read-only register. The SPR number for MPU0CFG is 692 in decimal. MPU0CFG provides information about the configuration of MPU0 in the e200z425n3 MPU. The MPU0CFG register is shown in [Figure 113](#).

Figure 113. MPU0 Configuration Register (MPU0CFG)

FASSOC	0	MINSIZE	MAXSIZE	IPROT	0	UAMSKA	0	SHENTRY	DENTRY	IENTRY

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

SPR 692; Read-Only

The MPU0CFG bits are described in [Table 209](#).

Table 209. MPU0CFG field descriptions

Bits	Name	Function
0	FASSOC	Fully Associative 1 Indicates that MPU0 is fully associative
1:7	—	Reserved for non-fully associative implementation use
8:11	MINSIZE	Minimum Region Size Due to the use of access address matching, the effective smallest region size is 8 bytes 0x0 Smallest region size is 1 byte
12:15	MAXSIZE	Maximum Region Size 0xB Largest region size is 4 GB
16	IProt	Invalidate Protect Capability 1 Invalidate Protect Capability is supported in MPU0
17	—	Reserved
18	UAMSKA	Upper Address Masking Availability 1 Upper Address Masking is Available
19:22	—	Reserved
23:25	SHENTRY	Number of Shared (configurable for I or D) Entries 0x2 Indicates that MPU0 contains six shared entries
26:28	DENTRY	Number of Data Entries 0x4 Indicates that MPU0 contains 12 dedicated data entries
29:31	IENTRY	Number of Instruction Entries 0x2 Indicates that MPU0 contains six dedicated Instruction entries

15.8.8 MPU0 Control and Status Register 0 (MPU0CSR0)

The MPU0 Control and Status Register 0 (MPU0CSR0) is a 32-bit register. The SPR number for MPU0CSR0 is 1014 in decimal. MPU0CSR0 controls the operation of the MPU. The MPU0CSR0 register is shown in [Figure 114](#).

Figure 114. MPU0 Control and Status Register 0 (MPU0CSR0)

0																BYPSR	BYPSW	BYPSX	BYPUR	BYPURW	BYPUX	0	DRDEN	DWDEN	IDEN	0	TIDCTL	0	MPUFI	MPUIEN

SPR 1014; Read/ Write; Reset: 0x0⁽¹⁾

- Reset by processor reset **p_reset_b** if EDBCR0_{EDM} = 0, as well as unconditionally by **m_por**. If EDBCR0_{EDM} = 1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Specifically, this applies to the DRDEN, DWDEN, and IDEN control bits.

The MPU0CSR0 bits are described in [Table 210](#).

Table 210. MPU0CSR0 field descriptions

Bits	Name	Description
0:15	—	Reserved
16	BYPSR	Bypass MPU protections for Supervisor Read accesses This bit controls whether supervisor-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode read accesses do not generate a DSI when no MPU match occurs. Supervisor-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Read accesses 1 Bypass MPU protections for Supervisor Read accesses
17	BYPSW	Bypass MPU protections for Supervisor Write accesses This bit controls whether supervisor-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode write accesses do not generate a DSI when no MPU match occurs. Supervisor-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for Supervisor Write accesses 1 Bypass MPU protections for Supervisor Write accesses
18	BYPSX	Bypass MPU protections for Supervisor Instruction accesses This bit controls whether supervisor-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, supervisor-mode instruction accesses do not generate an ISI when no MPU match occurs. Supervisor-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for Supervisor Instruction accesses 1 Bypass MPU protections for Supervisor Instruction accesses
19	BYPUR	Bypass MPU protections for User Read accesses This bit controls whether user-mode read accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode read accesses do not generate a DSI when no MPU match occurs. User-mode read accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Read accesses 1 Bypass MPU protections for User Read accesses
20	BYP UW	Bypass MPU protections for User Write accesses This bit controls whether user-mode write accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode write accesses do not generate a DSI when no MPU match occurs. User-mode write accesses are still compared to MPU entries, and a hit will provide access attributes (CI, G). 0 No Bypass of MPU protections for User Write accesses 1 Bypass MPU protections for User Write accesses
21	BYP UX	Bypass MPU protections for User Instruction accesses This bit controls whether user-mode instruction accesses bypass the MPU protection mechanism. When bypass is enabled, user-mode instruction accesses do not generate an ISI when no MPU match occurs. User-mode instruction accesses are still compared to MPU entries, and a hit will provide access attributes (CI). 0 No Bypass of MPU protections for User Instruction accesses 1 Bypass MPU protections for User Instruction accesses
22:23	—	Reserved

Table 210. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
24	DRDEN	Data Read Debug Enable This bit controls whether data read accesses are enabled to generate MPU debug events. When disabled, no data read access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data read accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data read accesses 1 MPU debug events are enabled for data read accesses
25	DWDEN	Data Write Debug Enable This bit controls whether data write accesses are enabled to generate MPU debug events. When disabled, no data write access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. If such a match occurs, no MPU debug event is generated, and no access protection is performed. When enabled, data write accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for data write accesses 1 MPU debug events are enabled for data write accesses
26	IDEN	Instruction Debug Enable This bit controls whether instruction accesses are enabled to generate MPU debug events. When disabled, no instruction access will generate an MPU debug event, regardless of whether an access match occurs to a valid MPU region descriptor with DEBUG = 1. When enabled, instruction accesses are not blocked from generating MPU debug events. 0 MPU debug events are disabled for instruction accesses 1 MPU debug events are enabled for instruction accesses
27	—	Reserved
28	TIDCTL	TID usage Control When TIDCTL is set to 1, the TID match is disabled (forced match) in Supervisor mode. 0 TID comparisons performed normally 1 No TID comparisons are performed for matching while in Supervisor mode
29	—	Reserved

Table 210. MPU0CSR0 field descriptions (continued)

Bits	Name	Description
30	MPUFI	MPU flash invalidate When written to a 1, a MPU invalidation operation is initiated by hardware. Once complete, this bit is reset to 0. Writing a 1 while an invalidation operation is in progress will result in an undefined operation. Writing a 0 to this bit while an invalidation operation is in progress will be ignored. MPU invalidation operations require 3 cycles to complete. 0 No flash invalidate 1 MPU1 invalidation operation <i>Note: Entries that have the IPROT bit set will not be invalidated.</i>
31	MPUEN	MPU Enable This bit enables operation of the MPU. When enabled, access addresses are compared to each entry in the MPU for a match condition. If no match condition occurs, and the access type is not enabled to bypass the MPU protections, then an ISI or DSI condition is signaled for the access. Note that this bit is ignored for matching entries with DEBUG = 1 if in EDM and hardware owns MPU Debug entries. 0 MPU is disabled 1 MPU is enabled

15.8.9 MPU Assist Registers (MAS)

The e200z425n3 uses four special-purpose registers (MAS0, MAS1, MAS2, and MAS3) to facilitate reading and writing MPU entries. The MAS registers can be read or written using the **mf spr** and **mt spr** instructions.

The MAS0 register is shown in [Figure 115](#). Fields are defined in [Table 211](#).

Figure 115. MPU Assist Register 0 (MAS0)

VALID	IPROT	SEL		0	RO	DEBUG	INST	SHD	0		ESEL				0	UAMSK				UW	SW	UX/UR	SX/SR	IOVR	GOVR ⁽¹⁾	1	1	I	0	G ₁ ⁽	0

SPR 624; Read/ Write; Reset: Unaffected

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1

Table 211. MAS0—MPU Read/Write and Replacement Control

Bit	Name	Comments, or Function when Set
0	VALID	MPU Entry Valid 0 This MPU entry is invalid 1 This MPU entry is valid
1	IPROT	Invalidation Protect 0 Entry is not protected from invalidation 1 Entry is protected from invalidation

Table 211. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
2:3	SEL	Selects MPU for access: 00 Reserved, no access 01 Reserved, no access 10 Select MPU 11 Reserved, no access
4	—	Reserved
5	RO	Read-Only When set to 1, the entry is no longer writable by software. Once set, this bit will remain set until a processor reset occurs. 0 This MPU entry is writable 1 This MPU entry is Read-only
6	DEBUG	Debug Control for Entry This bit is used to assign an entry for debug event use instead of normal access protection use. When used for debug purposes, an MPU debug event is generated when a hit to the entry occurs and the access permissions allow the access. 0 This MPU entry is used for access protections and allows accesses when matched based on protection attributes 1 This MPU entry is used for generating a debug event when a match occurs and the access protections would allow access
7	INST	Instruction Entry When SHD = 0, this bit is used to select the INST entry portion of the region descriptor table for mpure and mpuwe instruction operations. When SHD = 1, this bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for either instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. 0 This MPU entry is used for matching data accesses only 1 This MPU entry is used for matching instruction accesses only
8	SHD	Shared Entry Select This bit is used to control selection of the Shared portion of the region descriptor table. 0 The shared portion of the region descriptor table is not accessed on a mpure or mpuwe operation. Either the instruction portion or the data portion is accessed based on the setting of INST. The entry within the selected portion is based on ESEL. 1 The shared portion of the region descriptor table is accessed on a mpure or mpuwe operation. The instruction and data portions are not accessed. The INST bit is used to indicate whether the entry in the Shared portion of the region descriptor table is assigned as an entry for instruction access or data access matching. Only one of these access types is monitored for matching by a given shared region descriptor entry. ESEL defines which shared entry is selected.
9:11	—	Reserved
12:15	ESEL	Entry select for MPU. This field is used to select an entry for reading or writing in conjunction with the settings of SHD and INST. Only valid entry numbers should be used in this field, otherwise the result of an operation is boundedly undefined.
16	—	Reserved

Table 211. MAS0—MPU Read/Write and Replacement Control (continued)

Bit	Name	Comments, or Function when Set
17:19	UAMSK	Upper Address Mask Control This field is used to support masking of upper address bits before performing range comparisons. Masked bits will be forced to 0 for the purposes of the range compare. Range upper and lower bounds should be set accordingly. 000 No upper address bits are masked, address matching uses all 32 address bits for accesses 001 The most significant access address bit is forced to 0 before matching 010 The two most significant access address bits are forced to 0 before matching 011 The three most significant access address bits are forced to 0 before matching 100 The four most significant access address bits are forced to 0 before matching 101 The upper five access address bits are forced to 0 before matching 11x Reserved, do not use
20	UW	User Mode Write Permission Determines User mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 No User mode Write permission 1 User mode has Write permission
21	SW	Supervisor Mode Write / Read Permission Determines Supervisor mode Write (W) permission when INST = 0. Ignored when INST = 1. 0 No Supervisor mode Write permission 1 Supervisor mode has Write permission

1. This bit is not implemented in dedicated instruction entries, and is ignored in shared entries with INST = 1.

15.9 Local memories

15.9.1 Local Instruction and Data memory overview

In order to provide for low latency memory access for critical instruction routines and data operands, local instruction (IMEM) and data (DMEM) memory capabilities have been added. This provides low latency access (zero wait-states) similar to an instruction or data cache, but does not suffer from the overhead of cache miss or cache writethrough operations. Instead, it provides a large capacity “tightly coupled” storage capability.

15.9.2 Local memory control and configuration

DMEM and IMEM local memory configuration information is provided by a set of privileged read-only SPRs that are accessed using **mf spr** instructions. DMEM and IMEM local memory operation is controlled by a set of privileged device control registers (DCRs) that are accessed using the **mf dcr** and **mt dcr** instructions. These registers and a description of the operation of various features are described in the following subsections.

15.9.2.1 DMEM Configuration Register 0 (DMEMCFG0)

The DMEM Configuration Register 0 (DMEMCFG0) is a 32-bit read-only register. DMEMCFG0 provides information about the configuration of the e200z425n3 local data memory design. The contents of the DMEMCFG0 register can be read using a **mf spr**

instruction. The SPR number for DMEMCFG0 is 694 in decimal. The DMEMCFG0 register is shown in [Figure 120](#).

Figure 120. DMEM Configuration Register 0 (DMEMCFG0)

DMEM BASE ADDR																				0	DECUA	DECA	0	DMSIZE					0		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
CURRENT DMEM BASE ADDRESS VALUE																				0	1	1	0	001000 (32 KB)					00		
SPR 694; Read-only; Privileged																															

The DMEMCFG0 fields are described in [Table 215](#).

Table 215. DMEMCFG0 field descriptions

Bits	Name	Description
0:19	DMEM BASE ADDR	DMEM BASE ADDRESS (CPU Port) This field defines the current Base Address value being used for the CPU port to the DMEM. This field reflects the value of the external DMEM base address port inputs when the external base address port inputs are enabled via the DBAPD control bit, or the value of the BASE ADDRESS field of DMEMCTL0 when the external base address port inputs are disabled via the DBAPD control bit. <i>Note: Low order bits of this field are driven to 0s when the DMEM size is > 4 KB</i>
20	—	Reserved
21	DECUA	DMEM Error Correction Update Available DECUA indicates an error scrubbing function for the DMEM is available. 0 Error Correction Update is not available. 1 Error Correction Update is available for correction of a correctable single-bit error detected on a read access.
22	DECA	DMEM Error Correction Available DECA indicates an error correction function for the DMEM is available. 0 Error Correction is not available. 1 Error Correction is available.
23	—	Reserved
24:29	DMSIZE	DMEM Size 001000 The size of the DMEM is 32 KB.
30:31	—	Reserved

15.9.2.2 DMEM Control Register 0 (DMEMCTL0)

The DMEM Control Register 0 (DMEMCTL0) controls operation of certain functions of the DMEM logic.

Figure 121. DMEM Control Register 0 (DMEMCTL0)

DMEM BASE ADDR	0	DBYPCB	DBYPAT	DBYPDEC	DECUE	0	DBAPD	DPEIE	DICWE	DSWCE	DDAUEC	DCPECE	DSECE
----------------	---	--------	--------	---------	-------	---	-------	-------	-------	-------	--------	--------	-------

0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31

DCR 496; Read/Write; Reset⁽¹⁾: 19'b0 || p_dmem_rstcfg[8,6:7,0] || 4'b0 || p_dmem_rstcfg[1:5]; Privileged

1. Reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 216. DMEMCTL0 field descriptions

Bits	Name	Description
0:16	DMEM BASE ADDR	DMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the DMEM when the external base address port inputs are disabled via the DBAPD control bit.
17:18	—	Reserved
19	DBYPCB	DMEM Bypass Cache Bypass CPU accesses DBYPCB can be used to force Non-decorated Cache Bypass loads and Store with Writethrough (lbcbx , lhcbx , lwc bx , and stwwtx , sthwt x , stbwt x) accesses that target the DMEM address space to be presented to the external bus. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses do not bypass the DMEM CPU port. 1 Non-decorated Cache Bypass loads and Store with Writethrough CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[8] input.</i>
20	DBYPAT	DMEM Bypass Atomic CPU accesses DBYPAT can be used to force atomic (load and reserve, store conditional) accesses to the DMEM address space to be presented to external reservation hardware in systems that support reservation and/or decoration functionality, since no internal reservation hardware is present in the CPU for the DMEM. In general, software must not rely on normal CPU write accesses to clear a reservation, since they are not monitored by reservation hardware; instead only store conditional accesses should be used for this purpose. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Atomic CPU accesses do not bypass the DMEM CPU port. 1 Atomic CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[6] input.</i>

Table 216. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
21	DBYPDEC	DMEM Bypass Decorated CPU accesses DBYPDEC can be used to force decorated accesses (lbdx, lhdx, lwdx, lbdcbx, lhdcbx, lwdcbx, stbdx, sthdx, stwdx, stbdcbx, sthdcbx, stwdcbx, dsn, dsncb) to the DMEM address space to be presented to external decoration hardware for systems that support this functionality, since no internal decoration hardware is present in the CPU. Note that the protection settings in DMEMCTL1 are still applied to these accesses. 0 Decorated Load and Store CPU accesses do not bypass the DMEM CPU port. 1 Decorated Load and Store CPU accesses bypass the DMEM CPU port and are routed out through the BIU to the DAHB external interface. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[7] input.</i>
22	DECUE	DMEM Error Correction Update Enable DECUE can be used in conjunction with DCPECE and DSECE to provide an error scrubbing function for the DMEM. 0 Error Correction Update is disabled. 1 Error Correction Update is enabled. A correctable single-bit error detected on a read access from either the CPU or the slave port will cause the DMEM to be rewritten with the corrected data if the corresponding error checking enable bit is set (DCPECE for CPU accesses, DSECE for slave port accesses). (Write accesses perform this correction automatically during partial-width writes when error checking is enabled.) <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[0] input.</i>
23	—	Reserved
24	DBAPD	DMEM Base Address Port Disable This bit controls usage of the external Base Address port (p_dmem_baseaddr[0:n]) to define the base address of the DMEM for CPU port accesses. It has no effect on DMEM slave port accesses. 0 The external DMEM base address port (p_dmem_baseaddr[0:n]) is used to define the base address of the DMEM for CPU accesses. 1 The external DMEM base address port (p_dmem_baseaddr[0:n]) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the DMEM for CPU accesses.
25	DPEIE	DMEM Processor Error Injection Enable DPEIE will cause injection of errors regardless of the setting of DCPECE, although reporting of errors to the CPU will be masked while DCPECE = 0. 0 Error Injection is disabled. 1 A double-bit error will be injected on each CPU port write into the DMEM data array by inverting the two uppermost parity check bits (p_dchk[0:1]).
26	DICWE	DMEM Imprecise CPU Write Enable DICWE may allow for increased partial-width write performance when set. 0 Imprecise writes by the CPU are disabled. All partial-width write ECC errors are reported precisely (error report machine check). 1 Imprecise writes by the CPU are enabled. In certain cases, partial-width write errors may be reported imprecisely (async machine check only).

Table 216. DMEMCTL0 field descriptions (continued)

Bits	Name	Description
27:28	DSWCE	DMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the DMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 5, 6, or 7 byte, or misaligned 4-byte writes) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. Aligned word or doubleword writes are not checked or corrected for errors. <i>Note: This field is updated on m_por and slv_reset_b based on the values of the p_dmem_rstcfg[1:2] inputs.</i>
29	DDAUEC	DMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used for checkbit/syndrome generation for DMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[3] input.</i>
30	DCPECE	DMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[4] input.</i>
31	DSECE	DMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for Slave port partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed with single-bit error correction during read-modify-write operations for partial-width writes. Detection of uncorrectable single- or multi-bit errors on a Slave port partial-width write access causes a bus error ERROR response to be generated. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_dmem_rstcfg[5] input.</i>

15.9.2.3 DMEM Control Register 1 (DMEMCTL1)

The DMEM Control Register 1 (DMEMCTL1) provides protection functions for the DMEM. Separate Supervisor-mode and User-mode read and write access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of DMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings. The DMEMCTL1 settings are applied to all accesses that target DMEM address range, regardless of whether access may bypass the DMEM based on settings in DMEMCTL0_{DBYPCB}, DBYPATF, DBYPDEC.

1. Reset by **m_por** and **slv_reset_b**. Unaffected by **p_reset_b**.

Table 219. IMEMCTL0 field descriptions

Bits	Name	Description
0:17	IMEM BASE ADDR	IMEM BASE ADDRESS Field (CPU Port) This field defines the Base Address used for the CPU port to the IMEM when the external base address port inputs are disabled via the BAPD control bit. <i>Note: Changes to this value and to the BAPD control bit must be performed carefully by software to ensure coherency is maintained. Specifically, software must ensure that the BTB is invalidated, and that no cached entries are present in the I-Cache for the memory space to be occupied by the IMEM.</i>
18:19	—	Reserved for Base Address extension
20:21	—	Reserved
22	IECUE	IMEM Error Correction Update Enable IECUE can be used to provide an error scrubbing function. This field is updated on m_por and slv_reset_b based on the value of the p_imem_rstcfg[0] input. 0 Error Correction Update is disabled 1 Error Correction Update is enabled. A correctable single-bit error detected on CPU instruction fetches or slave port read cycles will cause the IMEM to be re-written with the corrected data if the corresponding error checking enable bit is set (ICPECE for CPU accesses, ISECE for slave port accesses). IECUE can be used in conjunction with ICPECE and ISECE to provide an error scrubbing function.
23	—	Reserved
24	IBAPD	IMEM Base Address Port Disable This bit controls usage of the external Base Address port (p_imem_baseaddr[0:n]) to define the base address of the IMEM for CPU port accesses. It has no effect on IMEM slave port accesses. 0 The external IMEM base address port (p_imem_baseaddr[0:n]) is used to define the base address of the IMEM for CPU accesses. 1 The external IMEM base address port (p_imem_baseaddr[0:n]) is disabled for use, and instead the BASE ADDR field value is used to define the base address of the IMEM for CPU accesses.
25:26	—	Reserved
27:28	ISWCE	IMEM Slave port Write Check/Correct Enable 00 Slave write data is not checked or corrected for errors. 01 Slave write data is checked but not corrected for errors. Detected errors generate a slave port ERROR response and no Write is performed to the IMEM. 10 Slave write data is checked and corrected for errors on all writes. Single-bit correctable errors do not automatically generate an ERROR response, but are instead corrected. 11 Slave write data is checked and corrected for errors on partial-width (1, 2, 3, 4, 5, 6, or 7 byte) writes. Single-bit correctable errors on partial-width writes do not automatically generate an ERROR response, but are instead corrected. <i>Note: This field is updated on m_por and slv_reset_b based on the values of the p_imem_rstcfg[1:2] inputs.</i>

Table 219. IMEMCTL0 field descriptions (continued)

Bits	Name	Description
29	IDAUEC	IMEM Disable Address Use in Error Check This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portions are not used. for checkbit/syndrome generation for IMEM CPU or slave port accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_imem_rstcfg[3] input.</i>
30	ICPECE	IMEM CPU Port ECC Enable (CPU port) 0 End-to-End ECC is disabled for the CPU interface. No checking of read data is performed by the CPU. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the CPU interface. Error checking of read data is performed with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a CPU port access cause a machine check to be generated. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_imem_rstcfg[4] input.</i>
31	ISECE	IMEM Slave port Error Checking Enable (Slave port) 0 End-to-End ECC checking logic is disabled for the Slave interface. No checking of read data is performed during read-modify-write operations for partial-width writes. Writes will still generate the proper check bit values to be written. 1 End-to-End ECC is enabled for performing ECC on the Slave Port interface. Error checking of read data is performed during read-modify-write operations for partial-width writes with single-bit error correction. Detection of uncorrectable single- or multi-bit errors on a Slave port access causes a bus error ERROR response to be generated. <i>Note: This field is updated on m_por and slv_reset_b based on the value of the p_imem_rstcfg[5] input.</i>

15.9.2.6 IMEM Control Register 1 (IMEMCTL1)

The IMEM Control Register 1 (IMEMCTL1) provides protection functions for the IMEM. Separate Supervisor-mode and User-mode instruction fetch access controls allow accesses to be granted, denied, or conditionally granted independently for four equally sized blocks of IMEM. Conditional granting of access permissions causes the MPU memory protection functions to be employed, all other settings override MPU settings.

15.10 End-to-End ECC support

This section describes end-to-end error detection and correction capability (e2eECC) enhancements to address additional diagnostic capabilities for the next generation of embedded designs.

15.10.1 End-to-End ECC control and configuration

e2eECC is controlled by a set of privileged device control registers (DCRs) accessed using the **mfdcr** and **mtdcr** instructions. These registers and the operation of various features are described in the following subsections.

15.10.1.1 End-to-End ECC Control Register 0 (E2ECTL0)

The End-to-End ECC Control Register 0 (E2ECTL0) controls operation of the e2eECC logic.

Figure 126. e2eECC Control Register 0 (E2ECTL0)

0																												IDAC	IECCEN	DDAC	DECCEN
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DCR 510; Read/Write; Reset: 0x0 || p_e2e_rstcfg[0:3]; Privileged

Table 221. E2ECTL0 field descriptions

Bits	Name	Description
0:27	—	Reserved
28	IDAC	Instruction Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Instruction AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. <i>Note: This field is updated on p_reset_b based on the value of the p_e2e_rstcfg[0] input.</i>
29	IECCEN	Instruction ECC Enable Field 0 End-to-End ECC is disabled for the Instruction interface. No checking of instruction fetch data is performed. 1 End-to-End ECC is enabled for performing error detection and correction on the Instruction interface. Checking of instruction fetch data is performed with correction of single-bit data errors. Detection of any address errors or uncorrectable multi-bit data errors cause a machine check to be generated if the instruction fetch information is attempted to be used for instruction decoding and execution. <i>Note: This field is updated on p_reset_b based on the value of the p_e2e_rstcfg[1] input.</i>
30	DDAC	Data Disable Address Checking This bit controls usage of the address portion of the ECC H matrix. When use is disabled, the address portion is not used for checkbit/syndrome generation for Data AHB accesses. 0 Use of access address is enabled in checkbit and syndrome generation. 1 Use of access address is disabled in checkbit and syndrome generation. <i>Note: This field is updated on p_reset_b based on the value of the p_e2e_rstcfg[2] input.</i>
31	DECCEN	Data ECC Enable Field 0 End-to-End ECC is disabled for the Data interface. No checking of read data is performed. Writes will still generate the proper check bit values to be supplied to external storage devices. 1 End-to-End ECC is enabled for performing error detection and correction on the Data interface. Checking of read data is performed with correction of single-bit data errors. Detection of any address errors, or uncorrectable multi-bit data errors cause a machine check to be generated. Writes generate the proper check bit values to be supplied to external storage devices. <i>Note: This field is updated on p_reset_b based on the value of the p_e2e_rstcfg[3] input.</i>

e2eECC is enabled by setting the [I,D]ECCEN bit of the E2ECTL0 DCR to a 1. On reset, e2eECC operation may be disabled from detecting or correcting errors based on reset configuration inputs, and no exceptions will be signaled for nonzero calculated syndrome values. This allows for the proper initialization of stored checkbits in any volatile storage by the CPU without causing error conditions due to uninitialized storage. Following the

initialization, software may enable e2eECC operation by writing the appropriate values to the E2ECTLO_{[I,D]ECCEN} control bits.

The E2ECTLO_{[I,D]DAC} control bits can be used to remove the address checking component of the ECC logic for the Instruction AHB and Data AHB when address inclusion is not desired.

15.10.1.2 End-to-End ECC error generation by software

Error generation provides a way to test error recovery and portions of the error detection/correction logic by intentionally injecting parity errors into the driven checkbit information on the external bus during write operations. No provision is made to generate internal errors on read data due to timing issues; instead, software may intentionally generate errors in the checkbit values to emulate data, address, or checkbit error on external bus write cycles, and read back the written data to cause an error to be detected.

The End-to-End ECC Error Control/Status Register (E2EECSR0) controls operation of the e2eECC error injection logic. It allows for generation of a single error injection operation on the next CPU data write to the external bus only, or for a series of error injection write operations to the external bus, using the WRC and INVC control fields. The WRCHKBIT/CHKINVT field controls which of the **p_hwchkbit[7:0]** outputs are affected.

Control is provided to allow for either inverting the value(s) of one or more of the checkbit outputs **p_hwchkbit[7:0]** in hardware on one or more external write accesses, or for software to directly supply checkbit values to be used for the external write access(es).

The End-to-End ECC Error Control/Status Register (E2EECSR0) also supports access to raw checkbit values via the RCHKBIT status field. This field is updated with checkbit values received on each CPU data read operation to either the DMEM or to the external bus (but not on cache hits).

Note that Nexus 3 accesses do not cause error injection or the capture of read checkbits, regardless of the settings of the E2EECSR0 register.

Figure 127 shows the layout of E2EECSR0.

Figure 127. e2eECC Error Control/Status Register 0 (E2EECSR0)

0				RCHKBIT								0				WRC	INVC	0				WCHKBIT/CHKINVT									
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

DCR 511; Read/Write; Reset: 0x0; Privileged

Table 222. E2EECSR0 field descriptions

Bits	Name	Description
0:3	—	Reserved
4:11	RCHKBIT	Read Checkbits This field provides the raw checkbits received on the last CPU data access to the DMEM or to external memory via the Data BIU. This field corresponds bit-wise to p_hrchkbit[7:0] for external reads and to p_dchk[0:7] for DMEM read accesses. Software may use this information to determine the stored checkbits of external memories or the DMEM by performing CPU load operations and then accessing this field prior to the next load operation (assuming interrupts are masked).
12:15	—	Reserved

Table 222. E2EECSR0 field descriptions (continued)

Bits	Name	Description
16:17	WRC	Write Control 00 No write checkbit substitution is performed by this control bit 01 Checkbit substitution is performed for the next CPU external write access (only) by driving p_hwchkbit[7:0] with the values in the WCHKBIT control field. Software must clear this field before rewriting to 01 in order to generate a subsequent checkbit substitution operation. 10 Checkbit substitution is performed for each CPU external write access while this field remains set to 10 by driving p_hwchkbit[7:0] with the values in the WCHKBIT control field. This field must be cleared by software to discontinue further checkbit substitution. 11 Reserved <i>Note: Checkbit substitution has priority over Error injection.</i>
18:19	INVC	Invert Control 00 No error injection is performed by this control bit 01 Error injection is performed for the next CPU external write access (only) by modifying p_hwchkbit[7:0] based on CHKINVT. Software must clear this field before rewriting to 01 in order to generate a subsequent error injection operation. 10 Error injection is performed for each CPU external write access while this field remains set to 10 by modifying p_hwchkbit[7:0] based on CHKINVT. This field must be cleared by software to discontinue further error generation. 11 Reserved <i>Note: Checkbit substitution has priority over Error injection.</i>
20:23	—	Reserved
24:31	WCHKBIT/ CHKINVT	Write Checkbits / Checkbit Invert Mask This field provides the checkbit substitution values when performing checkbit substitution via the WRC control field, and controls which checkbits are inverted when performing error injection via the INVC control field. This field corresponds bit-wise to p_hwchkbit[7:0]. For Checkbit inversion operations via error injection: 0 Checkbit is driven normally 1 Checkbit is inverted before being driven out on p_hwchkbit[7:0] when error injection occurs.

16 System Integration Unit Lite2 (SIUL2)

16.1 Introduction

16.1.1 Overview

The System Integration Unit Lite2 (SIUL2) provides control over all the I/O ports on this device and supports 13 ports with 16 bits of bidirectional, general-purpose input and output signals. It supports nine external interrupts with trigger event configuration. [Figure 128](#) is the block diagram of SIUL2 and its interfaces to other system components for this device.

The SIUL2 provides the GPIO ports on the device.

- When configured as output, you can write to the internal GPDO register to control the state driven on the associated output pad.
- When configured as input, you can detect the state of the associated pad by reading the value from the internal GPDI register.
- When configured as input and output, the pad value can be read back, which can be used as a method of checking the driven value on the associated I/O pad.

In order to assist in software development, there are different access mechanisms to the GPIO data registers. These differing mechanisms allow support for port access or for bit manipulation without the need to use read-modify-write operations or access with Power Architecture reservation.

- Access to two 16-bit ports in one access
- Read/Write access to a single bit
- A 16-bit port write with a bit mask, using single 32-bit access

There are nine external interrupt/DMA inputs to the SIUL2 that map to EIRQ pins on the device. The interrupt/DMA sources can be configured to have a digital filter to reject short glitches on the inputs.

Figure 128. SIUL2 block diagram

16.1.2 Features

The SIUL2 supports these distinctive features:

- 13 GPIO ports with data control
 - Drive data to up to 16 independent I/O channels
 - Sample data from up to 16 independent I/O channels

Two 16-bit registers can be read/written with one access to for a 32-bit port if needed.

External interrupt/DMA request support with:

- 2 system interrupt vectors for 9 interrupt sources (9 connected to EIRQ pins for this device) with independent interrupt mask
- 9 programmable digital glitch filters (one for each EIRQ)
- Independent DMA channel for each EIRQ pin
- Edge detection

Additionally the SIUL2 contains the multiplexed signal configuration registers that configure the electrical parameters and settings of all 202 functional pads. These are used to configure the following pad features:

- Drive strength
- Output impedance control
- Open drain/source output enable
- Slew rate control of JTAG and FlexRay pins
- Internal weak pull control
- Pin function assignment
- Control of analog path switches
- Safe mode behavior configuration
- TTL, CMOS, and Automotive input levels

16.1.3 Register protection

The System Integration Unit Lite2 uses the Register Protection Scheme to protect the individual registers from accidental writes. The following registers can be protected:

- SIUL2 DMA/Interrupt Request Enable Register 0(SIUL2_DIRER0)
- SIUL2 DMA/Interrupt Request Select Register 0(SIUL2_DIRSR0)
- SIUL2 Interrupt Rising-Edge Event Enable Register 0(SIUL2_IREER0)
- SIUL2 Interrupt Falling-Edge Event Enable Register 0(SIUL2_IFEER0)
- SIUL2 Interrupt Filter Enable Register 0(SIUL2_IFER0)
- SIUL2 Interrupt Filter Maximum Counter Register (SIUL2_IFMCR0–SIUL2_IFMCR31)
- SIUL2 Interrupt Filter Clock Prescaler Register (SIUL2_IFCPR)
- SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR0–SIUL2_MSCR1023)

Details about the protected registers at specific addresses can be found in the [Chapter 83: Register Protection \(REG_PROT\)](#) and [Chapter 7: Device Configuration](#).

16.2 Memory map and register description

This section provides a detailed description of all registers accessible in the SIUL2 module.

16.2.1 Memory map

[Table 223](#) gives an overview of the SIUL2 registers implemented.

Note: Reserved registers will be read as 0, write will have no effect. If supported and enabled in this MCU, a transfer error will be issued when trying to access completely reserved register space. 8/16 for when defined as only 32-bit access gives transfer error. Unimplemented registers accesses give transfer error i.e. due to register not being present.

16.2.2 Register descriptions

This section describes in address order all the SIUL2 registers. Each description includes a standard register diagram with an associated figure number. .

16.2.2.1 SIUL2 MCU ID Register #1 (SIUL2_MIDR1)

This register contains identification information about the device.

16.2.2.3 SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0)

The DMA/Interrupt Status Register contains flag bits that record an event on the external IRQ pins. When an event as defined in IRQ Rising-Edge Event Enable Register (SIUL2_IREEER0) and IRQ Falling-Edge Event Enable Register (SIUL2_IFEER0) occurs, the corresponding flag bit is set. The IRQ Flag bit is set irrespective of the corresponding DMA/Interrupt Request Enable bit in DMA/Interrupt Request Enable Register (SIUL2_DIRER0) is enabled. The EIF bit remains set until cleared by software or through the servicing of a DMA request. The EIF bits are cleared by writing a '1' to the bits. A write of '0' has no effect.

This register contains the interrupt flags.

28	Reserved
29:31 EIF2 EIF0	External Interrupt Status Flag x—This flag can be cleared only by writing 1. Writing 0 has no effect. If enabled (SIUL2_DIRER[x]), EIF[x] causes an interrupt or DMA request. 0 No interrupt or DMA event has occurred on the pad 1 An interrupt or DMA event as defined by SIUL2_IREER[x] and SIUL2_IFEER[x] has occurred

16.2.2.4 SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0)

The DMA/Interrupt Request Enable Register enables the assertion of DMA or interrupt request if the corresponding External IRQ Flag bit is set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0). The type of request enabled is determined by the corresponding DMA/Interrupt Request Select bit in SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0). This register enables the interrupt messaging to the interrupt controller.

16.2.2.5 SIUL2 DMA/Interrupt Request Select Register0 (SIUL2_DIRSR0)

The DIRSR selects between the DMA or interrupt request. If the corresponding bits are set in SIUL2 DMA/Interrupt Status Flag Register0 (SIUL2_DISR0) and SIUL2 DMA/Interrupt Request Enable Register0 (SIUL2_DIRER0), then the DMA/Interrupt Request Select bit determines whether DMA or an interrupt request is asserted. EIRQ are the external interrupt package pins on the device.

16.2.2.12 SIUL2 Multiplexed Signal Configuration Register (SIUL2_MSCR0–SIUL2_MSCR1023)

The MSCR registers control the I/O pin function and electrical properties for each pin on the device, and are used to select the input signal for IP blocks on the device that have multiple input sources. There is a dedicated MSCR register for each I/O pin on the device. Each MSCR register is independent of the others, except in the case of an LVDS configuration, where two MSCR registers must be configured together in this mode.

The MSCR registers are divided into two sets:

- I/O pin control registers, see [Section 16.2.2.13, I/O Pin Multiplexed Signal Configuration Registers \(SIUL2_MSCR0 - SIUL2_MSCR511\)](#).
- Multiplexed input selection registers [Section 16.2.2.14, Multiplexed Signal Configuration Registers for Multiplexed Input Selection \(SIUL2_MSCR512 - SIUL2_MSCR1023\)](#).

The signal data flow from IP blocks on the device to and from the I/O pins, and from IP block to IP block is given in [Figure 140](#).

Figure 140. MSCR I/O Pin and IP Block Port Connectivity

16.2.2.13 I/O Pin Multiplexed Signal Configuration Registers (SIUL2_MSCR0 - SIUL2_MSCR511)

Note:

The I/O pin MSCR register definition is given in [Figure 141](#). These registers select the output function on the associated I/O pin. The I/O MSCR registers control the drive strength, output drive circuit, pull up/down, input buffer enable, input hysteresis, input level selection, safe-mode operation, and analog input enable of the associated I/O pin. *Not all pads have all bits i.e., only some pads have hysteresis. See the SPC57EM80xx I/O Signal Description*

and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

When an I/O pin is configured as a single-ended input, the input buffer must be enabled for the pin using the MSCR[IBE] bit. This enables the input to all input destinations connected to the pin, including the GPIO input. In this way, the GPIO can be read at any time, regardless of the pin function. For IP blocks that have multiple input sources, the input source is selected in the multiplexed input selection MSCRs, and the associated I/O pin MSCR for the selected input must have the MSCR[IBE] bit enabled.

Double-click on the Excel file to open it and select the I/O Signal Description Table tab. See the device data sheet for the electrical characteristics of the weak, medium, strong, and very strong pad types. <i>Note: OERC[2] programming is required for forward compatibility.</i>
4	Reserved

Table 235. SIUL2_MSCR0 - SIUL2_MSCR511 field description (continued)

Field	Description
5:7 ODC	Output Drive Control—Specifies the type of output drive control for the associated pin. 000 Output buffer disabled 001 Open-drain 010 Push-pull 011 Open-source 100 Microsecond Channel LVDS 101 LFAST LVDS 110 - 111 Reserved
8 SMC	Safe Mode Control—Specifies whether the chip disables the pin's output buffer when the chip enters Safe mode . 0 Disable (the output buffer returns to its previous state when the chip leaves Safe mode) 1 Don't disable
9 APC	Analog Pad Control—Enables the pin's analog-input-path switch if the associated pin has an analog input function. 0 Disable (the switch is off) 1 Enable (another module can control the state of the switch)
10:11 ILS	Input Level Selection—Specifies the logic family for the associated pin, which determines its logic switching levels. 00 Automotive 01 TTL 10 LVDS 11 CMOS See the device data sheet for the electrical characteristics of the I/O pad input buffer types.
12 IBE	Input Buffer Enable—Enables the associated pin's input buffer. 0 Disabled 1 Enabled
13 HYS	Input Hysteresis—Enables input hysteresis for the associated pin. 0 Disabled 1 Enabled
14 WPDE	Weak Pulldown Enable—Used only when the associated destination is a chip pin. Enables the associated pin's weak pulldown resistor. It is OK for both WPDE and WPUE to be enabled, if they are, the pad is neither a weak pullup and a weak pulldown. 0 Disabled 1 Enabled
15 WPUE	Weak Pullup Enable—Used only when the associated destination is a chip pin. Enables the associated pin's weak pullup resistor. It is OK for both WPDE and WPUE to be enabled, if they are, the pad is neither a weak pullup and a weak pulldown. 0 Disabled 1 Enabled
16 INV	Invert—The output selected by the corresponding MSCR SSS field can be inverted before it is driven on the I/O pin with the INV bit. 0 The output selected by the SSS field is not inverted before being driven to the pin 1 The output selected by the SSS field is inverted before being driven to the pin <i>Note: Use of the INV bit is not supported when the ODC is configured for open-drain or open-source modes, and the output data will not be as expected for an inverted open-drain or open-source connection.</i>

Table 235. SIUL2_MSCR0 - SIUL2_MSCR511 field description (continued)

Field	Description
17:23	Reserved
24:31 SSS	Source Signal Select—Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. See Section 16.2.2.15, “Chip-pin MSCR assignments and related information” and Section 16.2.2.16, Module-port MSCR assignments and SSS values.”

All bits and fields in the I/O MSCR registers are applicable for all GPIO ports on the device. This includes all ports on the device with digital output function. For ADC input ports with digital input only (no output), the OERC, ODC, SMC, INV, and SSS bits/fields do not apply. The SSS is always 8b0 for input only ports, enabling the general purpose input. The analog input path is enabled in the ADC logic when the channel is selected for conversion.

The MSCR reset state given in [Figure 141](#) applies to all GPIO pins on the devices, which defaults to input/pull-up enabled. The exceptions to this are documented in [Table 236](#). Only the SMC, HYS, WPDE, and WPUE bits have exceptions to the default MSRC reset value.

1. When JTAG is enabled (JCOMP asserted) during reset, the TDO pin is pulled up during reset, but hi-z after. If JTAG is disabled, the TDO pin defaults to input/pull-up during and after reset.

16.2.2.14 Multiplexed Signal Configuration Registers for Multiplexed Input Selection (SIUL2_MSCR512 - SIUL2_MSCR1023)

The multiplexed input selection MSCR register definition is given in [Figure 142](#). These registers select the input source for IP blocks on the device that have inputs from multiple

sources, both other IP blocks and I/O pins. It is possible to configure the pad to be in input without having to connect it externally. This is possible, either by enabling internal pull-up/pull-down or disabling the input buffer (but in this case data is seen as 0 internally).

Table 237. SIUL2_MSCR512 - SIUL2_MSCR1023 field description

Field	Description
0:15	Reserved
16 INV	Invert— The input source signal selected by the corresponding SSS field for this MSCR can be inverted before it connects to the destination input with the INV bit. 0 SSS selected input signal is connected directly to the destination input 1 SSS selected input signal is inverted before it is connected to the destination input
17:23	Reserved
24:31 SSS	Source Signal Select—Selects which source signal is connected to the associated destination (chip pin or module port). For a chip pin, the source signals are outputs from module ports. For a module port, the source signals are either outputs from module ports or inputs from chip pins. The meaning of each value depends on the destination. See Section 16.2.2.15, “Chip-pin MSCR assignments and related information” and Section 16.2.2.16, Module-port MSCR assignments and SSS values .

16.2.2.15 Chip-pin MSCR assignments and related information

For device pin MSCR register definitions, see the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab.

16.2.2.16 Module-port MSCR assignments and SSS values

For each internal module port that is or can be configured as an input and has more than one possible source. See the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the Input

Multiplexing Table tab. The Input Multiplexing Table shows the assigned MSCR, and the SSS values and their corresponding source signals.

16.2.2.17 SIUL2 GPIO Pad Data Output Registers (SIUL2_GPDO0_3–SIUL2_GPDO508_511)

These registers can be used to set or clear a single GPIO pad with a byte access. For mapping of ports to GPDO registers, see the SPC57EM80xx I/O Signal Description and Input Multiplexing Tables (Excel file) attached to this document. Locate the paperclip symbol on the left side of the PDF window, and click it. Double-click on the Excel file to open it and select the I/O Signal Description Table tab. Note that the GPDO registers do not apply for ports PA[5], PA[6], PA[7], and PL[8]. The PA ports are JTAG pins with no GPIO, and PL[8] is not included on the device. Writes to the GPDO register corresponding to these ports have no effect.

16.2.2.19 SIUL2 Parallel GPIO Pad Data Out Register (SIUL2_PGPDO0 – SIUL2_PGPDO31)

These registers are used to set or clear the respective pads of the device. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDO and GPDO is that PGPDO registers can be used to set the values of all output pins assigned to a device port with a single 16-bit register write vs. the GPDO registers, which are used to set the value on a specific pin with a byte write. Note that the PGPDO registers do not apply for ports PA[5], PA[6], PA[7], and PL[8]. The PA ports are JTAG pins with no GPIO, and PL[8] is not included on the device. Writes to the PGPDO register corresponding to these ports have no effect.

Table 240. SIUL2_PGPDO0 field description

Field	Description
0:15 PPDO[x]	Parallel Pad Data Out—Write or read the data register that stores the value to be driven on the pad in output mode. Access to this register location are coherent with access to the bit-wise GPIO Pad Data Output Registers (SIUL2_GPDO). The x and y bit index define which PPDO register bit is equivalent to which PDO register bit according to the following equation: $PPDO[x][y] = PDO[(x*16)+y]$

Note: The SIUL2_PGPDO registers access the same physical resource as the SIUL2_PDO and SIUL2_MPGPDO address locations. Some examples of the mapping:

$PPDO[0][0] = PDO[0]$

$PPDO[2][0] = PDO[32]$

$PPDO[31][15] = PDO[511]$

16.2.2.20 SIUL2 Parallel GPIO Pad Data In Register (SIUL2_PGPDI0 – SIUL2_PGPDI31)

These registers hold the synchronized input value from the pads. Parallel port registers for input (PGPDI) and output (PGPDO) are provided to allow a complete port to be written or read in one operation, dependent on the individual pad configuration. The difference between PGPDI and GPDI registers is that PGPDI registers can be used to read the values of all input pins assigned to a device port with a single 16-bit register read vs. the GPDI registers, which are used to read the value on a specific pin with a byte read. Note that the GPDI registers do not apply for ports PA[5], PA[6], PA[7], and PL[8]. The PA ports are JTAG pins with no GPIO, and PL[8] is not included on the device. The GPDI values corresponding to these ports always read a value of zero.

16.3 Functional description

16.3.1 General

This section provides a complete functional description of the SIUL2.

16.3.2 Pad control

The SIUL2 controls the electrical characteristics of 199 pads on the device through the MSCR registers. It provides a consistent interface for all pads, both on a by-port and a by-bit basis. The following describes the pad characteristics that can be supported by the SIUL2.

The required controls are:

- Slew rate control
 - This is needed to offer improved EMC performance.
 - Support for a fast and a slow slew rate.
- Output Impedance Control
 - 4 output impedances supported
- Internal weak pull capability
 - This is needed to offer flexibility in the device configuration and the elimination of external hardware in some cases.
 - The configuration of the pull on any pad should be independently controlled to be either pull-up, pull-down or no-pull enabled.
- Control of analog path switches
- Safe Mode behavior configuration
- Open drain/source enable
 - Needed to support different pads muxed (e.g. mux IIC, with non open drain pads)
- Pin Function Assignment
 - This setting defines which chip function has control over the output of the pad.

The setting of each pad out of reset is fixed per MCU, but can be configured individually. In this way it is possible to select special pull settings or peripheral pad ownership per design.

It is possible for the user software to configure each pad independently of all other pads on the device or other pads grouped within a single port. This allows different pad types to be grouped together in ports and allows the necessary flexibility needed for the pads individual operation. This is achieved by grouping all of the above functions into a single register for each pad on the device, and allows each pad to be configured with a single write to one register and allowing simplified duplication of software for each pad with indexed changes for each pad.

16.3.3 General purpose input or output pads (GPIO)

The SIUL2 allows each pad to be configured as either a General Purpose Input Output pad (GPIO), and as one or more alternate functions (input or output), the function of which is determined by the peripheral that will use the pad.

GPIO pads can also optionally be implemented without any alternate function.

The SIUL2 is designed to manage 199 GPIO pads organized as ports that can be accessed for data reads and writes as 32-bit, 16-bit or 8-bit.

As shown in [Figure 148](#), all port accesses are identical with each read or write being performed only at a different location to access a different port width.

Figure 148. Data Port example arrangement showing configuration for different port width accesses

This implementation requires that the registers are arranged in such a way as to support this range of port widths without having to split reads or writes into multiple accesses.

The SIUL2 has separate data input and data output registers for all pads, allowing the possibility of reading back an input or output value of a pad directly. This supports the ability to validate what is present on the pad rather than simply confirming the value that was written to the data register by accessing the data input registers.

The data output registers support both read and write operations to be performed.

The data input registers support read access only.

When the pad is configured to use one of its alternate functions, the data input value reflect the respective value of the pad. If a write operation is performed to the data output register for a pad configured as an alternate function (non GPIO), this write will not be reflected by the pad value until reconfigured to GPIO.

All general purpose pads are implemented as bidirectional.

Note: In case the bi-directional operation impacts some performances (e.g. ADC accuracy), or is not required for a specific pad function it is acceptable to limit the functionality of some pads to "Input Only".

16.3.4 External interrupts/DMA requests (EIRQ pins)

The SIUL2 supports nine external interrupts which are allocated to EIRQ pins on the device.

The SIUL2 supports two interrupt vectors to the interrupt controller of the MCU. Each interrupt vector can support eight external interrupt sources from the device pads.

Refer to [Figure 149](#) for an overview of the external interrupt implementation.

Figure 149. External interrupt pad diagram

All the external interrupt pads within a single group (max 8 pads) have equal priority. It is the responsibility of the user software to search through the group of sources in the most appropriate way for their application.

The priority of the vectors used by the external interrupt pads is fixed based on the platform and the interrupt controller and its priority levels, but the allocation of pads to each group of interrupts can be independently configured by the MCU.

An MCU specific number of external interrupt lines can have a digital glitch filters applied to them. The supported range is 1 to 8. The glitch filters need a running internal oscillator clock to work. If no such clock is available, external interrupts will be effectively disabled when the glitch filter is enabled on an interrupt line.

16.3.4.1 External interrupt initialization

When an external interrupt pin is first enabled, it is possible to get a false interrupt flag. To prevent a false interrupt request, during pin interrupt initialization, the user must do the following:

- Mask interrupts by clearing the EIREn bits in DIRER0.
- Select the pin polarity by setting the appropriate IREEN bits in IREER0 and the appropriate IFEEEn bits in IFEER0 as desired.
- Configure the appropriate bits in the MSCR[0–511] register for the external interrupt pin(s) desired as follows:
 - Clear the ODC bits to do disable output.
 - Set the IBE bit to enable the pin's input buffer.
 - If using the internal weak pullup/pulldown, configure the appropriate WPUE and WPDE bits.

Note: MSCR_SSS bits do not need to be changed for either MSCR[0:511] or MSCR[512:1023] since the external interrupt pin input is directly connected to the SIUL for EIRQ pins.

External interrupt pins should never be configured as outputs (MSCR_ODC bits are not zeros) when external interrupt inputs are desired since false interrupts could be detected (such as from a GPIO configuration).

- Select the request desired between DMA or Interrupt by writing the appropriate DIRSn bits in DIRSR0.
- Select the desired glitch filter setup for the pins by writing the following:
 - Write the Filter Counter setting to the desired value by writing the MAXCNT[3:0] bits in the IFMCn register for the respective external interrupt that is being used.
 - Set the Filter Clock Prescaler setting from 0 to 15 to the desired value by writing the IFCP[3:0] bits in the IFCPR register.
 - Then enable the glitch filter for the desired external interrupt pins by setting the appropriate IFEn bits in IFER0.

Note: The glitch filter clock runs on the internal RC oscillator clock whereas the SIUL logic runs off of the PBRIDGEEx clock. The IRC clock is at a fixed frequency of 16 MHz. The PBRIDGEEx clock can run as high as 50 MHz when core clock is at 200 MHz.

The glitch filter is enabled on IRC clock, so make sure at least one IRC clock occurs after enabling it before trying to detect glitchless events.

- Write to EIFn bits in DISR0 to as desired to clear any flags (For DMA, its self clearing).
- Enable the interrupt pins by setting the appropriate EIREn bits in DIREER0.

16.3.4.2 External interrupt management

Each interrupt can be enabled or disabled independently. This can be performed using a single rolled up register (SIUL2_DIRER0 - [Figure 132](#)). A pad defined as an external interrupt can be configured by the user to recognize interrupts with an active rising edge, an active falling edge or both edges being active. A setting of having both edge events disabled is reserved and should not be configured.

The active IRQ edge is controlled by the users through the configuration of the registers SIUL2_IREER and SIUL2_IFEER.

Each external interrupt supports an individual flag which is held in the Flag register (DISR0). This register is a clear-by-write-1 register type, preventing inadvertent overwriting of other flags in the same register.

The SPC57EM80xx device supports two SIUL2 interrupt vectors aggregating a total of eight external interrupt sources as shown in [Figure 150](#).

Figure 150. Interrupt to vector mapping at MCU level

16.3.4.3 External interrupt request

The EIRQ input pins on the device are sources for interrupt or DMA requests. The nine EIRQ pins for the device map to two interrupt requests. The mapping of interrupt requests and EIRQ pins is given in [Table 243](#).

Table 243. Interrupt source mapping to SIUL2 interrupt request output

Interrupt requests	EIRQ pins
0	EIRQ0 EIRQ1 EIRQ2 EIRQ4 EIRQ5
1	EIRQ8 EIRQ9 EIRQ10 EIRQ11

16.3.4.4 Interrupt Vector

The nine EIRQ pins on the device map to an Interrupt Vector in the Interrupt Controller.

Note: See the [Chapter 7: Device Configuration](#) chapter, [Table 54](#) for Interrupt Vector table.

16.3.4.5 DMA requests

The nine EIRQ pins on the device map to an independent DMA request channel in the DMA controller.

Note: See the [Chapter 7: Device Configuration](#), [Table 57](#) for DMA request mapping table.

17 Crossbar Switch (XBAR)

17.1 Introduction

This chapter provides information on the layout, configuration, and programming of the crossbar switch. The crossbar switch connects bus masters and bus slaves using a hardware interconnect matrix. This structure allows all bus masters to access different bus slaves simultaneously with no interference while providing arbitration among the bus masters when they access the same slave. A variety of bus arbitration methods and attributes may be programmed on a slave-by-slave basis.

17.1.1 Features

The crossbar switch includes these distinctive features:

- Symmetric crossbar bus switch implementation
 - Concurrent accesses from different masters to different slaves
 - Configurable slave arbitration attributes on a slave-by-slave basis
- 64-bit datapath width
- Support for 8-, 16-, 32-, and 64-bit single transfers
- Support for a variety of 4-, 8-, and 16-beat burst transfers including a 4-beat, 64-bit burst for cache line accesses
- Operation at one-to-one clock frequency with the bus masters
- Support for low-power park mode

17.1.2 Memory map and register definition

Each slave port of the crossbar switch contains configuration registers. Read and write transfers of the configuration registers require two bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

A bus error response is returned if an unimplemented location is accessed within the crossbar switch.

The slave registers also feature a bit that, when set, prevents the registers from being written. The registers remain readable, but future write attempts have no effect on the registers and are terminated with a bus error response to the master initiating the write. The core, for example, takes a data storage interrupt.

Note: This section shows the registers for all eight master and slave ports. If a master or slave is not used on this particular device, then unexpected results occur when writing to its registers. See the Chip Configuration details for the exact master/slave assignments for your device. Additionally, all references to the crossbar switch registers are based on the physical port connections, not the logical port numbers.

17.1.2.1 XBAR Priority Registers Slave (XBARx_PRSn)

The priority registers (XBARx_PRSn) set the priority of each master port on a per-slave-port basis and reside in each slave port. The priority register can be accessed only with 32-bit accesses. The XBARx_PRSn register is read-only; attempts to write to it have no effect on it and result in a bus-error response to the master initiating the write.

See [Section 7.3.3, Crossbar switch configuration](#) for XBARx_PRSn priority values.

Table 245. XBARx_PRSn field descriptions

Field	Description
0 Reserved	This read-only bit is reserved and always has the value zero.
1–3 M7	Master 7 priority. Sets the arbitration priority for this port on the associated slave port: 000 This master has level 1 (highest) priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8 (lowest) priority when accessing the slave port.
4 Reserved	This read-only bit is reserved and always has the value zero.
5–7 M6	Master 6 priority. Sets the arbitration priority for this port on the associated slave port: 000 This master has level 1 (highest) priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8 (lowest) priority when accessing the slave port.
8 Reserved	This read-only bit is reserved and always has the value zero.
9–11 M5	Master 5 priority. Sets the arbitration priority for this port on the associated slave port: 000 This master has level 1 (highest) priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8 (lowest) priority when accessing the slave port.
12 Reserved	This read-only bit is reserved and always has the value zero.
13–15 M4	Master 4 priority. Sets the arbitration priority for this port on the associated slave port: 000 This master has level 1 (highest) priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8 (lowest) priority when accessing the slave port.
16 Reserved	This read-only bit is reserved and always has the value zero.

Table 245. XBARx_PRSn field descriptions (continued)

Field	Description
17–19 M3	Master 3 priority. Sets the arbitration priority for this port on the associated slave port: 000 This master has level 1 (highest) priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8 (lowest) priority when accessing the slave port.
20 Reserved	This read-only bit is reserved and always has the value zero.
21–23 M2	Master 2 priority. Sets the arbitration priority for this port on the associated slave port: 000 This master has level 1 (highest) priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8 (lowest) priority when accessing the slave port.
24 Reserved	This read-only bit is reserved and always has the value zero.
25–27 M1	Master 1 priority. Sets the arbitration priority for this port on the associated slave port: 000 This master has level 1 (highest) priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8 (lowest) priority when accessing the slave port.
28 Reserved	This read-only bit is reserved and always has the value zero.
29–31 M0	Master 0 priority. Sets the arbitration priority for this port on the associated slave port: 000 This master has level 1 (highest) priority when accessing the slave port. 001 This master has level 2 priority when accessing the slave port. 010 This master has level 3 priority when accessing the slave port. 011 This master has level 4 priority when accessing the slave port. 100 This master has level 5 priority when accessing the slave port. 101 This master has level 6 priority when accessing the slave port. 110 This master has level 7 priority when accessing the slave port. 111 This master has level 8 (lowest) priority when accessing the slave port.

Figure 152. XBAR Control Register (XBARx_CRSn)

[illegible]

Table 246. XBARx_CRSn field descriptions

Field	Description
0 RO	Read only Forces both of the slave port's registers to be read-only. After set, only a hardware reset clears it. 0 The slave port's registers are writable. 1 The slave port's registers are read-only and cannot be written (attempted writes have no effect on the registers and result in a bus error response).
1 HRP	Halt Request Priority Determines if a request to halt the crossbar is treated as the highest priority request, or the lowest priority request. 0 The halt request has the highest priority for arbitration on this slave port. 1 The halt request has the lowest initial priority for arbitration on this slave port.
2–7 Reserved	This read-only bitfield is reserved and always has the value zero.
8–15 HPEx	High Priority Enable Determines if Master x is able to temporarily elevate its request to the slave to high priority status. This can help reduce the amount of time the high priority requesting master must wait to gain control of the slave. 0 High Priority requests from Master x are ignored and are treated the same as regular requests. 1 High Priority requests from Master x can temporarily elevate the priority level of the master's request to the slave.
16–21 Reserved	This read-only bitfield is reserved and always has the value zero.

Table 246. XBARx_CRSn field descriptions (continued)

Field	Description
22–23 ARB	Arbitration mode Selects the arbitration policy for the slave port. 00 Fixed priority 01 Round-robin (rotating) priority 10 Reserved 11 Reserved
24–25 Reserved	This read-only bitfield is reserved and always has the value zero.
26–27 PCTL	Parking control Determines the slave port's parking control. The low-power park feature results in overall power savings if the slave port is not saturated; however, this forces an extra latency clock when any master tries to access the slave port while not in use because it is not parked on any master. 00 When no master makes a request, the arbiter parks the slave port on the master port defined by the PARK bit field. 01 When no master makes a request, the arbiter parks the slave port on the last master to be in control of the slave port. 10 When no master makes a request, the slave port is not parked on a master and the arbiter drives all outputs to a constant safe state. 11 Reserved
28 Reserved	This read-only bit is reserved and always has the value zero.
29–31 PARK	Park Determines which master port the current slave port parks on when no masters are actively making requests and the PCTL bits are cleared. <i>Note: Only select master ports that are actually present on the device. If not, undefined behavior may occur.</i> 000 Park on master port M0 001 Park on master port M1 010 Park on master port M2 011 Park on master port M3 100 Park on master port M4 101 Park on master port M5 110 Park on master port M6 111 Park on master port M7

17.2 Functional description

This section provides the functional details of the crossbar switch.

17.2.1 General operation

When a master sends an access to the crossbar switch, the access is immediately taken. If the targeted slave port of the access is available, then the access is immediately presented on the slave port. It is possible to make single-clock (zero wait state) accesses through the crossbar. If the targeted slave port of the access is busy or parked on a different master port, the requesting master simply sees wait states inserted until the targeted slave port can service the master's request. The latency in servicing the request depends on each master's priority level and the responding slave's access time.

Since the crossbar switch appears to be just another slave to the master device, the master device has no knowledge of whether it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting, it simply enters a wait state.

A master is given control of the targeted slave port only after a previous access to a different slave port completes, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when:

- A higher priority master has:
 - An outstanding request to one slave port that has a long response time and
 - A pending access to a different slave port, and
- A lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

After the master has control of the slave port it is targeting, the master remains in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a fixed-length burst transfer it retains control of the slave port until that transfer completes.

When a master has control of a given slave port, the crossbar returns all response information from the slave back to the requesting master.

The crossbar terminates all master IDLE transfers (as opposed to allowing the termination to come from one of the slave buses). Additionally, when no master is requesting access to a slave port, the crossbar drives IDLE transfers onto the slave bus even though a default master may be granted access to the slave port.

When a slave bus is being IDLEd by the crossbar, it can park the slave port on the master port indicated by the `XBARx_CRSn[PARK]`. This is done in an attempt to save the initial clock of arbitration delay that otherwise would be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low-power park mode in attempt to save power by using `XBARx_CRSn[PCTL]`.

17.2.2 Register coherency

Since the content of the registers has a real-time effect on the operation of the crossbar, it is important to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave-port-related master accesses; instead, they track only with slave accesses.

17.2.3 Arbitration

The crossbar switch supports two arbitration schemes: a simple fixed-priority comparison algorithm and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

17.2.3.1 Fixed-priority operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the `XBARx_PRSn` (priority registers). If two masters request access to a slave port, the master with the higher priority in the selected priority register gains control over the slave port.

When a master makes a request to a slave port, the slave port checks whether the new requesting master's priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port performs an

arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port, the new requesting master is granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed-length burst transfer or a locked transfer. In this case, the new requesting master must wait until the end of the burst transfer or locked transfer before it is granted control of the slave port.

If the new requesting master's priority level is lower than the master that currently has control of the slave port, the new requesting master is forced to wait until the current master runs one of the following cycles:

- An IDLE cycle
- A non-IDLE cycle to a location other than the current slave port

17.2.3.2 Round-robin priority operation

When operating in round-robin mode, each master is assigned a relative priority based on the physical master port number. This relative priority is compared to the ID (master port number) of the last master to perform a transfer on the slave bus. The highest priority requesting master becomes owner of the slave bus at the next transfer boundary (accounting for locked and fixed-length burst transfers). Priority is based on how far the ID of the requesting master is ahead of the ID of the last master.

After access is granted to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line is granted access to the slave port at the next transfer boundary, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the crossbar is implemented with master ports 0, 1, 4, and 5. If the last master of the slave port was master 1, and master 0, 4, and 5 make simultaneous requests, they are serviced in the order 4, 5, and then 0.

Parking may continue to be used in a round-robin mode, but it does not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff occurs to the next master in line after one cycle of arbitration. If the slave port is put into low-power park mode, the round-robin pointer is reset to point at master port 0, giving it the highest priority.

17.2.3.3 Priority assignment

Each master port needs to be assigned a unique 3-bit priority level. If an attempt is made to program multiple master ports with the same priority level within the priority registers (XBARx_PRSn), the crossbar switch responds with a bus error and the registers are not updated.

17.3 Initialization/application information

No initialization is required by or for the crossbar switch. Hardware reset ensures all the register bits used by the crossbar switch are properly initialized to a valid state. Settings and priorities should be programmed to achieve maximum system performance.

18 Crossbar Integrity Checker (XBIC)

18.1 Overview

The Crossbar Integrity Checker (XBIC) verifies the integrity of the crossbar transfers. For forward signals (master to slave), it is done by verifying the integrity of the attribute information using an 8-bit Error Detection Code (EDC). The EDC detects any single- or double-bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. For feedback signals (slave to master), it is done by comparing the consistence of the signals during the AHB dataphase. There are three signals from slave to master, hready, hresp0, and hresp2. If any of the master signals is different from the slave signals during dataphase, the error will be reported in the Error Status Register.

During the address phase of the system bus pipelined protocol, the XBIC generates an 8-bit EDC checkbit value for every transfer, passing these checkbits through the crossbar to the targeted slave where it is compared against the 8-bit EDC checkbits calculated from the crossbar slave attributes. The EDC is calculated for 64 bits of attribute information: 32 bits of system bus attribute control plus 32 bits associated with the processor core's decorated storage attribute. The resulting (72,64) code is a distance 4 encoding using a minimum odd weight H matrix definition. The EDC definition has been optimized for timing considerations with the system bus attribute signals exclusively using weight 3 code values and the decoration attribute using a mix of weight 3 and 5 codes.

During the data phase of the system bus pipelined protocol, the XBIC compares the three signals of hready, hresp0, hresp2 from entering the crossbar on the slave side to leaving the crossbar on the master side. Data phase is often more than one clock cycle due to wait cycles. All three signals are compared clock by clock during the whole data cycle.

18.2 Features

The XBIC has the following features:

- Verification of attribute information for all crossbar transfers
 - EDC (72,64) code protects against single and double bit errors
- Verification of feedback information for each data phase during crossbar transfer
 - hready, hresp0 & hresp2 are compared from entering the crossbar on the slave side to leaving the crossbar on the master side
- Error injection for testing
 - Programmable master and slave port specifiers
 - Programmable 8-bit toggle vector to insert error in master EDC checkbit value
 - Address, EDC syndrome, master and slave port information captured on error
- Programmable integrity check enable on a per-slave-port basis
- Programmable feedback check enable on a per-master-port basis

18.3 Block diagram

The crossbar transfer attribute information for all master and slave ports is routed to the XBIC, which calculates and checks the EDC parity over the attribute information as shown

in [Figure 153](#) and [Figure 154](#).

Figure 153. XBIC system block diagram

Figure 154. XBIC block diagram

18.4 External signal description

The XBIC has no external interface signals.

18.5 Memory map and register definition

The XBIC programming model has four 32-bit registers. The programming model can only be accessed in supervisor mode using 32-bit (word) accesses. Attempted references in user mode or using a different size are invalid and generate an error termination.

18.5.1 Memory map

The XBIC memory map is shown in [Table 247](#).

Table 247. XBIC memory map

Address offset	Register name	Register description	Size (bits)	Access
0x0000	XBIC_MCR	XBIC Module Control Register	32	R/W
0x0004	XBIC_EIR	XBIC Error Injection Register	32	R/W

MEn	Master Port Enable for slave driven signal safety check 0 Attribute integrity checking disabled for master port n. 1 Attribute integrity checking enabled for master port n.

18.5.2.2 XBIC Error Injection Register (XBIC_EIR)

The XBIC_EIR contains fields for controlling the XBIC error injection function. When an error is injected, the EDC syndrome associated with the programmed master and slave ports is modified, causing the XBIC to assert the error indication to the FCCU and capturing the transfer information in the XBIC_ESR and XBIC_EAR registers. Otherwise, transfers are not affected by XBIC error injection.

Figure 156. XBIC Error Injection Register (XBIC_EIR)

Offset 0x004																Access: Supervisor	
																Read/Write	
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

Table 249. XBIC_EIR field descriptions

Field	Description
EIE	Error Injection Enable. 0 Error injection disabled 1 Error injection enabled
SLV	Target Slave Port. Error injection is enabled for the designated slave port. Other slave ports are unaffected.
MST	Target Master ID. Error injection is enabled for the designated master ID. Transfers with other master IDs are not affected.
SYN	Syndrome. This value is exclusive-ored with the calculated syndrome (which should be zero) to generate an error with the specified syndrome. A value of zero does not generate an error.

18.5.2.3 XBIC Error Status Register (XBIC_ESR)

The Error Status Register (XBIC_ESR) contains two types of error information about the *last* transfer. If an attribute integrity check error was detected, the slave port, the master port and the syndrome are captured in the SLV, MST and SYN fields. If there is a mismatch among internal signals (hready, hresp0, and hresp2) during the data phase, the slave and master port are captured in the DPSE0-7 and DPME0-7 fields.

This register is cleared only on reset.

Figure 157. XBIC Error Status Register (XBIC_ESR)

Table 250. XBIC_ESR field descriptions

Field	Description
VLD	Error Status Valid. 0 No error detected, other fields of the ESR and EAR are not valid. 1 Error detected, all fields of the ESR and EAR are valid.
DPSEn	Data phase slave port error 0) No error on slave port n 1) Data phase error on slave port n
DPMEn	Data phase master port error 0) No error on master port n 1) Data phase error on master port n
SLV	Slave Port. The slave port targeted by the last transfer with an error.
MST	Master ID. The master ID value of the last transfer with an error.
SYN	Syndrome. The syndrome calculated for the last transfer with an error. For single bit errors the signal in error can be determined, see Table 252 .

18.5.2.4 XBIC Error Address Register (XBIC_EAR)

The Error Address Register (XBIC_EAR) contains the address of the *last* transfer in which an attribute integrity check error was detected on an enabled slave port. This register is only cleared on reset.

Figure 158. Error Address Register (XBIC_EAR)

Table 251. XBIC_EAR Register field descriptions

Field	Description
ADDR	The address of the last transfer with an error.

18.6 Functional description

The Crossbar Integrity Checker (XBIC) verifies the integrity of the attribute information for crossbar transfers using an 8-bit Error Detection Code (EDC). The EDC detects any single or double bit errors in the attribute information and signals the Fault Collection and Control Unit (FCCU) when an error is detected. The Module Control Register (XBIC_MCR) allows integrity checking to be enabled on a per-slave-port basis. The EDC parity is generated by the XBIC for each master port during the system bus address phase pipeline stage, routed through the crossbar via a sideband signal and checked against the slave attribute EDC generated for each enabled slave port during the first system bus data phase cycle. Detection of an error does *not* generate a bus error. The XBIC attribute integrity checking is independent from the end-to-end ECC that covers the transfer address and data.

The XBIC can be programmed to intentionally inject EDC errors for testing. Error injection is targeted toward a single slave port and a single master ID at a time as determined by the settings in the Error Injection Register (XBIC_EIR). When an error is injected, the EDC syndrome is modified which causes the XBIC to assert the error indication to the FCCU. Otherwise transfers are unaffected by XBIC error injection. This approach allows the check logic to be verified *without* compromising the integrity of the data transfer. Once the error injection function is enabled by setting XBIC_EIR[EIE], errors are induced on all subsequent targeted transactions until XBIC_EIR[EIE] is cleared.

When an error is detected, due either to a hardware fault or error injection, information related to the error is captured and reported in the Error Status Register (XBIC_ESR) and Error Address Register (XBIC_EAR). The XBIC_ESR and XBIC_EAR registers contain information about the *last* transfer with a detected error and are only cleared on reset. The cause of a single-bit error can be determined by the syndrome value reported in the XBIC_ESR as shown in [Table 250](#). Any other syndrome indicates a multi-bit error.

The above for XBIC to catch forwarding (master to slave) signal errors during AHB address phase. XBIC also detect backward signal (slave to master) errors during AHB data phase.

For the three slave driven signals (hready, hresp0 and hresp2), XBIC perform the comparison between the input of the slave port and output of the master port during the AHB data phase. When mis-match happening, the error will be captured. The current slave port will be registered in XBIC_ESR bit field DPSE0-7, and the current master port will be registered in XBIC_ESR bit field DSME0-7.

19 Crossbar Lock Control (CLC) module

19.1 Introduction

The crossbar switch connects bus masters and bus slaves using a hardware interconnect matrix. This structure allows all bus masters to access different bus slaves simultaneously with no interference while providing arbitration among the bus masters when they access the same slave.

The crossbar also provides a mechanism to support the lock mechanism as specified in the AMBA AHB protocol. The *hlock* signal (see [Figure 159](#)), when asserted, indicates to the crossbar that the master is performing a number of transfers to a targeted slave and the crossbar arbiter must not grant any other bus master access to the targeted slave until the locked sequence is complete. Requests by other bus masters while a slave is locked are stalled until the locked sequence is complete.

The crossbar lock control module (ACP_CLC) provides a programmable mechanism to configure a locked sequence. An instance of the ACP_CLC is associated with each crossbar switch in the device.

19.2 Block diagram

Figure 159. CLC block diagram

19.3 Memory Map and Register Definition

Each master port of the crossbar switch is provided a set of configuration registers to establish a locked transfer sequence targeting a specific slave. The registers can only be accessed in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

An error response is returned if an unimplemented location is accessed within the crossbar switch.

Note: This section shows the registers for all eight master and slave ports. If a master or slave is not used on this a device, then unexpected results occur when writing to its registers. See the Chip Configuration details for the exact master/slave assignments for your device. Additionally, all references to the crossbar switch master and slave ports are based on the physical port connections, not the logical port numbers.

Table 257. CLC_STGT field description

Field	Description
0–3 M0STGT	Master 0 Slave Target. When Master 0 is configured to trigger a locked sequence, this field specifies the targeted slave to receive the locked sequence. 0000 The slave connected to crossbar slave port 0 is the target for the Master 0 locked sequence. 0001 The slave connected to crossbar slave port 1 is the target for the Master 0 locked sequence. 0010 The slave connected to crossbar slave port 2 is the target for the Master 0 locked sequence. 0011 The slave connected to crossbar slave port 3 is the target for the Master 0 locked sequence. 0100 The slave connected to crossbar slave port 4 is the target for the Master 0 locked sequence. 0101 The slave connected to crossbar slave port 5 is the target for the Master 0 locked sequence. 0110 The slave connected to crossbar slave port 6 is the target for the Master 0 locked sequence. 0111 The slave connected to crossbar slave port 7 is the target for the Master 0 locked sequence. 1---- Reserved <i>Note: Master 0 relates to the physical crossbar port connections, not the logical master ID.</i>
4–7 M1STGT	Master 1 Slave Target. When Master 1 is configured to trigger a locked sequence, this field specifies the targeted slave to receive the locked sequence. 0000 The slave connected to crossbar slave port 0 is the target for the Master 1 locked sequence. 0001 The slave connected to crossbar slave port 1 is the target for the Master 1 locked sequence. 0010 The slave connected to crossbar slave port 2 is the target for the Master 1 locked sequence. 0011 The slave connected to crossbar slave port 3 is the target for the Master 1 locked sequence. 0100 The slave connected to crossbar slave port 4 is the target for the Master 1 locked sequence. 0101 The slave connected to crossbar slave port 5 is the target for the Master 1 locked sequence. 0110 The slave connected to crossbar slave port 6 is the target for the Master 1 locked sequence. 0111 The slave connected to crossbar slave port 7 is the target for the Master 1 locked sequence. 1---- Reserved <i>Note: Master 1 relates to the physical crossbar port connections, not the logical master ID.</i>
8–11 M2STGT	Master 2 Slave Target. When Master 2 is configured to trigger a locked sequence, this field specifies the targeted slave to receive the locked sequence. 0000 The slave connected to crossbar slave port 0 is the target for the Master 2 locked sequence. 0001 The slave connected to crossbar slave port 1 is the target for the Master 2 locked sequence. 0010 The slave connected to crossbar slave port 2 is the target for the Master 2 locked sequence. 0011 The slave connected to crossbar slave port 3 is the target for the Master 2 locked sequence. 0100 The slave connected to crossbar slave port 4 is the target for the Master 2 locked sequence. 0101 The slave connected to crossbar slave port 5 is the target for the Master 2 locked sequence. 0110 The slave connected to crossbar slave port 6 is the target for the Master 2 locked sequence. 0111 The slave connected to crossbar slave port 7 is the target for the Master 2 locked sequence. 1---- Reserved <i>Note: Master 2 relates to the physical crossbar port connections, not the logical master ID.</i>

Table 257. CLC_STGT field description (continued)

Field	Description
12–15 M3STGT	Master 3 Slave Target. When Master 3 is configured to trigger a locked sequence, this field specifies the targeted slave to receive the locked sequence. 0000 The slave connected to crossbar slave port 0 is the target for the Master 3 locked sequence. 0001 The slave connected to crossbar slave port 1 is the target for the Master 3 locked sequence. 0010 The slave connected to crossbar slave port 2 is the target for the Master 3 locked sequence. 0011 The slave connected to crossbar slave port 3 is the target for the Master 3 locked sequence. 0100 The slave connected to crossbar slave port 4 is the target for the Master 3 locked sequence. 0101 The slave connected to crossbar slave port 5 is the target for the Master 3 locked sequence. 0110 The slave connected to crossbar slave port 6 is the target for the Master 3 locked sequence. 0111 The slave connected to crossbar slave port 7 is the target for the Master 3 locked sequence. 1---- Reserved <i>Note: Master 3 relates to the physical crossbar port connections, not the logical master ID.</i>
16–19 M4STGT	Master 4 Slave Target. When Master 4 is configured to trigger a locked sequence, this field specifies the targeted slave to receive the locked sequence. 0000 The slave connected to crossbar slave port 0 is the target for the Master 4 locked sequence. 0001 The slave connected to crossbar slave port 1 is the target for the Master 4 locked sequence. 0010 The slave connected to crossbar slave port 2 is the target for the Master 4 locked sequence. 0011 The slave connected to crossbar slave port 3 is the target for the Master 4 locked sequence. 0100 The slave connected to crossbar slave port 4 is the target for the Master 4 locked sequence. 0101 The slave connected to crossbar slave port 5 is the target for the Master 4 locked sequence. 0110 The slave connected to crossbar slave port 6 is the target for the Master 4 locked sequence. 0111 The slave connected to crossbar slave port 7 is the target for the Master 4 locked sequence. 1---- Reserved <i>Note: Master 4 relates to the physical crossbar port connections, not the logical master ID.</i>
20–23 M5STGT	Master 5 Slave Target. When Master 5 is configured to trigger a locked sequence, this field specifies the targeted slave to receive the locked sequence. 0000 The slave connected to crossbar slave port 0 is the target for the Master 5 locked sequence. 0001 The slave connected to crossbar slave port 1 is the target for the Master 5 locked sequence. 0010 The slave connected to crossbar slave port 2 is the target for the Master 5 locked sequence. 0011 The slave connected to crossbar slave port 3 is the target for the Master 5 locked sequence. 0100 The slave connected to crossbar slave port 4 is the target for the Master 5 locked sequence. 0101 The slave connected to crossbar slave port 5 is the target for the Master 5 locked sequence. 0110 The slave connected to crossbar slave port 6 is the target for the Master 5 locked sequence. 0111 The slave connected to crossbar slave port 7 is the target for the Master 5 locked sequence. 1---- Reserved <i>Note: Master 5 relates to the physical crossbar port connections, not the logical master ID.</i>

Table 257. CLC_STGT field description (continued)

Field	Description
24–27 M6STGT	Master 6 Slave Target. When Master 6 is configured to trigger a locked sequence, this field specifies the targeted slave to receive the locked sequence. 0000 The slave connected to crossbar slave port 0 is the target for the Master 6 locked sequence. 0001 The slave connected to crossbar slave port 1 is the target for the Master 6 locked sequence. 0010 The slave connected to crossbar slave port 2 is the target for the Master 6 locked sequence. 0011 The slave connected to crossbar slave port 3 is the target for the Master 6 locked sequence. 0100 The slave connected to crossbar slave port 4 is the target for the Master 6 locked sequence. 0101 The slave connected to crossbar slave port 5 is the target for the Master 6 locked sequence. 0110 The slave connected to crossbar slave port 6 is the target for the Master 6 locked sequence. 0111 The slave connected to crossbar slave port 7 is the target for the Master 6 locked sequence. 1---- Reserved <i>Note: Master 6 relates to the physical crossbar port connections, not the logical master ID.</i>
28–31 M7STGT	Master 7 Slave Target. When Master 7 is configured to trigger a locked sequence, this field specifies the targeted slave to receive the locked sequence. 0000 The slave connected to crossbar slave port 0 is the target for the Master 7 locked sequence. 0001 The slave connected to crossbar slave port 1 is the target for the Master 7 locked sequence. 0010 The slave connected to crossbar slave port 2 is the target for the Master 7 locked sequence. 0011 The slave connected to crossbar slave port 3 is the target for the Master 7 locked sequence. 0100 The slave connected to crossbar slave port 4 is the target for the Master 7 locked sequence. 0101 The slave connected to crossbar slave port 5 is the target for the Master 7 locked sequence. 0110 The slave connected to crossbar slave port 6 is the target for the Master 7 locked sequence. 0111 The slave connected to crossbar slave port 7 is the target for the Master 7 locked sequence. 1---- Reserved <i>Note: Master 7 relates to the physical crossbar port connections, not the logical master ID.</i>

Note: The ACP_CLC locking mechanism is intended to associate a single master to each slave target. Configuring the ACP_CLC to execute locked sequences to a single slave from multiple masters will result in non-deterministic behavior.

19.4 Functional description

The Crossbar Lock Control module monitors the AHB buses that connect the various system masters to their corresponding master ports on the crossbar. When the ACP_CLC is enabled and configured to initiate a locked sequence for a given master, the ACP_CLC snoops the request activity on the master's AHB bus. Upon detection of transfer requests within the address range that corresponds to the targeted slave's memory map region, the ACP_CLC asserts the *hlock* signal and continues to assert *hlock* on all requests to the targeted slave until the locking mechanism is disabled. The lock configuration is disabled by clearing CLC_GEN[GEN], updating CLC_MEN[MxLEN] or updating CLC_STGT[MxTGT]. Once the lock configuration is cleared, the master must perform one additional, unlocked access to the target slave to relinquish the arbitration lock and allow the crossbar to resume normal arbitration.

19.5 Initialization/application information

The locking mechanism provided by the ACP_CLC should be established before executing locked code sequence. Once the ACP_CLC has been properly configured and enabled, the locking mechanism is available immediately.

Once the locked sequence is completed, the lock configuration in the ACP_CLC must be disabled, and the master must perform one additional, unlocked access to the target slave to relinquish the arbitration lock and allow the crossbar to resume normal arbitration.

It is strongly suggested that precautions should be taken in software to avoid locking the peripheral bridge slave. Such a risk may cause the ACP_CLC programming model to become inaccessible, causing deadlock in the system if the locking mechanism cannot be disabled.

20 Peripheral Bridge

20.1 Introduction

The peripheral bridge converts the crossbar switch interface to an interface that can access a majority of peripherals on the device.

The peripheral bridge occupies a 64 MB portion of the address space. (Not all peripheral slots may be used. See [Chapter 7: Device Configuration](#) or [Chapter 5: Memory Map](#) for details on slot assignment.) The bridge includes separate clock enable inputs for each of the slots, to accommodate slower peripherals.

20.1.1 Features

Key features of the peripheral bridge are:

- Supports a pair of 32-bit transactions for selected 64-bit memory accesses
- Each independently configurable peripheral includes a clock enable, which allows peripherals to operate at any speed less than the system clock rate
- Programming model that provides memory protection functionality

20.1.2 General operation

The slave devices connected to the peripheral bridge are modules that contain readable/writable control and status registers. The system masters read and write these registers through the peripheral bridge. The peripheral bridge generates module enables, the module address, transfer attributes, byte enables, and write data as inputs to the peripherals. The peripheral bridge captures read data from the peripheral interface and drives it to the crossbar switch.

Each peripheral is typically allocated one 16-KB block (or slot) of the memory map. Usually, the peripheral bridge uses the size of the addressed peripheral to perform proper data byte lane routing only; no bus decomposition (dynamic bus sizing) is performed. However, there are the following exceptions:

- Aligned 64-bit reads are permitted to 32-bit slots.
- Aligned 64-bit writes may be targeted to 32-bit slots.
- Aligned or misaligned 64-bit instruction fetches may also be performed to 32-bit slots.

All other 64-bit accesses result in an error response.

20.2.1 Master Privilege Registers (AIPS_MPRA & AIPS_MPRB)

Each MPR specifies eight 4-bit fields defining the access privilege level associated with a bus master in the device to the various peripherals. The register provides one field per bus master. Each master is assigned depending on its logical master number. See [Chapter 7: Device Configuration](#) for details about the master assignments to these registers.

Field	Description
0	Reserved, should be cleared
1 MTR	Master trusted for read Determines whether the master is trusted for read accesses. 0 This master is not trusted for read accesses. 1 This master is trusted for read accesses.
2 MTW	Master trusted for writes Determines whether the master is trusted for write accesses. 0 This master is not trusted for write accesses. 1 This master is trusted for write accesses.
3 MPL	Master privilege level Determines how the privilege level of the master is determined. 0 Accesses from this master are forced to user mode. 1 Accesses from this master are not forced to user mode.

20.2.2 Peripheral Access Control Registers (AIPS_PACRx)

Each of the on-platform peripherals has a four-bit PACR_n field which defines the access levels supported by the given module. Eight PACR fields are grouped together to form a 32-bit PACRx register.

The peripheral assignments to each PACR field are defined by the memory map slot to which the peripherals are assigned. See [Chapter 5: Memory Map](#) for the assignments for your particular device. If a peripheral is absent, the corresponding PACR field is not implemented. Reads to the location return zeroes, and writes are ignored.

[Table 260](#) shows the top-level structure of the PACRs.

Table 261. PACR n field descriptions

Field	Description
0	Reserved, should be cleared
1 SP	Supervisor protect Determines whether the peripheral requires supervisor privilege level for access. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor access attribute, and the MPROT n [MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated.
2 WP	Write protect Determines whether the peripheral allows write accesses. 0 This peripheral allows write accesses. 1 This peripheral is write-protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated.
3 TP	Trusted protect Determines whether the peripheral allows accesses from an untrusted master. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated.

20.2.3 Off-Platform Peripheral Access Control Registers (AIPS_OPACRx)

Each of the off-platform peripherals has a four-bit OPACR n field which defines the access levels supported by the given module. Eight OPACRs are grouped together to form a 32-bit OPACRx register.

The peripheral assignments to each OPACR field are defined by the memory map slot to which the peripherals are assigned. See [Chapter 5: Memory Map](#) for the assignments for your particular device. If a peripheral is absent, the corresponding OPACR is not implemented. Reads to the location return zeroes and writes are ignored.

Table 260 shows the top-level structure of the OPACR registers.

Field	Description
0	Reserved, should be cleared
1 SP	Supervisor protect Determines whether the peripheral requires supervisor privilege level for access. 0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor access attribute, and the MPROTn[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated.
2 WP	Write protect Determines whether the peripheral allows write accesses. 0 This peripheral allows write accesses. 1 This peripheral is write-protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated.
3 TP	Trusted protect Determines whether the peripheral allows accesses from an untrusted master. 0 Accesses from an untrusted master are allowed. 1 Accesses from an untrusted master are not allowed. If an access is attempted by an untrusted master, the access is terminated with an error response and no peripheral access is initiated.

20.3 Functional description

The peripheral bridge serves as an interface between the crossbar switch and the slave peripheral bus. It functions as a protocol translator. Support is provided for generating a pair of 32-bit slave accesses when performing certain 64-bit peripheral accesses.

Accesses which fall within the address space of the peripheral bridge are decoded to provide individual module selects for peripheral devices on the slave bus interface.

20.3.1 Access support

Aligned and misaligned 32-bit and 16-bit accesses, as well as byte accesses, are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the slave peripheral bus. Peripheral registers must not be misaligned, although no explicit checking is performed by the peripheral bridge. The peripheral bridge performs two slave peripheral bus transfers for allowed 64-bit transactions, to 32-bit sized peripheral slots only. All other accesses are performed with a single transfer.

All accesses to the peripheral slots must be sized less than or equal to the designated peripheral slot size. If an access is attempted which is larger (in size) than the targeted port, an error response is generated without a peripheral access.

21 System Memory Protection Unit (SMPU)

21.1 Overview

The System Memory Protection Unit (SMPU) provides hardware access control for system bus memory references. The SMPU concurrently monitors and evaluates system bus transactions using pre-programmed region descriptors that define memory spaces and their access rights. Memory references that have sufficient access control rights are allowed to complete, while references that are not mapped to any region descriptor or have insufficient rights are terminated with an access error response.

21.2 Block diagram

A simplified block diagram of the SMPU module is shown in the following figure. The hardware's two-dimensional connection matrix is clearly visible with the basic access evaluation macro shown as the replicated submodule block. The crossbar switch slave ports are shown on the left, the region descriptor registers are in the middle, and the peripheral bus interface is on the right side. The evaluation macro contains two magnitude comparators connected to the start and end address registers from each region descriptor as well as the combinational logic blocks to determine the region hit and detect protection violations.

For details of the access evaluation macro, see [Section 21.5.1, Access evaluation macro](#).

Figure 170. SMPU block diagram

21.3 Features

The SMPU feature set includes:

- Supports up to 24 program-visible 128-bit region descriptors, accessible as four 32-bit words each. (Specific module instances may support fewer than 24.)
 - Each region descriptor defines an arbitrarily sized space, aligned anywhere in memory
 - Region sizes can vary from a minimum of 1 byte to a maximum of (4 GB minus 1 byte)
 - Read/write access control permissions defined in region descriptor
 - Cache-inhibit attribute indicator per region descriptor
 - Hardware-assisted maintenance of the descriptor valid bit minimizes coherency issues
 - Priority given to granting permission over denying access for overlapping region descriptors

- Supports as many as eight crossbar slave ports
- Detects access errors if a memory reference does not hit in any memory region, or if the reference is illegal in all hit memory regions. If an access error occurs, the reference is terminated with an error response, and the SMPU inhibits the bus cycle being sent to the targeted slave device.
- Aborted core accesses generate instruction storage (ISI) or data storage (DSI) interrupts (see the documentation related to the core for details.)
- Error registers (per bus master ID) capture the last faulting address, attributes, and other information
- Global SMPU enable/disable control bit

21.4 Memory map and register definition

21.4.1 Memory map

The programming model is partitioned into three groups: control registers, error capture registers, and the data structure containing the region descriptors.

The programming model can only be referenced using 32-bit accesses. Attempted references using different access sizes, to undefined (reserved) addresses, or with a non-supported access type (a write to a read-only register, or a read of a write-only register) generate an error termination.

The programming model can be accessed only in supervisor mode.

Note: See the device configuration details for any chip-specific register information for this module. For example, a specific instance of a module may support only up to eight region descriptors.

Table 265. SMPUx_CESR0 field descriptions

Field	Description
0–15 MERR	Master <i>n</i> error, where the bus master number matches the bit number Indicates a captured error in <i>EARN</i> and <i>EDRN</i> . A bit is set when the hardware detects an error and records the faulting address and attributes. It is cleared by writing '1' to it. If another error is captured at the exact same cycle as the write, the flag remains set. A find-first-one instruction (or equivalent) can detect the presence of a captured error. 0 No error has occurred for bus master <i>n</i> . 1 An error has occurred for bus master <i>n</i> .
16 Reserved	This read-only bit is reserved and always has the value '1'.
17–27 Reserved	This read-only bitfield is reserved and always has the value '0'.
28–30 HRL	Hardware revision level Specifies the SMPU's hardware and definition revision level. It can be read by software to determine the functional definition of the module.
31 GVLD	Global Valid (global enable/disable for the SMPU) 0 SMPU is disabled. All accesses from all bus masters are allowed. 1 SMPU is enabled

21.4.2.2 Control/Error Status Register 1 (SMPUx_CESR1)

Figure 172. Control/Error Status Register 1 (SMPUx_CESR1)

Table 266. SMPUx_CESR1 field descriptions

Field	Description
0–15 MEOVR	Master <i>n</i> error overrun, where the bus master number matches the bit number Each bit in this field signals that another SMPU error for bus master <i>n</i> has occurred before the previous error was processed. The details of the first error are recorded in the <i>EARN</i> and <i>EDRn</i> registers, and no information on subsequent errors is recorded until the associated <i>CESR0[MERR]</i> flag is cleared. 0 No error overrun condition has been detected for bus master <i>n</i> . 1 An error overrun condition has been detected for bus master <i>n</i> .
16 Reserved	This read-only bit is reserved and always has the value '1'.
17–27 Reserved	This read-only bitfield is reserved and always has the value '0'.
28–31 NRGD	Number of region descriptors Indicates the number of region descriptors implemented in the SMPU. 0001 4 region descriptors 0010 8 region descriptors 0011 12 region descriptors 0100 16 region descriptors 0101 20 region descriptors 0110 24 region descriptors

21.4.2.3 Error Address Register, Bus Master *n* (SMPUx_EARn)

When the SMPU detects an access error on bus master *n*, the 32-bit reference address is captured in this read-only register and the corresponding bit in *CESR0[MERR]* is set. Additional information about the faulting access is captured in the corresponding *EDRn* at the same time.

Note: The corresponding $EARN$ and $EDRn$ registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the $CESR1[MEOVR]$ field until the original error is processed.

Figure 173. Error Address Register, Bus Master n (SMPUx_EARn)

Table 267. SMPUx_EARn field descriptions

Field	Description
0–31 EADDR	Error address Indicates the reference address from bus master n that generated the access error

21.4.2.4 Error Detail Register, Bus Master n (SMPUx_EDRn)

When the SMPU detects an access error associated with bus master n , 32 bits of error detail are captured in this read-only register and the corresponding bit in $CESR0[MERR]$ is set. Information on the faulting address is captured in the corresponding $EARN$ register at the same time.

Note: The corresponding $EARN$ and $EDRn$ registers contain information on the original access error; subsequent errors associated with the given master are recorded as overruns in the $CESR1[MEOVR]$ field until the original error is processed.

Figure 174. Error Detail Register, Bus Master n (SMPUx_EDRn)

Address: SMPU0_EDRn – FC01_0104h + (8d × n), where $n = 0d$ to $15d$
 SMPU1_EDRn – FC01_4104h + (8d × n), where $n = 0d$ to $15d$ Access: Supervisor read-only

**Table 268. SMPUx_EDRn field descriptions**

Field	Description
0–23 EACD	Error access control detail Indicates the region descriptor with the access error, where the region descriptor number matches the bit number. If EDRn contains a captured error and EACD is all zeroes, an access did not hit in any region descriptor. If only a single EACD bit is set, the access error was caused by a single non-overlapping region descriptor. If two or more EACD bits are set, the access error was caused by an overlapping set of region descriptors.
24 Reserved	This read-only bit is reserved and always has the value '1'.
25–26 EATTR	Error attributes Indicates attribute information about the faulting reference. 00 User mode, instruction access 01 User mode, data access 10 Supervisor mode, instruction access 11 Supervisor mode, data access
27 ERW	Error read/write Indicates the access type of the faulting reference. 0 Read 1 Write
28–31 EMN	Error master number Indicates the logical bus master number of the faulting reference. This field is used to determine the bus master that generated the access error.

21.4.2.5 Region Descriptor n , Word 0 (SMPUx_RGDn_WORD0)

Figure 175. Region Descriptor n , Word 0 (SMPUx_RGDn_WORD0)

Table 269. SMPUx_RGDn_WORD0 field descriptions

Field	Description
0–31 SRTADDR	Start address Defines the byte start address of the memory region.

21.4.2.6 Region Descriptor n , Word 1 (SMPUx_RGDn_WORD1)

Figure 176. Region Descriptor n , Word 1 (SMPUx_RGDn_WORD1)

Table 270. SMPUx_RGDn_WORD1 field descriptions

Field	Description
0–31 ENDADDR	End address Defines the byte end address of the memory region. <i>Note: The SMPU does not verify that ENDADDR ≥ SRTADDR.</i>

21.4.2.7 Region Descriptor *n*, Word 2 Format 0 (SMPUx_RGDn_WORD2_FMT0)

RGD_WORD2 has two formats as determined by the RGD_WORD3[FMT] field.

Note: RGD_WORD2_FMT0 applies when RGD_WORD3[FMT] = 0.

RGD_WORD2_FMT0 defines the access control rights of the memory region on a per master basis. The access control rights are defined by separate read and write permissions. For these fields, the bus master number refers to the *logical* bus master number.

For the access control rights, there are two flags per logical bus master:

- Read (r) permission refers to the ability to access the referenced memory address using an operand (data) fetch or an instruction fetch.
- Write (w) permission refers to the ability to update the referenced memory address using a store (data) instruction.

Each field consists of the two flags, with (r) being in the more significant position. For example, M0P has (r) as bit 0 and (w) as bit 1.

The bit settings are as follows:

- If set, the corresponding flag allows the specific access type (r = memory read, w = memory write).
- If cleared, the specific access type is not allowed.

Writes to this word clear the region descriptor's valid bit.

Table 272. SMPUX_RGD n _WORD3 field descriptions

Field	Description
0–26 Reserved	This read-only bitfield is reserved and always has the value '0'.
27 FMT	Region Descriptor Format This bit selects the configuration format (FMT0 or FMT1) for this region descriptor. <i>Note: A specific module instance of the SMPU may support only the FMT0 format. If so, the FMT field is read-only with a fixed value of 0 and only RGD_WORD2_FMT0 applies.</i> 0 Use format 0 (RGD_WORD2_FMT0) 1 Use format 1 (RGD_WORD2_FMT1)
28 RO	Read-Only This bit is intended to prevent accidental writes of an SMPU region descriptor. <i>Note: Setting RO in an RGD locks all four words of the RGD until a system reset; the valid bit of the RGD and the global valid bit have no effect.</i> 0 The region descriptor can be read or written. 1 Attempted writes to any location in the region descriptor are ignored with an error-free data transfer termination.
29 Reserved	This read-only bit is reserved and always has the value '0'.

Table 272. SMPUX_RGDn_WORD3 field descriptions (continued)

Field	Description
30 CI	Cache Inhibit Defines the cacheability attribute of the memory region. This bit is returned to the bus master that initiated the memory reference. <i>Note: An address range specified in an SMPU region descriptor for a cacheable space (that is, CI = 0) must be defined with a starting address aligned on a 0-modulo-32 byte address and with a multiple of the 32 byte cache line size.</i> 0 References to this region can be cached. 1 References to this region cannot be cached.
31 VLD	Valid Signals the region descriptor is valid. Any write to RGDn_WORD0–2 clears this bit. 0 Region descriptor is invalid 1 Region descriptor is valid

21.5 Functional description

In this section, the functional operation of the SMPU is detailed, including the operation of the access evaluation macro and the handling of error-terminated bus cycles.

21.5.1 Access evaluation macro

The basic operation of the SMPU is performed in the access evaluation macro, a hardware structure replicated in the two-dimensional connection matrix. As shown in [Figure 179](#), the access evaluation macro inputs the crossbar bus address phase signals and the contents of a region descriptor (RGDn), then performs two major functions: region hit determination and detection of an access protection violation. [Figure 179](#) shows a functional block diagram.

Figure 179. SMPU access evaluation macro

21.5.1.1 Hit determination

To determine if the current reference hits in the given region, two magnitude comparators are used with the region's start and end addresses. The boolean equation for this portion of the hit determination is:

```
region_hit = ((addr[0:31] >= RGDn_Word0[SRTADDR]) &
              (addr[0:31] <= RGDn_Word1[ENDADDR])) &
              RGDn_Word3[VLD]
```

where *addr* is the current reference address, *RGDn_Word0[SRTADDR]* and *RGDn_Word1[ENDADDR]* are the start and end addresses, and *RGDn_Word3[VLD]* is the valid bit.

Note: The SMPU does not verify that $ENDADDR \geq SRTADDR$.

Note: Region hit determination is based only on an address comparison of the first byte being accessed; that is, the SMPU does not check the size of the access to make sure it fits within an allowed region.

21.5.1.2 Privilege violation determination

While the access evaluation macro is determining the region hit, the logic is also evaluating whether the current access is allowed by the permissions defined in the region descriptor. Using the master signal, a set of effective permissions is generated from the relevant fields in the region descriptor. The protection violation logic then evaluates the access against the effective permissions, using the specification shown in [Table 273](#).

Table 273. Protection violation definition

Access type	Access permissions		Protection violation?
	r	w	
Instruction fetch read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data read	0	—	Yes, no read permission
	1	—	No, access is allowed
Data write	—	0	Yes, no write permission
	—	1	No, access is allowed

21.5.2 Putting it all together and error terminations

For each slave port monitored, the SMPU performs a reduction-AND of all the individual terms from each access evaluation macro. This expression then terminates the bus cycle with an error and reports an access error for three conditions:

1. The access does not hit in any region descriptor.
2. The access hits in a single region descriptor and that region has a protection violation.
3. The access hits in multiple (overlapping) regions and all regions have protection violations.

As shown in the third condition, granting permission is a higher priority than denying access for overlapping regions. This approach is more flexible to system software in region descriptor assignments. For an example of the use of overlapping region descriptors, see

Section 21.7, Application information.

21.6 Initialization information

At system startup, load the required number of region descriptors, including setting RGDn_Word3[VLD]. Setting CESR0[GVLD] enables the module.

If the system requires that all the loaded region descriptors be enabled simultaneously, first ensure that the entire SMPU is disabled (CESR0[GVLD] = 0). Next, load the appropriate region descriptors (RGDn), including the setting of the RGDn_Word3[VLD] bits. Finally, set CESR0[GVLD] to enable the entire module.

A region descriptor must be set to allow access to the SMPU registers if further changes are needed.

21.7 Application information

In an operational system, interfacing with the SMPU is generally classified into the following activities:

- Creating a new memory region—Load the appropriate region descriptor into an available RGDn, using four sequential 32-bit writes. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Modifying a region descriptor—Load the updates into the region descriptor using sequential 32-bit writes. Writing to Word3 re-enables the region descriptor valid bit. The hardware assists in the maintenance of the valid bit, so if this approach is followed, there are no coherency issues with the multi-cycle descriptor writes.
- Removing a region descriptor—Clearing RGDn_Word3[VLD] deletes an existing region descriptor.
- Accessing the SMPU—Allocate a region descriptor to restrict SMPU access to supervisor mode from a specific master.
- Detecting an access error—The current bus cycle is terminated with an error response and EARN and EDRn capture information on the faulting reference. The error-terminated bus cycle typically initiates an error response in the originating bus master. For example, a processor core may respond with a bus error exception, while a data movement bus master may respond with an error interrupt. The processor can retrieve the captured error address and detail information simply by reading E{A,D}Rn. CESR0[MERR] signals. The error registers contain the captured fault data.
- Overlapping region descriptors—Applying overlapping regions often reduces the number of descriptors required for a given set of access controls. In the overlapping memory space, the protection rights of the corresponding region descriptors are logically summed together (the boolean OR operator).

The following dual-core system example contains four bus masters: the two processors (CP0, CP1) and two DMA engines (DMA1, a traditional data movement engine transferring data between RAM and peripherals, and DMA2, a second engine transferring data to/from the RAM only). Consider the following region descriptor assignments:

Table 274. Overlapping region descriptor example

Region description	RGDn		CP0	CP1	DMA1	DMA2	System memory map space
CP0 code	0		rwX	r--	—	—	Flash
CP1 code	1		r--	rwX	—	—	
CP0 data & stack	2		rw-	—	—	—	RAM
CP0 → CP1 shared data	2	3	r--	r--	—	—	
CP1 → CP0 shared data	4						
CP1 data & stack	4		—	rw-	—	—	
Shared DMA data	5		rw-	rw-	rw	rw	
SMPU	6		rw-	rw-	—	—	
Peripherals	7		rw-	rw-	rw	—	Peripheral space

In this example, there are eight descriptors used to span nine regions in the three main spaces of the system memory map (flash, RAM, and peripheral space). Each region indicates the specific permissions for each of the four bus masters, and this definition provides an assigned set of shared, private, and executable memory spaces.

Of particular interest are the two overlapping spaces: region descriptors 2 & 3 and 3 & 4.

The space defined by RGD2 with no overlap is a private data and stack area that provides read/write access to CP0 only. The overlapping space between RGD2 and RGD3 defines a shared data space for passing data from CP0 to CP1, and the access controls are defined by the logical OR of the two region descriptors. Thus, CP0 has (rw- | r--) = (rw-) permissions, while CP1 has (--- | r--) = (r--) permission in this space. Both DMA engines are excluded from this shared processor data region. The overlapping spaces between RGD3 and RGD4 defines another shared data space, this one for passing data from CP1 to CP0. For this overlapping space, CP0 has (r-- | ---) = (r--) permission, while CP1 has (rw- | r--) = (rw-) permission. The non-overlapped space of RGD4 defines a private data and stack area for CP1 only.

The space defined by RGD5 is a shared data region, accessible by all four bus masters. Finally, the slave peripheral space mapped onto the peripheral bus is partitioned into two regions: one containing the SMPU's programming model accessible only to the two processor cores and the remaining peripheral region accessible to both processors and the traditional DMA1 master.

This simple example is intended to show one possible application of the capabilities of the SMPU in a typical system.

22 Intelligent AHB Gasket (IAHBG)

22.1 Introduction

This section details the intelligent bridging gasket between the fast and slow clock domains. The intelligent operation of the gasket initiates pending reads early and optimizes bursts to recover some of the performance that is lost on a registered interface between different clock domains. Pending reads begin even if there is not an hready to the master. Non-bursted writes only begin when the slave is IDLE, pending writes wait until IDLE.

The IAHBG complies with the AHBV6lite protocol, including an extension to support masters that do address retraction during the error termination sequence or abort a burst read due to an error termination or another non-error termination like cache inhibit termination.

[Table 275](#) lists the available operation modes.

Table 275. Operation modes available

Operating mode (Master:Slave)	Comments
0:0	Flowthru (no register wall)
1:1	Master and slave at same operating frequency; gasket performance optimizations on by default
2:1	Master at twice frequency of slave; gasket performance optimizations on by default
1:2	Slave at twice frequency of master; gasket performance optimizations on by default
4:1	Master at four times frequency of slave; gasket performance optimizations disabled at this time
1:4	Slave at four times frequency of master; gasket performance optimizations disabled at this time

22.2 Timing diagrams

The following are a sample of timing diagrams assuming a zero wait state response. The 0:0 flowthru mode is not shown.

22.2.1 1:1

In the 1:1 timing mode the master is running at the same clock frequency as the slave. There are different read slots that the pending read transaction can begin executing early, but only the first slot is shown. The pending read can either be a single or burst transaction.

Figure 180. Read, pending read (1:1 timing mode)

Figure 181. Write, pending read (1:1 timing mode)

Figure 182. Burst4 read (1:1 timing mode)

Figure 183. Burst4 write (1:1 timing mode)

22.2.2 2:1

In the 2:1 timing mode the master is running at twice the clock frequency of the slave. The 4:1 mode is not shown because it is very similar to the 2:1 mode. There are different read

slots that the pending read transaction can begin executing early, but only the first slot is shown. The pending read can either be a single or burst transaction.

Figure 184. Read, pending read (2:1 timing mode)

Figure 185. Write, pending read (2:1 timing mode)

Figure 186. Burst4 read (2:1 timing mode)

Figure 187. Burst4 write (2:1 timing mode)

22.2.3 1:2

In the 1:2 timing mode, the slave is running at twice the clock frequency of the master. The 1:4 mode is not shown because it is very similar to the 1:2 mode. There are different read slots that the pending read transaction can begin executing early, but only the first slot is shown. The pending read can either be a single or burst transaction.

Because the slave is operating at a faster clock frequency than the master, the transactions from the master must be stored into a queue of data and response attribute registers. At a certain point during the master burst transactions, the queue is either emptied into the master for a burst read or it is emptied into the slave for a burst write. Burst writes will only work across the IAHBG if an assumption is made where the hresp from the slave is accumulated into the last beat of the burst (implicit burst write mode).

Figure 188. Read, pending read (1:2 timing mode)

Figure 189. Write, pending read (1:2 timing mode)

Figure 190. Burst4 read (1:2 timing mode)

Figure 191. Burst4 write (1:2 timing mode)

22.2.4 64->32 Interface

The 64->32 interface translates a 64bit access to two 32bit accesses on the slave side. If there is an hresp on the first 32bit access to the slave, the iahb_gasket will still do the second 32-bit access. The hresp is aggregated and reported to the master in the data phase of the 64bit access. One of the 32bit writes could complete and the other write could return an hresp.

For burst encodings of WRAP4,INCR4 hsize=long, it translates to WRAP8,INCR8 hsize=word.

For burst encodings of WRAP8,INCR8 hsize=long, it translates to WRAP16,INCR16 hsize=word.

Burst encodings WRAP4,8 INCR4,8 of hsize<long are passed as is through to slave.

All other burst encodings are not optimized and are translated as NSEQ.

Unaligned bursts are not optimized and are translated as NSEQ.

22.2.5 32->64 Interface

The 32->64 interface translates two 32bit accesses to one 64bit access on the slave side.

All burst encodings are passed as is to the slave.

There is no special translation of WRAP8,INCR8 32bit to WRAP4,INCR4 64bit translation.

To support initializing ECC in the SRAM, the IOP core will send aligned (`haddr[2]==0`) double word transactions with a burst encoding of INCR with length fixed to 2. The `iahb_gasket` will translate these two 32bit writes to a single 64bit NSEQ. It will never report a `hresp` on the first 32bit write.

Burst encodings WRAP4,8 INCR4,8 of `hsize<long` are passed as is through to slave.

All other burst encodings are not optimized and are translated as NSEQ.

Unaligned bursts are translated to NSEQ.

23 Semaphores2 (SEMA42)

23.1 Introduction

The peripheral platform shell includes a memory-mapped module that provides robust hardware support needed in multi-core systems for implementing semaphores and provides a simple mechanism to achieve “lock and unlock” operations via a single write access. The hardware semaphore module is an architecture-neutral solution that provides hardware-enforced gates as well as other useful system functions related to the gating mechanisms.

The capabilities provided by the hardware semaphore module are currently utilized in dual-core AUTOSAR[®] implementations, and its use is expected to continue in future multi-core ports. The result is a second-generation module implementation known as Semaphores2 or SEMA42.

23.1.1 Multi-core programming 101: software gates

Multi-processor systems require a function that can be used to safely and easily provide a locking mechanism that is then used by system software to control access to shared data structures, shared hardware resources, and so on. These gating mechanisms are used by the software to serialize (and synchronize) writes to shared data and/or resources to prevent race conditions and preserve memory coherency between different processes and processors.

Consider the following description of a typical use-case. Processor X enters a section of code where shared data values are to be updated. It must first acquire a semaphore; this can be considered to be locking (or closing) a software gate. Once the gate has been locked, a properly architected software system does not allow other processes (or processors) to execute the same code segment or modify the shared data structure protected by the gate; in other words, other processes/processors are locked out. Many software implementations include a spin-wait loop within the lock function until the locking of the gate is accomplished. Once the lock has been obtained, processor X continues execution and updates the data values protected by the particular lock. Once the updates are complete, processor X unlocks (or opens) the software gate, allowing other processes/processors access to the updated data values.

There are three important rules that must be followed for a correctly implemented system solution:

1. All writes to shared data values or shared hardware resources must be protected by a “gate” variable.
2. Once a processor locks a gate, accesses to the shared data or resources by other processes/processors must be blocked. This is enforced by software conventions.
3. The processor that locks a particular gate is the only processor that can open (unlock) that gate.

Information in the hardware gate identifying the locking processor can be extremely useful for system-level debugging.

The Hennessy/Patterson text on computer architecture offers the following description of software gating.

“One of the major requirements of a shared-memory architecture multiprocessor is being able to coordinate processes that are working on a common task. Typically, a programmer will use *lock variables* to synchronize the processes.

The difficulty for the architect of a multiprocessor is to provide a mechanism to decide which processor gets the lock and to provide the operation that locks a variable. Arbitration is easy for shared-bus multiprocessors, since the bus is the only path to memory. The processor that gets the bus locks out all the other processors from memory. If the CPU and bus provide an atomic swap operation, programmers can create locks with the proper semantics. The adjective *atomic* is key, for it means that a processor can both read a location **and** set it to the locked value in the same bus operation, preventing any other processor from reading or writing memory.” [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 471-472]

The classic text continues with a description of the steps required to lock/unlock a variable using an *atomic swap instruction*.

“Assume that 0 means unlocked and 1 means locked. A processor first reads the lock variable to test its state. A processor keeps reading and testing until the value indicates that the lock is unlocked. The processor then races against all other processes that were similarly “spin waiting” to see who can lock the variable first. All processes use a swap instruction that reads the old value and stores a 1 into the lock variable. The single winner will see the 0, and the losers will see a 1 that was placed there by the winner. (The losers will continue to set the variable to the locked value, but this does not matter.) The winning processor executes the code after the lock and then stores a 0 into the lock when it exits, starting the race all over again. Testing the old value and then setting to a new value is why the atomic swap instruction is called *test and set* in some instruction sets.” [Hennessy/Patterson, *Computer Architecture: A Quantitative Approach*, ppg. 472-473]

Next, consider the features, programming model, and functional operation of the hardware semaphore module.

23.1.2 Features

The Semaphores module implements hardware-enforced semaphores as an IPS-mapped slave peripheral device. The feature set includes:

- Module definition supporting 16, 32, or 64 hardware-enforced gates in a multi-processor configuration, where up to 15 processors can be supported; cpX is meant to represent core processor X.
 - Gates appear as an n -entry byte-size array with read and write accesses ($n = 16, 32, 64$).
 - Processors lock gates by writing “processor_number+1” to the appropriate gate and must read back the gate value to verify the lock operation was successful.
 - Once locked, the gate is unlocked by a write of zeroes from the locking processor.
 - The number of implemented gates is specified by a hardware configuration define.
 - Each hardware gate appears as a 16-state, 4-bit state machine.
 - 16-state implementation
 - if gate = 0x0, then state = unlocked
 - if gate = 0x1, then state = locked by processor (master) 0
 - if gate = 0x2, then state = locked by processor (master) 1

- ...
- if gate = 0xF, then state = locked by processor (master) 14
- Uses the logical bus master number as a reference attribute plus the specified data patterns to validate all write operations.
 - Once locked, the gate can (and must) be unlocked by a write of zeroes from the locking processor.
 - Secure reset mechanisms are supported to clear the contents of individual gates, as well as a clear_all capability.
 - Memory-mapped IPS slave peripheral platform module
 - Interface to the IPS bus for programming-model accesses

A simplified block diagram of the Semaphores module is shown in [Figure 192](#). In the diagram, the register blocks named gate0, gate1,..., gate ($n - 2$), gate ($n - 1$) include the finite state machines implementing the semaphore gates.

Figure 192. Semaphores2 block diagram

23.2 Memory map/register definition

Offset address	Register name	Access	Reset value	Section/ page
0x0000–0x003F	Semphores2 Gate n (GATE n)	R/W	0x00	23.2.1/704
0x0040	Semphores2 Reset Gate (RSTGT)	R/W	0x0000	23.2.2/705
0x0042–0x3FFF	Reserved			

23.2.1 Semaphores Gate n Register (SEMA4_GATE)

Each semaphore gate is implemented in a 4-bit finite state machine, right-justified in a byte data structure. The hardware uses the logical bus master number in conjunction with the data patterns to validate all attempted write operations. Only processor bus masters can modify the gate registers. Once locked, a gate can (and must) be opened (unlocked) by the locking processor core.

Multiple gate values can be read in a single access, but only a single gate can be updated via a write operation at a time. Attempted writes with a data value that is neither the unlock value nor the appropriate lock value (processor_number + 1) are simply treated as “no operation” and do not affect any gate state. Attempts to write multiple gates in a single aligned access with a size larger than an 8-bit (byte) reference generate an error termination and do not allow any gate state changes.

Figure 193. Semaphore2 Gate Register (GATE)

Offset SEMA4_BASE + n ($n = 0, 1, 2, \dots, 15, \dots, 31, \dots, 63$)					Access: Supervisor Read/Write			
	0	1	2	3	4	5	6	7
R	0	0	0	0	GTFSM			
W								
Reset	0	0	0	0	0	0	0	0

Table 276. SEMA4_GATE field descriptions

Field	Description
0–3	Reserved
4–7 GTFSM	Gate Finite State Machine. The hardware gate is maintained in a 16-state implementation, defined as: 0000 The gate is unlocked (free). 0001 The gate has been locked by processor 0. 0010 The gate has been locked by processor 1. 0011 The gate has been locked by processor 2. 0100 The gate has been locked by processor 3. 0101 The gate has been locked by processor 4. 0110 The gate has been locked by processor 5. 0111 The gate has been locked by processor 6. 1000 The gate has been locked by processor 7. 1001 The gate has been locked by processor 8. 1010 The gate has been locked by processor 9. 1011 The gate has been locked by processor 10. 1100 The gate has been locked by processor 11. 1101 The gate has been locked by processor 12. 1110 The gate has been locked by processor 13. 1111 The gate has been locked by processor 14. <i>Note: The state of the gate reflects the last processor that locked it, which can be useful during system debug.</i> For more details, see Section 23.2.1, Semaphores Gate n Register (SEMA4_GATE).

23.2.2 Semaphores (Secure) Reset Gate (SEMA4_RSTGT)

Although the intent of the hardware gate implementation specifies a protocol where the locking processor must unlock the gate, it is recognized that system operation may require a reset function to re-initialize the state of any gate(s) without requiring a system-level reset.

To support this special gate reset requirement, the Semaphores module implements a “secure” reset mechanism that allows a hardware gate (or all the gates) to be initialized by following a specific dual-write access pattern. Using a technique similar to that required for the servicing of a software watchdog timer, the secure gate reset requires two consecutive writes with predefined data patterns from the same processor to force the clearing of the specified gate(s). The required access pattern is:

1. A processor performs a 16-bit write to the SEMA4_RSTGT memory location. The most significant byte (SEMA4_RSTGT[RSTGDP]) must be 0xE2; the least significant byte is a “don’t_care” for this reference.
2. The same processor then performs a second 16-bit write to the SEMA4_RSTGT location. For this write, the upper byte (SEMA4_RSTGT[RSTGDP]) is the logical complement of the first data pattern (0x1D) and the lower byte (SEMA4_RSTGT[RSTGTN]) specifies the gate(s) to be reset. This gate field can specify a single gate be cleared, or else that all gates are to be cleared. If the same processor writes incorrect data on the second access or another processor performs the second write access, the special gate reset sequence is aborted and no error signal will be asserted.
3. Reads of the SEMA4_RSTGT location return information on the 2-bit state machine (SEMA4_RSTGT[RSTGSM]) that implements this function, the bus master performing the reset (SEMA4_RSTGT[RSTGMS]), and the gate number(s) last cleared

(SEMA4_RSTGT[RSTGTN]). Reads of the SEMA4_RSTGT register do not affect the secure reset finite state machine in any manner.

Figure 194. Semaphore2 Reset Gate Register (RSTGT)

Table 277. RSTGT field descriptions

Field	Description
0–1	Reserved
2–3 RSTGSM	Reset Gate Finite State Machine. The reset state machine is maintained in a 2-bit, 3-state implementation, defined as: 00 Idle, waiting for the first data pattern write. 01 Waiting for the second data pattern write. 10 The 2-write sequence has completed. Generate the specified gate reset(s). After the reset is performed, this machine returns to the idle (waiting for first data pattern write) state. The “10” state persists for only one clock cycle. Software will never be able to observe this state. 11 This state encoding is never used and therefore reserved. Reads of the SEMA4_RSTGT register return the encoded state machine value. Note the RSTGSM = 10 state is valid for only a single machine cycle, so it is impossible for a read to return this value.
4–7 RSTGMS	Reset Gate Bus Master. This 4-bit read-only field records the logical number of the bus master performing the gate reset function. The reset function requires that the two consecutive writes to this register must be initiated by the same bus master to succeed. This field is updated each time a write to this register occurs. The association between system bus master port numbers, the associated bus master device, and the logical processor number is SoC-specific. Consult the device reference manual for this information.
8–15 RSTGTN	Reset Gate Number. This 8-bit field specifies the specific hardware gate to be reset. This field is updated by the second write. If RSTGTN < 64, then <i>reset the single gate</i> defined by RSTGTN, else <i>reset all the gates</i>.
0–7 RSTGDP	Reset Gate Data Pattern. This write-only field is accessed with the specified data patterns on the two consecutive writes to enable the gate reset mechanism. For the first write, RSTGDP = 0xE2 while the second write requires RSTGDP = 0x1D.

23.3 Functional description

Functional operation of the Semaphores module and specific details of the state machines of the SEMA4_GATE n registers are provided as follows.

As described previously, each of the SEMA4_GATE n registers implements a 4-bit, 16-state machine. A *simplified* diagram of the state transitions for each gate is shown in [Figure 195](#).

Figure 195. SEMA4_GATE n state machine

The bus master number is used to identify core processor X (cp X) where the notation cpE is used to represent core processor 14 (= 0xE). The platform passes the AHB bus master number through the AIPS controller and drives the signal to the Semaphores module as an IPS sideband signal.

The state transitions for SEMA4_GATE n are defined in [Table 278](#).

Table 278. SEMA4_GATE n state transitions

Current State	Next State	Transition	Description
—	idle	1	Any reset, whether a system reset or a software-initiated gate reset, unconditionally forces the gate into the idle state.
idle	idle	2	Unless a write of the appropriate lock value from the corresponding processor occurs, the gate remains in the idle state.

Table 278. SEMA4_GATE n state transitions (continued)

Current State	Next State	Transition	Description
idle	cp0_lock	3	When a write of the "cp0_lock" data value is initiated by processor 0, the gate transitions into the cp0_lock state.
idle	cpE_lock	4	When a write of the "cpE_lock" value is initiated by processor 0xE, the gate transitions into the cpE_lock state.
cp0_lock	cp0_lock	5	Once in this state, the gate remains here if any attempted write is not from cp0 with the unlock data value.
cp0_lock	idle	6	The gate returns to the idle (unlocked) state once a write from cp0 with the unlock data value occurs.
cpE_lock	cpE_lock	7	Once in this state, the gate remains here if any attempted write is not from cpE with the unlock data value.
cpE_lock	idle	8	The gate returns to the idle (unlocked) state once a write from cpE with the unlock data value occurs.

As previously noted, the following gate data values are used:

- The lock data value is (processor number + 1) where the processor number and the platform bus master number are the same.
- The unlock data value is 0x00.

24 Interrupt Controller (INTC)

24.1 Introduction

The INTC:

- Provides priority-based preemptive scheduling of interrupt requests
- Schedules interrupt requests (IRQs) from software and internal peripherals to one or more processors (PRCs)
- Provides interrupt prioritization and preemption, interrupt masking, interrupt priority elevation, and protocol support

This scheduling scheme is suitable for statically scheduled hard real-time systems.

The INTC is targeted to work with a Power Architecture processor and automotive powertrain applications where the Interrupt Service Routines (ISRs) nest to multiple levels, but it also can be used with other processors and applications.

For high-priority interrupt requests in these target applications, it is necessary to minimize the interval between the assertion of the interrupt request from the peripheral and the point at which the processor is performing useful work to service the interrupt request. The INTC supports this goal by providing a unique vector for each interrupt request source. It also provides 64 priorities so that lower priority ISRs do not delay the execution of higher priority ISRs. Since each individual application will have different priorities for each source of interrupt request, the priority of each interrupt request is configurable.

When multiple tasks share a resource, coherent accesses to that resource need to be supported. The INTC supports the Priority Ceiling Protocol for coherent accesses. By providing a modifiable priority mask, the priority can be raised temporarily so that all tasks which share the resource are unable to preempt each other.

Multiple processors can assert interrupt requests to each other through software-settable interrupt requests. These same software-settable interrupt requests can also be used to separate the work involved in servicing an interrupt request into two parts, a high-priority portion and a low-priority portion. The high-priority portion is initiated by a peripheral interrupt request, but then the ISR can assert a software-settable interrupt request to finish the servicing in a lower priority ISR. Therefore these software-settable interrupt requests can be used instead of having the peripheral ISR schedule a task through the RTOS.

24.2 Block diagram

The block diagram for the INTC is shown in [Figure 196](#).

Figure 196. INTC block diagram

24.3 Features

- Each peripheral interrupt source is software-steerable to processor 0, processor 1, processor 2, processor 3, or any combination of interrupt request outputs
- 32 software-settable interrupt request sources
- 10-bit vector
 - Unique vector for each interrupt request source
 - Hardware connection to processor or read from register
- Each interrupt source can be programmed to one of 64 priorities
- Each interrupt source can be triggered by software
- Preemption
 - Preemptive prioritized interrupt requests to processor
 - ISR with higher priority preempts ISRs or tasks with lower priorities
 - Automatic pushing or popping of preempted priority to or from a LIFO
 - Ability to modify the ISR or task priority; modifying the priority can be used to implement the Priority Ceiling Protocol for accessing shared resources
 - 3 INTC clock cycles from int request in to int request to CPU
- Low latency
 - 3 INTC clock cycles from receipt of interrupt request from peripheral to interrupt request to processor; four clock cycles from receipt of software request

24.4 Modes of operation

The interrupt controller has two handshaking modes with the processor: software vector mode and hardware vector mode. The state of the hardware vector enable bit, INTC_BCR[HVEN], determines which mode is used. In Power Architecture devices, software vector mode uses the autovector mode of the Processor for a single entry point for the ISR (16 s of vector space available), whereas the hardware vector mode uses the non-autovector mode where the vector offset from the INTC is provided to the Processor (4 s for each IRQ).

In debug mode the interrupt controller operation is identical to its normal operation of software vector mode or hardware vector mode.

24.4.1 Software vector mode

In software vector mode, software (that is, the interrupt exception handler) must read a register in the INTC to obtain the vector associated with the interrupt request to the processor. The INTC will use software vector mode for a given processor when its associated HVEN_PRCn bit in the INTC_BCR (see [Section 24.5.2.1, INTC Block Configuration Register \(INTC_BCR\)](#)) is negated. The hardware vector enable signal to any processor is driven as negated when its associated HVEN_PRCn bit is negated. The vector is read from the INTC_IACKRn registers (see [Section 24.5.2.4, INTC Interrupt Acknowledge Register for Processor n \(INTC_IACKRn\)](#)). Reading the INTC_IACKRn negates the interrupt request to the associated processor. Even if a higher priority interrupt request has arrived while waiting for this interrupt acknowledge, the interrupt request to the processor will negate for at least one clock. The reading also pushes the PRI value in the INTC_CPRn (see [Section 24.5.2.3, INTC Current Priority Register for Processor n \(INTC_CPRn\)](#)) onto

the associated LIFO, and updates PRI in the associated INTC_CPR_PRC_n with the new priority.

24.4.2 Hardware vector mode

In hardware vector mode, the hardware causes the first instruction that will be executed (when handling the interrupt request to the processor) to be an instruction that is specific to that vector. Therefore the interrupt exception handler is specific to a peripheral or software-settable interrupt request, rather than being common to all of them. The INTC will use hardware vector mode for a given processor when its associated HVEN_n bit in the INTC_BCR is asserted. The hardware vector enable signal to the associated processor is driven as asserted.

When the interrupt request to the associated processor asserts, the interrupt vector signal is updated. The value of that interrupt vector is the unique vector associated with the preempting peripheral or software-settable interrupt request. The vector value matches the value of the INTVEC field in the INTC_IACKR_n, depending on which processor was assigned to handle a given interrupt source.

The assertion of the interrupt acknowledge signal for a given processor pushes the associated PRI value in the associated INTC_CPR_n register onto the associated LIFO and updates the associated PRI in the associated INTC_CPR_n register with the new priority. This pushing of the PRI value onto the associated LIFO and updating PRI in the associated INTC_CPR_n does not occur when the associated interrupt acknowledge signal asserts and the INTC_SSCIRs (see [Section 24.5.2.6, INTC Software Set/Clear Interrupt Registers \(INTC_SSCIR0_3–INTC_SSCIR28_31\)](#)) is written at a time such that the PRI value in the associated INTC_CPR_n register would need to be pushed and the previously last pushed PRI value would need to be popped simultaneously. In this case, PRI in the associated INTC_CPR_n is updated with the new priority, and the associated LIFO is neither pushed or popped.

24.5 Memory map and register definition

24.5.1 Memory map

[Table 279](#) is the INTC memory map.

The actual availability and number of registers are chip-specific. For this information, see the chapter that describes how modules are configured and connected.

Table 279. INTC memory map

Address offset	Register	Location
000h	INTC Block Configuration Register (INTC_BCR)	on page 713
004h	INTC Master Protection Register (INTC_MPROT)	on page 713
008h–00Ch	Reserved	
010h	INTC Current Priority Register for Processor 0 (INTC_CPR0)	on page 715
014h	INTC Current Priority Register for Processor 1 (INTC_CPR1)	on page 715
018h	INTC Current Priority Register for Processor 2 (INTC_CPR2)	on page 715
01Ch	INTC Current Priority Register for Processor 3 (INTC_CPR3)	on page 715

Table 279. INTC memory map (continued)

Address offset	Register	Location
020h	INTC Interrupt Acknowledge Register for Processor 0 (INTC_IACKR0)	on page 716
024h	INTC Interrupt Acknowledge Register for Processor 1 (INTC_IACKR1)	on page 716
028h	INTC Interrupt Acknowledge Register for Processor 2 (INTC_IACKR2)	on page 716
02Ch	INTC Interrupt Acknowledge Register for Processor 3 (INTC_IACKR3)	on page 716
030h	INTC End Of Interrupt Register for Processor 0 (INTC_EOIR0)	on page 717
034h	INTC End Of Interrupt Register for Processor 1 (INTC_EOIR1)	on page 717
038h	INTC End Of Interrupt Register for Processor 2 (INTC_EOIR2)	on page 717
03Ch	INTC End Of Interrupt Register for Processor 3 (INTC_EOIR3)	on page 717
040h–05Ch	INTC Software Set/Clear Interrupt Register 0–3 (INTC_SSCIR0_3)– INTC Software Set/Clear Interrupt Register 28–31 (INTC_SSCIR28_31)	on page 718
060h–85Eh	INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023)	on page 719
860h–FFC	Reserved	

Note: A transfer error will be asserted if an access is attempted outside of the memory map or for any unimplemented registers. For example, if the design has only 512 interrupt sources and a source > 512 is accessed, a transfer error is asserted.

24.5.2 Register descriptions

With the exception of the INTC_SSCIR n and INTC_PSR n registers, all of the registers are 32-bit. Any combination of accessing the four s of a register with a single access is supported, provided that the access does not cross a register boundary. These supported accesses include types and sizes of 8 bits, aligned 16 bits, misaligned 16 bits to the middle two s, and aligned 32 bits.

Although INTC_SSI n are 8 bits wide and INTC_PSR n are 16 bits wide, they can be accessed with a single 16-bit or 32-bit access, provided that the access does not cross a 32-bit boundary.

Some registers have specific exceptions to these rules, as outlined in their definitions.

In software vector mode, the effects of a read of the INTC Interrupt Acknowledge register (INTC_IACKR n) are the same regardless of the size of the read. In either software or hardware vector mode, the size of a write to the INTC end-of-interrupt register (INTC_EOIR n) does not affect the operation of the write.

24.5.2.1 INTC Block Configuration Register (INTC_BCR)

The Block Configuration Register is used to configure options of the INTC.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] has write access, otherwise, a termination error is asserted.

Table 281. INTC_MPROT field descriptions

Field	Description
ID	ID This register can only be updated if MPROT=0 or if processor master ID=ID. When MPROT is set, the ID should also be updated to indicate which master can write to any register in the INTC memory map. 00 - master0 (reset default) 01 - master1 10 - master2 11 - master3
MPROT	Master Protection Controls what programming space a given master can write to. If MPROT is disabled, then all masters can write to any valid entry of the INTC memory map. If MPROT is enabled, INTC_MPROT[ID] can write to any valid entry of the INTC memory map but other masters can only write to their assigned resources. Once MPROT is enabled by a master, only that master may modify INTC_MPROT. 0 Master programming space protection disabled 1 Master programming space protection enabled

24.5.2.3 INTC Current Priority Register for Processor *n* (INTC_CPR_{*n*})

The INTC_CPR_{*n*} masks any peripheral or software-settable interrupt request that is set at the same or lower priority as the current value of the INTC_CPR_{*n*}[PRI] field from generating an interrupt request to the processor. When the INTC Interrupt Acknowledge register (INTC_IACKR_{*n*}) is read in software vector mode or the interrupt acknowledge signal from the processor is asserted in hardware vector mode, the value of PRI is pushed onto the LIFO, and PRI is updated with the priority of the preempting interrupt request. When the INTC end-of-interrupt register (INTC_EOIR_{*n*}) is written, the LIFO is popped into the INTC_CPR_{*n*} PRI field. An exception case in hardware vector mode to this behavior is described in [Section 24.4.2, Hardware vector mode](#).

The masking priority can be raised or lowered by writing to the PRI field, supporting the priority ceiling protocol. See [Section 24.7.5, Priority ceiling protocol](#).

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Note: *A store to modify the PRI field that closely precedes or follows an access to a shared resource may result in a non-coherent access to that resource. See [Section 24.7.5.2, Ensuring coherency](#), for example code to ensure coherency.*

PRI	Priority of the currently executing ISR, according to the field values 63 (highest priority) down to 0 (lowest priority).

24.5.2.4 INTC Interrupt Acknowledge Register for Processor *n* (INTC_IACKR_{*n*})

The Interrupt Acknowledge Register for Processor *n* provides a value which can be used to load the address of an ISR from a vector table. The vector table can be composed of addresses of the ISRs specific to their respective interrupt vectors.

Also, in software vector mode, the INTC_IACKR_{*n*} has side effects from reads unless INTC_MPROT[MPROT]=1 and processor with master ID (0-3) != INTC_MPROT[ID]. Therefore, it must not be read speculatively while in this mode. The side effects are the same regardless of the size of the read. Reading the INTC_IACKR_{*n*} does not have side effects in hardware vector mode.

If INTC_MPROT[MPROT]=0 (disabled), all processors have read and write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has read and write access, otherwise, a termination error is asserted.

1. When the corresponding INTC_BCR[HVEN_{*n*}] = 1, a read of the INTC_IACKR has no side effects.

Table 283. INTC_IACKR_{*n*} field descriptions

Field	Description
VTBA	Vector table base address. Can be the base address of a vector table of addresses of ISRs.
INTVEC	Interrupt vector. Vector of the peripheral or software-settable interrupt request that caused the interrupt request to the processor. When the interrupt request to the processor asserts, the INTVEC is updated, whether the INTC is in software or hardware vector mode.

24.5.2.5 INTC End of Interrupt Register for Processor *n* (INTC_EOIR_{*n*})

Writing to the INTC_EOIR_{*n*} signals the end of the servicing of the interrupt request. When the INTC_EOIR_{*n*} is written, the priority last pushed on the LIFO is popped into INTC_CPR_{*n*}. The values and size of data written to the INTC_EOIR_{*n*} are ignored. Those values and sizes written to this register neither update the INTC_EOIR_{*n*} contents nor affect whether the LIFO pops. When you write to this register, write four all-zero s.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access to this register.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access, otherwise, a termination error is asserted.

Field	Description
EOI	End of Interrupt. Write four all-zero s to this field to signal the end of the servicing of an interrupt request.

24.5.2.6 INTC Software Set/Clear Interrupt Registers (INTC_SSCIR0_3–INTC_SSCIR28_31)

The INTC_SSCIR registers support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. Unlike the SWT bit in the PSRs, the INTC_SSCIR registers do not require a read-modify-write. With the exception of being set by software, this flag bit behaves the same as a flag bit set within a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a 1 to SET n will leave SET n unchanged at 0 but will set CLR n . Writing a 0 to SET n will have no effect. CLR n is the flag bit. Writing a 1 to CLR n will clear it. Writing a 0 to CLR n will have no effect. If a 1 is written to a pair of SET n and CLR n bits at the same time, CLR n is asserted, regardless of whether CLR n was asserted before the write.

[Figure 202](#) shows the structure and numbering scheme of the first INTC_SSCIR. The other registers follow the same numbering scheme.

Any processor will be allowed to write to any of the SET bits in the INTC_SSCIR n registers.

If INTC_MPROT[MPROT]=0 (disabled), all processors can write to the CLR bit.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor can write to the CLR bit and not the SET bit, otherwise, a termination error is asserted.

Note: *If INTC_MPROT[MPROT] is enabled, processors with master ID $\neq$ INTC_MPROT[ID] must only write the INTC_SSCIR n registers using a byte operation. A write of any other size will result in a termination error.*

Table 285. INTC_SSICRn field descriptions

Field	Description
SETn	Set flag bits. Writing a 1 will set the corresponding CLRn bit. Writing a 0 will have no effect. Each SETn is always read as a 0.
CLRn	Clear flag bits. CLRn is the flag bit. Writing a 1 to CLRn will clear it provided that a 1 is not written simultaneously to its corresponding SETn bit. Writing a 0 to CLRn will have no effect. 0 Interrupt request not pending within INTC. 1 Interrupt request pending within INTC.

24.5.2.7 INTC Priority Select Registers (INTC_PSR0 – INTC_PSR1023)

The Priority Select Registers support the selection of an individual priority for each source of interrupt request, and the routing of the request to one or more processors. The unique vector of each peripheral or software-settable interrupt request determines which INTC_PSRn is assigned to that interrupt request. The software-settable interrupt requests are assigned the lowest numbered vectors, and their priorities are configured in the lowest numbered INTC_PSR registers. The peripheral interrupt requests are assigned to vectors immediately following the software-settable interrupt requests, and their priorities are configured in the immediately following INTC_PSR registers. The peripheral interrupt requests are assigned vectors 32–1023, and their priorities are configured in INTC_PSR32–1023, respectively.

[Figure 203](#) and [Figure 204](#) show the structure and numbering scheme of the first and last PSRs, respectively. The other registers follow the same numbering scheme.

If INTC_MPROT[MPROT]=0 (disabled), all processors have write access.

If INTC_MPROT[MPROT]=1 (enabled), the processor with master ID (0-3) = INTC_MPROT[ID] or the corresponding processor has write access to INTC_PSRn[PRC_SEL,SWT], otherwise, a termination error is asserted. When writing the INTC_PSRn[PRI], only the processor with master ID (0-3) = INTC_MPROT[ID] and the processor who's master ID (0-3) matches the setting of the INTC_PSRn[PRC_SEL] will be allowed to write the INTC_PSRn[PRI]. An attempt by any other processor to write the INTC_PSRn[PRI] will result in a termination error.

Note: *S.Unlike the peripheral interrupt request PSRs, there is no SWT bit in the PSRs corresponding to the software-settable interrupt requests.*

Interrupts are not detected while the PSRs are being written.

If INTC_MPROT[MPROT] is enabled, the core with master ID (0-3) = INTC_MPROT[ID] will be able to write the INTC_PSRn with either , half-word or word operations. All other master IDs are restricted to operations to the INTC_PSRn[PRI] bits (i.e the odd addresses). Any other sized write operation, or a operation to the INTC_PSRn[PRC_SEL] (i.e. the even) will result in a termination error.

Table 286. INTC_PSRn field descriptions

Field	Description
PRC_SELn	Processor select bits. See Table 287 . If an interrupt source is enabled, PRC_SELn[3:0] selects whether the interrupt request is to be sent to processor 0, processor 1, processor 2, processor 3, or any combination.
SWTn	This bit is only available in PSRs that do not correspond to the SSCIRs. The SWT bit supports triggering an interrupt by software rather than hardware. This is an alternative to setting a flag bit in a peripheral. This flag bit generates an interrupt request within the INTC just like a peripheral interrupt request. Writing a '1' to SWTn sets the bit. On the interrupt acknowledge cycle, the SWTn bit is cleared. The SWT function works both in hardware and software vector mode. It is only cleared by the enabled Processor(s) defined in the PRC_SELn field of the PSR.
PRI _n	Priority select. Selects the priority for the interrupt requests. PRI has values 63 (highest priority) down to 0 (lowest priority).

Table 287. Selected Processor for Interrupt Request

PRC_SEL n [3:0]	Meaning
0000	No interrupt request sent
0001	Interrupt request sent to processors 3
0010	Interrupt request sent to processors 2
0011	Interrupt request sent to processors 2, 3
0100	Interrupt request sent to processors 1
0101	Interrupt request sent to processors 1, 3
0110	Interrupt request sent to processors 1, 2
0111	Interrupt request sent to processors 1, 2, 3
1000	Interrupt request sent to processors 0
1001	Interrupt request sent to processors 0, 3
1010	Interrupt request sent to processors 0, 2
1011	Interrupt request sent to processors 0, 2, 3
1100	Interrupt request sent to processors 0, 1
1101	Interrupt request sent to processors 0, 1, 3
1110	Interrupt request sent to processors 0, 1, 2
1111	Interrupt request sent to processors 0, 1, 2, 3

24.6 Functional description

The functional description involves the areas of interrupt request sources, priority management, and handshaking with the processor. In addition, spaces in the memory map have been reserved for other possible implementations of the INTC.

24.6.1 Interrupt request sources

The INTC has two types of interrupt requests, peripheral and software-settable. These interrupt requests can assert on any clock cycle.

The INTC has no spurious vector support. Therefore, if an asserted peripheral or software-settable interrupt request, whose PRI n value in INTC_PSR n is higher than the PRI value in INTC_CPR n , negates before the interrupt request to the processor for that peripheral or software-settable interrupt request is acknowledged, then the interrupt request to the processor still can assert (or will remain asserted) for that peripheral or software-settable interrupt request. In this case, the interrupt vector will correspond to that peripheral or software-settable interrupt request. Also, the PRI value in the associated INTC_CPR n is updated with the corresponding PRI n value in INTC_PSR n .

Furthermore, clearing the peripheral interrupt request's enable bit in the peripheral, or (alternatively) setting its mask bit, has the same consequences as clearing its flag bit. Setting its enable bit or clearing its mask bit while its flag bit is asserted has the same effect on the INTC as an interrupt event setting the flag bit.

24.6.1.1 Peripheral interrupt requests

An interrupt event in a peripheral's hardware sets a flag bit which resides in that peripheral. The interrupt request from the peripheral is driven by that flag bit.

The time from when the peripheral starts to drive its peripheral interrupt request to the INTC, to the time that the INTC starts to drive the interrupt request to the processor, is three clocks.

24.6.1.2 Software-settable interrupt requests

The software set/clear interrupt registers (INTC_SSCIR n) support the setting or clearing of software-settable interrupt requests. These registers contain independent sets of bits to set and clear a corresponding flag bit by software. An interrupt request is triggered by software by writing a 1 to a SET n bit in INTC_SSCIR n . This write sets the corresponding CLR n bit, which is a flag bit, resulting in the interrupt request. The interrupt request is cleared by writing a 1 to the CLR n bit. Specific behavior includes the following:

- Writing a 1 to SET n leaves SET n unchanged at 0 but sets the flag bit (which is the CLR n bit).
- Writing a 0 to SET n has no effect.
- Writing a 1 to CLR n clears the flag (CLR n) bit.
- Writing a 0 to CLR n has no effect.
- If a 1 is written to a pair of SET n and CLR n bits at the same time, the flag (CLR n) is set, regardless of whether CLR n was asserted before the write.

The time from the write to the SET n bit, to the time that the INTC starts to drive the interrupt request to the processor, is four clocks.

Any Processor n will be allowed to write to any of the SET bits in the Software Set/Clear Interrupt registers. The CLR bit will only be writable by the Processor n which has been assigned to handle that interrupt request, as determined by the setting of the INTC_PSR n [PRC_SEL n] bits.

24.6.1.3 Unique vector for each interrupt request source

Each peripheral and software-settable interrupt request is assigned a hardwired unique 10-bit vector. Software-settable interrupts 0–31 are assigned vectors 0–31, respectively. The peripheral interrupt requests are assigned vectors from 32 to a number as high as needed to cover all peripheral interrupt requests.

24.6.2 Priority management

The asserted interrupt requests are compared to each other based on their PRI n and PRC_SEL n values set in INTC_PSR n . The result of that comparison also is compared to PRI in the associated INTC_CPR n . The results of those comparisons are used to manage the priority of the ISR being executed by the associated processor. The associated LIFO also assists in managing that priority.

24.6.2.1 Current priority and preemption

The priority arbitrator, selector, encoder, and comparator logic shown in [Figure 196](#) are used to compare the priority of the asserted interrupt requests to the current priority. If the priority of any asserted peripheral or software-settable interrupt request is higher than the current priority for a given processor, then the interrupt request to the processor is asserted. Also, a

unique vector for the preempting peripheral or software-settable interrupt request is generated for the associated INTC_IACKR n , and if in hardware vector mode, for the interrupt vector provided to the processor.

24.6.2.1.1 Priority tree

The priority tree for each processor compares all the priorities of all of the asserted interrupt requests assigned to that processor, both peripheral and software-settable. The output of the priority tree is the highest of those priorities assigned to a given processor. Also, any interrupt requests which have this highest priority are output as asserted interrupt requests to the associated selector logic.

24.6.2.1.2 Selector

If only one interrupt request from the associated priority tree is asserted, then it is passed as asserted to the associated encoder logic. If multiple interrupt requests from the associated priority tree are asserted, then only the one with the lowest vector is passed as asserted to the associated encoder logic. The lower vector is chosen regardless of the time order of the assertions of the peripheral or software-settable interrupt requests.

24.6.2.1.3 Encoder

The encoder logic generates the unique 10-bit vector for the asserted interrupt request from the request selector subblock for the associated processor.

24.6.2.1.4 Comparator

The comparator logic compares the highest priority output from the associated priority arbitrator subblock with PRI in the associated INTC_CPR n . If the comparator detects that this highest priority is higher than the current priority, then it asserts the interrupt request to the associated processor. This interrupt request to the processor asserts whether this highest priority is raised above the value of PRI in the associated INTC_CPR n , or the PRI value in the associated INTC_CPR n is lowered below this highest priority. This highest priority then becomes the new priority which is written to PRI in the associated INTC_CPR n when the interrupt request to the processor is acknowledged. Interrupt requests whose PRI n in INTC_PSR n are zero will not cause a preemption because their PRI n will not be higher than PRI in the associated INTC_CPR n .

Another function of the comparator is to signal an update of the INTC_IACKR n with the vector number of the first interrupt that arrives that has a priority higher than the current priority. Once the vector number and priority are captured, they cannot be superseded by a higher priority interrupt until an update of the INTC_CPR n occurs. In software vector mode, higher priority interrupts can supersede the previously captured interrupt vector number and priority until the time a hardware or software interrupt acknowledge is processed.

24.6.2.2 Stack (LIFO)

The LIFO stores the preempted PRI values from the associated INTC_CPR n . Therefore, because these priorities are stacked within the INTC, if interrupts need to be enabled during the ISR, at the beginning of the interrupt exception handler the PRI value in the associated INTC_CPR n does not need to be loaded from the associated INTC_CPR n and stored onto the context stack. Likewise at the end of the interrupt exception handler, the priority does not need to be loaded from the context stack and stored into the associated INTC_CPR n .

The PRI value in the associated INTC_CPR n is pushed onto the LIFO when the associated INTC_IACKR n is read in software vector mode or the interrupt acknowledge signal from the

associated processor is asserted in hardware vector mode. The priority is popped into PRI in the associated INTC_CPR n whenever the associated INTC_EOIR n is written. An exception case in hardware vector mode to this behavior is described in [Section 24.4.2, Hardware vector mode](#).

Although the INTC supports up to 64 priorities, an ISR executing with PRI in the INTC_CPR n equal to 63 will not be preempted. Therefore, the LIFO supports the stacking of 63 priorities. However, the LIFO is only 62 entries deep. An entry for a priority of 0 is not needed because of the ways that pushing onto a full LIFO and popping an empty LIFO are treated. If the LIFO is pushed 63 or more times than it is popped, the priorities first pushed are overwritten. A priority of 0 would be an overwritten priority. However, the LIFO will pop zeroes if it is popped more times than it is pushed. Therefore, although a priority of 0 was overwritten, it is regenerated with the popping of an empty LIFO.

24.6.3 Handshaking with processor

24.6.3.1 Software vector mode handshaking

24.6.3.1.1 Acknowledging interrupt request to processor

The software vector mode handshaking can be used with processors that only support an interrupt request to them, or processors that support both an interrupt request by itself as well as an interrupt request with an interrupt vector. The software vector mode handshaking even supports processors that always expect an interrupt vector with the interrupt request to them. Refer to [Figure 205](#).

A timing diagram of the interrupt request and acknowledge handshaking in software vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in [Figure 205](#). The INTC examines the peripheral and software-settable interrupt requests. When it finds an asserted peripheral or software-settable interrupt request with a higher priority than PRI in the associated INTC_CPR n , it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKR n is updated with the preempting interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the processor is asserted. The rest of the handshaking is described in [Section 24.4.1, Software vector mode](#).

24.6.3.1.2 End of interrupt exception handler

Before the interrupt exception handling completes, INTC_EOIR n must be written. When it is written, the associated LIFO is popped so that the preempted priority is restored into PRI of the associated INTC_CPR n . Before it is written, the peripheral or software-settable flag bit must be cleared so that the peripheral or software-settable interrupt request is negated.

When returning from the preemption, the INTC does not search for the peripheral or software-settable interrupt request whose ISR was preempted. Depending on how much the ISR has progressed, that interrupt request may no longer even be asserted. When PRI in the associated INTC_CPR n is lowered to the priority of the preempted ISR, the interrupt request for the preempted ISR or any other asserted peripheral or software-settable interrupt request at or below that priority will not cause a preemption. Instead, after the restoration of the preempted context, the processor will return to the instruction address that it had been going to execute next, before it was preempted. This next instruction is part of the preempted ISR or the interrupt exception handler's prolog or epilog.

Figure 205. Timing diagram of software vector mode handshaking

24.6.3.2 Hardware vector mode handshaking

A timing diagram of the interrupt request and acknowledge handshaking in hardware vector mode, along with the handshaking near the end of the interrupt exception handler, is shown in [Figure 206](#). As in software vector mode, the INTC examines the peripheral and software-settable interrupt requests, and when it finds an asserted interrupt request with a higher priority than PRI in the associated INTC_CPRn, it asserts the interrupt request to the associated processor. The INTVEC field in the associated INTC_IACKRn is updated with the preempting peripheral or software-settable interrupt request's vector when the interrupt request to the processor is asserted. The INTVEC field retains that value until the next time the interrupt request to the associated processor is asserted. In addition, the value of the interrupt vector to the associated processor matches the value of the INTVEC field in the associated INTC_IACKRn. The rest of the handshaking is described in [Section 24.4.2, Hardware vector mode](#).

The handshaking near the end of the interrupt exception handler, that is the writing to the associated INTC_EOIRn, is the same as in software vector mode. See [Section 24.6.3.1.2, End of interrupt exception handler](#).

Figure 206. Timing diagram for hardware vector mode handshaking

24.7 Initialization/application information

24.7.1 Initialization flow

After exiting reset, all of the $PRIn$ and PRC_SELn fields in $INTC_PSRn$ are zero, and PRI in the $INTC_CPRn$ registers is 63. These reset values will prevent the INTC from asserting the interrupt request to the processors. The enable or mask bits in the peripherals are reset such that the peripheral interrupt requests are negated. An initialization sequence for allowing the peripheral and software-settable interrupt requests to cause an interrupt request to the processor is:

```
interrupt_request_initialization:
configure HVENn in INTC_BCR
configure VTBAn in INTC_IACKRn
raise the  $PRIn$  fields and set the  $PRC\_SELn$  fields to the desired processor
in INTC_PSRn
set the enable bits or clear the mask bits for the peripheral interrupt
requests
lower  $PRI$  in INTC_CPRn to zero
enable processor(s) recognition of interrupts
```

24.7.2 Interrupt exception handler

These example interrupt exception handlers excerpts use Power Architecture assembly code.

24.7.2.1 Software vector mode

In software vector mode for Power Architecture, there are 16 s of vector space available at the single ISR entry point.

```

24.7.3 ISR, RTOS, and task hierarchy

The RTOS and all of the tasks under its control typically execute with PRI in INTC_CPRn having a value of 0. The RTOS will execute the tasks according to whatever priority scheme it may have, but that priority scheme is independent and has a lower priority of execution than the priority scheme of the INTC. In other words, the ISRs execute above INTC_CPRn priority 0 and outside the control of the RTOS, the RTOS executes at INTC_CPRn priority 0, and while the tasks execute at different priorities under the control of the RTOS, they also execute at INTC_CPRn priority 0.

If a task shares a resource with an ISR and the Priority Ceiling Protocol (PCP) is being used to manage that shared resource, then the task's priority can be elevated in the INTC_CPRn while the shared resource is being accessed.

An ISR whose PRIn in INTC_PSRn has a value of 0 will not cause an interrupt request to the selected processor, even if its peripheral or software-settable interrupt request is asserted. For a peripheral interrupt request, not setting its enable bit or disabling the mask bit will cause it to remain negated, which consequently also will not cause an interrupt request to the processor. Since the ISRs are outside the control of the RTOS, this ISR will not run unless called by another ISR or the interrupt exception handler, perhaps after executing another ISR.

24.7.4 Order of execution

An ISR with a higher priority can preempt an ISR with a lower priority, regardless of the unique vectors associated with each of their peripheral or software-settable interrupt requests. However, if multiple peripheral or software-settable interrupt requests are asserted, more than one of these interrupt requests has the highest priority and that priority

is high enough to cause preemption, the INTC selects the one with the lowest unique vector regardless of the order in time that they asserted. However, the ability to meet deadlines with this scheduling scheme is no less than if the ISRs execute in the time order that their peripheral or software-settable interrupt requests asserted.

The example in [Table 288](#) shows the order of execution of both cases, ISRs with different priorities and ISRs with the same priority.

Table 288. Order of ISR execution example

Step #	Step Description	Code executing at end of step						PRI in INTC_CPR at end of step
		RTOS	ISR108 ⁽¹⁾	ISR208	ISR308	ISR408	interrupt exception handler	
1	RTOS at priority 0 is executing.	X						0
2	Peripheral interrupt request 100 at priority 1 asserts. Interrupt taken.		X					1
3	Peripheral interrupt request 400 at priority 4 asserts. Interrupt taken.					X		4
4	Peripheral interrupt request 300 at priority 3 asserts.					X		4
5	Peripheral interrupt request 200 at priority 3 asserts.					X		4
6	ISR408 completes. Interrupt exception handler writes to INTC_EOIRn.						X	1
7	Interrupt taken. ISR208 starts to execute, even though peripheral interrupt request 300 asserted first.			X				3
8	ISR208 completes. Interrupt exception handler writes to INTC_EOIRn.						X	1
9	Interrupt taken. ISR308 starts to execute.				X			3
10	ISR308 completes. Interrupt exception handler writes to INTC_EOIRn.						X	1
11	ISR108 completes. Interrupt exception handler writes to INTC_EOIRn.						X	0
12	RTOS continues execution.	X						0

1. ISR108 executes for peripheral interrupt request 100 because the first eight ISRs are for software-settable interrupt requests.

24.7.5 Priority ceiling protocol

24.7.5.1 Elevating priority

The PRI field in INTC current priority register (INTC_CPR_n) is elevated in the OSEK PCP to the ceiling of all of the priorities of the ISRs that share a resource. This protocol therefore allows coherent accesses of the ISRs to that shared resource.

For example, ISR1 has a priority of 1, ISR2 has a priority of 2, and ISR3 has a priority of 3. They all share the same resource. Before ISR1 or ISR2 can access that resource, they must raise the PRI value in INTC_CPR_n to 3, the ceiling of all of the ISR priorities. After they release the resource, they must lower the PRI value in INTC_CPR_n to prevent further priority inversion. If they do not raise their priority, then ISR2 can preempt ISR1, and ISR3 can preempt ISR1 or ISR2, possibly corrupting the shared resource. Another possible failure mechanism is deadlock if the higher priority ISR needs the lower priority ISR to release the resource before it can continue, but the lower priority ISR cannot release the resource until the higher priority ISR completes and execution returns to the lower priority ISR.

Using the PCP instead of disabling processor recognition of all interrupts eliminates the time when accessing a shared resource that all higher priority interrupts are blocked. For example, while ISR3 cannot preempt ISR1 while it is accessing the shared resource, all of the ISRs with a priority higher than 3 can preempt ISR1.

24.7.5.2 Ensuring coherency

24.7.5.2.1 Interrupt with blocked priority

A scenario can exist that can cause non-coherent accesses to the shared resource. As an example, ISR1 and ISR2 both share a resource. ISR1 has a lower priority than ISR2. ISR1 is executing, and it writes to the INTC_CPR_n. The instruction following this store is a store to a value in a shared coherent data block. Either just before or at the same time as the first store, the INTC asserts the interrupt request to the processor because the peripheral interrupt request for ISR2 has asserted. As the processor is responding to the interrupt request from the INTC, and as it is aborting transactions and flushing its pipeline, it is possible (in some implementations) that both of these stores are executed. ISR2 thereby assumes that it can access the data block coherently, but the data block has been corrupted.

OSEK uses the GetResource and ReleaseResource system services to manage access to a shared resource. To prevent this corruption of a coherent data block, modifications to PRI in INTC_CPR_n can be made by those system services with the code sequence:

GetResource:

```
wrtteei 0# disable external interrupts to the Processor
raise PRI# Write to CPR, cache inhibit, guarded
mbar # flush out writes from store buffer
wrtteei 1# enable external interrupts to the Processor
isync# re-fetch Processor pipeline
```

ReleaseResource:

```
mbar # flush out writes from store buffer
wrtteei 0# disable external interrupts to the Processor
lower PRI# Write to CPR, cache inhibit, guarded
```

```
wrtteei 1# enable external interrupts to the Processor
```

Figure 207. OSEK Code Sequence

24.7.5.2.1.1 Interrupt request to processor

Referencing [Figure 196](#), the interrupt request logic to the processor is shown in [Figure 208](#).

Figure 208. Interrupt request block diagram

Assuming that there are no $IRQn$ deasserted (no pending interrupt requests to processor n), if one of the external interrupt sources ($INT_SOURCES$) has a priority higher than the $INTC_CPRn$, then interrupt request to the processor ($IRQn$) is asserted. It will stay asserted until one of the following conditions is true:

- Interrupt acknowledge ($IACK$) is asserted
- If the $EEEn$ bit has been cleared by the `wrtteei` instruction (see [Figure 207](#)), $IRQn$ will be re-evaluated when processor n writes to the $INTC_CPRn$ while processor n ignores $IRQn$

This provides a safe way to guarantee that no interrupts will be recognized by processor n while updating the $INTC_CPRn$.

24.7.5.2.2 Raised priority preserved

Before the instruction after the `GetResource` system service executes, all pending transactions have completed. These pending transactions can include an ISR for a peripheral or software-settable interrupt request whose priority was equal to or lower than the raised priority. Also, during the epilog of the interrupt exception handler for this preempting ISR, the raised priority has been restored from the LIFO to PRI in $INTC_CPRn$. The shared coherent data block now can be accessed coherently. [Figure 209](#) shows the timing diagram for this scenario, and [Table 289](#) explains the events. The example is for software vector mode. Except for the method of retrieving the vector and acknowledging the interrupt request to the processor, hardware vector mode is identical.

Figure 209. Timing diagram of raised priority preserved

Table 289. Raised priority preserved events

Event	Description
A	Peripheral interrupt request 200 asserts during execution of ISR108 running at priority 1.
B	Interrupt request to processor asserts. INTVEC in INTC_IACKRn updates with vector for that peripheral interrupt request.
C	ISR108 writes to INTC_CPRn to raise priority to 3 before accessing shared coherent data block.
D	PRI in INTC_CPRn now at 3, reflecting the write. This write, just before accessing data block, is the last instruction the processor executes before being interrupted.
E	Interrupt exception handler prolog acknowledges interrupt by reading INTC_IACKRn.
F	PRI of 3 pushed onto LIFO. PRI in INTC_CPRn updates to 2, the priority of ISR208.
G	ISR208 clears its flag bit, deasserting its peripheral interrupt request.
H	Interrupt exception handler epilog writes to INTC_EOIRn.
I	LIFO pops 3, restoring the raised priority onto PRI in INTC_CPRn. Next value to pop from LIFO is the priority from before peripheral interrupt request 100 interrupted. ISR108 now can access data block coherently after interrupt exception handler executes rfi instruction.

24.7.6 Selecting priorities according to request rates and deadlines

The selection of the priorities for the ISRs can be made using Rate Monotonic Scheduling (RMS) or a superset of it, Deadline Monotonic Scheduling (DMS). In RMS, the ISRs which have higher request rates have higher priorities. In DMS, if the deadline is before the next time the ISR is requested, then the ISR is assigned a priority according to the time from the request for the ISR to the deadline, not from the time of the request for the ISR to the next request for it.

For example, ISR1 executes every 100 μ s, ISR2 executes every 200 μ s, and ISR3 executes every 300 μ s. ISR1 has a higher priority than ISR2 which has a higher priority than ISR3. However, if ISR3 has a deadline of 150 μ s, then it has a higher priority than ISR2.

The INTC supports 64 priorities, which may be many fewer than the number of ISRs. In this case, the ISRs should be grouped with other ISRs that have similar deadlines. For example, a priority could be allocated for every time the request rate doubles. ISRs with request rates around 1 ms would share a priority, ISRs with request rates around 500 μ s would share a priority, ISRs with request rates around 250 μ s would share a priority, and so on. With this approach, a range of ISR request rates of 2^{16} could be covered, regardless of the number of ISRs.

Reducing the number of priorities does cause some priority inversion, which reduces the processor's ability to meet its deadlines. However, reducing the number of priorities can reduce the size and latency through the interrupt controller. It also allows easier management of ISRs with similar deadlines that share a resource. They can be placed at the same priority without any further priority inversion, and they do not need to use the PCP to access the shared resource.

24.7.7 Software-settable interrupt requests

The software-settable interrupt requests can be used in two ways. They can be used to schedule a lower priority portion of an ISR and for processors to interrupt other processors in a multiple processor system.

24.7.7.1 Scheduling a lower priority portion of an ISR

A portion of an ISR needs to be executed at the PRI_n value in $INTC_PSR_n$, which becomes the PRI value in $INTC_CPR_n$ with the interrupt acknowledge. The ISR, however, can have a portion of it which does not need to be executed at this higher priority. Therefore, executing this later portion which does not need to be executed at this higher priority can prevent the execution of ISRs which do not have a higher priority than the earlier portion of the ISR but do have a higher priority than the later portion of the ISR needs. This preemptive scheduling inefficiency reduces the processor's ability to meet its deadlines.

One option is for the ISR to complete the earlier higher priority portion, but then schedule through the RTOS a task to execute the later lower priority portion. However, some RTOSs can require a large amount of time for an ISR to schedule a task. Therefore, a second option is for the ISR, after completing the higher priority portion, to set a SET_n bit in $INTC_SSCIR_n$. Writing a 1 to SET_n causes a software-settable interrupt request. This software-settable interrupt request, which usually will have a lower PRI_n value in the $INTC_PSR_n$, therefore will not cause preemptive scheduling inefficiencies.

24.7.7.2 Scheduling an ISR on another processor

Since the SET n bits in the INTC_SSCIR n are memory mapped, processors in multiple processor systems can schedule ISRs on the other processors. One possible application is if one processor simply wants to command another processor to perform a piece of work, and the initiating processor does not need to use the results of that work. If the initiating processor needs to know if the processor executing the software-settable ISR has not completed the work before asking it to again execute that ISR, it can check if the corresponding CLR n bit in INTC_SSCIR n is asserted before again writing a 1 to the SET n bit.

Another application is the sharing of a block of data. For example, a first processor has completed accessing a block of data and wants a second processor to then access it. Furthermore, after the second processor has completed accessing the block of data, the first processor again wants to access it. The accesses to the block of data must be done coherently. The procedure is that the first processor writes a 1 to a SET n bit on the second processor. The second processor, after accessing the block of data, clears the corresponding CLR n bit and then writes 1 to a SET n bit on the first processor, informing it that it now can access the block of data.

24.7.8 Lowering priority within an ISR

In implementations without the software-settable interrupt requests in INTC_SSCIR n , one way (besides scheduling a task through an RTOS) to prevent preemptive scheduling inefficiencies with an ISR whose work spans multiple priorities (as described in [Section 24.7.7.1, Scheduling a lower priority portion of an ISR](#)) is to lower the current priority. However, the INTC has a LIFO whose depth is determined by the number of priorities.

Note: Lowering the PRI value in INTC_CPR n within an ISR to below the ISR's corresponding PRI value in INTC_PSR n allows more preemptions than the depth of the LIFO can support.

Therefore, through its use of the LIFO the INTC does not support lowering the current priority within an ISR as a way to avoid preemptive scheduling inefficiencies.

24.7.9 Negating an interrupt request outside of its ISR

24.7.9.1 Negating an interrupt request as a side effect of an ISR

Some peripherals have flag bits which can be cleared as a side effect of servicing a peripheral interrupt request. For example, reading a specific register can clear the flag bits, and consequently their corresponding interrupt requests too. This clearing as a side effect of servicing a peripheral interrupt request can cause the negation of other peripheral interrupt requests besides the peripheral interrupt request whose ISR presently is executing. This negating of a peripheral interrupt request outside of its ISR can be a desired effect.

24.7.9.2 Negating multiple interrupt requests in one ISR

An ISR can clear other flag bits besides its own flag bit. One reason that an ISR clears multiple flag bits is because it serviced those other flag bits, and therefore the ISRs for these other flag bits do not need to be executed.

24.7.9.3 Proper setting of interrupt request priority

Whether an interrupt request negates outside of its own ISR due to the side effect of an ISR execution or the intentional clearing of a flag bit, the priorities of the peripheral or software-settable interrupt requests for these other flag bits must be selected properly. Their PRI_n values in $INTC_PSR_n$ must be selected to be at or lower than the priority of the ISR that cleared their flag bits. Otherwise, those flag bits still can cause the interrupt request to the processor to assert. Furthermore, the clearing of these other flag bits also has the same timing relationship to the writing to $INTC_SSCIR_n$ as the clearing of the flag bit that caused the present ISR to be executed. Refer to [Section 24.6.3.1.2, End of interrupt exception handler](#) for more information.

A flag bit whose enable bit or mask bit is negating its peripheral interrupt request can be cleared at any time, regardless of the peripheral interrupt request's PRI_n value in $INTC_PSR_n$.

24.7.10 Examining LIFO contents

Normally the user does not need to know the contents of the LIFO, or even how deep the LIFO is nested. Although the LIFO contents are not memory-mapped, the user can read the contents by popping the LIFO and reading the PRI field in the INTC current priority register ($INTC_CPR_n$). Disabling processor recognition of interrupts while examining the LIFO contents provides a coherent view of the preempted priorities. The code sequence is:

```
:
pop_lifo:
    store to INTC_EOIRn
    load INTC_CPRn, examine PRI, and store onto stack
    if PRI is not zero or value when interrupts were enabled, branch to
pop_lifo
```

When the examination is complete, the LIFO can be restored using this code sequence:

```
push_lifo:
    load stacked PRI value and store to INTC_CPRn
    load INTC_IACKRn
    if stacked PRI values are not depleted, branch to push_lifo
```

24.8 Interrupt sources

The list of interrupt sources is chip-specific. For this list, see the chapter that describes how modules are configured and connected.

25 Enhanced Direct Memory Access (eDMA)

25.1 Introduction

The enhanced direct memory access (eDMA) controller is a second-generation module capable of performing complex data transfers with minimal intervention from a host processor. The hardware microarchitecture includes a DMA engine that performs source- and destination-address calculations, and the actual data-movement operations, along with local memory containing transfer control descriptors for each of the 64 channels.

Figure 210 illustrates the eDMA module.

Figure 210. eDMA block diagram

25.1.1 Features

The eDMA is a highly-programmable data-transfer engine optimized to minimize the intervention from the host processor. It is intended for use in applications where the data

size to be transferred is statically known and not defined within the data packet itself. The eDMA module features:

- All data movement via dual-address transfers—read from source, write to destination: Programmable source and destination addresses and transfer size, plus support for enhanced addressing modes
- 64-channel implementation that performs complex data transfers with minimal intervention from a host processor
 - Internal data buffer, used as temporary storage to support 16- and 32-byte burst transfers
 - Connections to the crossbar switch for bus mastering the data movement
- Transfer control descriptor (TCD) organized to support two-deep, nested transfer operations
 - 32-byte TCD stored in local memory for each channel
 - An inner data transfer loop defined by a minor byte transfer count
 - An outer data transfer loop defined by a major iteration count
- Channel activation via one of three methods:
 - Explicit software initiation
 - Initiation via a channel-to-channel linking mechanism for continuous transfers
 - Peripheral-paced hardware requests (one per channel)
- Fixed-priority and round-robin channel arbitration
- Channel completion reported via optional interrupt requests
 - One interrupt per channel, optionally asserted at completion of major iteration count
 - Optional error terminations per channel and logically summed together to form one error interrupt to the interrupt controller
- Optional support for scatter/gather DMA processing
- Support for complex data structures
- Support to cancel transfers via software

Throughout this chapter, *n* is used to reference the channel number.

25.2 Modes of operation

The eDMA supports the following modes of operation.

25.2.1 Normal mode

In Normal mode, the eDMA transfers data between a source and a destination. The source and destination can be a memory block or an I/O block capable of operation with the eDMA.

A service request initiates a transfer of a specific number of bytes (NBYTES) as specified in the transfer control descriptor (TCD). The minor loop is the sequence of read-write operations that transfers these NBYTES per service request. Each service request executes one iteration of the major loop, which transfers NBYTES of data.

25.2.2 Debug mode

DMA operation is configurable in Debug mode via the control register:

- If CR[EDBG] is cleared, the DMA continues to operate.
- If CR[EDBG] is set, the eDMA stops transferring data. If Debug mode is entered while a channel is active, the eDMA continues operation until the channel retires.

25.2.3 Wait mode

Before entering Wait mode the DMA attempts to complete its current transfer. After the transfer completes the device enters Wait mode.

25.3 Memory map/register definition

The eDMA's programming model is partitioned into two regions:

- The first region defines a number of registers providing control functions.
- The second region corresponds to the local transfer control descriptor memory.

Some registers are implemented as two 32-bit registers, and include an H and L suffix, signaling the high and low portions of the control function. [Table 290](#) provides a 32-bit view of the eDMA's memory map.

Each channel requires a 32-byte transfer control descriptor for defining the desired data movement operation. The channel descriptors are stored in the local memory in sequential order: channel 0 to channel 63. Each TCD_n definition is presented as 11 registers of 16 or 32 bits.

Reading reserved bits in a register returns the value of zero and writes to reserved bits in a register are ignored. Reading or writing a reserved memory location generates a bus error.

Table 290. DMA memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Location
FC0A_0000	Control Register (DMA_CR)	32	R/W	0000_0000h	on page 783

25.3.1 Control Register (DMA_CR)

The CR defines the basic operating configuration of the DMA.

The DMA arbitrates channel service requests in four groups (0, 1, 2, 3) of 16 channels each. Group 3 contains channels 63–48; group 2 contains channels 47–32; group 1 contains channels 31–16; and group 0 contains channels 15–0.

Arbitration within a group can be configured to use a fixed-priority or a round-robin scheme. In fixed-priority arbitration, the highest priority channel requesting service is selected to execute. The channel priority registers assign the priorities (see the DCHPRI registers). In Round-Robin Arbitration mode, the channel priorities are ignored, and channels within each group are cycled through without regard to priority.

Note: *Writes to the DMA_CR must be performed only when the DMA channels are inactive (TCDn_CSR[ACTIVE] bits are cleared).*

The group priorities operate in a similar fashion. In Group Fixed-Priority Arbitration mode, channel service requests in the highest priority group are executed first where priority level 3 is the highest and priority level 0 is the lowest. The group priorities are assigned in the GRPnPRI fields of the DMA Control Register (CR). All group priorities must have unique values prior to the occurrence of any channel service requests; otherwise, a configuration error will be reported. In Group Round-Robin mode, the group priorities are ignored and the groups are cycled through without regard to priority.

Figure 211. Control Register (DMA_CR)

Address: FCOA_0000 + 0x0000

Access: User read/write

Table 291. DMA_CR field descriptions

Field	Description
0–13 Reserved	This read-only field is reserved and always has the value zero.
14 CX	Cancel transfer 0 Normal operation 1 Cancel the remaining data transfer. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The CXFR bit clears itself after the cancel has been honored. This cancel retires the channel normally as if the minor loop was completed.
15 ECX	Error cancel transfer 0 Normal operation 1 Cancel the remaining data transfer in the same fashion as the CX bit. Stop the executing channel and force the minor loop to finish. The cancel takes effect after the last write of the current read/write sequence. The ECX bit clears itself after the cancel is honored. In addition to cancelling the transfer, ECX treats the cancel as an error condition; thus updating the ES register and generating an optional error interrupt.
16–17 GRP3PRI	Channel group 3 priority Group 3 priority level when fixed-priority group arbitration is enabled.
18–19 GRP2PRI	Channel group 2 priority Group 2 priority level when fixed-priority group arbitration is enabled.
20–21 GRP1PRI	Channel group 1 priority Group 1 priority level when fixed-priority group arbitration is enabled.
22–23 GRP0PRI	Channel group 0 priority Group 0 priority level when fixed-priority group arbitration is enabled.
24 EMLM	Enable minor loop mapping 0 Disabled. TCDn.word2 is defined as a 32-bit NBYTES field 1 Enabled. TCDn.word2 is redefined to include individual enable fields, an offset field, and the NBYTES field. The individual enable fields allow the minor loop offset to be applied to the source address, the destination address, or both. The NBYTES field is reduced when either offset is enabled.

Table 291. DMA_CR field descriptions (continued)

Field	Description
25 CLM	Continuous Link mode 0 A minor loop channel link made to itself goes through channel arbitration before being activated again. 1 A minor loop channel link made to itself does not go through channel arbitration before being activated again. Upon minor loop completion, the channel activates again if that channel has a minor loop channel link enabled and the link channel is itself. This effectively applies the minor loop offsets and restarts the next minor loop.
26 HALT	Halt DMA operations 0 Normal operation 1 Stall the start of any new channels. Executing channels are allowed to complete. Channel execution resumes when this bit is cleared.
27 HOE	Halt on error 0 Normal operation 1 Any error causes the HALT bit to set. Subsequently, all service requests are ignored until the HALT bit is cleared.
28 ERGA	Enable round-robin group arbitration 0 Fixed-priority arbitration is used for selection among the groups. 1 Round-robin arbitration is used for selection among the groups.
29 ERCA	Enable round-robin channel arbitration 0 Fixed-priority arbitration is used for channel selection. 1 Round-robin arbitration is used for channel selection.
30 EDBG	Enable debug 0 When in Debug mode the DMA continues to operate. 1 When in Debug mode, the DMA stalls the start of a new channel. Executing channels are allowed to complete. Channel execution resumes when the system or the EDBG bit is cleared.
31 Reserved	This read-only bit is reserved and always has the value zero.

25.3.2 Error Status Register (DMA_ES)

The ES provides information concerning the last recorded channel error. Channel errors can be caused by a configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode) or an error termination to a bus master read or write cycle.

See [Section 25.4.3, Error reporting and handling](#), for more details.

Table 292. DMA_ES field descriptions

Field	Description
0 VLD	ERRH and ERRL status bits 0 No ERR bits are set 1 At least one ERR bit is set indicating a valid error exists that has not been cleared
1–13 Reserved	This read-only bitfield is reserved and always has the value zero.
14 UCE	Uncorrectable ECC error 0 No uncorrectable ECC error 1 The last recorded error was an uncorrectable TCD RAM error
15 ECX	Transfer cancelled 0 No cancelled transfers 1 The last recorded entry was a cancelled transfer by the error cancel transfer input
16 GPE	Group priority error 0 No group priority error 1 The last recorded error was a configuration error among the group priorities. All group priorities are not unique
17 CPE	Channel priority error 0 No channel priority error 1 The last recorded error was a configuration error in the channel priorities. Channel priorities are not unique.
18–23 ERRCHN	Error channel number or cancelled channel number GPE and/or last recorded error cancelled transfer
24 SAE	Source address error 0 No source address configuration error. 1 The last recorded error was a configuration error detected in the TCDn_SADDR field. TCDn_SADDR is inconsistent with TCDn_ATTR[SSIZE]
25 SOE	Source offset error 0 No source offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_SOFF field. TCDn_SOFF is inconsistent with TCDn_ATTR[SSIZE].

Table 292. DMA_ES field descriptions (continued)

Field	Description
26 DAE	Destination address error 0 No destination address configuration error 1 The last recorded error was a configuration error detected in the TCDn_DADDR field. TCDn_DADDR is inconsistent with TCDn_ATTR[DSIZE].
27 DOE	Destination offset error 0 No destination offset configuration error 1 The last recorded error was a configuration error detected in the TCDn_DOFF field. TCDn_DOFF is inconsistent with TCDn_ATTR[DSIZE].
28 NCE	NBYTES/CITER configuration error 0 No NBYTES/CITER configuration error 1 The last recorded error was a configuration error detected in the TCDn_NBYTES or TCDn_CITER fields.
29 SGE	Scatter/gather configuration error 0 No scatter/gather configuration error 1 The last recorded error was a configuration error detected in the TCDn_DLASTSGA field. This field is checked at the beginning of a scatter/gather operation after major loop completion if TCDn_CSR[ESG] is enabled. TCDn_DLASTSGA is not on a 32-byte boundary.
30 SBE	Source bus error 0 No source bus error 1 The last recorded error was a bus error on a source read
31 DBE	Destination bus error 0 No destination bus error 1 The last recorded error was a bus error on a destination write

25.3.3 Enable Request Register High (DMA_ERQH)

The ERQ{H,L} registers provide a bitmap for the 64 implemented channels to enable the request signal for each channel. ERQH supports channels 63–32, while EQRL covers channels 31–00. The state of any given channel enable is directly affected by writes to this register; it is also affected by writes to the SERQ and CERQ. The {S,C}ERQ registers are provided so the request enable for a single channel can easily be modified without needing to perform a read-modify-write sequence to the ERQ{H,L}.

DMA request input signals and this enable request flag must be asserted before a channel's hardware service request is accepted. The state of the eDMA enable request flag does not affect a channel service request made explicitly through software or a linked channel request.

25.3.5 Enable Error Interrupt Register High (DMA_EEIH)

The EEI{H,L} registers provide a bit map for the 64 channels to enable the error interrupt signal for each channel. EEIH supports channels 63–32, while EEIL covers channels 31–00. The state of any given channel's error interrupt enable is directly affected by writes to this register; it is also affected by writes to the SEEI and CEEI. The {S,C}EEI are provided so the error interrupt enable for a single channel can easily be modified without the need to perform a read-modify-write sequence to the EEI{H,L} registers.

The DMA error indicator and the error interrupt enable flag must be asserted before an error interrupt request for a given channel is asserted to the interrupt controller.

25.3.7 Set Enable Request Register (DMA_SERQ)

The Set Enable Request Register (DMA_SERQ) provides a simple memory-mapped mechanism to set a given bit in the ERQ{H,L} to enable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ{H,L} to be set. Setting the SAER bit provides a global set function, forcing the entire contents of ERQ{H,L} to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

Figure 217. Set Enable Request Register (DMA_SERQ)

Address: FCOA_0000 + 0x0018

Access: User write-only

Field	Description
0 NOP	0 Normal operation 1 No operation, ignore bits 1–7 of this register
1 SAER	Set all enable requests 0 Set only those ERQ bits specified in the SERQ field 1 Set all bits in ERQ{H,L}
2–7 SERQ	Set enable request Sets the corresponding bit in ERQ{H,L}

25.3.8 Clear Enable Request Register (DMA_CERQ)

The Clear Enable Request Register (DMA_CERQ) provides a simple memory-mapped mechanism to clear a given bit in the ERQ{H,L} to disable the DMA request for a given channel. The data value on a register write causes the corresponding bit in the ERQ{H,L} to be cleared. Setting the CAER bit provides a global clear function, forcing the entire contents of the ERQ{H,L} to be cleared, disabling all DMA request inputs.

If NOP is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2–7 CERQ	Clear enable request Clears the corresponding bit in ERQ{H,L}

25.3.9 Set Enable Error Interrupt Register (DMA_SEEI)

The Set Enable Error Interrupt Register (DMA_SEEI) provides a simple memory-mapped mechanism to set a given bit in the EEI{H,L} to enable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI{H,L} to be set. Setting the SAAE bit provides a global set function, forcing the entire EEI{H,L} contents to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

1 SAAE	Sets all enable error interrupts 0 Set only those EEI bits specified in the SEEI field. 1 Sets all bits in EEI
2–7 SEEI	Set enable error interrupt Sets the corresponding bit in EEI{H,L}

25.3.10 Clear Enable Error Interrupt Register (DMA_CEEI)

The Clear Enable Error Interrupt Register (DMA_CEEI) provides a simple memory-mapped mechanism to clear a given bit in the EEI{H,L} to disable the error interrupt for a given channel. The data value on a register write causes the corresponding bit in the EEI{H,L} to be cleared. Setting the CAEE bit provides a global clear function, forcing the EEI{H,L} contents to be cleared, disabling all DMA request inputs.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2–7 CEEI	Clear enable error interrupt Clears the corresponding bit in EEI{H,L}

25.3.11 Clear Interrupt Request Register (DMA_CINT)

The Clear Interrupt Request Register (DMA_CINT) provides a simple, memory-mapped mechanism to clear a given bit in the INT{H,L} to disable the interrupt request for a given channel. The given value on a register write causes the corresponding bit in the INT{H,L} to be cleared. Setting the CAIR bit provides a global clear function, forcing the entire contents of the INT{H,L} to be cleared, disabling all DMA interrupt requests.

If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2–7 CINT	Clear interrupt request Clears the corresponding bit in INT{H,L}

25.3.12 Clear Error Register (DMA_CERR)

The CERR provides a simple memory-mapped mechanism to clear a given bit in the ERR{H,L} to disable the error condition flag for a given channel. The given value on a register write causes the corresponding bit in the ERR{H,L} to be cleared. Setting the CAEI bit provides a global clear function, forcing the ERR{H,L} contents to be cleared, clearing all channel error indicators. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

1 CAEI	Clear all error indicators 0 Clear only those ERR bits specified in the CERR field 1 Clear all bits in ERR
2–7 CERR	Clear error indicator Clears the corresponding bit in ERR{H,L}

25.3.13 Set START Bit Register (DMA_SSRT)

The Set START Bit Register (DMA_SSRT) provides a simple memory-mapped mechanism to set the START bit in the TCD of the given channel. The data value on a register write causes the START bit in the corresponding transfer control descriptor to be set. Setting the SAST bit provides a global set function, forcing all START bits to be set. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

0 NOP	0 Normal operation 1 No operation, ignore bits 1–7 of this register
1 SAST	Set all START bits (activates all channels) 0 Set only those TCD _n _CSR[START] bits specified in the SSRT field 1 Set all bits in TCD _n _CSR[START]
2–7 SSRT	Set START bit Sets the corresponding bit in TCD _n _CSR[START]

25.3.14 Clear DONE Status Bit Register (DMA_CDNE)

The Clear DONE Status Bit Register (DMA_CDNE) provides a simple memory-mapped mechanism to clear the DONE bit in the TCD of the given channel. The data value on a register write causes the DONE bit in the corresponding transfer control descriptor to be cleared. Setting the CADN bit provides a global clear function, forcing all DONE bits to be cleared. If the NOP bit is set, the command is ignored. This allows you to write multiple-byte registers as a 32-bit word. Reads of this register return all zeroes.

2–7 CDNE	Clear DONE bit Clears the corresponding bit in TCDn_CSR[DONE]

25.3.15 Interrupt Request Register High (DMA_INTH)

The Interrupt Request Register High (DMA_INTH) provides a bit map for the upper half of 64 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptions, the eDMA engine generates an interrupt on a data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L}.

25.3.16 Interrupt Request Register Low (DMA_INTL)

The Interrupt Request Register Low (DMA_INTL) provides a bit map for the lower half of the 64 channels signaling the presence of an interrupt request for each channel. Depending on the appropriate bit setting in the transfer-control descriptors, the eDMA engine generates an interrupt at data transfer completion. The outputs of this register are directly routed to the interrupt controller (INTC). During the interrupt-service routine associated with any given channel, it is the software's responsibility to clear the appropriate bit, negating the interrupt request. Typically, a write to the CINT in the interrupt service routine is used for this purpose.

The state of any given channel's interrupt request is directly affected by writes to this register; it is also affected by writes to the CINT. On writes to the INT, a '1' in any bit position clears the corresponding channel's interrupt request. A zero in any bit position has no effect on the corresponding channel's current interrupt status. The CINT is provided so the interrupt request for a single channel can easily be cleared without the need to perform a read-modify-write sequence to the INT{H,L}.

25.3.17 Error Register High (DMA_ERRH)

The ERR{H,L} provides a bit map for the 64 channels, signaling the presence of an error for each channel. ERRH supports channels 63–32, while ERRL covers channels 31–00. The eDMA engine signals the occurrence of a error condition by setting the appropriate bit in this register. The outputs of this register are enabled by the contents of the EEI, then logically summed across groups of 16, 32, and 64 channels to form several group error interrupt requests that are then routed to the interrupt controller. During the execution of the interrupt-service routine associated with any DMA errors, it is software's responsibility to clear the appropriate bit, negating the error-interrupt request. Typically, a write to the CERR in the interrupt-service routine is used for this purpose. The normal DMA channel completion indicators (setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request) are not affected when an error is detected.

The contents of this register can also be polled because a nonzero value indicates the presence of a channel error regardless of the state of the EEI. The state of any given channel's error indicators is affected by writes to this register; it is also affected by writes to the CERR. On writes to the ERR, a one in any bit position clears the corresponding

channel's error status. A zero in any bit position has no effect on the corresponding channel's current error status. The CERR is provided so the error indicator for a single channel can easily be cleared.

25.3.19 Hardware Request Status Register High (DMA_HRSH)

The HRS{H,L} provides a bit map for the DMA channels, signaling the presence of a qualified hardware service request for each channel. HRSH supports channels 63–32, while HRSL covers channels 31–00. The Hardware Request Status bits reflect the current state of the register and qualified (via the ERQ{H,L} fields) DMA request signals as seen by the

DMA's arbitration logic. This view into the hardware request signals may be used for debug purposes.

Note: *Note: These bits reflect the state of the request as seen by the arbitration logic. Therefore, this status is affected by the ERQ{H,L} bits.*

25.3.21 Channel *n* Priority Register (DMA_DCHPRIn)

When the Fixed-Priority Channel Arbitration mode is enabled (CR[ERCA] = 0), the contents of these registers define the unique priorities associated with each channel within a group. The channel priorities are evaluated by numeric value; for example, 0 is the lowest priority, 1 is the next higher priority, then 2, 3, and so on. Software must program the channel priorities with unique values. Otherwise, a configuration error is reported. The range of the priority value is limited to the values of 0 through 15.

When read, the GRPPRI bits of the DCHPRIn register reflect the current priority level of the group of channels in which the corresponding channel resides. GRPPRI bits are not affected by writes to the DCHPRIn registers. The group priority is assigned in the DMA control register.

Figure 231. Channel n Priority Register (DMA_DCHPRIn)Address: FCOA_0000h base + 100h offset + (1d × n), where n = 0d to 63d

Table 311. DMA_DCHPRIn field descriptions

Field	Description
0 ECP	Enable channel preemption This bit resets to zero. 0 Channel n cannot be suspended by a higher priority channel's service request 1 Channel n can be temporarily suspended by the service request of a higher priority channel
1 DPA	Disable preempt ability This bit resets to zero. 0 Channel n can suspend a lower priority channel 1 Channel n cannot suspend any channel, regardless of channel priority
2–3 GRPPRI	Channel n current group priority Group priority assigned to this channel group when fixed-priority arbitration is enabled. These two bits are read only; writes are ignored. <i>Note: Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, i.e., DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.</i>
4–7 CHPRI	Channel n arbitration priority Channel priority when fixed-priority arbitration is enabled <i>Note: Reset value for the group and channel priority fields, GRPPRI and CHPRI, is equal to the corresponding channel number for each priority register, i.e., DCHPRI31[GRPPRI] = 0b01 and DCHPRI31[CHPRI] equals 0b1111.</i>

25.3.22 Channel n Master ID Register (DMA_DCHMIDn)

The DMA Master ID Replication registers allow the DMA to use the same protection level and AHB system bus ID of the master programming the DMA's TCD. When enabled, the DMA uses the master ID and protection level stored in the DCHMID register instead of the DMA's default values. When a master (a core, for example) programs a TCD, its master ID and protection level are captured when the TCD Word 7 control attributes are written. Although the scatter/gather operation can change the contents of TCD Word 7, that operation does not affect the DCHMID n registers.

Figure 232. Channel *n* Master ID Register (DMA_DCHMIDn)Address: FC0A_0000h base + 140h offset + (1d × *n*), where *n* = 0d to 63d

Table 314. DMA_TCDn_ATTR field descriptions

Field	Description
16–20 SMOD	Source address modulo. 0 Source address modulo feature is disabled ≠0 This value defines a specific address range specified to be the value after SADDR + SOFF calculation is performed on the original register value. Setting this field provides the ability to implement a circular data queue easily. For data queues requiring power-of-2 size bytes, the queue should start at a 0-modulo-size address and the SMOD field should be set to the appropriate value for the queue, freezing the desired number of upper address bits. The value programmed into this field specifies the number of lower address bits allowed to change. For a circular queue application, the SOFF is typically set to the transfer size to implement post-increment addressing with the SMOD function constraining the addresses to a 0-modulo-size range.
21–23 SSIZE	Source data transfer size Using a reserved encoding causes a configuration error. 000 8-bit 001 16-bit 010 32-bit 011 64-bit 100 Reserved 101 32-byte burst 110 Reserved 111 Reserved

16–31 SOFF	Source address signed offset Sign-extended offset applied to the current source address to form the next-state value as each source read is completed.

25.3.26 TCD Minor Byte Count (Minor Loop Disabled) (DMA_TCDn_NBYTES_MLNO)

See TCD Minor Byte Count (Minor Loop Disabled) register figure and DMA_TCDn_NBYTES_MLNO field descriptions table below.

If minor loop mapping is disabled (CR[EMLM] = 0), TCD word 2 is defined as follows.

Figure 236. TCD Minor Byte Count (Minor Loop Disabled) (DMA_TCDn_NBYTES_MLNO)

Address: FC0A_0000h base + 1008h offset + (32d × n), where n = 0d to 63d Access: User read/write

1. x = Undefined at reset.

Table 316. DMA_TCDn_NBYTES_MLNO field descriptions

Field	Description
0–31 NBYTES	Minor byte transfer count Number of bytes to be transferred in each service request of the channel. As a channel activates, the appropriate TCD contents load into the eDMA engine, and the appropriate reads and writes perform until the minor byte transfer count has transferred. This is an indivisible operation and cannot be halted. (Although, it may be stalled by using the bandwidth control field, or via preemption.) After the minor count is exhausted, the SADDR and DADDR values are written back into the TCD memory, the major iteration count is decremented and restored to the TCD memory. If the major iteration count is completed, additional processing is performed. <i>Note: An NBYTES value of 0x0000_0000 is interpreted as a 4 GB transfer.</i>

25.3.27 TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled) (DMA_TCDn_NBYTES_MLOFFNO)

TCD Word 2 is defined as follows if:

- Minor loop mapping is enabled (CR[EMLM] = 1) and
- SMLOE = 0 and DMLOE = 0

**Figure 237. TCD Signed Minor Loop Offset (Minor Loop Enabled and Offset Disabled)

1. x = Undefined at reset.

Table 320. DMA_TCDn_CITER_ELINKYES field descriptions

Field	Description
16 ELINK	Enable channel-to-channel linking on minor-loop complete As the channel completes the minor loop, this flag enables linking to another channel, defined by the LINKCH field. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. If channel linking is disabled, the CITER value is extended to 15 bits in place of a link channel number. If the major loop is exhausted, this link mechanism is suppressed in favor of the MAJORELINK channel linking. <i>Note: This bit must be equal to the BITER[ELINK] bit. Otherwise, a configuration error is reported.</i> 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
17–22 LINKCH	Link channel number If channel-to-channel linking is enabled (ELINK = 1), then after the minor loop is exhausted, the eDMA engine initiates a channel service request to the channel defined by these six bits by setting that channel's TCDn_CSR[START] bit.
23–31 CITER	Current major iteration count This 9-bit (ELINK = 1) or 15-bit (ELINK = 0) count represents the current major loop count for the channel. It is decremented each time the minor loop is completed and updated in the transfer control descriptor memory. After the major iteration count is exhausted, the channel performs a number of operations (e.g., final source and destination address calculations), optionally generating an interrupt to signal channel completion before reloading the CITER field from the beginning iteration count (BITER) field. <i>Note: When the CITER field is initially loaded by software, it must be set to the same value as that contained in the BITER field. If the channel is configured to execute a single service request, the initial values of BITER and CITER should be 0x0001.</i>

25.3.32 TCD Current Minor Loop Link, Major Loop Count (Channel Linking Disabled) (DMA_TCDn_CITER_ELINKNO)

1. x = Undefined at reset.

Table 326. DMA_TCDn_CSR field descriptions

Field	Description
16–17 BWC	Bandwidth control Throttles the amount of bus bandwidth consumed by the eDMA. In general, as the eDMA processes the minor loop, it continuously generates read/write sequences until the minor count is exhausted. This field forces the eDMA to stall after the completion of each read/write access to control the bus request bandwidth seen by the crossbar switch (XBS). <i>Note: If the source and destination sizes are equal, this field is ignored between the first and second transfers and after the last write of each minor loop. This behavior is a side effect of reducing start-up latency.</i> 00 No eDMA engine stalls 01 Reserved 10 eDMA engine stalls for 4 cycles after each r/w 11 eDMA engine stalls for 8 cycles after each r/w
18–23 MAJORLINKCH	Link channel number If (MAJORELINK = 0) then – No channel-to-channel linking (or chaining) is performed after the major loop counter is exhausted. else – After the major loop counter is exhausted, the eDMA engine initiates a channel service request at the channel defined by these six bits by setting that channel's TCDn_CSR[START] bit.
24 DONE	Channel done This flag indicates the eDMA has completed the major loop. The eDMA engine sets it as the CITER count reaches zero; The software clears it, or the hardware when the channel is activated. <i>Note: This bit must be cleared to write the MAJORELINK or ESG bits.</i> This bit resets to zero.
25 ACTIVE	Channel active This flag signals the channel is currently in execution. It is set when channel service begins, and the eDMA clears it as the minor loop completes or if any error condition is detected.

Table 326. DMA_TCDn_CSR field descriptions (continued)

Field	Description
26 MAJORELINK	Enable channel-to-channel linking on major loop complete As the channel completes the major loop, this flag enables the linking to another channel, defined by MAJORLINKCH. The link target channel initiates a channel service request via an internal mechanism that sets the TCDn_CSR[START] bit of the specified channel. <i>Note: To support the dynamic linking coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.</i> 0 The channel-to-channel linking is disabled 1 The channel-to-channel linking is enabled
27 ESG	Enable scatter/gather processing As the channel completes the major loop, this flag enables scatter/gather processing in the current channel. If enabled, the eDMA engine uses DLASTSGA as a memory pointer to a 0-modulo-32 address containing a 32-byte data structure loaded as the transfer control descriptor into the local memory. <i>Note: To support the dynamic scatter/gather coherency model, this field is forced to zero when written to while the TCDn_CSR[DONE] bit is set.</i> 0 The current channel's TCD is normal format. 1 The current channel's TCD specifies a scatter gather format. The DLASTSGA field provides a memory pointer to the next TCD to be loaded into this channel after the major loop completes its execution.
28 DREQ	Disable request {H,L} 0 The channel's ERQ bit is not affected 1 The channel's ERQ bit is cleared when the major loop is complete
29 INTHALF	Enable an interrupt when major counter is half complete. If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches the halfway point. Specifically, the comparison performed by the eDMA engine is (CITER == (BITER >> 1)). This halfway point interrupt request is provided to support double-buffered (aka ping-pong) schemes or other types of data movement where the processor needs an early indication of the transfer's progress. <i>Note: If BITER is set, do not use INTHALF. Use INTMAJOR instead.</i> 0 The half-point interrupt is disabled 1 The half-point interrupt is enabled
30 INTMAJOR	Enable an interrupt when major iteration count completes If this flag is set, the channel generates an interrupt request by setting the appropriate bit in the INT when the current major iteration count reaches zero. 0 The end-of-major loop interrupt is disabled 1 The end-of-major loop interrupt is enabled
31 START	Channel start If this flag is set, the channel is requesting service. The eDMA hardware automatically clears this flag after the channel begins execution. This bit resets to zero. 0 The channel is not explicitly started 1 The channel is explicitly started via a software initiated service request

25.4 Functional description

This section provides a description of the DMA request sources, an overview of the microarchitecture, and functional operation of the eDMA module.

25.4.1 eDMA microarchitecture

The eDMA module is partitioned into two major modules: the eDMA engine and the transfer-control descriptor local memory. Additionally, the eDMA engine is further partitioned into four submodules:

- eDMA engine
 - Address path:

This block implements registered versions of two channel transfer control descriptors, channel x and channel y, and manages all master bus-address calculations. All the channels provide the same functionality. This structure allows data transfers associated with one channel to be preempted after the completion of a read/write sequence if a higher priority channel activation is asserted while the first channel is active. After a channel is activated, it runs until the minor loop is completed, unless preempted by a higher priority channel. This provides a mechanism (enabled by DCHPRIn[ECPI]) where a large data move operation can be preempted to minimize the time another channel is blocked from execution.

When any channel is selected to execute, the contents of its TCD are read from local memory and loaded into the address path channel x registers for a normal start and into channel y registers for a preemption start. After the minor loop completes execution, the address path hardware writes the new values for the $TCDn_SADDR$, $TCDn_DADDR$, $TCDn_CITER$ back to local memory. If the major iteration count is exhausted, additional processing is performed, including updates to the final address pointer, reloading the $TCDn_CITER$ field, and a possible fetch of the next $TCDn$ from memory as part of a scatter/gather operation.
 - Data path:

This block implements the bus master read/write datapath. It includes 32 bytes of register storage and the necessary multiplex logic to support any data alignment. The internal read data bus is the primary input, and the internal write data bus is the primary output.

The address and data path modules directly support the two-stage pipelined internal bus. The address path module represents the first stage of the bus pipeline (address phase), while the data path module implements the second stage of the pipeline (data phase).
 - Program model/channel arbitration:

This block implements the first section of the eDMA programming model as well as the channel arbitration logic. The programming model registers are connected to the internal peripheral bus (not shown). The eDMA peripheral request inputs and interrupt request outputs are also connected to this block (via control logic).
 - Control:

This block provides all the control functions for the eDMA engine. For data transfers where the source and destination sizes are equal, the eDMA engine performs a series of source read/destination write operations until the number of bytes specified in the minor loop byte count has moved. For descriptors where the sizes are not equal, multiple accesses of the smaller size data are required for each reference of the larger size. As an example, if the source size references 16-

bit data and the destination is 32-bit data, two reads are performed, then one 32-bit write.

- Transfer control descriptor memory
 - Memory controller:

This logic implements the dual-ported controller, managing accesses from the eDMA engine as well as references from the internal peripheral bus.

As noted earlier, in the event of simultaneous accesses, the eDMA engine is given priority and the peripheral transaction is stalled.
 - Memory array:

TCD storage is implemented using a single-port, synchronous RAM array.

25.4.2 eDMA basic data flow

The basic flow of a data transfer can be partitioned into three segments. As shown in [Figure 248](#), the first segment involves the channel activation. In the diagram, this example uses the assertion of the eDMA peripheral request signal to request service for channel n . Channel activation via software and the $TCDn_CSR[START]$ bit follows the same basic flow as peripheral requests. The eDMA request input signal is registered internally and then routed through the eDMA engine: first through the control module, then into the program model and channel arbitration. In the next cycle, channel arbitration is performed, using the fixed-priority or round-robin algorithm. After arbitration is complete, the activated channel number is sent through the address path and converted into the address to access the local memory for $TCDn$. Next, the TCD memory is accessed and the descriptor read from the local memory and loaded into the eDMA engine address path channel x or y registers. The TCD memory is 64 bits wide to minimize the time needed to fetch the activated channel descriptor and load it into the address path channel x or y registers.

Figure 248. DMA operation, part 1

In the second part of the basic data flow as shown in [Figure 249](#) the modules associated with the data transfer (address path, data path, and control) sequence through source reads and destination writes to perform the actual data movement. The source reads are initiated and the fetched data is temporarily stored in the data path block until it is gated onto the internal bus during the destination write. This source read/destination write processing continues until the minor byte count has transferred.

Figure 249. DMA operation, part 2

After the minor byte count has moved, the final phase of the basic data flow is performed. In this segment, the address path logic performs updates to certain fields in the appropriate TCD, for example, SADDR, DADDR, and CITER. If the major iteration count is exhausted, additional operations are performed. These include the final address adjustments and reloading of the BITER field into the CITER. Assertion of an optional interrupt request also occurs at this time, as does a possible fetch of a new TCD from memory using the scatter/gather address pointer included in the descriptor. The updates to the TCD memory and the assertion of an interrupt request are shown in [Figure 250](#).

Figure 250. DMA operation, part 3

25.4.3 Error reporting and handling

Channel errors are reported in the ES register and can be caused by:

- A configuration error (an illegal setting in the transfer-control descriptor or an illegal priority register setting in Fixed Arbitration mode),
- An uncorrectable ECC error, or
- An error termination to a bus master read or write cycle.

A configuration error is reported when the starting source or destination address, source or destination offsets, minor loop byte count, or the transfer size represent an inconsistent state. Each of these possible causes are detailed in the list below:

- The addresses and offsets must be aligned on 0-modulo-transfer-size boundaries.
- The minor loop byte count must be a multiple of the source and destination transfer sizes.
- All source reads and destination writes must be configured to the natural boundary of the programmed transfer size, respectively.
- In Fixed Arbitration mode, a configuration error is caused by any two channel priorities being equal within a group, or any group priority levels being equal among the groups.

All channel priority levels within a group must be unique and all group priority levels among the groups must be unique when Fixed Arbitration mode is enabled.

- If a scatter/gather operation is enabled upon channel completion, a configuration error is reported if the scatter/gather address (DLAST_SGA) is not aligned on a 32-byte boundary.
- If minor loop channel linking is enabled upon channel completion, a configuration error is reported when the link is attempted if the TCDn_CITER[E_LINK] bit does not equal the TCDn_BITER[E_LINK] bit.

If enabled, all configuration error conditions, except the scatter/gather and minor-loop link errors, report as the channel activates and asserts an error interrupt request. A scatter/gather configuration error is reported when the scatter/gather operation begins at major loop completion when properly enabled. A minor loop channel link configuration error is reported when the link operation is serviced at minor loop completion.

If a system bus read or write is terminated with an error, the data transfer is stopped and the appropriate bus error flag set. In this case, the state of the channel's transfer control descriptor is updated by the eDMA engine with the current source address, destination address, and current iteration count at the point of the fault. When a system-bus error occurs, the channel terminates after the read or write transaction (which is already pipelined after errant access) has completed. If a bus error occurs on the last read prior to beginning the write sequence, the write executes using the data captured during the bus error. If a bus error occurs on the last write prior to switching to the next read sequence, the read sequence executes before the channel terminates due to the destination bus error.

If an uncorrectable ECC error occurs during a peripheral bus access, the access is terminated with a bus error. The occurrence of an uncorrectable ECC error during an eDMA engine read causes the eDMA engine to stop the active channel immediately. The ECC error and channel number are recorded in the eDMA's Error Status register.

A transfer may be cancelled by software with the CR[CX] bit. When a cancel transfer request is recognized, the DMA engine stops processing the channel. The current read-write sequence is allowed to finish. If the cancel occurs on the last read-write sequence of a major or minor loop, the cancel request is discarded and the channel retires normally.

The error cancel transfer is the same as a cancel transfer except the ES register is updated with the cancelled channel number and ECX is set. The TCD of a cancelled channel contains the source and destination addresses of the last transfer saved in the TCD. If the channel needs to be restarted, you must re-initialize the TCD since the aforementioned fields no longer represent the original parameters. When a transfer is cancelled by the error cancel transfer mechanism, the channel number is loaded into DMA_ES[ERRCHN] and ECX and VLD are set. In addition, an error interrupt may be generated if enabled.

The occurrence of any error causes the eDMA engine to stop the active channel immediately, and the appropriate channel bit in the eDMA error register is asserted. At the same time, the details of the error condition are loaded into the ES register. The major loop complete indicators, setting the transfer control descriptor DONE flag and the possible assertion of an interrupt request, are not affected when an error is detected. After the error status has been updated, the eDMA engine continues operating by servicing the next appropriate channel. A channel that experiences an error condition is not automatically disabled. If a channel is terminated by an error and then issues another service request before the error is fixed, that channel executes and terminates with the same error condition.

25.4.4 Channel preemption

Channel preemption is enabled on a per-channel basis by setting the DCHPRIn[ECP] bit. Channel preemption allows the executing channel's data transfers to temporarily suspend in favor of starting a higher priority channel. After the preempting channel has completed all its minor loop data transfers, the preempted channel is restored and resumes execution. After the restored channel completes one read/write sequence, it is again eligible for preemption. If any higher priority channel is requesting service, the restored channel is suspended and the higher priority channel is serviced. Nested preemption (attempting to preempt a preempting channel) is not supported. After a preempting channel begins execution, it cannot be preempted. Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes.

A channel's ability to preempt another channel can be disabled by setting DCHPRIn[DPA]. When a channel's preempt ability is disabled, that channel cannot suspend a lower priority channel's data transfer; regardless of the lower priority channel's ECP setting. This allows for a pool of low-priority, large data-moving channels to be defined. These low-priority channels can be configured so that they do not preempt each other, thus preventing a low-priority channel from consuming the preempt slot normally available to a true, high-priority channel.

25.4.5 eDMA performance

This section addresses the performance of the eDMA module, focusing on two separate metrics. In the traditional data movement context, performance is best expressed as the peak data transfer rates achieved using the eDMA. In most implementations, this transfer rate is limited by the speed of the source and destination address spaces. In a second context where device-paced movement of single data values to/from peripherals is dominant, a measure of the requests that can be serviced in a fixed time is a more interesting metric. In this environment, the speed of the source and destination address spaces remains important, but the microarchitecture of the eDMA also factors significantly into the resulting metric.

The peak transfer rates for several different source and destination transfers are shown in [Table 327](#) and [Table 328](#). The following assumptions apply to those tables:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait-state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- All internal peripheral bus accesses are 32 bits in size.
- All internal SRAM accesses are 64 bits in size.

[Table 327](#) presents a peak transfer rate comparison, measured in megabytes per second.

Table 327. eDMA peak transfer rates (Mbyte/s)

System speed, width	From internal SRAM to internal SRAM	From 32-bit internal peripheral bus to internal SRAM	From internal SRAM to 32-bit internal peripheral bus
100 MHz, 64 bits	400.0	160.0	160.0
150 MHz, 64 bits	600.0	240.0	240.0
200 MHz, 64 bits	800.0	320.0	320.0

The second performance metric is a measure of the number of DMA requests that can be serviced in a given amount of time. For this metric, it is assumed the peripheral request causes the channel to move a single internal peripheral bus-mapped operand to/from internal SRAM. The same timing assumptions used in the previous example apply to this calculation. In particular, this metric also reflects the time required to activate the channel. The eDMA design supports the following hardware service request sequence:

- Cycle 1: eDMA peripheral request is asserted.
- Cycle 2: The eDMA peripheral request is registered locally in the eDMA module and qualified. (TCDn_CSR[START] bit initiated requests start at this point with the registering of the user write to TCDn Word 7).
- Cycle 3: Channel arbitration begins.
- Cycle 4: Channel arbitration completes. The transfer control descriptor local memory read is initiated.
- Cycles 5–6: The first two parts of the activated channel's TCD is read from the local memory. The memory width to the eDMA engine is 64 bits, so the entire descriptor can be accessed in four cycles.
- Cycle 7: The first system bus read cycle is initiated, as the third part of the channel's TCD is read from the local memory. Depending on the state of the crossbar switch, arbitration at the system bus may insert an additional cycle of delay here.
- Cycles 8 to x^(e): The last part of the TCD is read in. This cycle represents the first data phase for the read, and the address phase for the destination write.

The exact timing from this point is a function of the transfer size and response times for the channel's read and write accesses. In this case of two internal peripheral bus reads and a single 64-bit internal SRAM write, the combined data phase time is five cycles.

e. "x" represents an undefined cycle value dependant on transfer sizes and response times for the channel's read and write accesses.

For a single SRAM read and two 64-bit internal peripheral bus writes, the combined data phase time is five cycles.

- Cycle $x^{(e)} + 1$: This cycle represents the data phase of the last destination write.
- Cycle $x^{(e)} + 2$: The eDMA engine completes the execution of the inner minor loop and prepares to write back the required TCDn fields into the local memory. The TCDn Word 7 is read and checked for channel linking or scatter/gather requests.
- Cycle $x^{(e)} + 3$: The appropriate fields in the first part of the TCDn are written back into the local memory.
- Cycle $x^{(e)} + 4$: The fields in the second part of the TCDn are written back into the local memory. This cycle coincides with the next channel arbitration cycle start.
- Cycle $x^{(e)} + 5$: The next channel to be activated performs the read of the first part of its TCD from the local memory. This is equivalent to Cycle 4 for the first channel's service request.

Assuming zero wait states on the system bus, DMA requests can be processed every nine cycles. Assuming an average of the access times associated with internal peripheral bus-to-SRAM (three cycles) and SRAM-to-internal peripheral bus (three cycles), DMA requests can be processed every 10 cycles ($4 + (3 + 3)/2 + 3$). This is the time from Cycle 4 to Cycle $x + 5$. The resulting peak request rate, as a function of the system frequency, is shown in [Table 328](#). This metric represents millions of requests per second. A single read/write operation with same transfer size for the source and destination is assumed.

Table 328. eDMA peak request rate (MReq/s)

System frequency (MHz)	Request rate	
	zero wait states	with wait states
100.0	11.1	10.0
150.0	16.6	15.0
200.0	22.2	20.0

A general formula to compute the peak request rate (with overlapping requests) is:

Equation 1 $PEAKreq = freq / [entry + (1 + read_ws) + (1 + write_ws) + exit]$

where:

- PEAKreq = peak request rate
- freq = system frequency
- entry = channel startup (4 cycles)
- read_ws = wait states seen during the system bus read data phase
- write_ws = wait states seen during the system bus write data phase
- exit = channel shutdown (3 cycles)

For example: consider a system with the following characteristics:

- Internal SRAM can be accessed with zero wait states when viewed from the system bus data phase.
- All internal peripheral bus reads require one wait state, and internal peripheral bus writes one wait-state, again viewed from the system bus data phase.
- System operates at 150 MHz.

For an SRAM to internal peripheral bus transfer,

Equation 2 $\text{PEAKreq} = 150 \text{ MHz} / [4 + (1 + 0) + (1 + 1) + 3] \text{ cycles} = 15.0 \text{ Mreq/s}$

For an internal peripheral bus-to-SRAM transfer,

Equation 3 $\text{PEAKreq} = 150 \text{ MHz} / [4 + (1 + 1) + (1 + 0) + 3] \text{ cycles} = 15.0 \text{ Mreq/s}$

The minimum number of cycles to perform a single read/write, with zero wait states on the system bus, from a cold start (where no channel is executing and the eDMA is idle):

- 11 cycles for a software (TCDn_CSR[START] bit) request
- 12 cycles for a hardware (eDMA peripheral request signal) request

Two cycles account for the arbitration pipeline and one extra cycle on the hardware request resulting from the internal registering of the eDMA peripheral request signals. For the peak request rate calculations above, the arbitration and request registering are absorbed in or overlap the previous executing channel.

When channel linking or scatter/gather is enabled, a two cycle delay is imposed on the next channel selection and startup. This allows the link channel or the scatter/gather channel to be eligible and considered in the arbitration pool for next channel selection.

25.5 Initialization/application information

The following sections discuss initialization of the eDMA and programming considerations.

25.5.1 eDMA initialization

A typical initialization of the eDMA has the following sequence:

1. Write the CR register if a configuration other than the default is desired.
2. Write the channel priority levels into the DCHPRIn registers if a configuration other than the default is desired.
3. Enable error interrupts in the EEI registers if so desired.
4. Write the 32-byte TCD for each channel that may request service.
5. Enable any hardware service requests via the ERQ register.
6. Request channel service by software (setting the TCDn_CSR[START] bit) or hardware (slave device asserting its eDMA peripheral request signal).

After any channel requests service, a channel is selected for execution based on the arbitration and priority levels written into the programmer's model. The eDMA engine reads the entire TCD, including the TCD control and status fields (shown in [Table 329](#)) for the selected channel into its internal address path module. As the TCD is read, the first transfer is initiated on the internal bus unless a configuration error is detected. Transfers from the source (as defined by the source address, TCDn_SADDR) to the destination (as defined by

the destination address, TCDn_DADDR) continue until the specified number of bytes (TCDn_NBYTES) are transferred. When the transfer is complete, the eDMA engine's local TCDn_SADDR, TCDn_DADDR, and TCDn_CITER are written back to the main TCD memory and any minor loop channel linking is performed, if enabled. If the major loop is exhausted, further post processing executes (interrupts, major loop channel linking, and scatter/gather operations) if enabled.

Table 329. TCD control and status fields

TCDn_CSR field name	Description
START	Control bit to start channel explicitly when using a software initiated DMA service (automatically cleared by hardware)
ACTIVE	Status bit indicating the channel is currently in execution
DONE	Status bit indicating major loop completion (cleared by software when using a software initiated DMA service)
D_REQ	Control bit to disable DMA request at end of major loop completion when using a hardware initiated DMA service
BWC	Control bits for throttling bandwidth control of a channel
E_SG	Control bit to enable scatter-gather feature
INT_HALF	Control bit to enable interrupt when major loop is half complete
INT_MAJ	Control bit to enable interrupt when major loop completes

[Figure 251](#) shows how each DMA request initiates one minor-loop transfer (iteration) without CPU intervention. DMA arbitration can occur after each minor loop, and one level of minor loop DMA preemption is allowed. The number of minor loops in a major loop is specified by the beginning iteration count (BITER).

Figure 251. Example of multiple loop iterations

Figure 252 lists the memory array terms and how the TCD settings interrelate.

Figure 252. Memory array terms

25.5.2 DMA programming errors

The eDMA performs various tests on the transfer control descriptor to verify consistency in the descriptor data. Most programming errors are reported on a per-channel basis with the exception of two errors: group priority error (ES[GPE]) and channel priority error (ES[CPE]).

For all error types other than group or channel priority errors, the channel number causing the error is recorded in the ES register. If the error source is not removed before the next activation of the problem channel, the error is detected and recorded again.

Channel priority errors are identified within a group once that group has been selected as the active group. For example:

1. The eDMA is configured for fixed-group and fixed-channel arbitration modes.
2. Group 3 is the highest priority and all channels are unique in that group.
3. Group 2 is the next highest priority and has two channels with the same priority level.
4. If Group 3 has any service requests, those requests will be executed.
5. Once all of Group 3 requests have completed, Group 2 will be the next active group.
6. If Group 2 has a service request, then an undefined channel in Group 2 will be selected and a channel priority error will occur.
7. This repeats until all of the Group 2 requests have been removed or a higher priority Group 3 request comes in.

In this sequence, for item 2, the eDMA Acknowledge lines will assert only if the selected channel is requesting service via the eDMA peripheral request signal. If interrupts are enabled for all channels, the user will get an error interrupt, but the channel number for the ERR register and the error interrupt request line may be wrong because they reflect the

selected channel. A group priority error is global and any request in any group will cause a group priority error.

If priority levels are not unique, when any channel requests service, a channel priority error is reported. The highest (channel/group) priority with an active request is selected, but the lowest numbered (channel/group) with that priority is selected by arbitration and executed by the eDMA engine. The hardware service request handshake signals, error interrupts, and error reporting is associated with the selected channel.

25.5.3 DMA Arbitration mode considerations

This section discusses arbitration considerations for the eDMA.

25.5.3.1 Fixed-group arbitration, fixed-channel arbitration

In this mode, the channel service request from the highest priority channel in the highest priority group is selected to execute. If the eDMA is programmed so the channels within one group use “fixed” priorities, and that group is assigned the highest “fixed” priority of all groups, it is possible for that group to take all the bandwidth of the eDMA controller—that is, no other groups will be serviced if there is always at least one DMA request pending on a channel in the highest priority group when the controller arbitrates the next DMA request. The advantage of this scenario is that latency can be small for channels that need to be serviced quickly. Preemption is available in this scenario only.

25.5.3.2 Round-robin group arbitration, fixed-channel arbitration

The occurrence of one or more DMA requests from one or more groups, the channel with the highest priority from a specific group will be serviced first. Groups are serviced starting with the highest group number with a service request and rotating through to the lowest group number containing a service request.

Once the channel request is serviced, the group round-robin algorithm will select the highest pending request from the next group in the round-robin sequence. Servicing continues round-robin, always servicing the highest priority channel in the next group in the sequence, or just skipping a group if it has no pending requests.

If a channel requests service at a rate that equals or exceeds the round-robin service rate, then that channel will always be serviced before lower priority channels in the same group, and thus the lower priority channels will never be serviced. The advantage of this scenario is that no one group will consume all the eDMA bandwidth. The highest priority channel selection latency is potentially greater than fixed/fixed arbitration. Excessive request rates on high priority channels could prevent the servicing of lower priority channels in the same group.

25.5.3.3 Round-robin group arbitration, round-robin channel arbitration

Groups will be serviced as described in [Section 25.5.3.2, Round-robin group arbitration, fixed-channel arbitration](#), but this time channels will be serviced in channel number order. Only one channel is serviced from each requesting group for each round-robin pass through the groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to channel priority levels.

Because channels are serviced in round-robin manner, any channel that generates DMA requests faster than a combination of the group round-robin service rate and the channel

service rate for its group will not prevent the servicing of other channels in its group. Any DMA requests that are not serviced are simply lost, but at least one channel will be serviced.

This scenario ensures that all channels will be guaranteed service at some point, regardless of the request rates. However, the potential latency could be quite high. All channels are treated equally. Priority levels are not used in round-robin/round-robin mode.

25.5.3.4 Fixed-group arbitration, round-robin channel arbitration

The highest priority group with a request will be serviced. Lower priority groups will be serviced if no pending requests exist in the higher priority groups.

Within each group, channels are serviced starting with the highest channel number and rotating through to the lowest channel number without regard to the channel priority levels assigned within the group.

This scenario could cause the same bandwidth consumption problem as indicated in [Section 25.5.3.1, Fixed-group arbitration, fixed-channel arbitration](#) but all the channels in the highest priority group will get serviced. Service latency will be short on the highest priority group, but could potentially get very much longer and longer as the group priority decreases.

25.5.4 DMA transfer

This section discusses how to perform DMA transfers with the eDMA.

25.5.4.1 Single request

To perform a simple transfer of n bytes of data with one activation, set the major loop to one ($\text{TCDn_CITER} = \text{TCDn_BITER} = 1$). The data transfer begins after the channel service request is acknowledged and the channel is selected to execute. After the transfer is complete, the $\text{TCDn_CSR}[\text{DONE}]$ bit is set and an interrupt generates if properly enabled.

For example, the following TCD entry is configured to transfer 16 bytes of data. The eDMA is programmed for one iteration of the major loop, transferring 16 bytes per iteration. The source memory has a byte wide memory port located at 0x1000. The destination memory has a 32-bit-wide port located at 0x2000. The address offsets are programmed in increments to match the transfer size: one byte for the source and four bytes for the destination. The final source and destination addresses are adjusted to return to their beginning values.

```

TCDn_CITER = TCDn_BITER = 1
TCDn_NBYTES = 16
TCDn_SADDR = 0x1000
TCDn_SOFF = 1
TCDn_ATTR[SSIZE] = 0
TCDn_SLAST = -16
TCDn_DADDR = 0x2000
TCDn_DOFF = 4
TCDn_ATTR[DSIZE] = 2
TCDn_DLAST_SGA = -16
TCDn_CSR[INT_MAJ] = 1

```

```

TCDn_CSR[START] = 1 (Should be written last after all other fields have
been
    initialized)
All other TCDn fields = 0

```

This generates the following event sequence:

1. User write to the TCDn_CSR[START] bit requests channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: TCDn_CSR[DONE] = 0, TCDn_CSR[START] = 0, TCDn_CSR[ACTIVE] = 1.
4. eDMA engine reads: channel TCD data from local memory to internal register file.
5. The source-to-destination transfers are executed as follows:
 - a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
 - b) Write 32 bits to location 0x2000 → first iteration of the minor loop.
 - c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
 - d) Write 32 bits to location 0x2004 → second iteration of the minor loop.
 - e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
 - f) Write 32 bits to location 0x2008 → third iteration of the minor loop.
 - g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
 - h) Write 32 bits to location 0x200C → last iteration of the minor loop → major loop complete.
6. The eDMA engine writes: TCDn_SADDR = 0x1000, TCDn_DADDR = 0x2000, TCDn_CITER = 1 (TCDn_BITER).
7. The eDMA engine writes: TCDn_CSR[ACTIVE] = 0, TCDn_CSR[DONE] = 1, INT[n] = 1.
8. The channel retires and the eDMA goes idle or services the next channel.

25.5.4.2 Multiple requests

Besides transferring 32 bytes via two hardware requests, the next example is the same as previous. The only fields that change are the major loop iteration count and the final address offsets. The eDMA is programmed for two iterations of the major loop transferring 16 bytes per iteration. After the channel's hardware requests are enabled in the ERQ register, the slave device initiates channel service requests.

```

TCDn_CITER = TCDn_BITER = 2
TCDn_SLAST = -32
TCDn_DLAST_SGA = -32

```

This would generate the following sequence of events:

1. First hardware (eDMA peripheral) request for channel service.
2. The channel is selected by arbitration for servicing.
3. eDMA engine writes: $TCDn_CSR[DONE] = 0$, $TCDn_CSR[START] = 0$, $TCDn_CSR[ACTIVE] = 1$.
4. eDMA engine reads: channel $TCDn$ data from local memory to internal register file.
5. The source to destination transfers are executed as follows:
 - a) Read byte from location 0x1000, read byte from location 0x1001, read byte from 0x1002, read byte from 0x1003.
 - b) Write 32 bits to location 0x2000 → first iteration of the minor loop.
 - c) Read byte from location 0x1004, read byte from location 0x1005, read byte from 0x1006, read byte from 0x1007.
 - d) Write 32 bits to location 0x2004 → second iteration of the minor loop.
 - e) Read byte from location 0x1008, read byte from location 0x1009, read byte from 0x100A, read byte from 0x100B.
 - f) Write 32 bits to location 0x2008 → third iteration of the minor loop.
 - g) Read byte from location 0x100C, read byte from location 0x100D, read byte from 0x100E, read byte from 0x100F.
 - h) Write 32 bits to location 0x200C → last iteration of the minor loop.
6. eDMA engine writes: $TCDn_SADDR = 0x1010$, $TCDn_DADDR = 0x2010$, $TCDn_CITER = 1$.
7. eDMA engine writes: $TCDn_CSR[ACTIVE] = 0$.
8. The channel retires → one iteration of the major loop. The eDMA goes idle or services the next channel.
9. Second hardware (eDMA peripheral) requests channel service.
10. The channel is selected by arbitration for servicing.
11. eDMA engine writes: $TCDn_CSR[DONE] = 0$, $TCDn_CSR[START] = 0$, $TCDn_CSR[ACTIVE] = 1$.
12. eDMA engine reads: channel TCD data from local memory to internal register file.
13. The source to destination transfers are executed as follows:
 - a) Read byte from location 0x1010, read byte from location 0x1011, read byte from 0x1012, read byte from 0x1013.
 - b) Write 32 bits to location 0x2010 → first iteration of the minor loop.
 - c) Read byte from location 0x1014, read byte from location 0x1015, read byte from 0x1016, read byte from 0x1017.
 - d) Write 32 bits to location 0x2014 → second iteration of the minor loop.
 - e) Read byte from location 0x1018, read byte from location 0x1019, read byte from 0x101A, read byte from 0x101B.
 - f) Write 32 bits to location 0x2018 → third iteration of the minor loop.
 - g) Read byte from location 0x101C, read byte from location 0x101D, read byte from 0x101E, read byte from 0x101F.
 - h) Write 32 bits to location 0x201C → last iteration of the minor loop → major loop complete.
14. eDMA engine writes: $TCDn_SADDR = 0x1000$, $TCDn_DADDR = 0x2000$, $TCDn_CITER = 2(TCDn_BITER)$.
15. eDMA engine writes: $TCDn_CSR[ACTIVE] = 0$, $TCDn_CSR[DONE] = 1$, $INT[n] = 1$.

16. The channel retires → major loop complete. The eDMA goes idle or services the next channel.

25.5.4.3 Modulo feature

The modulo feature of the eDMA provides the ability to implement a circular data queue in which the size of the queue is a power of 2. MOD is a 5-bit field for the source and destination in the TCD, and it specifies which lower address bits increment from their original value after the address+offset calculation. All upper address bits remain the same as in the original value. A setting of 0 for this field disables the modulo feature.

[Table 330](#) shows how the transfer addresses are specified based on the setting of the MOD field. Here a circular buffer is created where the address wraps to the original value while the 28 upper address bits (0x1234567x) retain their original value. In this example the source address is set to 0x12345670, the offset is set to 4 bytes, and the MOD field is set to 4, allowing for a 16-byte size queue.

Table 330. Modulo feature example

Transfer number	Address
1	0x12345670
2	0x12345674
3	0x12345678
4	0x1234567C
5	0x12345670
6	0x12345674

25.5.5 eDMA TCD_n status monitoring

This section discusses how to monitor eDMA status.

25.5.5.1 Minor loop complete

There are two methods to test for minor loop completion when using software initiated service requests. The first is to read the TCD_n_CITER field and test for a change. Another method may be extracted from the sequence shown below. The second method is to test the TCD_n_CSR[START] bit and the TCD_n_CSR[ACTIVE] bit. The minor-loop-complete condition is indicated by both bits reading zero after the TCD_n_CSR[START] was set. Polling the TCD_n_CSR[ACTIVE] bit may be inconclusive, because the active status may be missed if the channel execution is short in duration.

The TCD status bits execute a sequence for a software activated channel as shown in the following table.

Table 331. TCD status sequence – software activated channel

Step	TCD _n _CSR bits			State
	START	ACTIVE	DONE	
1	1	0	0	Channel service request via software
2	0	1	0	Channel is executing

Table 331. TCD status sequence – software activated channel (continued)

Step	TCDn_CSR bits			State
	START	ACTIVE	DONE	
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

The best method to test for minor-loop completion when using hardware (peripheral) initiated service requests is to read the TCDn_CITER field and test for a change. The hardware request and acknowledge handshake signals are not visible in the programmer's model.

The TCD status bits execute a sequence for a hardware-activated channel as shown in the following table.

Table 332. TCD status sequence – hardware activated channel

Step	TCDn_CSR bits			State
	START	ACTIVE	DONE	
1	0	0	0	Channel service request via hardware (peripheral request asserted)
2	0	1	0	Channel is executing
3a	0	0	0	Channel has completed the minor loop and is idle
3b	0	0	1	Channel has completed the major loop and is idle

For both activation types, the major-loop-complete status is explicitly indicated via the TCDn_CSR[DONE] bit. The TCDn_CSR[START] bit is cleared automatically when the channel begins execution regardless of how the channel activates.

25.5.5.2 Active channel TCDn reads

The eDMA reads back the true TCDn_SADDR, TCDn_DADDR, and TCDn_NBYTES values if read while a channel executes. The true values of the SADDR, DADDR, and NBYTES are the values the eDMA engine currently uses in its internal register file and not the values in the TCD local memory for that channel. The addresses (SADDR and DADDR) and NBYTES (decrements to zero as the transfer progresses) can give an indication of the progress of the transfer. All other values are read back from the TCD local memory.

25.5.5.3 Preemption status

Preemption is available only when fixed arbitration is selected for both group and channel arbitration modes. A preemptive situation is one in which a preempt-enabled channel runs and a higher priority request becomes active. When the eDMA engine is not operating in Fixed-Group, Fixed-Channel Arbitration mode, the determination of the actively running relative priority outstanding requests become undefined. Channel and/or group priorities are treated as equal (constantly rotating) when Round-Robin Arbitration mode is selected.

The TCDn_CSR[ACTIVE] bit for the preempted channel remains asserted throughout the preemption. The preempted channel is temporarily suspended while the preempting channel executes one major loop iteration. If two TCDn_CSR[ACTIVE] bits are set

simultaneously in the global TCD map, a higher priority channel is actively preempting a lower priority channel.

25.5.6 Channel linking

Channel linking (or chaining) is a mechanism where one channel sets the TCD_n_CSR[START] bit of another channel (or itself), therefore initiating a service request for that channel. When properly enabled, the EDMA engine automatically performs this operation at the major or minor loop completion.

The minor loop channel linking occurs at the completion of the minor loop (or one iteration of the major loop). The TCD_n_CITER[E_LINK] field determines whether a minor loop link is requested. When enabled, the channel link is made after each iteration of the major loop except for the last. When the major loop is exhausted, only the major loop channel link fields are used to determine if a channel link should be made. For example, the initial fields of:

```
TCDn_CITER[E_LINK] = 1
TCDn_CITER[LINKCH] = 0xC
TCDn_CITER[CITER] value = 0x4
TCDn_CSR[MAJOR_E_LINK] = 1
TCDn_CSR[MAJOR_LINKCH] = 0x7
```

executes as:

1. Minor loop done → set TCD12_CSR[START] bit
2. Minor loop done → set TCD12_CSR[START] bit
3. Minor loop done → set TCD12_CSR[START] bit
4. Minor loop done, major loop done → set TCD7_CSR[START] bit

When minor loop linking is enabled (TCD_n_CITER[E_LINK] = 1), the TCD_n_CITER[CITER] field uses a 9-bit vector to form the current iteration count. When minor loop linking is disabled (TCD_n_CITER[E_LINK] = 0), the TCD_n_CITER[CITER] field uses a 15-bit vector to form the current iteration count. The bits associated with the TCD_n_CITER[LINKCH] field are concatenated onto the CITER value to increase the range of the CITER.

Note: *The TCD_n_CITER[E_LINK] bit and the TCD_n_BITER[E_LINK] bit must equal or a configuration error is reported. The CITER and BITER vector widths must be equal to calculate the major loop, half-way done interrupt point.*

[Table 333](#) summarizes how a DMA channel can link to another DMA channel (that is, how it can use another channel's TCD) at the end of a loop.

Table 333. Channel linking parameters

Desired link behavior	TCD control field name	Description
Link at end of minor loop	CITER[E_LINK]	Enable channel-to-channel linking on minor loop completion (current iteration)
	CITER[LINKCH] Link channel number when linking at end of minor loop (current iteration)	

Table 333. Channel linking parameters (continued)

Desired link behavior	TCD control field name	Description
Link at end of major loop	CSR[MAJOR_E_LINK]	Enable channel-to-channel linking on major loop completion
	CSR[MAJOR_LINKCH] Link channel number when linking at end of major loop	

25.5.7 Dynamic programming

25.5.7.1 Dynamic priority changing

The following two options are recommended for dynamically changing channel priority levels:

1. Switch to Round-Robin Channel Arbitration mode, change the channel priorities, then switch back to Fixed Arbitration mode.
2. Disable all the channels within a group, then change the channel priorities within that group only, then enable the appropriate channels.

The following two options are available for dynamically changing group priority levels:

1. Switch to Round-Robin Group Arbitration mode, change the group priorities, then switch back to Fixed Arbitration mode.
2. Disable all channels, change the group priorities, then enable the appropriate channels.

25.5.7.2 Dynamic channel linking

Dynamic channel linking is the process of setting the TCD.major.e_link bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic channel link by enabling the TCD.major.e_link bit at the same time the eDMA engine is retiring the channel. The TCD.major.e_link would be set in the programmer's model, but it would be unclear whether the actual link was made before the channel retired.

The coherency model in [Table 334](#) is recommended when executing a dynamic channel link request.

Table 334. Coherency model for a dynamic channel link request

Step	Action
1	Write 1b to the TCD.major.e_link bit.
2	Read back the TCD.major.e_link bit.
3	Test the TCD.major.e_link request status: – If TCD.major.e_link = 1b, the dynamic link attempt was successful. – If TCD.major.e_link = 0b, the attempted dynamic link did not succeed (the channel was already retiring).

For this request, the TCD local memory controller forces the TCD.major.e_link bit to zero on any writes to a channel's TCD.word7 after that channel's TCD.done bit is set, indicating the major loop is complete.

Note: *The user must clear the TCD.done bit before writing the TCD.major.e_link bit. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.*

25.5.7.3 Dynamic scatter/gather

Dynamic scatter/gather is the process of setting the TCD.e_sg bit during channel execution. This bit is read from the TCD local memory at the end of channel execution, thus allowing the user to enable the feature during channel execution.

Because the user is allowed to change the configuration during execution, a coherency model is needed. Consider the scenario where the user attempts to execute a dynamic scatter/gather operation by enabling the TCD.e_sg bit at the same time the eDMA engine is retiring the channel. The TCD.e_sg would be set in the programmer's model, but it would be unclear whether the actual scatter/gather request was honored before the channel retired.

Two methods for this coherency model are shown in the following subsections. Method 1 has the advantage of reading the major.linkch field and the e_sg bit with a single read. For both dynamic channel linking and scatter/gather requests, the TCD local memory controller forces the TCD.major.e_link and TCD.e_sg bits to zero on any writes to a channel's TCD.word7 if that channel's TCD.done bit is set indicating the major loop is complete.

Note: *The user must clear the TCD.done bit before writing the TCD.major.e_link or TCD.e_sg bits. The TCD.done bit is cleared automatically by the eDMA engine after a channel begins execution.*

25.5.7.3.1 Method 1 (channel not using major loop channel linking)

For a channel not using major loop channel linking, the coherency model in [Table 335](#) may be used for a dynamic scatter/gather request.

When the TCD.major.e_link bit is zero, the TCD.major.linkch field is not used by the eDMA. In this case, the TCD.major.linkch bits may be used for other purposes. This method uses the TCD.major.linkch field as a TCD identification (ID).

Table 335. Coherency model for method 1

Step	Action
1	When the descriptors are built, write a unique TCD ID in the TCD.major.linkch field for each TCD associated with a channel using dynamic scatter/gather.
2	Write 1b to the TCD.d_req bit. <i>Note: Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.</i>
3	Write the TCD.dlast_sga field with the scatter/gather address.
4	Write 1b to the TCD.e_sg bit.

Table 335. Coherency model for method 1 (continued)

Step	Action
5	Read back the 16 bit TCD control/status field.
6	Test the TCD.e_sg request status and TCD.major.linkch value: – If e_sg = 1b, the dynamic link attempt was successful. – If e_sg = 0b and the major.linkch (ID) did not change, the attempted dynamic link did not succeed (the channel was already retiring). – If e_sg = 0b and the major.linkch (ID) changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

25.5.7.3.2 Method 2 (channel using major loop linking)

For a channel using major loop channel linking, the coherency model in [Table 336](#) may be used for a dynamic scatter/gather request. This method uses the TCD.dlast_sga field as a TCD identification (ID).

Table 336. Coherency model for method 2

Step	Action
1	Write 1b to the TCD.d_req bit. <i>Note: Should a dynamic scatter/gather attempt fail, setting the d_req bit will prevent a future hardware activation of this channel. This stops the channel from executing with a destination address (daddr) that was calculated using a scatter/gather address (written in the next step) instead of a dlast final offset value.</i>
2	Write the TCD.dlast_sga field with the scatter/gather address.
3	Write 1b to the TCD.e_sg bit.
4	Read back the TCD.e_sg bit.
5	Test the TCD.e_sg request status: – If e_sg = 1b, the dynamic link attempt was successful. – If e_sg = 0b, read the 32 bit TCD dlast_sga field. – If e_sg = 0b and the dlast_sga did not change, the attempted dynamic link did not succeed (the channel was already retiring). – If e_sg = 0b and the dlast_sga changed, the dynamic link attempt was successful (the new TCD's e_sg value cleared the e_sg bit).

26 DMACHMUX

26.1 Introduction

26.1.1 Overview

The DMA Mux allows to route 64 DMA peripheral sources (called slots) to 16 DMA channels. This is illustrated in [Figure 253](#).

Figure 253. DMA Mux Block Diagram

26.1.2 Features

The DMA Channel Mux provides these features:

- 64 peripheral slots + 5 always-on slots can be routed to 16 channels
- 16 independently selectable DMA channels routers
 - the first 5 channels additionally provide a trigger functionality
- Each channel router can be assigned to one of 64 possible peripheral DMA slots or to one of the 5 always-on slots.

26.1.3 Modes of Operation

The following operation modes are available:

- **Disabled Mode**
In this mode, the DMA channel is disabled. Since disabling and enabling of DMA channels is done primarily via the DMA configuration registers, this mode is used mainly as the reset state for a DMA channel in the DMA Channel Mux. It may also be used to temporarily suspend a DMA channel while reconfiguration of the system takes place (e.g. changing the period of a DMA trigger).
- **Normal Mode**
In this mode, a DMA source (such as DSPI transmit or DSPI receive for example) is routed directly to the specified DMA channel. The operation of the DMA Mux in this mode is completely transparent to the system.
- **Periodic Trigger Mode**
In this mode, a DMA source may only request a DMA transfer (such as when a transmit buffer becomes empty or a receive buffer becomes full) periodically. Configuration of the period is done in the registers of the Periodic Interrupt Timer (PIT). This mode is only available for channels 0-5.

26.2 External Signal Description

26.2.1 Overview

The DMA Mux has no external pins.

26.3 Memory Map and Register Definition

This section provides a detailed description of all memory-mapped registers in the DMA Mux.

[Table 337](#) shows the memory map for the DMA Mux. Note that all addresses are offsets; the absolute address may be computed by adding the specified offset to the base address of the DMA Mux.

Table 337. Module memory map

Address	Use	Access
Base + \$0x00	Channel #0 Configuration (CHCONFIG0)	R/W
Base + \$0x01	Channel #1 Configuration (CHCONFIG1)	R/W
..	..	..
Base + #n-1	Channel #n Configuration (CHCONFIG#n-1) ⁽¹⁾	R/W

1. In the table *n* refers to the *number of channels - 1*

All registers are accessible via 8-bit, 16-bit or 32-bit accesses. However, 16-bit accesses must be aligned to 16-bit boundaries, and 32-bit accesses must be aligned to 32-bit boundaries. As an example, CHCONFIG0 through CHCONFIG3 are accessible by a 32-bit

READ/WRITE to address 'Base + 0x00', but performing a 32-bit access to address 'Base + 0x01' is illegal.

26.3.1 Register Descriptions

The following memory-mapped registers are available in the DMA Channel Mux.

26.3.1.1 Channel Configuration Registers

Each of the DMA channels can be independently enabled/disabled and associated with one of the DMA slots (peripheral slots or always-on slots) in the system.

Figure 254. Channel Configuration Registers (CHCONFIG#n)

Table 338. CHCONFIGxx Field Descriptions

Field	Description
ENBL	DMA Channel Enable. ENBL enables the DMA Channel 0 DMA channel is disabled. This mode is primarily used during configuration of the DMA Mux. The DMA has separate channel enables/disables, which should be used to disable or re-configure a DMA channel. 1 DMA channel is enabled
TRIG	DMA Channel Trigger Enable (for triggered channels only). TRIG enables the periodic trigger capability for the DMA Channel 0 Triggering is disabled. If triggering is disabled, and the ENBL bit is set, the DMA Channel will simply route the specified source to the DMA channel. 1 Triggering is enabled.
SOURCE	DMA Channel Source (slot). SOURCE specifies which DMA source, if any, is routed to a particular DMA channel. Please check your SoC-Guide for further details about the peripherals and their slot numbers.

Table 339. Channel and Trigger Enabling

ENBL	TRIG	Function	Mode
0	X	DMA Channel is disabled	Disabled Mode
1	0	DMA Channel is enabled with no triggering (transparent)	Normal Mode
1	1	DMA Channel is enabled with triggering	Periodic Trigger Mode

Note: Setting multiple CHCONFIG registers with the same Source value will result in unpredictable behavior.

Note: Before changing the trigger or source settings a DMA channel must be disabled via the CHCONFIG[#n].ENBL bit.

26.4 Functional description

This section provides a functional description of the DMA Mux. The primary purpose of the DMA Mux is to provide flexibility in the system's use of the available DMA channels. As such, configuration of the DMA Mux is intended to be a static procedure done during execution of the system boot code. However, if the procedure outlined in [Section 26.5.2, "Enabling and Configuring Sources"](#) is followed, the configuration of the DMA MUX may be changed during the normal operation of the system.

Functionally, the DMA Mux channels may be divided into two classes: Channels, which implement the normal routing functionality plus periodic triggering capability, and channels, which implement only the normal routing functionality.

26.4.1 DMA channels with periodic triggering capability

Besides the normal routing functionality, the first 5 channels of the DMA Mux provide a special periodic triggering capability that can be used to provide an automatic mechanism to transmit bytes, frames or packets at fixed intervals without the need for processor intervention. The trigger is generated by the Periodic Interrupt Timer (PIT); as such, the configuration of the periodic triggering interval is done via configuration registers in the PIT. Please refer to the Periodic Interrupt Timer chapter for more information on this topic.

Note: Because of the dynamic nature of the system (i.e. DMA channel priorities, bus arbitration, interrupt service routine lengths, etc.), the number of clock cycles between a trigger and the actual DMA transfer cannot be guaranteed.

Figure 255. DMA Mux triggered channels

The DMA channel triggering capability allows the system to schedule regular DMA transfers, usually on the transmit side of certain peripherals, without the intervention of the processor. This trigger works by gating the request from the Peripheral to the DMA until a trigger event has been seen. This is illustrated in [Figure 256](#).

Figure 256. DMA Mux Channel Triggering: Normal Operation

Once the DMA request has been serviced, the peripheral will negate its request, effectively resetting the gating mechanism until the peripheral re-asserts its request AND the next trigger event is seen. This means that if a trigger is seen, but the peripheral is not requesting a transfer, that trigger will be ignored. This situation is illustrated in [Figure 257](#).

Figure 257. DMA Mux Channel Triggering: Ignored Trigger

This triggering capability may be used with any peripheral that supports DMA transfers, and is most useful for two types of situations:

- Periodically polling external devices on a particular bus. As an example, the transmit side of an SPI is assigned to a DMA channel with a trigger, as described above. Once setup, the SPI will request DMA transfers (presumably from memory) as long as its transmit buffer is empty. By using a trigger on this channel, the SPI transfers can be automatically performed every 5μs (as an example). On the receive side of the SPI, the SPI and DMA can be configured to transfer receive data into memory, effectively implementing a method to periodically read data from external devices and transfer the results into memory without processor intervention.
- Using the GPIO Ports to drive or sample waveforms. By configuring the DMA to transfer data to one or more GPIO ports, it is possible to create complex waveforms using tabular data stored in on-chip memory. Conversely, using the DMA to periodically transfer data from one or more GPIO ports, it is possible to sample complex waveforms and store the results in tabular form in on-chip memory.

A more detailed description of the capability of each trigger (i.e.-resolution, range of values, etc.) may be found in the Periodic Interrupt Timer (PIT) chapter.

26.4.2 DMA Channels with no triggering capability

The other channels of the DMA Mux provide the normal routing functionality as described in [Section 26.1.3, “Modes of Operation.”](#)

26.4.3 “Always Enabled” DMA Sources

In addition to the peripherals that can be used as DMA sources, there are 5 additional DMA sources that are “always enabled”. Unlike the peripheral DMA sources, where the peripheral controls the flow of data during DMA transfers, the “always enabled” sources provide no such “throttling” of the data transfers. These sources are most useful in the following cases:

- Doing DMA transfers to/from GPIO - Moving data from/to one or more GPIO pins, either un-throttled (i.e.-as fast as possible), or periodically (using the DMA triggering capability).
- Doing DMA transfers from memory to memory - Moving data from memory to memory, typically as fast as possible, sometimes with software activation.
- Doing DMA transfers from memory to the external bus (or vice-versa) - Similar to memory to memory transfers, this is typically done as quickly as possible.
- Any DMA transfer that requires software activation - Any DMA transfer that should be explicitly started by software.

In cases where software should initiate the start of a DMA transfer, a “always enabled” DMA source can be used to provide maximum flexibility. When activating a DMA channel via software, subsequent executions of the minor loop require a new “start” event be sent. This can either be a new software activation, or a transfer request from the DMA Channel Mux. The options for doing this are:

- Transfer all data in a single minor loop. By configuring the DMA to transfer all of the data in a single minor loop (i.e.-major loop counter = 1), no re-activation of the channel is necessary. The disadvantage to this option is the reduced granularity in determining the load that the DMA transfer will incur on the system. For this option, the DMA channel should be disabled in the DMA Channel Mux.
- Use explicit software re-activation. In this option, the DMA is configured to transfer the data using both minor and major loops, but the processor is required to re-activate the channel (by writing to the DMA registers) *after every minor loop*. For this option, the DMA channel should be disabled in the DMA Channel Mux.
- Use a “always enabled” DMA source. In this option, the DMA is configured to transfer the data using both minor and major loops, and the DMA Channel Mux does the channel re-activation. For this option, the DMA channel should be enabled and pointing to an “always enabled” source. Note that the re-activation of the channel can be continuous (DMA triggering is disabled) or can use the DMA triggering capability. In this manner, it is possible to execute periodic transfers of packets of data from one source to another, without processor intervention.

26.5 Initialization/Application Information

26.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (See [Section 26.3.1, “Register Descriptions”](#)). In summary, after reset, all channels are disabled and must be explicitly enabled before use.

26.5.2 Enabling and Configuring Sources

Enabling a source with periodic triggering

1. Determine with which DMA channel the source will be associated. Note that only the first 5 DMA channels have periodic triggering capability.
2. Clear the ENBL and TRIG bits of the DMA channel
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point
4. Configure the corresponding timer
5. Select the source to be routed to the DMA channel. Write to the corresponding CHCONFIG register, ensuring that the ENBL and TRIG bits are set

Example 1 Configure source #5 Transmit for use with DMA Channel 2, with periodic triggering capability

1. Write 0x00 to CHCONFIG2 (Base Address + 0x02)
2. Configure Channel 2 in the DMA, including enabling the channel
3. Configure a timer for the desired trigger interval
4. Write 0xC5 to CHCONFIG2 (Base Address + 0x02)

The following code example illustrates steps #1 and #4 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR      0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCONFIG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCONFIG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCONFIG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCONFIG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCONFIG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCONFIG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCONFIG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCONFIG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCONFIG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCONFIG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCONFIG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCONFIG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCONFIG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCONFIG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCONFIG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCONFIG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

```
In File main.c:
#include "registers.h"

:
:
*CHCONFIG2 = 0x00;
*CHCONFIG2 = 0xC5;
```

Enabling a source without periodic triggering

1. Determine with which DMA channel the source will be associated. Note that only the first 5 DMA channels have periodic triggering capability.
2. Clear the ENBL and TRIG bits of the DMA channel
3. Ensure that the DMA channel is properly configured in the DMA. The DMA channel may be enabled at this point
4. Select the source to be routed to the DMA channel. Write to the corresponding CHCONFIG register, ensuring that the ENBL is set and the TRIG bit is cleared

Example 2 Configure source #5 Transmit for use with DMA Channel 2, with no periodic triggering capability.

1. Write 0x00 to CHCONFIG2 (Base Address + 0x02)
2. Configure Channel 2 in the DMA, including enabling the channel
3. Write 0x85 to CHCONFIG2 (Base Address + 0x02)

The following code example illustrates steps #1 and #3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR      0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCONFIG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCONFIG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCONFIG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCONFIG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCONFIG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCONFIG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCONFIG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
volatile unsigned char *CHCONFIG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCONFIG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCONFIG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCONFIG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCONFIG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCONFIG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCONFIG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCONFIG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
```

```
volatile unsigned char *CHCONFIG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c**:

```
#include "registers.h"

:

:

*CHCONFIG2 = 0x00;
*CHCONFIG2 = 0x85;
```

Disabling a source

A particular DMA source may be disabled by not writing the corresponding source value into any of the CHCONFIG registers. Additionally, some module specific configuration may be necessary. Please refer to the appropriate section for more details.

Switching the source of a DMA Channel

1. Disable the DMA channel in the DMA and re-configure the channel for the new source
2. Clear the ENBL and TRIG bits of the DMA channel
3. Select the source to be routed to the DMA channel. Write to the corresponding CHCONFIG register, ensuring that the ENBL and TRIG bits are set

Example 3 Switch DMA Channel 8 from source #5 transmit to source #7 transmit

1. In the DMA configuration registers, disable DMA channel 8 and re-configure it to handle the transfers to peripheral slot 7. This example assumes channel 8 doesn't have triggering capability.
2. Write 0x00 to CHCONFIG8 (Base Address + 0x08)
3. Write 0x87 to CHCONFIG8 (Base Address + 0x08). (In this example, setting the TRIG bit would have no effect, due to the assumption that channels 8 does not support the periodic triggering functionality).

The following code example illustrates steps #2 and #3 above:

```
In File registers.h:
#define DMAMUX_BASE_ADDR      0xFC084000/* Example only ! */
/* Following example assumes char is 8-bits */
volatile unsigned char *CHCONFIG0 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0000);
volatile unsigned char *CHCONFIG1 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0001);
volatile unsigned char *CHCONFIG2 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0002);
volatile unsigned char *CHCONFIG3 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0003);
volatile unsigned char *CHCONFIG4 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0004);
volatile unsigned char *CHCONFIG5 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0005);
volatile unsigned char *CHCONFIG6 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0006);
```

```
volatile unsigned char *CHCONFIG7 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0007);
volatile unsigned char *CHCONFIG8 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0008);
volatile unsigned char *CHCONFIG9 = (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x0009);
volatile unsigned char *CHCONFIG10= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000A);
volatile unsigned char *CHCONFIG11= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000B);
volatile unsigned char *CHCONFIG12= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000C);
volatile unsigned char *CHCONFIG13= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000D);
volatile unsigned char *CHCONFIG14= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000E);
volatile unsigned char *CHCONFIG15= (volatile unsigned char *)
(DMAMUX_BASE_ADDR+0x000F);
```

In File **main.c**:

```
#include "registers.h"
:
:
*CHCONFIG8 = 0x00;
*CHCONFIG8 = 0x87;
```

27 Clocking

27.1 Introduction

This chapter describes the architecture for the system level clocks and includes the following information:

- System clock specifics
- Clock architecture
- Clock sources
- Clock monitoring
- Programmable clock dividers
- Clock control registers

Note: *.This chapter covers only clocks that are generated on the device. Protocol clocks that are provided by external devices are covered in the respective chapters where they are used.*

The system clock (CLKOUT) for the computational shell (which includes the three main CPUs (Main Core_1, Main Core_0, Checker Core_0s) as well as all modules that run in the high speed domain), memories, and debug logic is independent from the peripheral clocks. This allows CLKOUT to be a frequency modulated clock to reduce electromagnetic emissions, while having a precise clock for the peripheral timer and communication functions. It also allows the system clock to be reduced during low computational activity periods to help reduce power consumption, while providing a fixed frequency to the communication interfaces and timers.

This device boots from the internal 16 MHz RC oscillator (IRCOSC), and uses this as a backup clock in the event of a PLL or oscillator failure (if backup clock is enabled). The backup clock can be enabled in the Mode Entry Module (MC_ME). See the “Mode Entry Module (MC_ME)” chapter for details.

There are three possible ways to provide the source clock:

- External oscillator
- External crystal
- Internal 16 MHz RC oscillator

From one of these input sources, the internal clocks are generated from one of the two PLLs, PLL0 and PLL1, using PLL0_PHI and PLL1_PHI outputs, respectively. These two clocks, along with the XOSC and IRCOSC, can be selected to drive system peripherals depending on the configuration of the Auxiliary Clock Selectors in the \ Module (MC_CGM). The PHI1 output of PLL0 can also be used as the clock source for PLL1. Eleven Auxiliary Clock Selectors are utilized, allowing developers to select an independent clock source for each of the system peripherals. There is one additional clock selector that is used exclusively for the system clock.

Each of the outputs of the module clock selectors have individual dividers that allow for more clock frequency granularity with the ability to divide the clock selector outputs by up to 512 for a given peripheral. Clock Monitor Units (CMUs) are connected to outputs of clock dividers as shown in [Figure 258 \(Clock generation \(part 1 of 2\)\)](#) to verify that their clock frequencies stay within necessary operating limits. The action taken when a CMU detects an issue with the monitored clock depends on the CMU configuration. When an issue with a clock is found, the CMUs can signal an interrupt or initiate a system reset.

27.2 Clock generation

The top-level clock generation architecture can be seen in [Figure 258](#). See the Clock Generation Module (MC_CGM) chapter for details on the Fractional Clock Dividers. All clock selectors and dividers are located and programmed in the MC_CGM, with the exception of the Hardware Security Module (HSM) clock divider. All dividers are integer dividers (1, 2, 3, ..., n) with the ranges shown in the divider blocks in [Figure 258](#). All dividers connected to the System Clock Selector must have 50% duty cycle outputs.

Note: CMU1...CMU10 in [Figure 258](#) use IRCOSC for their reference clock. However, the user can select either IRCOSC or XOSC for the reference in CMU0.

Figure 258. Clock generation (part 1 of 2)

Note: All dividers shown in the diagram are integer dividers with a range of 1, 2, 3,..., n.

FCD are fractional clock dividers.

All clock dividers are 50% duty cycle.

1. See [Figure 263](#) for Ethernet clocking details
2. See [Figure 262](#) for LFAST clocking details
3. See the "Password and Device Security Module (PASS)" chapter for Jitter Enable details.
4. The COMP_CLK and CHKR_CLK clock trees are isolated downstream of System Clock Divider 0. Isolation is maintained in the physical design of the clock trees.
5. DSPI_CLK1 and DSPI_CLK0 are the protocol clocks as described in the "Deserial Serial Peripheral Interface (DSPI)" chapter.
6. See the MC_CGM chapter for details of the Fractional Clock Divider (FCD).

Figure 259. Clock generation (part 2 of 2)

27.2.1 MC_CGM registers

Table 340 shows the relationship between the clocks in Figure 258 and the MC_CGM registers.

Table 340. MC_CGM relationship to clocks⁽¹⁾

2. CMU_0 not shown in table since it does not monitor an output clock from the MC_CGM.

27.3 System clock frequency limitations

The maximum frequency of operation for the device system level clocks is given in [Table 342](#).

Note: The output of the system clock selector mux has a maximum frequency of 200 MHz

Table 341. Maximum system level clock frequencies^{(1),(2)}

Clock Selector	Nominal programmed Max output frequency for input to dividers	Divider	Divider logic	Nominal programmed divider max output frequency (MHz)
System clock selector ⁽³⁾	200	0	CMU_1 IOP core FXBAR Core_0 Core_0s Core_1	200

Aux Clock 10 Selector	400	0	FEC_REF_CLK	50
—	—	—	FEC_TXCLK	25
—	—	—	FEC_RXCLK	25

1. The user is responsible to verify that these values are not exceeded.
2. See [Figure 258](#) for clocking architecture overview.
3. System clock selection is a component of the device run mode switching process. See the Mode Entry Module (ME_ME) chapter for details.
4. Each peripheral bridge (PBRIDGE_A, PBRIDGE_B) is capable of clocking the bus interface of each peripheral slot individually at the slow XBAR frequency, or at the slow XBAR frequency divided by two. The GTM is clocked at the slow XBAR frequency, and all other peripherals on both AIPS bridges are clocked at the slow XBAR frequency divided by two.

In order to maintain synchronization between the different system clock branches (for example, SYS_CLK output from the System Clock Selector), there are limitations on the frequencies of those clocks. The system clocks must be binary multiples of each other with the frequency relationships described in the electrical specifications.

27.3.1 JTAG frequencies

[Table 343](#) shows the maximum frequencies of the JTAG interface.

Table 343. JTAG frequencies

Device	Configuration	e200z4 max. internal JTAG frequency	Buddy device max. RWA internal frequency	Max. external JTAG frequency	Notes
PD ⁽¹⁾	Unconfigured clock	—	N/A		Assumes 16 MHz clock on PD (IRC) with +/- 1.5% tolerance, and JTAG usable at 1/2 CPU frequency
	Clock configured to 200 MHz	100 MHz			JTAG usable at 1/2 CPU frequency
ED ⁽²⁾	BD only powered	N/A	22.4 MHz	See electrical characteristics for maximum usable external JTAG frequency	BD clocked by internal 64 MHz RC clock (RCOSC64) with +/- 30% tolerance and BD RWA usable at 1/2 frequency
	PD and BD powered, unconfigured clock	—	—		ED clocked by internal 8 MHz RC clock (IRC) with +/- 1.5% tolerance, and BD RWA usable at 1/2 frequency
	PD and BD powered, PD clock configured clock to 200 MHz	100 MHz	100 MHz		100 MHz JTAG achievable using LFAST mode debug, or s/w mode JTAGM. JTAG messages are generated internally by JTAGM and stay within BD and PD domain. The external tool interface is LFAST only

1. PD = Production Die

2. ED = Emulation and Debug Device = Production Die + Buddy Die

27.4 Default clock configuration

At power up, the IRCOSC is the default clock for the entire system. All system clock dividers are set to '1' at power on reset, except for the HSM, which is set to its maximum value.

27.5 Clock sources

The following clock sources are described in this section:

- PLL0
- PLL1 (FMPLL)
- External oscillator (XOSC)
- External clock (EXTAL bypass)
- 16 MHz internal RC oscillator (IRCOSC)

27.5.1 PLL

The PLL is a dual-PLL providing separate system and peripheral clocks as shown in [Figure 258](#). The PLLs are disabled after power is cycled and must be enabled by software. The block diagram for the Dual PLL is shown in [Figure 260](#).

Figure 260. SPC57EM80xx Dual PLL digital interface block diagram

27.5.1.1 PLL0 — base PLL (non-FM)

PLL0 is the primary PLL. This PLL provides a non-Frequency Modulated clock to the peripheral IPs and the reference clock to PLL1.

27.5.1.1.1 PLL0 input clocks

The input clock sources for PLL0 are the XOSC, IRCOSC, and external reference clock. The external reference clock is input on the EXTAL pin.

27.5.1.1.2 PLL0 output clocks

The output clocks from PLL0 are PHI and PHI1. The PHI output clock drives the peripheral clock and the system clock when PLL1 is not locked or active. The PHI1 output clock provides the input reference clock for PLL1.

27.5.1.2 PLL1 — FMPLL

PLL1 is a Frequency Modulated PLL (FMPLL) that is used to drive the system clock.

27.5.1.2.1 PLL1 input clocks

The input clocks to PLL1 are the PHI1 output clock from PLL0 and the external reference clock.

27.5.1.2.2 PLL1 output clocks

The output clock from PLL1 is the PHI clock, which drives the system clock. The PHI output clock contains a fractional divider that can be applied to the loop divide of the PLL to achieve good granularity in the PLL1 PHI output clock frequency.

27.5.1.2.3 PLL register interface

This device has a single digital interface for the dual PLLs. The digital interface provides register control of all features of the PLLs. Details are provided in the “Dual PLL Digital Interface” chapter.

27.5.1.2.4 PLL register write protection

The PLL registers with write protection are defined in [Table 344](#). The protected registers have write protection with both soft and hard locking. A soft lock can be unlocked by software after being previously locked. A hard lock is only unlocked by a reset once locked. The REG_PROT module is used to implement the PLL register write protection.

Table 344. PLL register write protection⁽¹⁾

Offset	Register	Protection
00h	PLL0 Control Register (PLL0CR)	Yes
04h	PLL0 Status Register (PLL0SR)	No
08h	PLL0 Divider Register (PLL0DIVR)	Yes
20h	PLL1 Control Register (PLL1CR)	Yes
24h	PLL1 Status Register (PLL1SR)	No
28h	PLL1 Divider Register (PLL1DIVR)	Yes
2Ch	PLL1 Frequency Modulation Register (PLL1FMR)	Yes
30h	PLL1 Fractional Divider Register (PLL1FDR)	Yes

1. See Register Protection Configuration chapter for bit field details.

27.5.1.3 PLL register reset values

All reset values for the PLLDIG registers that are device specific are shown in [Table 345](#). All other register reset values are shown in the Dual PLL Digital Interface chapter.

Table 345. Dual PLL Digital Interface register reset values

Offset (hex)	Register	Reset value (hex)
0008	PLL0DV — PLL0 Divider Register	0000_0000
0028	PLL1DV — PLL1 Divider Register	0000_0000

27.5.1.4 Loss of clock detection

Loss of clock detection should be enabled at all times when the PLLs are enabled. There is a software option to generate a reset or interrupt in the event of a loss of clock condition. An optional backup clock is implemented within the PLL that software may enable or disable.

27.5.2 External oscillator (XOSC)

The external oscillator (XOSC) is provided as a reference for the on-chip PLLs. It can also be used as a clock source to the ADCs, timer, serial interfaces, RTI, LFAST, and as a system clock source. It is available for observation on either of the CLKOUT pins, and is used as a reference to calibrate the IRCOSC frequency.

The external oscillator allows a crystal or external clock to be used as the reference clock for the microcontroller. The XOSC has the following features:

- Internal load capacitors for 20 MHz/40 MHz crystal oscillators
- Automatic Loop Control (ALC) to remove need for external series resistor
- Gain selection for ≤ 20 MHz and 40 MHz crystals to allow for optimal startup margin without overdrive issues
- Reference clock to PLL0
- Reference clock to CMU0 (IRCOSC trimming)
- Option to drive the CAN and FlexRay protocol clocks directly from the XOSC

The XOSC provides support for 8 – 44 MHz crystal inputs, has integrated load capacitors and ALC to remove the need for external series resistor.

27.5.2.1 XOSC Start-up

Enabling of the oscillator at startup is determined by a bit in the UTEST row of flash memory (UTEST DCF Miscellaneous row, bit 7). The default value has the XOSC disabled (UTEST Misc bit 7 = 0 (XOSC EN)).

If enabled, the oscillator is started in phase 3 of the reset sequence, after negation of the internal POR circuits, but while the external PORST input is asserted. This is done to allow fast application start-up time while accounting for settling time of the power regulators.

The selection of internal or external load capacitors on the XTAL/EXTAL pins is also determined by a bit in the UTEST row of flash memory. The default value is external load capacitors (UTEST Misc bit 6 = 1 (XOSC EXT LOAD)). Load capacitor values are determined by the crystal manufacturer data sheet requirements, while accounting for stray PCB and on-chip capacitance. See the device data sheet for on-chip capacitance values.

When using the internal load capacitors for the oscillator, the startup value of the capacitors is stored in the UTEST row of the flash memory. During phase 3 of the device reset sequence, the oscillator UTEST values are read and driven to the oscillator. The enable/disable state of the oscillator is captured in the MC_ME module at this time. After reset, the oscillator can be enabled/disabled by software in the MC_ME module. Internal load capacitor selection is maintained by the oscillator if disabled after reset. The default reset value for the XOSC trimming capacitors does not trim the internal capacitor values (UTEST Misc bit 5:1 = 00000b (XOSC LOAD CAP SEL)).

The internal load capacitor values stored in UTEST flash memory row have triple-voting flip-flop (TVF) implementation to prevent an incorrect value, and thus an undetectable error in the system.

The XOSC has the ability to be started with either 8 MHz to 20 MHz, or 40 MHz to 44 MHz crystal. The XOSC EN_40MHz bit in the UTEST Misc row selects which crystal source will be used. The default value of this field is for an 8 MHz to 20 MHz crystal (UTEST Misc bit 10 = 0).

See the flash memory chapter for more information on the UTEST row programming.

27.5.2.2 XOSC register write protection

The XOSC registers with write protection are defined in [Table 346](#). The protected registers have write protection with both soft and hard locking. A soft lock can be unlocked by software after being previously locked. A hard lock is only unlocked by a reset once locked. The REG_PROT module is used to implement the XOSC register write protection.

Table 346. XOSC register write protection⁽¹⁾

Offset	Register	Protections?
00h	XOSC_CTL—XOSC Control Register	Yes

1. See Register Protection Configuration chapter for bit field details

27.5.2.3 XOSC reset value

[Table 347](#) shows the default reset value for the XOSC registers.

Table 347. XOSC register reset values

Offset	Register	Reset value
00h	XOSC_CTL—XOSC Control Register	8030_8000h

27.5.3 16 MHz internal RC oscillator (IRCOSC)

The microcontroller has a 16 MHz internal RC oscillator that is always enabled and can be used as the clock source for the PLLs. The IRCOSC is the default clock after reset. The register interface is used for user trimming of the oscillator and dividing the output from 1 to 32.

27.5.3.1 IRCOSC register interface

This device has a dedicated digital interface for the IRCOSC. The digital interface provides a register for fine tuning the IRCOSC frequency by the user. Other registers allow reading of the settings of IRCOSC temperature sensor, voltage regulator and capacitor trimming values that are set by the factory. The IRCOSC is always enabled when the device is powered.

27.5.3.2 IRCOSC reset value

[Table 348](#) shows the default reset value for the IRCOSC registers. The values of the IRCOSC registers are loaded from TEST DCF flash memory (16 MHz RCOSC_1, 16 MHz RCOSC_2, 16 MHz RCOSC_3, 16 MHz RCOSC_4) (see Device Configuration Format Records chapter for details).

Table 348. IRCOSC register reset values

Offset	Register	Reset value
04h	NT—IRCOSC Native Trimming Register	0000_0000h
08h	TT—IRCOSC Temperature Trimming Register	0000_0000h

27.5.3.3 IRCOSC register write protection

The IRCOSC registers do not utilize write protection.

27.6 Peripheral clocks

[Figure 261](#) shows the clock distribution to the cores and peripheral modules.

27.6.1 HSM clock divider

The clock dividers for the HSM core and random number generator (TRNG) are located outside the HSM, but not in the MC_CGM. These dividers are controlled by the HSM.

The HSM contains an internal PIT/RTI block, which is clocked by the IRCOSC.

The HSM has an internal clock monitor on its input clock, so there is no need for a Clock Monitoring Unit (CMU) for the HSM_CLK in [Figure 258](#).

27.6.2 PSI5 clock dividers

The SPC57EM80xx microcontroller includes three PSI5 modules, all of which use the three common clocks shown in [Figure 258](#). The required frequencies for these clocks are generated from PLL0 as follows:

- $F_{\text{PSI5_f189_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC0}[\text{DIV}] + 1) / 10 \text{CGM_AC5_DC0}[\text{FMT}]) = 6.048 \text{ MHz} \pm 0.1\%$
- $F_{\text{PSI5_f125_CLK}} = F_{\text{PLL0_PHI}} / (\text{CGM_AC5_DC1}[\text{DIV}] + 1) = 4 \text{ MHz}$
- $F_{\text{PSI5_1us_CLK}} = F_{\text{PLL0_PHI}} / (\text{CGM_AC5_DC2}[\text{DIV}] + 1) = 1 \text{ MHz}$

The nine PSI5-S clocks are generated by dividing the PSI5_1μs_CLK further via a second and a third level of 'cascaded' clock dividers. The individual frequencies are, therefore, derived from the PLL0 PHI frequency as follows:

- $F_{\text{PSI5_S_TS_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC0}[\text{DIV}] + 1))$
- $F_{\text{PSI5_S_DDSR0_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC1}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC10}[\text{DIV}] + 1))$
- $F_{\text{PSI5_S_DDSR1_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC1}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC11}[\text{DIV}] + 1))$
- $F_{\text{PSI5_S_DDSR2_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC1}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC12}[\text{DIV}] + 1))$
- $F_{\text{PSI5_S_DDSR3_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC1}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC13}[\text{DIV}] + 1))$
- $F_{\text{PSI5_S_WD0_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC20}[\text{DIV}] + 1))$
- $F_{\text{PSI5_S_WD1_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC21}[\text{DIV}] + 1))$
- $F_{\text{PSI5_S_WD2_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC22}[\text{DIV}] + 1))$
- $F_{\text{PSI5_S_WD3_CLK}} = F_{\text{PLL0_PHI}} / ((\text{CGM_AC5_DC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC2}[\text{DIV}] + 1) * (\text{CGM_AC5_CDC23}[\text{DIV}] + 1))$

27.6.3 LFAST clocking

The SPC57EM80xx includes two LFAST modules, one to support interprocessor communications in conjunction with the SIPI module, and one to support high speed debug in conjunction with the JTAGM module. A single LFAST PLL that requires a 10–20 MHz reference supports high speed operation of both LFAST modules. For low speed LFAST operation, the reference clock is used directly by the LFAST modules.

The LFAST PLL reference clock source may be the PLL0:PHI output, external oscillator (XOSC) or input from the external LFAST device via the DRCLK_IO package pin. When this reference clock is generated internally, it can be output on the DRCLK_IO pin.

The debug LFAST module only supports the operation mode where it outputs the reference clock to a connected LFAST capable tool, as the DRCLK pin only supports output of the DRCLK reference.

On Emulation and Debug Devices (ED), the LFAST module on the Buddy Die (BD) is used and connected to the package debug pins instead of the Production Die (PD) debug LFAST module. This module has a separate dedicated LFAST PLL, although as with non EDs', the DRCLK pin only supports output of the reference clock to a connected LFAST capable tool.

[Figure 262](#) shows the clock routing for the various LFAST modules on the device, including connections to the DRCLK_IO and DRCLK pins.

Figure 262. Device LFAST clocking

27.6.4 Ethernet clocking

Both internal and external clocks sources for both MII and RMII Ethernet interface modes are supported. The MII clocks (FEC_TXCLK/FEC_RXCLK) are 25 MHz, and the RMII clock (FEC_REF_CLK) is 50 MHz. [Figure 263](#) gives the connections for the Ethernet clocks.

The RXCLK pin is an input, used in MII mode only, and ignored by the RMII gasket in RMII mode.

The FEC_TXCLK pin is an input, used in MII mode only, but is shared with the FEC_REF_CLK input of the RMII gasket. Therefore, the Aux clock selector is required to select between FEC_TXCLK and FEC_REF_CLK for MII and RMII modes.

The FEC_REF_CLK can be generated internally or input to the device. For MII mode, the FEC_REF_CLK can be used for the 25 MHz reference for the external Ethernet PHY, which provides the TXCLK/RXCLK clocks back to the device. For RMII mode, FEC_REF_CLK can

be generated internally and fed to both the PHY device and to the RMI1 gasket by enabling the FEC_REF_CLK pad input and output buffers. FEC_REF_CLK can also be provided externally as an input to the device.

Figure 263. Device Ethernet clocking

27.6.5 FlexRay clocking

The FlexRay protocol clock is sourced from either PLL0:PHI clock or the external oscillator (XOSC), but its source selection is different from other modules. PLL0:PHI enters the MC_CGM where it is divided by a value that is configured in the CGM_AC2_DC0. The output of the divider is the FRAY_PLL_CLK, which then passes through the Pseudo Random Clock Divider (PRCD). This module is passive in normal operation and has no impact on the clock frequency, but when enabled it divides the FRAY_PLL_CLK by 16 and adds approximately 40% of random jitter to both edges of the clock. The PHI output of PLL0 is the source whenever the PRCD is enabled.

The FRAY_CLK is selected for the FlexRay block via an internal multiplexer. Either the XOSC or the output of the PRCD can be used as the FRAY_CLK. When using the XOSC, a 40 MHz crystal is required for proper operation. When a 40MHz oscillator is used as the input clock to the FlexRay controller, both edges of the clock are used by the module to

achieve the required 80 MHz frequency. Selection of PLL or external oscillator as the FlexRay clock is configured in the MC_CGM (see [Figure 350 \(MC_CGM auxiliary clock 2 generation overview\)](#) in [Chapter 30: Clock Generation Module \(MC_CGM\)](#)).

27.6.6 M_TTCAN/M_CAN clocking

The CAN_CLK is generated from either the XOSC or PLL0:PHI clocks, depending on the configuration of CGM_AC8_SC in the MC_CGM. The CAN_CLK can also be reduced by configuring the dividing factor in the CGM_AC8_DC0 (divide by 1 to 64). The CAN_CLK then passes through the PRCD. This module is passive in normal operation and has no impact on the clock frequency, but when enabled it divides the CAN_CLK by 16 and adds approximately 40% of random jitter to both edges of the clock. The PHI output of PLL0 is the source whenever the PRCD is enabled.

27.6.7 Sigma-Delta ADC clocking

The analog portion of the Sigma-Delta ADC (SDADC) works with either an internal or external modulator. The internal clock (SD_CLK, see [Figure 261](#)) is always used when the internal modulator in the SDADC is enabled. This device supports either an external input clock (BS_CK), or internally generated output clock (SD_CLK) when using an external modulator. The output clock is generated internally and connected to the external modulator clock package pin (BS_CK). There is a dedicated external modulator clock pin for each SDADC.

The SDADC contains an internal mux for selection between the internal and external clocks. The internal clock is selected when the internal modulator is enabled, and the external clock is selected when it is disabled. In order to provide an internal clock option when the internal modulator is enabled, the SD_CLK output from the MC_CGM must be connected to the BS_CK pin as shown in [Figure 264](#). Control of the input/output direction of the BS_CK pin is handled by writing the MSCR in the SIUL2. Each SDADC is connected as shown in [Figure 264](#), with the SD_CLK being common to all modules, but each SDADC having a dedicated BS_CK pin.

Figure 264. Sigma-Delta ADC clocking

27.6.7.1 System Clock/GTM output clock/Ethernet clock pin muxing

There are two system clock output pins on the device, SYSCLK[1:0]. The output clock from either of the PLLs, the internal oscillator (IRCOSC), or external oscillator (XOSC) can be individually selected for either SYSCLK[1:0]. See [Figure 258](#).

There are three GTM output clocks available on package pins, EXTCLK[2:0]. EXTCLK[1:0] are muxed on the same pins as SYSCLK[1:0]. EXTCLK[2] is muxed on the same pin as the Ethernet RMII clock (FEC_REF_CLK). The selection of EXTCLK[n], SYSCLK[n] or FEC_REF_CLK is done in the SIUL2_MSCR registers and shown in [Figure 265](#).

Figure 265. SYSCLK/EXTCLK/REF_CLK pin muxing

27.7 Clock monitoring

For all safety relevant clocks the microcontroller uses clock monitoring units (CMUs) to detect a missing clock or incorrect frequency. Each CMU is programmed independently (see [Figure 258](#) for CMU distribution). The IRCOSC and XOSC are used as the clock monitor references. Detailed information on the CMUs can be found in the Clock Monitor Unit chapter.

27.7.1 CMU configuration

This section explains the CMU configuration.

[Figure 266](#) shows the block diagram for CMU0 on the SPC57EM80xx.

Figure 266. CMU0 block diagram

Figure 267 shows the block diagram for CMU[1:10] on the SPC57EM80xx.

Figure 267. CMU[1:10] block diagram

27.7.1.1 Clock input sources

[Table 349](#) shows the clocks that are monitored by each CMU. These signals are connected internally on the chip, but are not accessible via pins on the boundary of the device. IRCOSC is the reference clock for all clock monitors. Only CMU0 implements the XOSC monitor. CMU0 uses the IRCOSC clock to measure if the XOSC is too low. CMU0 can also be used to calibrate the IRCOSC frequency using the XOSC. All other CMUs are configured identically.

Table 349. Clock input sources

Clock module	Monitored clock
CMU0	PLL0:PHI, XOSC, IRCOSC
CMU1	Peripheral Core_2, Main Core_1, Safety Core (Main Core_0, Checker Core_0s), FXBAR_CLK
CMU2	SXBAR_CLK
CMU3	PBRIDGE_CLK
CMU4	PER_CLK
CMU5	SD_CLK
CMU6	SAR_CLK
CMU7	SENT_CLK
CMU8	PS15_f189_CLK
CMU9	PS15_f125_CLK
CMU10	PS15_1μs_CLK

27.7.1.2 CMU registers and field availability

[Table 350](#) specifies which registers and fields are available on a given CMU for this device.

Table 350. CMU registers availability

Address offset	Register	CMU	Note
0000h	CMU_CSR	All	CMU_CSR[SFM] and CMU_CSR[CLSEL1] are in CMU0 only.
0004h	CMU_FDR	CMU0	—
0008h	CMU_HFREFR	All	—
000Ch	CMU_LFREFR	All	—
0010h	CMU_ISR	All	CMU_MDR[OLRI] are in CMU0 only.
0014h	Reserved	—	—
0018h	CMU_MDR	CMU0	—

27.7.1.3 CMU register write protection

The CMU registers have write protection as shown in [Table 346](#). A soft lock can be unlocked by software after being previously locked. A hard lock is only unlocked by a reset once locked. The REG_PROT module is used to implement the CMU register write protection.

Table 351. CMU register write protection

Offset	Register ⁽¹⁾	Protections?
0000h	CMU Control Status Register (CMU_CSR)	Yes
0004h	CMU Frequency Display Register (CMU_FDR)	No
0008h	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	No
000Ch	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	No
0010h	CMU Interrupt Status Register (CMU_ISR)	No
0014h	Reserved	No
0018h	CMU Measurement Duration Register (CMU_MDR)	No

1. See Register Protection chapter for bit field details.

27.7.2 PLL0 monitor

Software can program an upper and lower limit on the expected PLL0 PHI output clock frequency. If the monitor is enabled and the measured frequency is above or below the limits, a flag bit is set and an interrupt, if enabled, is generated. The default condition of the clock monitor is disabled.

27.7.3 External oscillator (XOSC) monitor

The XOSC frequency is compared to a minimum value limit. If the measured XOSC frequency is below the limit, a flag is set and an interrupt, if enabled, is generated.

27.7.4 Internal RC oscillator (IRCOSC) monitor

The period of the IRCOSC can be measured in CMU0, using the XOSC as a reference. This allows for application trimming of the IRCOSC frequency.

27.7.5 System clock monitors

A CMU is assigned to monitor the frequency of the computational core, IOP core, fast and slow XBAR, both peripheral bridges, peripheral, PSI5, SENT and ADC clocks (refer to [Figure 258](#)). The HSM does not have an assigned CMU since it has its own internal clock monitor.

27.8 Loss of system clock behavior

This device has built-in mechanisms for detecting loss of the oscillator or PLL clocks, and provides several options for reaction to a loss of clock in the application. [Figure 268](#) gives a high-level view of the loss of clock logic.

27.8.1 Loss of PLL/XOSC clock

As shown in [Figure 268](#), each loss of lock signal from each PLL and the XOSC failure signals are monitored by the FCCU. The FCCU can be programmed to generate a short or long reset sequence when a clock failure occurs, or simply to generate an interrupt. In the case of the interrupt, only the backup clock in the PLL can provide clocks to the system in

order to perform a system clock switch. There is no automatic system clock switch, and the user is required to program the switch through the Mode Entry module (MC_ME).

If a long reset is selected the PLL, XOSC, MC_ME, and MC_CGM are reset to their default states, and the system clock is switched to the IRCOSC. If a short reset is selected, the clock configuration is maintained, but again, the PLL backup clock is the only available clock to clock the system through an MC_ME mode switch.

27.8.2 Loss of IRCOSC clock

The frequency of the IRCOSC clock is monitored by the frequency meter in CMU_0. There is no automated trigger of an FCCU error condition if the IRCOSC fails. Since the IRCOSC is the boot and backup clock, a failure is a catastrophic failure.

Figure 268. Loss of clock logic

28 Dual PLL Digital Interface (PLLDIG)

28.1 Introduction

The MCU provides a user interface and control over the dual PLL system composed of PLL0 and PLL1 blocks (PLLDIG). The two analog PLL blocks are cascaded, with the PHI1 output of PLL0 feeding the clock input of PLL1 as shown in the “Clocking” chapter. The key feature of the dual PLL architecture is the ability to drive peripherals from the PLL0 PHI output, which is non-modulated and independent of the core clock frequency. The core and platform clocks are driven by the PLL1 PHI frequency modulated output.

28.2 Block Diagram

The block diagram of the PLLDIG block is found in the “Clocking chapter” of the *SPC57EM80xx Reference Manual*.

28.3 Features

The dual PLL has the following features:

- Supports dual PLL in cascaded mode with PLL0 clock out as reference clock to PLL1.
- Reference clock pre-divider for finer frequency synthesis resolution.
- Reduced frequency divider for reducing the PLL0/PLL1 output clock frequency without causing the PLLs to lose lock.
- Input clock frequency range from 8 MHz to 56 MHz before the prescaler, and output clock from 4.762 MHz to 625 MHz for PLL0.
- Input clock frequency range from 37.5 MHz to 78.125 MHz, and output clock from 4.762 MHz to 625 MHz for PLL1.
- Programmable frequency modulation on PLL1.
- Lock detect circuitry reports when PLL0 and PLL1 achieves frequency lock, and continuously monitors lock status to report loss of lock conditions.
 - User-selectable ability to generate an interrupt request upon loss of lock.
 - User-selectable ability to generate a system reset upon loss of lock.
 - [BLG_PLLDIG_003][Covers: ADD12.023][Covers: Saf3005]The loss of lock indication is sent to the FCCU via the system glue logic. [end]

28.4 Modes of operation

The operating modes of the PLLs is determined by the value of PLLnCR[CLKCFG]. The various modes of operation for the PLL are:

- Normal mode with reference, and either PLL0 or both PLLs enabled

Note: .Mode changes are controlled by configuring the MC_ME Mode Configuration registers (MC_ME_<mode>_MC).

Normal mode is defined as the mode where the clocks are driven by the PLL. When using a crystal for the clock reference, reset should remain asserted until the oscillator has stabilized.

28.4.1 Normal mode with reference, PLL0 or both PLLs enabled

In the normal mode, PLL0 receives an input clock from the reference and the pre-divider. PLL0 multiplies the frequency to create the PLL0 output clock. The user must supply a crystal that is within the appropriate frequency range, the crystal manufacturer recommended external support circuitry and short signal route from the MCU to the crystal.

PLL0 generates a non-modulated clock which drives PLL0_PHI1. PLL1 can generate a frequency modulated clock or a non-modulated clock (for example, locked on a single frequency). The modulation rate, modulation depth, output divider (Reduced Frequency Divider) and whether the PLL1 is modulating or not can be programmed by writing to the PLL1FM register, [Section 28.5.2.7, PLL1 Frequency Modulation Register \(PLL1FM\)](#).

Note: While powering down the PLLs, user must ensure that PLL1 is powered down first followed by powering down PLL0 for proper shut off.

Only when the PLL0 achieves lock should PLL1 be configured to work in either mode by programming the appropriate MC_ME_<mode>_MC register.

28.5 Memory map and register definition

This section provides the memory map and detailed descriptions of all registers for configuring the PLLs.

28.5.1 Memory map

[Table 352](#) shows the memory map. Addresses are given as offsets from the module base address. All registers can be accessed using 8-bit, 16-bit or 32-bit addressing.

Table 352. Dual PLL Digital Interface memory map

1. CLKCFG can be written, but writes have no effect. Mode changes are implemented by writing to the appropriate MC_ME_<mode>_MC register.

Table 353. PLL0CR field descriptions

Field	Description
0:21	Reserved
22:23 CLKCFG	Clock Configuration. This field indicates the operational state of PLL. 00PLL off. 01Reserved 10Reserved. 11Normal mode with PLL running When PLLs are externally powered down the CLKCFG field changes to 00b. When external power down is removed, these bits will read 11b. <i>Note: In cascaded PLL configuration (PLL0 driving the reference clock for PLL1) the external power down signal for PLL1 must be removed only when PLL0 has locked, PLL0SR[LOCK] = 1.</i>
24 EXPDIE	External Power Down Cycle Complete indication interrupt enable. This bit enables generation of an interrupt when the external power down of the PLL is complete (for example, PLLs are powered down and powered back up). 0 Ignore interrupt. Interrupt not requested 1 Enable interrupt request on power down cycle completion
25	Reserved
26	Reserved
27	Reserved

Table 353. PLL0CR field descriptions (continued)

Field	Description
28 LOLIE	Loss of lock interrupt enable. The LOLIE bit enables a loss of lock interrupt request when PLL0SR[LOLF] = 1. If PLL0SR[LOLF] = 0 or PLL0CR[LOLIE] = 0, the interrupt request is ignored. The interrupt request only occurs in normal mode. 0Ignore loss of lock. Interrupt not requested. 1Enable interrupt request upon loss of lock.
29 LOLRE	Loss of lock reset enable. The PLL0CR[LOLRE] bit determines whether system reset is asserted or not upon a loss of lock indication from PLL. If both PLL0CR[LOLRE] = 1 and PLL0CR[LOLIE] = 1, PLL0CR[LOLRE] has precedence and the device asserts reset with the interrupt not being taken. 0Ignore loss of lock. Reset not asserted. 1Assert reset on loss of lock when operating in normal mode.

28.5.2.3 PLL0 Divider Register (PLL0DV)

The PLL0DV register provides the PHI/PHI1 output clock reduced frequency dividers, pre-divider, and loop divider. The values of PREDIV and MFD should not be changed when the PLL is on and locked (working in Normal mode). If these fields are changed without powering down the PLL, the PLL will lose lock and generate either a reset or an interrupt, based on which is enabled. The reduced frequency divider fields (RFDPHI, RFDPHI1) can be modified at anytime, but the changes only become effective after PLL0 is disabled, then reenabled.

28.5.2.7 PLL1 Frequency Modulation Register (PLL1FM)

The PLL1FM register enables frequency modulation on PLL1 and provides controls for the FM spread spectrum, modulation depth and modulation rate. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of PLL1PLL2FM[MODEN] and PLL1PLL2FM[MODSEL] fields once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality. The modulation period (PLL1FM[MODPRD]) and increment step fields (PLL1FM[INCSTP]) can be changed without losing lock, however, the output clock from PLL may have an incorrect frequency for a few cycles after either of these updates (as defined in the datasheet).

1 MODEN	Modulation enable. This bit enables the frequency modulation. 0Frequency modulation disabled. 1Frequency modulation enabled.
2 MODSEL	Modulation selection. This bit selects whether modulation is centered around the nominal frequency or spread below the nominal frequency. 0Modulation centered around nominal frequency. 1Modulation spread below nominal frequency.
3:15 MODPRD	Modulation period. This 13-bit field is the binary equivalent of the modulation period variable derived from the formula: $\text{MODPRD} = \text{round}\left(\frac{f_{\text{ref}}}{4 \times f_{\text{mod}}}\right)$ where f_{ref} represents the frequency of the feedback divider and f_{mod} represents the modulation frequency.
16	Reserved
17:31 INCSTP	Increment step. This 15-bit field is the binary equivalent of the INCSTP variable derived from the formula: $\text{INCSTEP} = \text{round}\left(\frac{(2^{15} - 1) \times md \times \text{PLL1CR}[\text{MFD}]}{100 \times 5 \times \text{MODPRD}}\right)$ where md represents the peak modulation depth in percentage (+/- md for centered modulation, - $2 \times md$ for modulation below nominal frequency), and MFD represents the nominal value of the feedback loop divider.

28.5.2.8 PLL1 Fractional Divider Register (PLL1FD)

The PLL1FD register provides the enable and fractional divide factor for the loop divider. This register should be written when PLL1CR[CLKCFG] = 00b (PLL1 powered down). Changing the values of FDEN once the PLL is running, and has locked, can result in the PLL losing its lock and the device being reset (if PLL1CR[LOLRE] = 1). The PLL would then require power cycling to regain normal functionality. The dither disable and fractional divider fields can be changed without losing lock, however, the output clock from PLL can have an incorrect frequency for a few cycles after either of these updates.

Figure 276. PLL1 Fractional Divider Register (PLL1FD)

Table 360. PLL1FD field descriptions

Field	Description
0	Reserved
1 FDEN	Fractional Divide Enable. This bit enables the fractional divider in the loop divider for PLL1. 0Fractional divide disabled. 1Fractional divide enabled.
2:13	Reserved
14:15 DTHDIS	Dither Disable. See chip specific chapter for more details on dither.
16:19	Reserved
20:31 FRCDIV	Fractional divide input. When the fractional divide is disabled, the VCO clock frequency is the product of the input clock and the loop divide factor (MFD). When fractional divide is enabled, the VCO clock frequency is given by: $\text{VCO Frequency} = \text{InputClock} \times (\text{PLL1DV}[\text{MFD}] + (\text{FRCDIV} \div 2^{12}))$ where FRCDIV is the decimal equivalent of the FRCDIV bits.

28.5.3 Register classification for safety requirements

This module is classified as a safety Vital Module (ViMo). Hence, the registers of this module have been classified as shown in the SPC57EM80xx Reference Manual “Functional Safety” chapter.

28.6 Functional description

This section explains the operation and configuration of the Dual PLLDIG module.

28.6.1 Input clock frequency

PLL0 and PLL1 are designed to operate over an input clock frequency range. The operating ranges for each PLL are discussed in detail in the *SPC57EM80xx Data Sheet*.

28.6.2 Clock configuration

The relationship between input and output frequency is determined by programming the PLL0DV and PLL1DV registers, and calculated according to the following equations:

Equation 4

$$f_{\text{pll0_phi}} = f_{\text{pll0_ref}} \times \frac{\text{PLL0DV}[\text{MFD}]}{\text{PLL0DV}[\text{PREDIV}] \times \text{PLL0DV}[\text{RFDPHI}]}$$

Equation 5

$$f_{\text{pll0_phi1}} = f_{\text{pll0_ref}} \times \frac{\text{PLL0DV}[\text{MFD}]}{\text{PLL0DV}[\text{PREDIV}] \times \text{PLL0DV}[\text{RFDPHI1}] \times 2}$$

Equation 6

$$f_{\text{pll1_phi}} = f_{\text{pll1_ref}} \times \frac{\text{PLL1DV}[\text{MFD}]}{\text{PLL1DV}[\text{RFDPHI}]}$$

When PLL0s PHI1 is used as the reference for PLL1:

Equation 7

$$f_{\text{pll1_phi}} = \frac{f_{\text{pll0_ref}} \times \text{PLL0DV}[\text{MFD}] \times \text{PLL1DV}[\text{MFD}]}{\text{PLL0DV}[\text{PREDIV}] \times \text{PLL0DV}[\text{RFDPHI1}] \times \text{PLL1DV}[\text{RFDPHI}] \times 2}$$

The relationship between the VCO frequency f_{VCO} and the output frequency of the PLLs is determined by the value of PLL1DV[RFDPHI], PLL0DV[RFDPHI] and PLL0DV[RFDPHI1], according to the following equations:

Equation 8

$$f_{\text{pll0_VCO}} = f_{\text{pll0_phi}} \times \text{PLL0DV}[\text{RFDPHI}]$$

Equation 9

$$f_{pll1_vco} = f_{pll1_phi} \times PLL1DV[RFDPHI]$$

Equation 10

$$f_{pll0_vco} = f_{pll0_phi1} \times 2 \times PLL0DV[RFDPHI1]$$

Note: f_{pll0_phi1} is the reference clock generated by PLL0 for PLL1

When programming the PLLs, user software must not violate the maximum system clock frequency or max/min VCO frequency specification for PLL0 or PLL1. Furthermore, the PLL0DV[PREDIV] value must not be set to any value that causes the input frequency to the phase detector of analog PLL blocks to go below the prescribed ranges.

The lock signal and PLLnSR[LOCK] flag are immediately negated if the fields of PLLnDV are changed without powering down the analog PLLs.

Upon any of these events an internal timer is initialized to count 64 cycles of the PLL input clock. During this period (64 cycles and a few extra clock cycles for synchronization, for example, 64 to 72 cycles), the PLLnSR[LOCK] flag is held negated. After the timer expires, the PLLnSR[LOCK] flag reflects the value coming from the PLL lock detection circuitry. To prevent an immediate reset, the PLLnCR[LOLRE] bit of the respective PLLs must be cleared before doing any of the above operations.

Note: The PLL must be powered down and powered up by configuring MC_ME_<mode>_MC before PLL0CR[PREDIV], PLL0CR[MFD], PLL1CR[MFD] or the input reference clock values are modified.

The recommended procedure to program the PLLs and engage normal mode is shown in [Section 28.7, Initialization information](#).

28.6.3 Loss of lock

The PLL digital interface registers provide the flexibility to select whether to generate an interrupt assert system reset or do nothing in the event that the PLL loses lock according to the available PLLnCR options.

Loss of lock reset and interrupt are only generated when the PLL is operating in normal mode. The PLLDIG_PLLnSR[LOLF] bits are not asserted by a loss of lock condition detected during Bypass mode, although going to Bypass mode from normal mode does not automatically clear the flag if it was previously asserted while the PLL was in normal mode.

The lock indication from the analog PLL is synchronized and stored in the status register. When the analog PLL loses lock or regains lock, it will be immediately indicated in the status register (after synchronization time).

A pair of counters monitor the reference and feedback clocks to determine when the system has acquired frequency lock. Once the PLL has locked, the counters continue to monitor the reference and feedback clocks and report whether the PLL has lost lock. The lock status is indicated in the status register.

28.6.4 Frequency modulation

Frequency modulation uses a triangular profile as shown in [Figure 277](#). The modulation frequency and depth are controlled using PLL1FM[MODPRD] and PLL1FM[INCSTP].

Note: The device maximum operating frequency includes the frequency modulation. If center modulation is selected, the fsys must be below fmax by MD percentage such that

Figure 277. Triangular frequency modulation

The following equations define how to calculate PLL1FM[MODPRD] ([Equation 11](#)) and PLL1FM[INCSTP] ([Equation 12](#)) based on the frequency of the feedback divider (f_{ref}), the modulation frequency (f_{mod}) and the modulation depth percentage (MD):

Equation 11

$$PLL1FM[MODPRD] = \text{round}\left(\frac{f_{ref}}{4 \times f_{mod}}\right)$$

Equation 12

$$PLL1FM[INCSTP] = \text{round}\left(\frac{(2^{15} - 1) \times MD \times PLL1DV[MFD]}{100 \times 5 \times PLL1FM[MODPRD]}\right)$$

PLL1FM[MODPRD] and PLL1FM[INCSTP] are subject to the following restriction:

Equation 13

$$(PLL1FM[MODPRD] \times PLL1FM[INCSTP]) < 2^{15}$$

Because of the above rounding operations, the effective modulation depth applied to the FMPLL is given by the following formula:

Equation 14

$$\text{ModulationDepth} = \text{round}\left(\frac{\text{PLL1FM}[\text{MODPRD}] \times \text{PLL1FM}[\text{INCSTP}] \times 100 \times 5}{(2^{15} - 1) \times \text{MFD}}\right)$$

As an example, suppose the following configuration:

- Input frequency: 4 MHz
- Loop divider (PLL n CR[MFD]): 64
- Input divider: 1
- VCO frequency: 4 MHz $\times$ 64 = 256 MHz
- PLL output frequency: 256 MHz / RFD
- Center spread (PLL1FM[MODSEL] = 0)
- Modulation frequency: 24 kHz
- Modulation depth: +/- 2.0% (4% peak-to-peak)
- PLL1FM[MODPRD] = Round[(4 $\times$ 10⁶)/(4 $\times$ 24 $\times$ 10³)] = Round[41.66] = 42
- PLL1FM[INCSTP] = Round[((2¹⁵ - 1) $\times$ 2 $\times$ 64) / (100 $\times$ 5 $\times$ 42)] = Round[199.722] = 200
- PLL1FM[MODPRD] $\times$ PLL1FM[INCSTP] = 42 $\times$ 200 = 8400 (which is less than 2¹⁵)
- MD (quantized) = ((42 $\times$ 200 $\times$ 100 $\times$ 5) / ((2¹⁵ - 1) $\times$ 64) = 2.00278%

In this example, the modulation error is 0.00278%.

The FM parameters can only be changed, and FM can only be enabled, when PLL0 is locked. Writing to the PLL1FM while the PLL0 is unlocked has no effect. Furthermore, when PLL0 loses lock, the FM modulation parameters are reset and modulation is disabled until PLL0 relocks and PLL1FM is reprogrammed. The sequence for reprogramming the FM is:

1. Power down PLL1^(f).
2. Program the PLL1FM while PLL1 is powered down.
3. Power up the PLL1^(g).

28.7 Initialization information

Coming out of reset PLL0 and PLL1 are enabled. The recommended procedure to program the PLLs and enter normal mode is:

1. Program PLL0DV[PREDIV], PLL0DV[RFDPHI1], PLL0DV[MFD] and PLL0DV[RFDPHI].
2. Provide a power down pulse (controlled by configuring the appropriate MC_ME_<mode>_MC register).
3. Poll PLL0SR[LOCK] until it asserts.
4. Program PLL1DV[MFD] and PLL1DV[RFDPHI].

f. By writing MC_ME_<mode>_MC[PLL1ON] = 0b.

g. By writing MC_ME_<mode>_MC[PLL1ON] = 1b.

5. If required, program the PLL1FM register with the desired frequency modulation parameters and enable FM modulation, PLL1FM[MODEN] = 1. The PLL1FM register must not be written after PLL1 is enabled and operating in normal mode.
6. Provide a power down pulse (controlled by configuring the appropriate MC_ME_<mode>_MC register).
7. Poll PLL1SR[LOCK] until it asserts.

Engage normal mode.

At this point, the PLL is configured and is generating a output clock; however, the PLL is not the system clock until it is configured in the Mode Entry Module (MC_ME) and a mode change has taken place. See the “Mode Entry Module (MC_ME)” chapter for more details.

29 Clock Monitor Unit (CMU)

29.1 Introduction

The Clock Monitor Unit (CMU), also referred to as Clock Quality Checker or Clock Fault Detector, serves three purposes:

- Measures the frequency of clock sources CLKMT0_RMN with CLKMN0_RMT as the reference clock
- Monitors CLKMN0_RMT frequency with CLKMT0_RMN as reference clock
- Monitors CLKMN1 frequency with CLKMT0_RMN as reference clock and also detects if the monitored clock frequency leaves an upper or lower frequency boundary

One of the tasks is to supervise the integrity of the various clock sources on the chip, for example CLKMN0_RMT or CLKMN1. If the monitored clock frequency is less than the reference clock, or it violates an upper or lower frequency boundary, the CMU detects and reports this event. These events signal the FCCU, which in turn can then take whatever corrective action is required as configured in the FCCU.

The CMU can monitor CLKMN0_RMT, which must have a frequency higher than that of CLKMT0_RMN divided by the division factor given by the RCDIV field of CMU Control Status Register and reports this event. The CMU can also monitor CLKMN1 and generate events when the CLKMN1 frequency is less than the CLKMT0_RMN frequency divided by four or if CLKMN1 leaves an upper or lower frequency boundary. The upper and lower frequency boundaries are defined by the CMU High Frequency Reference Register (CMU_HFREFR) and CMU Low Frequency Reference Register (CMU_LFREFR).

The second task of the CMU is to provide a frequency meter, which allows measuring the frequency of one clock source against a reference clock. This is useful to allow the calibration of the metered clocks (such as CLKMT0_RMN), as well as to be able to correct/calculate the time deviation of a counter that is clocked by the metered clocks.

Note: See the “Clocking” chapter for the number of instances of the CMU in this device.

29.1.1 Main features

- CLKMT0_RMN frequency measurement with CLKMN0_RMT as the reference clock.
- CLKMN0_RMT monitoring with respect to CLKMT0_RMN/n clock.
- CLKMN1 frequency monitoring with respect to CLKMT0_RMN / 4 and upper or lower frequency boundary.
- Event generation for various failures detected inside monitoring unit.

29.2 Block diagram

*Not used in all CMU block configurations. See the “Clocking” chapter for specific CMU implementations.

Figure 278. Clock Monitor Unit diagram

29.3 Signals

Table 361 describes the signals on the boundary of the CMU (in alphabetical order).

Table 361. Signal description

Signal	I/O	Description
CLKMN0_RMT	I	Monitored Clock Signal 0/Metered Clock Signal Reference — Receives a clock signal that the CMU compares to a specified low-limit frequency to determine whether the frequency of the clock signal is greater than the specified limit. Also provides a reference clock signal for all metered clock signals.

Table 361. Signal description (continued)

Signal	I/O	Description
CLKMN1	I	Monitored Clock Signal 1 — Receives a clock signal that the CMU compares to specified low-limit and high-limit frequencies to determine whether the frequency of the clock signal is between the specified limits.
CLKMT0_RMN	I	Metered Clock Signal 0/Monitored Clock Signal Reference — Receives a clock signal that the CMU measures against a reference clock frequency. Also provides a reference clock signal for all monitored clock signals.

Note: See the “Clocking” chapter for device specific clock sources of the CMU.

29.4 Register description and memory map

This section describes in address order all the CMU registers. Each description includes a standard register diagram with an associated figure number. The CMU memory map is listed in [Table 362](#).

Table 362. CMU register summary

Offset (hex)	Register	Location
0000	CMU Control Status Register (CMU_CSR)	on page 917
0004	CMU Frequency Display Register (CMU_FDR)	on page 918
0008	CMU High Frequency Reference Register CLKMN1 (CMU_HFREFR)	on page 918
000C	CMU Low Frequency Reference Register CLKMN1 (CMU_LFREFR)	on page 919
0010	CMU Interrupt Status Register (CMU_ISR)	on page 920
0014	Reserved	—
0018	CMU Measurement Duration Register (CMU_MDR)	on page 921

Note: See the “Clocking” chapter for register and field availability details.

20:31 LFREF	Low Frequency reference value — These bits determine the low reference value for the CLKMN1 frequency. The reference value is given by: $(LFREF/16) * (f_{CLKMTO_RMN}/4)$.

29.4.1.5 CMU Interrupt Status Register (CMU_ISR)

Note: : All the flags in CMU_ISR register are set asynchronously. This register must be read only after an interrupt (safe mode entry) is triggered by the CMU as confirmed by MC_RGM. Otherwise, the read access on this register may fetch an incorrect value.

Note: Before entering low-power stop modes, all clock frequency measurements in CMU should be disabled. Failing to do so may result in spurious interrupts.

Table 368. CMU_MDR field descriptions

Field	Description
0:11	Reserved
12:31 MD	Measurement duration bits — This field displays the measurement duration in terms of selected clock (CLKMT0_RMN) cycles. This value is loaded in the frequency meter down-counter. When CMU_CSR [SFM] = 1, the down-counter starts counting.

29.5 Functional description

This section describes the functionality of the clocks.

29.5.1 Frequency meter

The purpose of frequency meter is to evaluate the deviation from the nominal metered source (such as, CLKMT0_RMN) frequencies. This in turn allows either recalibration of these clocks or other timing corrections. Programming of the CMU_CSR[CKSEL1] field is used to select one of metered clocks from a multiplexer that drives a simple Frequency Meter (see [Figure 278](#)). The reference clock for the Frequency Meter is the CLKMN0_RMT signal. The measurement starts when CMU_CSR[SFM] = 1. The measurement duration is given by the contents of CMU_MDR[MD] in terms of number of clock cycles of the selected metered clock. The CMU_CSR[SFM] bit is cleared by hardware once the frequency measurement is complete and the count is loaded in CMU_FDR[FD]. The frequency of the selected clock (f_{sel}) can be derived from the value loaded in the CMU_FDR as shown in the following equation:

$$\text{Equation 15} \quad f_{sel} = (f_{CLKMN0_RMT} \times MDR[MD]) / FDR[FD]$$

29.5.2 CLKMN0_RMT supervisor

If frequency of CLKMN0_RMT is smaller than frequency of CLKMT0_RMN divided by $2^{CMU_CSR[RCDIV]}$ and CLKMN0_RMT is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[OLRI].
- The CMU asserts the OLR signal.

Note: f_{CLKMN0_RMT} must be greater than f_{CLKMT0_RMN} divided by 2^{RCDIV} by at least 0.5 MHz in order to guarantee correct f_{CLKMN0_RMT} monitoring.

29.5.3 CLKMN1 supervisor

The frequency of CLKMN1(f_{CLKMN1}) can be monitored by programming CMU_CSR[CME] = 1. CLKMN1 monitoring starts as soon as CMU_CSR[CME] = 1. This monitor can be disabled at any time by programming CMU_CSR[CME] = 0.

If f_{CLKMN1} is greater than the reference value determined by fields CMU_HFREFR[HFREF] and CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FHHI]
- The CMU asserts the FHH signal

If f_{CLKMN1} is less than a reference value determined by the bits CMU_LFREFR[LFREF] and the CLKMN1 is 'ON' as signaled by the MC_ME, then:

- The CMU writes 1 to CMU_ISR[FLLI].
- The CMU asserts the FLL signal.

Note: f_{CLKMN1} must be greater than $f_{CLKMT0_RMN} / 4$ by at least 0.5 MHz in order to guarantee correct CLKMN1 monitoring.

30 Clock Generation Module (MC_CGM)

30.1 Introduction

30.1.1 Overview

The clock generation module (MC_CGM) generates reference clocks for all the modules on the chip. The MC_CGM selects one of the system clock sources to supply the system clock. The MC_ME controls the system clock selection (see the MC_ME chapter for more details). A set of MC_CGM registers controls the clock dividers which are used for divided system and peripheral clock generation. The memory spaces of system and peripheral clock sources which have addressable memory spaces are accessed through the MC_CGM memory space.

[Figure 285](#) shows the MC_CGM block diagram.

Figure 285. MC_CGM block diagram

30.1.2 Features

The MC_CGM includes the following features:

- generates system and peripheral clocks
- selects and enables/disables the system clock supply from system clock sources according to MC_ME control
- performs progressive system clock frequency change depending on MC_ME mode configuration
- contains a set of registers to control clock dividers for divided clock generation
- supports multiple clock sources and maps their address spaces to its memory map
- guarantees glitch-less clock transitions when changing the system clock selection
- supports 8, 16, and 32-bit wide read/write accesses

30.2 External signal description

The MC_CGM delivers output clocks to the SYSCLK0 and SYSCLK1 pins for off-chip use and/or observation.

30.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the CGM_PCS_DIVC1 register RATE bits may be accessed as a word at address offset 0x0704, as a half-word at address offset 0x0706, or as a byte at address offset 0x0707.

30.3.1.1 Auxiliary Clock 5 Cascaded Divider 0 Configuration Register (CGM_AC5_CDC0)

This register controls auxiliary clock 5 cascaded divider 0.

Note: Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Figure 286. Auxiliary Clock 5 Cascaded Divider 0 Configuration Register (CGM_AC5_CDC0)

Address 0x0680

Access: User read/write, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	DE	0	0	0	0	0	DIV

Table 371. CGM_AC5_CDC0 field descriptions

Field	Description
DE	Divider Enable. 0 Disable auxiliary clock 5 cascaded divider 0 1 Enable auxiliary clock 5 cascaded divider 0
DIV	Divider Division Value — The resultant peripheral clock will have a period ' $(DIV + 1) \times (CGM_AC5_DC2[DIV] + 1)$ ' times that of auxiliary clock 5. If DE is set to 0 (divider is disabled), any write access to the DIV field is ignored and the peripheral clock remains disabled.

30.3.1.2 Auxiliary Clock 5 Cascaded Divider 1 Configuration Register (CGM_AC5_CDC1)

This register controls system clock divider 1.

Note: *Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.*

Figure 287. Auxiliary Clock 5 Cascaded Divider 1 Configuration Register (CGM_AC5_CDC1)

Address 0x0684

Table 372. CGM_AC5_CDC1 field descriptions

Field	Description
DE	Divider Enable. 0 Disable auxiliary clock 5 cascaded divider 1 1 Enable auxiliary clock 5 cascaded divider 1
DIV	Divider Division Value — The resultant peripheral clock will have a period ' $(DIV + 1) \times (CGM_AC5_DC2[DIV] + 1)$ ' times that of auxiliary clock 5. If DE is set to 0 (divider is disabled), any write access to the DIV field is ignored and the peripheral clock remains disabled.

30.3.1.3 Auxiliary Clock 5 Cascaded Divider 2 Configuration Register (CGM_AC5_CDC2)

This register controls system clock divider 2.

Note: *Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.*

Table 389. CGM_PCS_DIVS2 field descriptions

Field	Description
INIT	Divider Change Initial Value — This is initial change value of the clock divider for the clock ramp-up phase when switching to the PLL1 PHI.
RATE	Divider Change Rate — This value controls the change value of the clock divider for the clock ramp-up and ramp-down phase when switching to/from the PLL1 PHI.

30.3.1.20 PCS Divider Start Register 4 (CGM_PCS_DIVS4)

This register defines the initial division value for the progressive system clock switching when switching the system clock source to the PLL1 PHI on ramp-up. See [Section 30.4.1.2, Progressive system clock switching](#) for details on how to set this value. This register is reset only on a power-on reset.

Note: Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

Table 405. CGM_AC1_DC0 field descriptions

Field	Description
DE	Divider Enable 0 Disable auxiliary clock 1 divider 0 1 Enable auxiliary clock 1 divider 0
DIV	Divider Division Value — The resultant LFAST clock will have a period 'DIV + 1' times that of auxiliary clock 1. If DE is set to 0 (divider 0 is disabled), any write access to the DIV field is ignored and the LFAST clock remains disabled.

30.3.1.36 Auxiliary Clock 2 Divider 0 Configuration Register (CGM_AC2_DC0)

This register controls auxiliary clock 2 divider 0 when the “CAN jitter” feature is not enabled (see [Section 30.4.3.1, Divider jitter injection](#)).

Note: Byte and half-word write accesses are not allowed for this register. Such an access will not result in an exception; however, the value will not be loaded with the new value.

DE	Divider Enable 0 Disable auxiliary clock 7 divider 0 1 Enable auxiliary clock 7 divider 0
DIV	Divider Division Value — The resultant SYSCLK1 pin clock will have a period 'DIV + 1' times that of auxiliary clock 7. If DE is set to 0 (divider 0 is disabled), any write access to the DIV field is ignored and the SYSCLK1 pin clock remains disabled.

30.3.1.51 Auxiliary Clock 8 Select Control Register (CGM_AC8_SC)

This register is used to select the current clock source for the following clocks:

- undivided: (unused)
- divided by auxiliary clock 8 divider 0: CAN clock

See [Figure 356](#) for details.

30.4 Functional description

30.4.1 System clock generation

[Figure 345](#) shows the block diagram of the system clock generation logic. The MC_ME provides the system clock select and switch mask (see MC_ME chapter for more details), and the MC_RGM provides the safe clock request (see MC_RGM chapter for more details). The safe clock request forces the selector to select the 16 MHz int. RC osc. as the system clock and to ignore the system clock select.

Figure 345. MC_CGM system clock generation overview

30.4.1.1 System clock source selection

During normal operation, the system clock selection is controlled

- on a SAFE mode or reset event, by the MC_RGM
- otherwise, by the MC_ME

30.4.1.2 Progressive system clock switching

In order to prevent sudden voltage drops and overshoots due to frequency and load changes, the MC_ME requests the MC_CGM to ramp the system clock frequency down and/or up based on the power level values of the current and target modes. During ramp-down, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVEN registers, where n corresponds to the current system clock source selection. During ramp-up, the rate of the frequency change is based on the CGM_PCS_SDUR, CGM_PCS_DIVCn, and CGM_PCS_DIVSn registers, where n corresponds to the target system clock source selection.

30.4.1.2.1 Generic clock change requirements

For a maximum allowed change of the frequency (f_{chg}) and for a given source clock frequency f_{src} (current or target clock source), the maximum allowed frequency change rate a_{max} is given in [Equation 16](#).

$$\text{Equation 16} \quad a_{max} = \frac{f_{chg}}{f_{src}}$$

30.4.1.2.2 Configuration of CGM_PCS_SDUR

The switch duration field CGM_PCS_SDUR[SDUR] defines the duration of one system clock switch step in terms of 16 MHz int. RC osc.. After the expiration of this time, the module changes the clock divider value which changes the frequency of the system clock.

30.4.1.2.3 Configuration of CGM_PCS_DIVCn[RATE]

For a given maximum allowed frequency change rate a_{max} the value d to be programmed into the PCS_DIVCn[RATE] register is given in [Table 430](#).

Table 430. MC_CGM CGM_PCS_DIVCn[RATE] values

a_{max}	d	CGM_PCS_DIVCn[RATE]
0.05	0.012	12
0.10	0.048	48
0.15	0.112	112
0.20	0.184	184

30.4.1.2.4 Generic clock change properties

The number k of required steps to reach or leave the divided system clock with frequency f_{div} from the source clock with frequency f_{src} is given in [Equation 17](#).

$$\text{Equation 17} \quad k = \left\lceil 0.5 + \sqrt{0.25 - \frac{2 \left(1 - \frac{f_{src}}{16\text{MHz}} \right)}{d}} \right\rceil$$

30.4.1.2.5 Clock ramp-down

The clock ramp-down starts with the divider value 1 and with the given divider increment value PCS_DIVCn[RATE] and ends with the given divider value PCS_DIVEn[DIVE].

The divider end value for clock ramp-down is given in [Equation 18](#).

$$\text{Equation 18} \quad \text{PCS_DIVEn[DIVE]} = \frac{f_{src}}{16\text{MHz}} \times 1000 - 1$$

Where f_{curr} is the frequency of the currently selected system clock source.

Figure 346. MC_CGM System Clock Ramp-Down Timing (k = 6 example)

30.4.1.2.6 Clock ramp-up

The clock ramp-up starts with the given divider value PCS_DIVSn[DIVS] and with the given divider decrement value PCD_DIVCn[INIT] and ends with the divider value 1.

The initial divider change start value PCS_DIVCn[INIT] for system clock ramp-up is given in [Equation 19](#).

Equation 19 $PCS_DIVCn[INIT] = d \times k \times 1000 - 1$

Where k is calculated from [Equation 17](#) using the target system clock source frequency f_{targ} . The divider start value for clock ramp-up is given in [Equation 20](#).

Equation 20 $PCS_DIVSn[DIVS] = \left(1 + d \frac{k(k+1)}{2}\right) \times 1000 - 1$

Figure 347. MC_CGM System Clock Ramp-Up Timing (k = 6 example)

30.4.1.3 System clock disable

During the TEST mode, the system clock can be disabled by the MC_ME.

30.4.1.4 System clock dividers

The MC_CGM generates the following derived clocks from the system clock:

- fast XBAR clock - controlled by the CGM_SC_DC0 register
- slow XBAR clock - controlled by the CGM_SC_DC1 register
- PBRIDGE clock - controlled by the CGM_SC_DC2 register

30.4.1.4.1 System clock divider synchronization

The system clock dividers are synchronized to each other such that the rising edges of the lower frequency clocks are aligned with those of the higher frequency clocks. This, however, imposes limitations on the division factors which can be used. In order for the synchronization to work properly, each division factor must be selected such that its value is an integer multiple of each division factor that has a lower value.

[Table 431](#) shows an example of a correct divider configuration.

Example 4 Correct system clock divider configuration

Table 431. MC_CGM Example System Clock Division Values Compatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	CGM_SC_DC0[DIV] = 0
1	2	CGM_SC_DC1[DIV] = 1
2	6	CGM_SC_DC2[DIV] = 5

In this case, system clock divider 1 has a division factor greater than that of system clock divider 0. Since 2 is an integer multiple of 1, its configuration is correct. Also, system clock divider 3 has a division factor that is greater than those of both system clock dividers 0 and 1. Since 6 is an integer multiple of 1 and 6 is an integer multiple of 2, its configuration is also correct.

[Table 432](#) shows an example of an incorrect divider configuration.

Example 5 Incorrect system clock divider configuration

Table 432. MC_CGM Example System Clock Division Values Compatible with Divider Synchronization

Divider	Division Factor	Register Value
0	1	CGM_SC_DC0[DIV] = 0
1	4	CGM_SC_DC1[DIV] = 3
2	6	CGM_SC_DC2[DIV] = 5

In this case, system clock divider 1 has a division factor greater than that of system clock divider 0. Since 4 is an integer multiple of 1, its configuration is correct. Also, system clock divider 3 has a division factor that is greater than those of both system clock dividers 0 and 1. Since 6 is not an integer multiple of 4, its configuration is incorrect.

Caution: Configuring the system clock dividers incorrectly will cause the divided clocks to become unsynchronized. This may lead to lost communication between the clock domains and/or the inability to further change the system clock divider division factors without first disabling them or performing a reset.

30.4.1.4.2 System clock divider update triggering

As opposed to the auxiliary clock dividers, which update immediately on a configuration change, the system clock dividers are updated only with the next software triggered mode change. This is to ensure that the system clock dividers are updated simultaneously and that no intermediate inconsistent configurations can occur. It also ensures that the divider configurations are aligned with the target mode's system clock selection.

The system clock divider configuration update sequence is as follows:

1. Configure the target mode in the MC_ME to select the desired system clock source.
2. Configure the CGM_SC_DC0...2 registers as desired and aligned with the target system clock source frequency making sure that the dividers are configured consistently as described in [Section 30.4.1.4.1, System clock divider synchronization](#).
3. Request a mode change in the MC_ME to the desired target mode.
4. When mode change has completed and the system clock switching has been successful, the new system clock divider configuration will be in effect.

See [Chapter 62: Mode Entry Module \(MC_ME\)](#), for details on how to configure modes and make mode change requests.

30.4.2 Auxiliary clock generation

Figure 348 through *Figure 358* show the block diagrams of the generation logic for the various auxiliary clocks. See the following sections for auxiliary clock selection control:

- [Section 30.3.1.26, Auxiliary Clock 0 Select Control Register \(CGM_AC0_SC\)](#)
- [Section 30.3.1.33, Auxiliary Clock 1 Select Control Register \(CGM_AC1_SC\)](#)

30.4.2.1 Auxiliary clock dividers

The MC_CGM generates the following derived clocks:

- peripheral clock - controlled by the CGM_AC0_DC0 register
- sigma delta ADC clock - controlled by the CGM_AC0_DC1 register
- SAR ADC clock - controlled by the CGM_AC0_DC2 register
- DSPI clock 0 - controlled by the CGM_AC0_DC3 register
- LFAST clock - controlled by the CGM_AC1_DC0 register
- FlexRay clock - controlled by the CGM_AC2_DC0 register
- SENT clock - controlled by the CGM_AC2_DC1 register
- PSi5_f189 clock - controlled by the CGM_AC5_DC0 register
- PSi5_f125 clock - controlled by the CGM_AC5_DC1 register
- PSi5_1us clock - controlled by the CGM_AC5_DC2 register
- PS_S_TS clock - controlled by the CGM_AC5_DC2 and CGM_AC5_CDC0 registers
- PSi5_S_DDSR0 clock - controlled by the CGM_AC5_DC2, CGM_AC5_CDC1, and CGM_AC5_CDC10 registers
- PSi5_S_DDSR1 clock - controlled by the CGM_AC5_DC2, CGM_AC5_CDC1, and CGM_AC5_CDC11 registers
- PSi5_S_DDSR2 clock - controlled by the CGM_AC5_DC2, CGM_AC5_CDC1, and CGM_AC5_CDC12 registers
- PSi5_S_DDSR3 clock - controlled by the CGM_AC5_DC2, CGM_AC5_CDC1, and CGM_AC5_CDC13 registers
- PSi5_S_WD0 clock - controlled by the CGM_AC5_DC2, CGM_AC5_CDC2, and CGM_AC5_CDC20 registers

- ethernet REF clock - controlled by the CGM_AC10_DC0 register

30.4.3 Dividers functional description

Dividers are used for the generation of divided system and peripheral clocks. The MC_CGM has the following control registers for built-in dividers:

- [Section 30.3.1.23, System Clock Divider 0 Configuration Register \(CGM_SC_DC0\)](#)
- [Section 30.3.1.24, System Clock Divider 1 Configuration Register \(CGM_SC_DC1\)](#)
- [Section 30.3.1.25, System Clock Divider 2 Configuration Register \(CGM_SC_DC2\)](#)
- [Section 30.3.1.28, Auxiliary Clock 0 Divider 0 Configuration Register \(CGM_AC0_DC0\)](#)
- [Section 30.3.1.29, Auxiliary Clock 0 Divider 1 Configuration Register \(CGM_AC0_DC1\)](#)
- [Section 30.3.1.30, Auxiliary Clock 0 Divider 2 Configuration Register \(CGM_AC0_DC2\)](#)

- [Section 30.3.1.56, Auxiliary Clock 9 Divider 0 Configuration Register \(CGM_AC9_DC0\)](#)

The reset value of all counters is '1'. If a divider has its DE bit in the respective configuration register set to '0' (the divider is disabled), any value in its DIV field is ignored.

30.4.3.1 Divider jitter injection

The clock dividers for the FlexRay clock and the CAN clock inject a jitter so that off-chip communication via the associated peripherals is not possible. For details on enabling this feature, see the "Production Disable" and "CAN Jitter Enable" sections of the PASS chapter.

In addition, PLL0 PHI is always selected to source the FlexRay clock when jitter injection is enabled (see [Figure 350](#)).

30.4.3.2 Fractional divider details

The clock divider used to generate the PSI5_f189 clock and the DSPI clock 0 divides the selected clock source frequency by a fractional value given by the DIV and DIV_FMT fields of the CGM_AC5_DC0 register.

Equation 21
$$F_{\text{divided clock}} = F_{\text{source clock}} \div ((\text{DIV} + 1) \div 10^{\text{DIV_FMT}})$$

The divided clock frequency is actually an average frequency, since the divider uses only the available rising and falling edges of the source clock. Therefore, the actual frequency switches between two frequencies which are the two frequencies closest to the desired frequency (above and below) which can be extracted by a division factor $n/2$, where n is an integer greater than 1. The switching between the two frequencies is such that the resultant clock's rising edge never deviates from the ideal clock's rising edge by more than 25% of the source clock period and that the resultant average frequency over $\text{DIV} + 1$ source clock periods ($= 10^{\text{DIV_FMT}}$ divided clock periods) is the desired frequency.

30.4.3.2.1 Example: Fractional clock division

Desired division factor = 2.3

DIV = 22

DIV_FMT = 1

Figure 360. MC_CGM fractional division example waveform (divide by 2.3)

$$\text{Equation 22} \quad F_{\text{divided clock}}|_{\text{max}} = F_{\text{source clock}} \div 2.0$$

$$\text{Equation 23} \quad F_{\text{divided clock}}|_{\text{min}} = F_{\text{source clock}} \div 2.5$$

$$\text{Equation 24} \quad F_{\text{divided clock}}|_{\text{ave}} = F_{\text{source clock}} \div \frac{((2.5 \times 6) + (2.0 \times 4))}{10}$$

Therefore,

$$\text{Equation 25} \quad F_{\text{divided clock}}|_{\text{ave}} = F_{\text{source clock}} \div 2.3$$

As can be seen in [Figure 360](#), the rising edge of the actual divided clock is 'snapped' to the rising or falling edge of the source clock closest to the rising edge of the ideal divided clock. This results in a theoretical maximum deviation, or jitter, of $\pm 25\%$ of the source clock period. In this particular case, the maximum deviation is $\pm 20\%$ of the source clock period.

30.4.3.3 Divider Update Triggering

There are two methods for updating the dividers associated with the system clock and each auxiliary clock: immediate and register triggered. Which method is used for which set of dividers is controlled by the CGM_DIV_UPD_TYPE register.

Regardless of which method is selected for a given group of dividers, once an update of one of the dividers of that group has been triggered, the associated bit in the CGM_UPD_STAT register is set. This bit is then cleared when all the dividers of that group have completed the update process and are running with the current configuration.

30.4.3.3.1 Immediate Divider Update

If a divider group has been configured to be updated immediately (i.e., the corresponding CGM_DIV_UPD_TYPE register bit = '0'), the configuration of a divider in that group will be applied immediately on the write to that divider's configuration register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

30.4.3.3.2 Software-triggered divider update

If a divider group has been configured to be updated via a software trigger (i.e., the corresponding CGM_DIV_UPD_TYPE register bit = '1'), the configuration of a divider in that group will not be applied immediately on the write to that divider's configuration register. Instead, the configuration in the corresponding configuration register will be applied only when software writes any value to the CGM_DIV_UPD_TRIG register. The actual update will take some time to actually reach the divider output due to the clock domain crossing and edge alignment mechanisms.

In the case of the system clock dividers, if the SYS_DIV_RATIO_CHNG bit in the CGM_SC_DIV_RC register = '1', the crossbar switch is requested to halt its ongoing transactions, and only after the crossbar switch has acknowledged the request does the update of the system clock dividers take place. Once these updates have completed, the halt request to the crossbar is deasserted.

Note: If halting the crossbar can cause a bus master to starve and thus lead to lost data or other problems, it is recommended to vary the system clock divider configurations without changing the ratios and to set CGM_SC_DIV_RC[SYS_DIV_RATIO_CHNG] to '0'.

Note: In order to ensure a clean clock divider configuration update, software must check that all ongoing updates have already completed (i.e., all relevant bits in the CGM_DIV_UPD_STAT register are '0') before triggering a new update via the CGM_DIV_UPD_TRIG register.

31 OSC Digital Interface (XOSC)

31.1 Introduction

The XOSC digital interface is used to control the on-chip oscillator (XOSC) and provide the register interface for the programmable features. Selection of the XOSC as a source clock is controlled the Clock Generation module (MC_CGM). The XOSC is enabled and disabled by configuring the Mode Entry module (MC_ME).

The programmable features of the XOSC digital interface are as follows:

- Oscillator power-down control and status
- Oscillator startup delay
- Oscillator clock available interrupt
- Oscillator bypass mode control

31.2 Functional description

The XOSC digital interface provides control of the on-chip oscillator and the register interface for the mode and startup delay control. The oscillator provides an output clock that is used as an input to PLL0 and can be selected as the reference clock for many of the peripherals on the device.

[Table 433](#) shows the possible configurations of the XOSC.

Table 433. XOSC configurations

OSC EN	CTL[OSCBYP]	XTAL	EXTAL	XOSC Output	XOSC MODE
0	0	No crystal, high-impedance	No crystal, high-impedance	0	Power down, IDDQ
x	1	x	external clock	XTALOUT	Bypass, OSC Disabled
1	0	crystal	crystal	XTALOUT	Normal, OSC Enabled
		ground	external clock	XTALOUT	Normal, OSC Enabled

31.2.1 Oscillator power-down control and status

Enabling and disabling of the oscillator is done in the Mode Entry (MC_ME) module (see “Mode Entry Module (MC_ME)” chapter). The ME_<mode>_MC[XOSCON] controls the power-down of oscillator based on the current device mode (see “MC_ME Memory Map” table for available *modes*). The status of the XOSC is provided in the MC_ME_GS[S_XOSC] field.

31.2.2 Oscillator startup delay

A bit in the UTEST flash memory determines whether the oscillator is enabled at power-up of the device. If enabled, the oscillator is started after Phase3 of the device reset sequence. In order to allow the oscillator to reach full amplitude before use, the internal counter (OSCCNT) is started when the device exits reset. The counter is driven by the oscillator output clock. When the counter reaches XOSC_CTL[EOCV] × 512, a signal is sent to the

MC_ME module, allowing a mode switch to the oscillator (when used as a system clock or an input to PLL0).

The default value for this field after reset depends on implementation and can be found in the XOSC Device Configuration. After reset, software can clear or change the EOCV field in order to shorten or lengthen the delay until the oscillator is ready.

Note: It is advised that if the EOCV value is modified it should be done as early as possible in user code. This will ensure that the new value will be used before OSCCNT reaches the count value.

31.2.3 Oscillator clock available interrupt

An interrupt can be generated when the count value is reached ($OSCCNT = XOSC_CTL[EOCV] \times 512$). The `XOSC_CTL[I_OSC]` will be set and an interrupt will be generated if the interrupt mask is set (`XOSC_CTL[M_OSC] = 1`).

31.2.4 Oscillator bypass mode

The oscillator circuit can be bypassed by setting `XOSC_CTL[OSCBYP]`. This bit can only be set by software, and is only cleared by a system reset. In bypass mode, the oscillator is disabled and the input clock on the EXTAL pins is level-shifted and driven to the logic on the device. The bypass configuration is independent of the power-down mode of the oscillator.

31.3 Memory map and register definition

[Table 434](#) shows the memory map of the XOSC registers.

Field	Description
24 I_OSC	Crystal oscillator clock interrupt. This bit is set by hardware when OSCCNT counter reaches the count value $EOCV \times 512$. It is cleared by software by writing 1. 0 No oscillator clock interrupt occurred. 1 Oscillator clock interrupt pending.
25:31	Reserved

32 IRCOSC digital interface

The Internal RC Oscillator digital interface (IRCOSC) controls the internal 16 MHz RC oscillator system. This oscillator system includes the main internal RC oscillator (MRC), as well as an internal temperature sensor and an internal voltage regulator used to compensate external variations in temperature and voltage. It also provides access to trimming information used for safety implementations.

32.1 Functional description

The IRCOSC provides a high frequency (f_{MRC}) clock. After deassertion of reset, the output clock is available after a short time (see Electrical Specifications for timing information) which is required for stabilization. IRCOSC status indication is found in the MC_ME_GS[S_IRC] field (see Mode Entry Module in the device reference manual).

During power on reset sequence, native trimming bits, fine trimming bits, and TSENS code bits are initialized from the TEST flash memory. These bits can be accessed for safety reasons through the IRCOSC native trimming register (IRCOSC_NT). Based on native trimming, the main RC oscillator output frequency can be incrementally trimmed by IRCOSC_CTL[USER_TRIM[4:0]]. The USER_TRIM bits can be programmed to modify internal capacitor/resistor values to match output clock frequency with dfvar_SW, as defined in the datasheet.

32.2 Memory map and register definition

[Table 436](#) shows the memory map of the IRCOSC registers.

Table 436. IRCOSC memory map

Offset (hex)	Register	Access	Reset Value (hex)	Location
00	CTL—IRCOSC Control Register	R/W	0000_0000	32.2.1.1/1012

24:25	Reserved
26:31 TSENS_TRIM	Ambient temperature reference code value for safety check

33 RAM controller (PRAM)

33.1 Introduction

This section provides an overview of the Platform RAM Controller. The RAM controller acts as an interface between the system bus (AHB-Lite 2.v6) and the integrated system RAM. It converts the protocols between the system bus and the dedicated RAM array interface.

The RAM controller supports two 64-bit AHB interfaces and a 64-bit RAM array interface. The primary AHB port provides a connection to the platform crossbar for direct RAM access from the various crossbar masters. The backdoor AHB port provides a connection from the flash controller to facilitate calibration overlay access. [Figure 365](#) is a simplified block diagram depicting the position of the RAM controller within a typical platform architecture:

Figure 365. Simplified platform block diagram

The following list summarizes the key features of the RAM controller:

- System bus supports 64-bit data + 8-bit ECC AHB interfaces
- Array interface supports a 64-bit data + 8-bit ECC interface
- Late-write support via 64-bit data + 8-bit ECC storage buffer to support single-cycle write accesses
- Configurable read access timing (zero or one wait-state programmable) allowing use in large range of frequency targets
- Read-modify-write operation to support array write size less than a doubleword.

The address path of the RAM controller contains a mux that chooses among the addresses presented on the system bus for a read request, either the address from the temporary holding register or the address from the late-write buffer. The temporary holding register contains the address which was presented during the AHB address phase of the write request. The request is stalled from being presented to the RAM by one cycle in order to

present simultaneously the address and associated write data, which is not valid until the AHB dataphase. The late-write buffer holds write requests which are delayed to facilitate single-cycle response on the system bus.

The read datapath contains a mux that chooses the source of the read data to be presented on the system bus on a read request. In the event that a read request matches the contents of the late-write buffer, a RAM access is not required and the late-write buffer contents are selected onto the read databus. Otherwise, the read data is a result of a RAM access. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the RAM controller, including the late-write storage buffer, to support end-to-end ECC (e2eECC) coverage.

The write datapath contains the mux that chooses the source of the write data as well as the control logic for generating read-modify-write operations on writes that are less than 64 bits in size. A write operation can be performed to empty the contents of the late-write buffer. In the case of back-to-back writes, the write may be forced to bypass the late-write buffer and instead be stored directly, precisely in the RAM.

33.2 SRAM controller memory map and register definition

The RAM controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses will generate an IPS error termination.

Table 441. RAM controller memory map

Offset	Register	Size	Access	Mode
PRAMC_BASE+00x00	Platform RAM Configuration Register 1 (PRAMC_PRCR1)	32b	R/W	Supr ⁽¹⁾

25 P0_BO_DIS	Port p0 read burst optimization disable 0 64-bit WRP4 read bursts are optimized such that the controller returns a 2-1-1-1 response ⁽¹⁾ when PRCR[FT_DIS]=1 1 64-bit WRP4 read bursts are not optimized; the controller returns a 2-2-2-2 response ⁽¹⁾ when PRCR[FT_DIS]=1
26 – 30	Reserved
31 FT_DIS	Flow through disabled This field defines the AHB response of the RAM controller on reads. The state of this field has no impact on the response latency on writes. This bit is cleared by hardware reset. 0 RAM read data is passed directly to the system bus, incurring no additional latency 1 RAM read data is registered prior to returning on the system bus, incurring 1 extra cycle of latency

1. The number of cycles taken for a RAM access can vary ± 1 clock cycle depending on the RAM speed relative to the PRAM controller clock frequency. If system RAM is running at the same frequency as the PRAM controller a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to PRAM controller clock frequency.

33.3 Functional description

33.3.1 Read / Write introduction

The RAM controller generates chip-select and write-enable, the array address, and write data as inputs to the RAM array. The RAM controller captures read data from the RAM array and drives it onto the AHB along with the associated datapath termination signals. To facilitate operating at higher frequencies, the RAM controller can optionally incur a single wait state on the AHB response.

33.3.1.1 Reads

Read transfers, of any size, can be configured to complete with a zero or one additional wait state response on the AHB.

33.3.1.2 Optional read wait-state

The RAM controller can be optionally programmed to register RAM read data prior to returning it on the system bus. Setting the PRCR1[FT_DIS] field inserts a register in the

read data path for use when operating the controller at high frequencies. The state of PRCR1[FT_DIS] field has no effect on writes.

A random, initial access will take 2 clock cycles (2T) to complete if PRCR1[FT_DIS]=0, and a WRAP4 burst will have an access time of 2-2-2-2. A random, initial access will take 3 clock cycles (3T) to complete if PRCR1[FT_DIS]=1, and a WRAP4 burst will have an access time of 3-2-2-2

Note: The number of cycles taken for a RAM access can vary ± 1 clock cycle depending on the RAM speed relative to the PRAM controller clock frequency. If system RAM is running at the same frequency as the PRAM controller a random initial access takes 2 clock cycles. If system RAM is running at a slower frequency a random initial access may take 3 clock cycles. Subsequent burst beats take either 1 or 2 cycles depending on RAM speed relative to PRAM controller clock frequency.

33.3.2 Writes

33.3.2.1 64-bit writes

Aligned 64-bit writes execute in a single AHB data phase cycle, allowing for zero wait states on back-to-back writes of these sizes. If, during the data phase of a write, a read is requested on the AHB, the write is registered in the late-write buffer, allowing the read to take place without a wait state. The valid buffered or late-write data is stored on the next available array address phase.

Back-to-back 64-bit writes execute slightly differently whereby the first write bypasses the late-write buffer. Rather, the write data is stored directly to the array in the same cycle in which it is valid on the AHB.

33.3.2.2 Less than 64-bit writes

Writes of size less than 64 bits incur a read-modify-write action as a consequence of the ECC coding scheme's 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The write data is merged into the appropriate byte lanes along with the potentially-corrected read data. A new codeword is generated based on the newly formed doubleword. The newly formed doubleword and its associated checkbits are subsequently written to the RAM. [Figure 367](#) provides details on the read-modify-write datapath. For details on the ECC coding scheme, refer to [Section 33.5, "Safety considerations."](#)

Figure 367. Read-modify-write datapath

On a read-modify-write operation, the array read data is registered after it is decoded and before it is merged with the AHB write data. Therefore, writes of size less than 64 bits require the insertion of one wait state before the data phase can be completed.

33.3.2.3 Unaligned writes

The RAM controller is compliant with the AMBA-AHB2.v6 Extensions specification with regard to byte strobes. The size of the transfer is sufficient to cover all bytes being written and covers more bytes in the case of an unaligned transfer. The address of the transfer is rounded down to the nearest boundary of the size of the transaction.

It should be noted that unaligned writes always generate read-modify-write operations in the RAM controller in order to preserve the validity of the ECC codeword.

33.4 Initialization/application information

It is essential that each memory address be written to a known value before it is read, to initialize the ECC. This includes reads generated from the read-modify-write operation which occurs when a write transfer of less than 64 bits or an unaligned write is requested. Without writing an address to a known value first, a read from this address will most likely generate an uncorrectable ECC event.

A possibility for initializing PRAM memory space would be to use a stored 64-bit word instruction such as Store Multiple Word (e_stmw) in Power Architecture VLE.

33.5 Safety considerations

33.5.1 Hsiao ECC algorithm

The e2eECC scheme implements a single-error correction, double-error detection (SECDED) code using the so-called Hsiao odd-weight column criteria. These codes are named for M.Y. Hsiao, an IBM researcher who published extensively in the early 1970s on SECDED codes better suited for implementation in protecting (mainframe) computer memories than traditional Hamming codes.

The Hsiao codes are Hamming distance 4 implementations which provide the SECDED capabilities. The minimum odd-weight constraints defined by Hsiao are relatively simple in the resulting implementation of the parity check H matrix which defines the association between the data (and address) bits and the checkbits. They are:

1. There are no all-zeroes columns.
2. Every column is distinct.
3. Every column contains an odd number of ones, and hence is "odd weight".

In defining the H-matrix for this family of devices, these requirements from Hsiao were applied. Additionally, there are a variety of ECC codeword requirements associated with specific functional requirements associated with the system RAM that further dictated the specific column definitions. In any case, the resulting ECC is organized based on 64 data bits plus 29 address bits (the upper bits of the 32-bit address field minus the 3 bits which select the byte within the 64-bit (8-byte) data field).

The basic H-matrix for this (101, 93) code (93 is the total number of data bits, 101 is the total number of data bits (93) plus 8 checkbits) is shown in [Table 443](#). A '*' in [Table 443](#) indicates the corresponding data or address bit is XOR'ed to form the final checkbit value on the left. For 64-bit data writes, the table sections corresponding to D[63:32], D[31:0], and A[31:3] are logically summed (output of each table section is XOR'ed) together to the final value driven on the hwchckbit[7:0] outputs. Note that this table uses *the AHB bit numbering convention where bit[0] is the least significant bit*.

Table 443. RAM controller basic H-matrix definition

1. Bit numbering is AHB convention: bit 0 is LSB. D[7:0] corresponds to byte at address 0. D[63:56] corresponds to byte at address 7.

33.5.1.1 E2EECC considerations on less-than-64-bit write transactions

Recall writes of size less than 64-bit incur a read-modify-write action as a consequence of the ECC coding scheme 64-bit granularity. In the case of a read-modify-write action, the RAM controller performs SEC/DED on the read data. The RAM controller uses the following checkbit manipulation technique to ensure any faults in the PRAM control logic associated with performing the read-modify-write action will ultimately be detectable by e2eECC:

- On an 8-, 16-, or 32-bit write request, the write data is presented by the master on the AHB bus in the correct byte lanes, with the non-pertinent byte lanes zeroed out, and the associated checkbit is based on this “zero-padded” write data.

Consider the following example whereby the master presents a 16-bit write request at address 0x40000000:

- The RAM controller detects that the request is a less-than-64-bit write request and initiates a read to address 0x40000000. An ECC check and potential single-bit correction is performed on the data returned from the RAM. In addition, the ECC event is reported to the Memory Error Management Unit (MEMU).

If a non-correctable ECC event is detected, the AHB request is terminated with error on the system bus. In addition, the ECC event is reported to the MEMU.

- The RAM controller isolates the pertinent byte lanes of the read data by zero-padding the non-pertinent byte lanes and calculating the checkbit contribution associated with the read data in the byte lanes to be updated as a result of the write request.

- Merge the non-pertinent read data bytes with the write data in the appropriate byte lanes. Take the checkbit value that was stored in the RAM and remove the checkbit contribution associated with the read data in the byte lanes to be updated. Then introduce the checkbits associated with the write data. The result is ultimately a checkbit value associated with the complete 64-bit data to be written to the array.

This technique calculates the ultimate checkbit value on a read-modify-write transaction through a series of data manipulations, taking care to avoid discarding the original checkbits provided by the requesting master, such that faults in the crossbar (XBAR) and RAM controller datapath and control logic are covered by e2eECC.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The RAM controller performs EDC after ECC check on all read-modify-write transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the FCCU module.

33.5.2 Transaction monitor

The integrity of the address and data on a system RAM transaction is covered by e2eECC check performed by the requesting master. Functional safety coverage of the address path and control within the RAM controller is handled by a transaction monitor which verifies the integrity of the transactions between the RAM controller and the RAM array. The transaction monitor verifies RAM transactions initiated to service the following types of transactions

- Direct, system bus read or write request
- Read followed by write to fulfill a read-modify write transaction
- Write transaction to empty the late-write buffer

The function of the transaction monitor relies on a feedback path between the RAM controller and RAM array, wherein the RAM provides latched address and control feedback outputs as in indication of received inputs when a RAM access is initiated.

Table 444. RAM safety feature outputs

Signal Name	Description
pram_addr_co[17:0]	Safety feature compare outputs for address bus
pram_cs_b_co	Safety feature compare output for chip-select control input
pram_we_co	Safety feature compare output for write-enable control input

This feedback information is used by the RAM controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the RAM controller or the transmission path between the RAM controller and RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

Since writes to the RAM can be buffered, the transaction monitor also tracks the contents of the late-write buffer. When the late-write buffer is emptied, the safety feature compare outputs from the RAM are evaluated against the expected contents of the late-write buffer as tracked by the transaction monitor.

As a countermeasure against false misses to the late-write buffer on reads, the transaction monitor must also verify the expected source of data returned on a read as supplied either from the RAM or from the late-write buffer.

Figure 368. RAM controller transaction monitor block diagram

34 Flash memory controller

34.1 Introduction

The flash memory controller has these functions:

- It acts as an interface between the system bus (AHB-Lite 2.v6) and the flash memory array.
- It serves as the interface to the on-chip overlay RAM.
- It serves as the interface to the off-chip buddy device.^(h)
- It acts as the interface between the ASC Modeling Unit (AMU) and the c55fm flash memory array.

The flash memory controller supports two 64-bit AHB buses and a 256-bit read data interface from each flash memory array. Each AHB port contains a 4-entry, 2-way set-associative mini-cache as well as an associated controller that prefetches sequential lines of data from the flash arrays into the mini-cache. This buffer mechanism serves to deliver flash read data with zero-wait state response on lines that reside in the cache. AHB requests that miss the cache generate the needed flash array access and are forwarded to the AHB upon completion. Each mini-cache entry is 256 bits in size, matching the flash array page size and providing 512 bytes of high-speed local storage. Along with the read and write data, the corresponding ECC codewords traverse the entire datapath of the flash memory controller, including the mini-cache, to support end-to-end ECC (e2eECC) coverage (e2eECC).

34.2 Features

The following list summarizes the key features of the flash memory controller:

- Two 64-bit AHB interface ports (p0, p1) allowing simultaneous access to dedicated prefetch mini-cache per slave port.
- 256-bit read data bus + 64-bit write data bus
- Configurable read buffering and line prefetching support via 4-entry, 2-way set-associative mini-cache plus prefetch controller per AHB port to provide single-cycle “buffer hit” read response.
- Configurable access control based on read/write and AHB master ID attributes.
- Configurable access timing (wait-state programmable) allowing use in a wide range of frequency targets.
- Optional address pipelining capability to maximize throughput.
- Support for reporting of single- and multi-bit flash ECC events on a 64-bit doubleword boundary.
- Configurable overlay remapping of logical flash accesses to on-chip calibration RAM, extended off-chip calibration RAM, on-chip system RAM
- Nexus trace stream interface supports message dumping to the on-chip overlay RAM
- Dedicated flash access port for servicing the AMU

h. The term “buddy device” refers to an optional companion chip with additional memory and debug features that is paired with a production chip during system development. It is not used in production devices.

34.3 Block diagrams

Figure 369 provides a block diagram showing the flash memory controller and the attached flash array.

Note: This module is also known as the Platform Flash controller, that is, PFlash or PFLASH_C55FM.

Figure 369. Platform-centric simple block diagram with flash memory controller

34.4 Flash memory controller memory map

34.4.1 Overview

The flash memory controller module provides an IPS programming model mapped to a standard 16 KB on-platform peripheral slot. The programming model consists of flash memory access configuration and overlay remapping configuration.

The programming model can only be referenced using a 32-bit (word) access. Attempted references using different access sizes or to undefined (reserved) addresses or in user mode generates an IPS error termination. The flash controller allows access to the programming model by all system bus masters.

The programming model can only be accessed in supervisor mode.

Attempted updates to the programming model while the flash memory controller module is in the midst of an operation will result in non-deterministic behavior. Software must be architected to avoid this scenario.

There is no idle indicator for the flash controller. The recommended flow for multi-core devices is to start only one core and execute initialization code to completion before starting the remaining cores. If the user needs to reconfigure the flash, code execution must be temporarily moved to system RAM.

9 P0_M6PFE	Port0 Master 6 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 6. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
10 P0_M5PFE	Port0 Master 5 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 5. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
11 P0_M4PFE	Port0 Master 4 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 4. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
12 P0_M3PFE	Port0 Master 3 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 3. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master

Table 446. PFCR1 field descriptions (continued)

Field	Description
13 P0_M2PFE	Port0 Master 2 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 2. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
14 P0_M1PFE	Port0 Master 1 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 1. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
15 P0_M0PFE	Port0 Master 0 Prefetch enable. This bit controls whether prefetching may be triggered by AHB master 0. This bit is cleared by hardware reset. 0 No prefetching may be triggered by this master 1 Prefetching may be triggered by this master
16–18 APC	Address Pipeline Control. This field controls the number of cycles that a subsequent flash read from the opposite AHB port can be initiated prior to the previous read data being valid. This field applies to the configuration of Port0 and Port1. 000 Pipelined access to the flash disabled. 001 A pipelined access can be initiated 1 cycle before the previous data is valid 010 A pipelined access can be initiated 2 cycles before the previous data is valid 011 A pipelined access can be initiated 3 cycles before the previous data is valid 1-- Pipelined access to the flash is disabled and one wait state is inserted before a subsequent access can be initiated
19–23 RWSC	Read Wait State Control. This field controls the number of wait-states to be added to the best-case flash array access time for reads. The best-case flash array access time for reads is one cycle. This field must be set to a value corresponding to the operating frequency of the flash memory controller and the actual read access time of the flash memory controller. The required settings are documented in the SoC specification. Higher operating frequencies require non-zero settings for this field for proper flash operation. This field is set to 5'b00110 by hardware reset. This field applies to the configuration of Port0 and Port1. 00000 No additional wait-states are added 00001 One additional wait-state is added ... 11111 Thirty-one additional wait-states are added

Table 446. PFCR1 field descriptions (continued)

Field	Description
25 P0_DPFEN	Port0 Data Prefetch Enable. This field enables or disables prefetching initiated by a data read access. This field is cleared by hardware reset. 0 No prefetching is triggered by a data read access 1 Prefetching may be triggered by any data read access
27 P0_IPFEN	Port0 Instruction Prefetch Enable. This bit enables or disables prefetching initiated by an instruction read access. This field is cleared by hardware reset. 0 No prefetching is triggered by an instruction read access 1 Prefetching may be triggered by any instruction read access
29–30 P0_PFLIM	Port0 PFlash Prefetch Limit. This field controls the prefetch algorithm used by the prefetch controller. This field defines a limit on the maximum number of sequential prefetches which will be attempted between buffer misses. In all situations when enabled, only a single prefetch is initiated on each buffer miss or hit. This field is cleared by hardware reset. 00 No prefetching or buffering is performed. 01 The referenced line is prefetched on a buffer miss, that is, prefetch on miss. 1x The referenced line is prefetched on a buffer miss, or the next sequential line is prefetched on a buffer hit (if not already present), that is, prefetch on miss or hit.
31 P0_BFEN	Port0 PFlash Line Read Buffers Enable. This bit enables or disables line read buffer hits. It is also used to invalidate the buffers. This bit can only be updated while PFCR3[BAF_DIS] = 0. After execution of the boot code, as indicated by PFCR3[BAF_DIS] = 1, this bit becomes read-only until the next hardware reset. 0 The line read buffers are disabled from satisfying read requests, and all buffer valid bits are cleared. 1 The line read buffers are enabled to satisfy read requests on hits. Buffer valid bits may be set when the buffers are successfully filled.

34.4.1.2 Platform Flash Configuration Register 2 (PFCR2)

The PFlash Configuration Register 2 (PFCR2) specifies operation Port1 of the PFLASH_C55FM flash memory controller.

Table 448. PFCR3 field descriptions

Name	Description
0–1 P0_WCFG	Port0 Way Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers in an indexed set are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers in an indexed set are partitioned into two groups with way 0 allocated for instruction fetches and way 1 for data accesses. 11 Reserved.

Table 448. PFCR3 field descriptions (continued)

Name	Description
2–3 P1_WCFG	Port1 Line Buffer Configuration. This field controls the configuration of the line buffers for a given set across two ways in the controller cache. The indexed set can be organized as a “pool” of available resources, or with a fixed partition between instruction and data buffers. In all cases, when a buffer miss occurs, the flash page is assigned a location within the controller cache. Within the indexed set, the way is selected using a least-recently-used replacement policy, and the entry is then marked as most-recently-used for that set. If the flash access is for the next-sequential line (prefetch), the buffer is not marked as most-recently-used until the given address produces a buffer hit. This field is initialized by hardware reset. 00 Both buffers are available for any flash access, that is, there is no partitioning of the buffers based on the access type. 01 Reserved 10 The buffers are partitioned into two groups with buffer 0 allocated for instruction fetches and buffer 1 for data accesses. 11 Reserved
11 BDRM	Buddy Device Read Mode - This field controls the PFLASH_C55FM bus response when the master presents a read request targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address. This field is ignored on production ECUs where the Buddy Device is not present. On production ECUs, this memory map region is provided for the “OLDA” (on-line data acquisition) function. Read requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address are terminated with error on the system bus. This field is ignored on write requests targeting the extended overlay RAM using the direct, non-remapped address. Write requests on production ECUs targeting the non-existent extended overlay RAM using the direct, non-remapped address and terminate cleanly on the system bus. Write requests on engineering ECUs targeting the extended overlay RAM using the direct, non-remapped address are ignored are executed. This field is initialized by hardware reset. 0 Read request targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address are aborted, and the request is terminated with error on the system bus. 1 Read request targeting the extended overlay RAM on the Buddy Device (BD) using the direct, non-remapped address are allowed. The PFLASH_C55FM returns the requested data from the extended overlay RAM, which resides on the BD. Any system bus errors returned by the BD are passed onto the master.

Table 448. PFCR3 field descriptions (continued)

Name	Description
15 BAF_DIS	BAF Disable. This field controls executable access to the BAF (Boot Assist Flash) region of the flash. Once this field is set, attempted instruction accesses targeting the BAF region are aborted and terminated with a system bus error. The affect of this field applies to system bus transfers through both, Port0 and Port1. Data-type accesses to the BAF region are not affected by this field. Once this field is set, it becomes a read-only field and can only be cleared by hardware reset. Once this field is set, any subsequent write attempts to modify this field are ignored with an error-free data transfer termination. This field is initialized by hardware reset. 0 Executable access to the BAF flash region is allowed. 1 Executable access to the BAF flash region is prohibited.
16–17 ARBM	Arbitration Mode. This 2-bit field controls the arbitration of concurrent flash access requests from the two AHB ports of the flash memory controller. In both fixed priority or round-robin modes, write requests are prioritized higher than read requests, and read requests are prioritized higher than speculative prefetch requests whenever both ports issue concurrent requests. This field is initialized by hardware reset. 00 Fixed priority arbitration with AHB p0>p1 01 Fixed priority arbitration with AHB p1>p0 1- Round-robin arbitration

34.4.1.4 Platform Flash Access Protection Register (PFAPR)

The PFlash Access Protection Register (PFAPR) is used to control read and write accesses to the flash array.

Table 449. PFlash Access Protection Register field descriptions

Name	Description
0–1 M0AP	Master 0 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
2–3 M1AP	Master 1 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
4–5 M2AP	Master 2 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

Table 449. PFlash Access Protection Register field descriptions (continued)

Name	Description
6–7 M3AP	Master 3 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
8–9 M4AP	Master 4 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
10–11 M5AP	Master 5 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
12–13 M6AP	Master 6 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
14–15 M7AP	Master 7 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master
16–17 M8AP	Master 8 Access Protection. This field controls whether read and write accesses to the flash are allowed based on the master ID of a requesting master. These fields are initialized by hardware reset. 00 No accesses may be performed by this master 01 Only read accesses may be performed by this master 10 Only write accesses may be performed by this master 11 Both read and write accesses may be performed by this master

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 450. PFCRCR field descriptions

Field	Description
23 SAFE_CAL	Safe Calibration. This bit facilitates the use of safety-critical calibration data. When this bit is enabled, the flash memory controller is configured to perform redundancy checking on the calibration remap function and reduce the total number of potential calibration regions from 32 to 16. This field is initialized by hardware reset. 0 Established calibration overlay regions are considered safety-critical. 1 Established calibration overlay regions are not considered safety-critical.
27 IRMEN	Instruction Remap. This bit enables calibration remapping evaluation on instruction fetches. When PFCRCR[GRMEN] is disabled, this bit is ignored. This field is initialized by hardware reset. 0 Calibration remap evaluation is performed on any incoming data fetch requests only. 1 Calibration remap evaluation is performed on all incoming flash access requests - data and instruction fetches.
31 GRMEN	Global Remap Enable. This bit globally enables or disables the calibration remap evaluation on system flash accesses. Calibration remap evaluation is immediately available the next cycle following an update to enable PFCRCR[GRMEN] This field is initialized by hardware reset. 0 Calibration remap evaluation is not performed on any incoming system flash access requests. 1 Calibration remap evaluation is performed on all incoming system flash access requests.

34.4.1.6 PFlash Remap Descriptor Enable Register (PFCRDE)

The PFlash Calibration Remap Descriptor Enable Register (PFCRDE) is used to enable or disable up to 32 calibration remap descriptors. Note there is also a global remap enable (PFCRCR[GRMEN]) that also must be asserted in conjunction with the individual CRDnEN flags to enable a given remap descriptor.

Table 451. PFCRDE field descriptions

Field	Description
0 CRD0EN	Calibration Remap Descriptor 0 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor <i>n</i> invalid 1 Calibration Remap Descriptor <i>n</i> valid
1 CRD1EN	Calibration Remap Descriptor 1 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other types of system reset. 0 Calibration Remap Descriptor <i>n</i> invalid 1 Calibration Remap Descriptor <i>n</i> valid
2 CRD2EN	Calibration Remap Descriptor 2 Enable. This bit indicates whether the corresponding remap descriptor is valid. There is also a global calibration remap enable (PFCRCR[GRMEN]) that also must be asserted to enable any remap functionality. Any write to PFCRDn.Word{0,1,2} clears the corresponding PFCRDE[CRDnEN] bit, leaving the calibration remap descriptor invalid. This bit is cleared by power-on reset and unaffected by other type of system reset. 0 Calibration Remap Descriptor <i>n</i> invalid 1 Calibration Remap Descriptor <i>n</i> valid

34.4.1.7 PFlash Calibration Region Descriptor *n* (PFCRDn)

Each 96-bit (12-byte) region descriptor specifies an overlay region where a flash access can be remapped during calibration and debug. The calibration remap descriptors are organized sequentially as 128-bit (16-byte) structures in the Platform Flash Controller's programming model. Each of the three 32-bit words that define a single calibration region are detailed in the subsequent sections; the fourth word is unused.

34.4.1.7.1 PFlash Calibration Region Descriptor *n*, Word0 (PFCRDn.Word0)

The first word of the flash memory controller overlay region descriptor defines the 0-modulo-size logical start (byte) address of the calibration remap region. It is software's responsibility

to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Successful writes to this word clear the calibration remap descriptor's valid bit.

Figure 376. PFlash Calibration Region Descriptor *n*, Word0 (PFCRD*n*.Word0)

Table 452. PFlash Calibration Region Descriptor *n*, Word 0 description

Name	Description
0–27 LSTARTADDR	Logical Start Address. This field defines the most significant bits of the 0-modulo-size logical start address of the overlay remap region. It corresponds to the logical system address which maps to the flash memory space. Any write to PFCRD <i>n</i> .Word{0,1,2} clears the corresponding PFCRDE[CRD <i>n</i> EN] bit, leaving the calibration remap descriptor invalid.

34.4.1.7.2 PFlash Calibration Region Descriptor *n*, Word1 (PFCRD*n*.Word1)

The second word of the flash memory controller calibration region descriptor defines the 0-modulo-size byte physical start (byte) address of the calibration remap region. *The contents of this word define the targeted destination overlay memory.* It is software's responsibility to guarantee the low-order bits of the address, as defined by the remap descriptor size, are zeroed to enable the remap descriptor hit logic to function correctly.

Successful writes to this word clear the calibration remap descriptor's valid bit.

Figure 377. PFlash Calibration Region Descriptor n , Word1 (PFCRD n .Word1)Table 453. PFlash Overlay Region Descriptor n , Word 1 description

Name	Description
0–27 PSTARTADDR	Calibration Remap Descriptor n Physical Start Address - This field defines the most significant bits of the 0-modulo-size physical start byte address of the calibration remap descriptor. This address corresponds to the physical address which maps to the destination calibration overlay memory. Any write to PFCRD n .Word{0,1,2} clears the corresponding PFCRDE[CRD n EN] bit, leaving the calibration remap descriptor invalid.

34.4.1.7.3 PFlash Calibration Region Descriptor n , Word2 (PFCRD n .Word2)

The third word of the calibration region descriptor defines a per-master calibration remap enable and the remap region size. For cacheable spaces being remapped, the minimum region size is 32 bytes to match the flash page and cache line sizes. Writes to this word clear the calibration remap descriptor's valid bit.

Figure 378. PFlash Calibration Region Descriptor n , Word2 (PFCRD n .Word2)

Table 454. PFlash Overlay Region Descriptor *n*, Word 2 description

Name	Description
0-15 MxEN	Calibration Remap Descriptor <i>n</i> Master <i>x</i> Enable - These bits determine whether calibration remapping is performed as defined by this descriptor based on the logical master ID of the requesting AHB master. If the current access hits in the remap region defined by this descriptor, and the MxEN field which corresponds to the requesting AHB master is asserted, then calibration remapping is performed and the content is fetched from the overlay RAM. If the current access hits in the remap region defined by this descriptor, but the MxEN field which corresponds to the requesting AHB master is deasserted, then calibration remapping is not performed and the content is fetched from the flash. 0 Calibration remap evaluation is ignored on flash access requests from Master <i>X</i> as defined by this region descriptor. 1 Calibration remap evaluation is enabled on flash access requests from Master <i>X</i> as defined by this region descriptor.
27-31 CRDSize	Calibration Remap Descriptor <i>n</i> Size - This field specifies the size of the calibration remap region. 00000 Region size is 1 byte. 00001 Region size is 2 bytes. Low-order bit of LSTARTADDR and PSTARTADDR must be zero 00010 Region size is 4 bytes. Low-order 2 bits of LSTARTADDR and PSTARTADDR must be zero 00011 Region size is 8 bytes. Low-order 3 bits of LSTARTADDR and PSTARTADDR must be zero 00100 Region size is 16 bytes. Low-order 4 bits of LSTARTADDR and PSTARTADDR must be zero 00101 Region size is 32 bytes. Low-order 5 bits of LSTARTADDR and PSTARTADDR must be zero 00110 Region size is 64 bytes. Low-order 6 bits of LSTARTADDR and PSTARTADDR must be zero 00111 Region size is 128 bytes. Low-order 7 bits of LSTARTADDR and PSTARTADDR must be zero 01000 Region size is 256 bytes. Low-order 8 bits of LSTARTADDR and PSTARTADDR must be zero 01001 Region size is 512 bytes. Low-order 9 bits of LSTARTADDR and PSTARTADDR must be zero 01010 Region size is 1 KB. Low-order 10 bits of LSTARTADDR and PSTARTADDR must be zero 01011 Region size is 2 KB. Low-order 11 bits of LSTARTADDR and PSTARTADDR must be zero 01100 Region size is 4 KB. Low-order 12 bits of LSTARTADDR and PSTARTADDR must be zero 01101 Region size is 8 KB. Low-order 13 bits of LSTARTADDR and PSTARTADDR must be zero 01110 Region size is 16 KB. Low-order 14 bits of LSTARTADDR and PSTARTADDR must be zero 01111 Region size is 32 KB. Low-order 15 bits of LSTARTADDR and PSTARTADDR must be zero 10000 Region size is 64 KB. Low-order 16 bits of LSTARTADDR and PSTARTADDR must be zero 10001 Region size is 128 KB. Low-order 17 bits of LSTARTADDR and PSTARTADDR must be zero 10010 Region size is 256 KB. Low-order 18 bits of LSTARTADDR and PSTARTADDR must be zero 10011 Region size is 512 KB. Low-order 19 bits of LSTARTADDR and PSTARTADDR must be zero 10100 Region size is 1 MB. Low-order 20 bits of LSTARTADDR and PSTARTADDR must be zero 10101 Region size is 2 MB. 34.5 Functional description

As shown in [Figure 369](#) the flash memory controller interfaces between:

- AHB system bus ports
- ASC Modeling Unit (AMU)
- Nexus trace
- Flash memory array
- Overlay RAM
- Off-chip Buddy Device

For accesses targeting the flash array, the flash memory controller generates read and write enables, block selects, array address, write size and write data as inputs to the flash array. The flash memory controller captures read data from the flash array and drives it onto the AHB system bus. Up to four pages of data (256-bit page size) may be buffered in each of two ways of the flash memory controller mini-cache. Lines may be prefetched in advance of being requested, allowing single-cycle (zero AHB wait-states) read data responses on buffer hits.

Several prefetch control algorithms are available for controlling line read buffer fills. Prefetch triggering may be restricted to instruction accesses only, data accesses only, or may be unrestricted. Prefetch triggering may also be controlled on a per-master basis.

Buffers may also be selectively enabled or disabled for allocation by instruction and data prefetch.

Access protections may be applied on a per-master basis for both reads and writes to support security and privilege mechanisms.

34.5.1 Basic interface protocol

Read accesses are terminated under control of the appropriate wait state settings. Thus, the access time of the operation is determined by the setting of the PFCR1[RWSC] field. Access timing can be varied to account for the operating conditions of the SoC (frequency, voltage, temp) by appropriately setting the PFCR1[RWSC] field.

34.5.2 Access protections

34.5.2.1 PFAPR - Platform Flash Access Protection Register (PFAPR)

The flash memory controller provides programmable, configurable access protections for both read and write cycles on a per-master basis via the PFlash Access Protection Register (PFAPR). It allows restriction of read and write requests on a per-master basis. This functionality is described in [Section 34.4.1.4, "Platform Flash Access Protection Register \(PFAPR\)"](#). Detection of a protection violation results in an error response from the flash memory controller on the AHB transfer.

34.5.2.2 BAF execution disable

The flash memory controller provides a mechanism to disable instruction execution of the BAF (Boot Assist Flash) code. Setting the BAF Disable field (BAF_DIS) in the PFlash Configuration Register 3 (PFCR3) prevents execution of the BAF instructions. When this field is set, all incoming requests from the system bus on either Port0 or Port1 are evaluated. If the flash memory controller detects an attempted instruction fetch access to

the BAF region of the flash, the flash memory controller aborts the access and returns a system bus error. Data accesses to the BAF region are not affected by the state of PFCR3[BAF_DIS].

34.5.3 Read cycles - buffer miss

On an incoming AHB read request, a mini-cache lookup and access privilege evaluation are performed during the AHB address phase. In the event of a buffer miss, a flash access is initiated. If globally enabled, the calibration remap evaluation is also performed. If the access is to be remapped, the appropriate access is routed to the destination memory.

If the flash access was the direct result of an AHB transaction, the corresponding page buffer is loaded and marked as most-recently-used. If the flash access was the result of a speculative prefetch to the next sequential line, it is loaded into the least-recently-used buffer. The status of this buffer is not changed to most-recently-used until a subsequent buffer hit occurs as a result of an AHB read request.

34.5.4 Read cycles - buffer hit

Single cycle read responses to the AHB are possible with the flash memory controller when the requested read access was previously loaded into one of the page buffers. In these “buffer hit” cases, read data is returned on the system bus with a zero wait-state response.

34.5.5 Error termination

The flash memory controller may invoke a system bus error termination in the following scenarios:

- Attempted access by an AHB master whose corresponding Read Access Control or Write Access Control settings do not allow the access, thus causing a protection violation. See ^(34.4.1.4) for more detail. In this case the flash memory controller does not initiate a flash array access.
- Attempted instruction fetch by an AHB master to the BAF flash region when the PFCR3[BAF_DISABLE] field in Platform Flash Configuration Register 3 (PFCR3) is set. The assertion of PFCR3[BAF_DISABLE] indicates that code stored in the BAF region should not be executed. See [Section 34.4.1.3, Platform Flash Configuration Register 3 \(PFCR3\)](#) for more detail. In this case, the flash memory controller does not initiate a flash array access.
- Attempted access by an AHB master to a flash region, where the corresponding censorship control is asserted.
- The flash or overlay RAM returns an error response on an attempted access (see ^(34.5.6)).
- Attempted access by an AHB master to a reserved region in the flash memory map.

34.5.6 Flash error response operation

The flash array may signal an error response to terminate a requested access due to improper sequencing during program/erase operations, improper sequencing during array integrity testing. When an error response is received, the flash memory controller does not update or validate a page read buffer. An error response may be signaled on read or interlock write operation. For more information on the specifics related to signaling of flash errors, including flash ECC events, array integrity testing and read-while-write events, refer to the flash NVM documentation.

34.5.7 Censorship

The entire flash space is defined by five major regions:

- Code flash (instruction and constant data)
- Data flash (data for EEPROM emulation):
- Secure code flash (instruction for security module)
- Secure data flash (data for security module)
- UTEST flash

Each section can be independently censored, and the flash memory controller provides independent censorship control inputs for each region on a read vs. write basis.

34.5.8 Security module exclusive control

During “Production at OEM” lifecycle state and beyond, the HSM can establish the secure flash blocks to be exclusive to the HSM and route program or erasing of secure flash blocks to the alternate programming interface.

The secure flash space is independently controlled for each of the following four regions:

- 16 KB secure code flash block at address range 0x0060_C0000 - 0x0060_FFFF
- 64 KB secure code flash blockA at address range 0x0061_0000 - 0x0061_FFFF
- 64 KB secure code flash blockB at address range 0x0062_0000 - 0x0062_FFFF
- Two 16 KB secure data flash blocks at address range 0x0068_0000 - 0x0068_7FFF

The HSM provides flags to individually control the HSM-exclusivity for each of the four secure flash regions. When a given secure flash block is marked as exclusive to the HSM, the HSM is the only system bus master granted access to that block and access attempts by non-HSM masters are terminated with error. Once HSM-exclusivity is established for a given secure flash block, the HSM is guaranteed access to that block, regardless of the state of the censorship controls. Secure flash exclusivity applies to read and write accesses.

The HSM provides flags to individually control the routing interlock write for each of the four secure flash regions to either the main program/erase interface or the alternate program/erase interface. When a given secure flash block is assigned to the alternate program interface, the flash controller appropriately routes incoming interlock write requests within the given secure flash block address range to the flash's alternate program interface. Alternate program control can be controlled independent of HSM exclusivity for a given secure flash block.

Figure 379. Interlock Write Alternate Programming Interface Routing Flowchart

34.5.9 Access pipelining

Accesses to the flash array may be pipelined by driving a subsequent access address and control signals while waiting for the current access to complete. Pipelined access requests are always run to completion and are not aborted by the flash memory controller. Flash access pipelining allows for improved performance by reducing the access latency seen by the AHB master. Access pipelining may be applied only to read cycles targeting the flash array. Address pipelining is enabled by setting the PFCR1[APC] field.

Access pipelining is only supported for normal flash access and is not supported for calibration overlay RAM fetches. On calibration reads, the setting of PFCR1[APC] is ignored.

Note: Not all combinations of PFCR1[APC] (Address Pipeline Control) and PFCR1[RWSC] (Read Wait State Control) settings are recommended or supported. Please refer to the device data sheet for guidance.

Figure 384. Port0 Access Followed By Port1 Access(RWSC=5, APC=3'b1xx)

34.5.10 Line read buffers and prefetch operation

The AHB ports of the flash memory controller each contain a two-way set-associative mini cache, where each way contains four page buffers which are used to hold data read from the flash arrays. Each 256-bit buffer operates independently, and is filled using a single array access. The buffers are used for both prefetch and normal demand fetches.

Prefetch triggering is controllable on a per-master and access-type basis (see [Section 34.4.1.1, "Platform Flash Configuration Register 1 \(PFCR1\)"](#)). Bus masters may be enabled or disabled from triggering prefetches, and triggering may be further restricted based on whether a read access is for instruction or data. A read access by the flash memory controller may trigger a prefetch to the next sequential line of array data on the cycle following the request. The access address is incremented by 32-bytes, and a subsequent flash access is initiated. A flash array prefetch is initiated if the data is not already resident in a line read buffer. Prefetched data is always loaded into the least-recently-used buffer.

Figure 385. Flash memory controller 4-entry, 2-way mini-cache organization

Once the candidate line buffer has been selected, the flash array is accessed and read data loaded into the buffer. If the buffer load was in response to a miss, the buffer which was loaded is immediately marked as most-recently-used. If the buffer load was in response to a speculative fetch to the next-sequential line address after a buffer hit, *the recently-used status is not changed*. Rather, it is marked as most-recently-used only after a subsequent buffer hit.

This policy maximizes performance based on reference patterns of flash accesses and allows for prefetched data to remain valid when non-prefetch enabled bus masters are granted flash access.

Several algorithms are available for prefetch control which trade off performance for power. They are described in [Section 34.4.1.1, Platform Flash Configuration Register 1 \(PFCR1\)](#). More aggressive prefetching may increase power due to the number of potentially discarded prefetches, but may increase performance by lowering average read latency.

For prefetching to occur, all of the following must apply:

1. PFCR{1,2}[P{0,1}_BFEN] must be set to '1',
2. PFCR{1,2}[P{0,1}_PFLIM] must be non-zero, and
3. either PFCR{1,2}[P{0,1}_IPFEN] or PFCR{1,2}[P{0,1}_DPFEN] must be asserted.

Refer to [Section 34.4.1.1, Platform Flash Configuration Register 1 \(PFCR1\)](#) for a description of these controls.

34.5.11 Instruction/Data prefetch triggering

Port0 prefetch triggering may be enabled for instruction reads via the PFCR1[IPFEN] control field, while Port0 prefetching for data reads is enabled via the PFCR1[DPFEN] control field. Additionally, the PFCR1[PFLIM] must also be set to enable prefetching on Port0. Refer to [Section 34.4.1.1, Platform Flash Configuration Register 1 \(PFCR1\)](#) for a description of these controls. Prefetches are never triggered by write cycles.

Port1 prefetch triggering may be enabled for instruction reads via the PFCR2[IPFEN] control field, while Port1 prefetching for data reads is enabled via the PFCR2[DPFEN] control field. Additionally, the PFCR2[PFLIM] must also be set to enable prefetching on Port1. Refer to [Section 34.4.1.2, Platform Flash Configuration Register 2 \(PFCR2\)](#) for a description of these controls. Prefetches are never triggered by write cycles.

34.5.12 Per-Master prefetch triggering

Prefetch triggering may be controlled for individual bus masters. Refer to [Section 34.4.1.1, Platform Flash Configuration Register 1 \(PFCR1\)](#) for a description of these controls.

34.5.13 Buffer allocation

Allocation of the line read buffers is controlled via the PFCR3 control register, specifically the line buffer configuration ({P0,P1}_WCFG) field. Refer to [Section 34.4.1.3, Platform Flash Configuration Register 3 \(PFCR3\)](#). The buffers can be organized as a “pool” of available resources (with both ways within a given set) or with a fixed partition between ways allocated to instruction or data accesses. For the fixed partitions, way 0 is allocated for instruction fetches and way 1 for data accesses.

34.5.14 PFlash calibration remap support

The flash memory controller supports calibration development by providing a remapping function to route flash accesses to overlay RAM. Recall this family of devices includes a comprehensive set of features including dedicated overlay RAM arrays to aid calibration and debug. The overlay function supports the following features:

- Can be mapped over internal flash memory
 - Allows calibration of constant data without requirement for additional external RAMs and calibration memory interfaces
- Can be used to hold device debug trace stream
 - Allows limited trace based debug without requirement for complex debug tool hardware and access to high speed trace port
- Protected with error detection and correction mechanism
 - Accesses to all overlay RAMs can achieve the same timing as accesses to internal flash. Timing for calibration accesses to a particular overlay RAM is only guaranteed if it is not being used as a destination for trace streaming at the same time
 - Timing for calibration accesses to overlay RAM is only guaranteed if RWSC is set sufficiently high to cover the intrinsic burst access incurred when fetching a full page of calibration data
- Support for up to 32 distinct calibration remap regions.
- Protection against accidental enable and reconfiguration of calibration remap function:
 - Two stage mechanism to enable remap, using both global and individual calibration region descriptor enable bits
 - Optional configuration of calibration region descriptors as redundant pairs, allowing detection of accidental region reconfiguration.
- Support for overlay remapping to unique calibration regions on a per-master basis.

The calibration remap function supports the following overlay RAM targets:

- An internal overlay RAM is included on all standard production devices.
- An extended overlay RAM is an additional memory that is only available on special ED devices.
- A portion of the system RAM can be used for overlay.

The overlay RAM is selected based on the translated physical address.

To better understand the functionality of the calibration remap, consider more detailed block diagrams, one showing the overall structure of the calibration remap function and another showing more detail on the actual remap logic. Recall the flash memory controller implements a hardware interconnection matrix connecting the four input ports and four destination memories. See [Figure 386](#).

The following figure illustrates the calibration remap connection matrix.

Figure 386. PFlash calibration remap connection matrix

Note the 64-bit on-chip overlay RAM is split into 2 equal-sized memories to allow concurrent accesses for calibration data from the P0, P1 (where these are the crossbar slave input ports) and AMU ports plus trace data writes from the Production Device Nexus Aurora Router (PD-NAR).

The translated physical address defines the destination memory. [Table 455](#) shows the base addresses for the calibration data memories as defined by the system memory map.

Table 455. Calibration data memory base addresses

Calibration Memory	Base Address	Possible Access Sources
Flash Arrays	0x0{8,9,A}-_----	P0, P1, AMU
System RAM	0x40{0,1}-_----	P0, P1, AMU
On-chip Overlay RAM	0x0D00_----	P0, P1, AMU, PD-NAR
Buddy Device (Extended) Overlay RAM	0x0C{0,1}-_----	P0, P1, AMU

Note the trace data from the Nexus Aurora Router (PD-NAR) can only be routed to the on-chip overlay RAM; there is a different connection path in the Buddy Device from the BD-NAR into the extended overlay RAM.

The system RAM connection from the calibration remap logic is implemented via a *private 64-bit connection to the platform RAM controller*.

Accesses to the flash arrays always use the logical, non-remapped system address. Calibration data store references to the system RAM, on-chip or buddy device (extended) overlay RAM always use the physical, non-remapped system address. Conversely, calibration data load references can be accessed using a *translated physical address or, if provided by the requesting master, the physical, non-remapped system address*. Byte-, halfword-, word- and doubleword-sized data store references to the on-chip overlay RAM are supported. Byte-, halfword-, word- and doubleword-sized store references to the buddy device (extended) overlay RAM are supported.

The read data interface of system RAM, on-chip overlay RAM and buddy (extended) device is 64 bits wide for each, whereas the flash read data interface is 256 bits wide. As a result, a remapped calibration load access initiates a four-beat burst sequence to mimic the throughput of a single flash access. There is a direct relationship between the operating frequency range and the required number of wait states to correctly sample flash read data. By contrast, a remapped calibration load access has a fixed, intrinsic 4-beat latency, where the access time of each individual beat depends on the overlay target - system RAM, on-chip overlay RAM or buddy device. The access time when fetching data from the buddy device presents the longest latency. Therefore, in order for an initial, random calibration load access to mimic the flash access time, PFCR1[RWSC] read wait state setting must be programmed to a value which sufficiently covers the intrinsic access time to complete a four-beat burst sequence from the slowest available overlay target at the specified device operating frequency. Expressed mathematically:

$$(RWSC + 2) \geq \left(\frac{\text{IntrinsicFlashAccessTime}}{\text{OperatingFrequencyClockPeriod}} + 2 \right) \geq (\text{OverlayRAMTransferBurstLatency})$$

Notice the overall latency on a random, initial flash access that does not hit in the prefetch mini-buffer incurs an additional cycle latency beyond the intrinsic flash access time. This cycle accounts for pipeline stalls incurred by the flash controller state machine. The formula above is based on specified intrinsic flash access times of the C55FMC array at 150C. Calibration data that is loaded in the flash controller's mini-cache is returned with single-cycle latency.

The memory-mapped calibration remap (region) descriptor (CRDn) registers define the required address translation. Each calibration remap descriptor includes the logical base address, the translated physical base address and a region size (plus other control bits). The calibration remap evaluation is initiated when the flash controller is presented with a flash access request from any system bus master to a location in the mirrored flash address space. Conversely, references using the associated non-mirrored flash system address are not evaluated for calibration remapping. Generally, not all areas of the flash memory map are available for calibration remapping. Secure flash blocks, EEPROM, BAF and UTEST are usually not available for calibration remapping. Flash access requests which present an address targeting the secure flash blocks, EEPROM, BAF or UTEST will bypass calibration remap evaluation and return flash data.

The address translation mechanism requires the logical and physical base addresses of the region be aligned on 0-modulo-size boundaries. See [Figure 387](#).

Figure 387. PFlash calibration remap logic detail

Each instantiation of the basic calibration remap function $\{RMD0, \dots, RMD(n-1)\}$ in [Figure 387](#) includes the three descriptor registers containing the logical start address (LADDR in the figure), the physical start address (PADDR) and the region size (SZ). The region size is decoded to create the appropriate address bit enables which are then applied to the registered logical flash address. An equality comparator then compares the adjusted logical flash address against the logical address from the calibration remap descriptor to

determine the region “hit”. The hit determination is further qualified based on the bus master number that initiated the flash access. At the same time, the logical flash address and the physical address defined in the calibration remap descriptor are merged to form the translated address to be used in the event of a calibration region hit. Aside from the individual instantiations of the calibration remap descriptors, this logic examines all the descriptor hit indicators to select the appropriate translated address.

In the absence of a region “hit” data is returned from the flash at the provided logical address.

It should be noted in the event of *overlapping remap regions*, the calibration remap descriptor with the largest number is used for the address translation, that is, if a logical flash address hits in multiple descriptors, say CRD_x and CRD_y, the translated address from CRD_y is used, given $y > x$. This definition is selected as it minimizes the gate cost and timing impact of the calibration remap descriptor “hit” logic.

In general, the calibration remap logic operates only on flash *data* accesses. However, flash instruction references can optionally remapped while in debug modes of operation to support the use of software breakpoints when PFCRC[IRMEN] is set.

Figure 388. Flash memory controller and associated calibration remap targets

34.5.14.1 Overlay Access and Buddy Device Considerations

34.5.15 AMU dedicated flash port

The flash memory controller provides a dedicated flash interface for servicing the DMA function in the ASC Modeling unit (AMU). This facilitates the AMU's minimum bandwidth requirement for feeding the dual calculation channels, which process complex multidimensional data models using a kind of neural network technology. The AMU uses the DMA to move data tables from the flash to a local RAM. In the event of concurrent flash requests from the crossbar slave port(s) of the flash controller and the AMU, the crossbar slave port(s) have priority over the AMU by default. However, the AMU can dynamically elevate its priority over the crossbar slave ports to avoid starvation of its computation engine.

34.5.16 Safety considerations

34.5.16.1 e2eECC (End-to-End ECC)

34.5.16.1.1 e2eECC and flash accesses

There are multiple complications associated with the use of the standard e2eECC algorithm with flash memory. The basic issues involve: the default state of a flash block that is erased (all ones) and the fact that programming an erased flash involves changing the state of memory bit from a logical 1 to a logical 0. These factors require that the system level e2eECC must be modified on references to the flash memory in three ways.

First, the all ones codeword, since it reflects the state of an erased flash location, is treated as a valid, error free encoding; in particular, it is required that the checkbits associated with the all ones data value and the all zeroes data value are required to be the same with a checkbit value of 0xFF. Second, since an erased flash block generates an all ones data for all locations, the address field cannot be included in the ECC code used by the flash. The flash array implements special address re-encoding logic based on the decoded array address to protect against address faults. Third, there are additional ECC implications associated with the flash memory and its support for EEPROM emulation. Lastly, there are ECC implications associated with the storage and retrieval of overlaid calibration data.

In summary, the basic operation of an NVM bit cell impacts the e2eECC algorithm used in the flash memory in multiple ways. The required ECC adjustments are handled by the platform flash controller before data is written to the flash array(s) or applied to read data accessed from the array(s). These adjustments are two-fold. Consider a flash write during a programming event:

1. Remove the address field from the ECC codeword by XOR'ing the address calculation of the H-matrix from the checkbits.
2. Invert the resulting 8-bit ECC checkbit vector. This step is required to support the all ones erased state.

On a flash read operation, a similar but "reversed" set of steps are performed as the data is driven into the system bus interconnect:

1. Invert the 8-bit ECC checkbit vector read from the flash.
2. Factor the address field into the ECC checkbits by XOR'ing the address calculation of the H-matrix.

Consider the following flash ECC example. Let the flash block containing address 0x00345678 be erased. The following is the sequence of operations:

1. Read address 0x00345678. Flash array returns `fl_rdata = 0xFFFFFFFF_FFFFFFFF`, `fl_cdata = 0xFF`. The flash memory controller calculates the `addr_chkbit = 0xC4` using the H-matrix; it inverts the `fl_cdata` vector to 0x00 and factors in the `addr_chkbit = 0xC4` to produce the following valid e2eECC codeword:

`addr = 0x00345678`, `rdata = 0xFFFFFFFF_FFFFFFFF`, `rchkbit = 0xC4` ($0x00 \wedge 0xC4$)

2. Program address 0x00345678 with data = 0xBABEFACE_DEADBEEF. The initiating bus master calculates the e2eECC codeword as:

`addr = 0x00345678`, `wdata = 0xBABEFACE_DEADBEEF`, `wchkbit = 0xE3`

Before performing the interlock write to the flash array, the flash memory controller adjusts the `chkbit` value as `fl_wchkbit = 0xD8` ($0xE3 \wedge 0xFF \wedge 0xC4$) by toggling the original write checkbits and then factoring in the `addr_ecc`. Accordingly, the codeword stored in the flash array is:

`fl_data = 0xBABEFACE_DEADBEEF`, `fl_checkbit = 0xD8`

3. Read address 0x00345678. The flash array returns the stored codeword, `fl_rdata = 0xBABEFACE_DEADBEEF`, `fl_rchkbit = 0xD8`. The flash memory controller inverts the checkbit vector and factors in the address checkbits ($0xD8 \wedge 0xFF \wedge 0xC4$) to produce:

`addr = 0x00345678`, `rdata = 0xBABEFACE_DEADBEEF`, `rchkbit = 0xE3`

This read codeword matches the original e2eECC codeword generated by the write.

Malfunction of the ECC logic described above may result in the corruption of the SEC/DED event reporting. The flash memory controller performs EDC after ECC check on all flash transactions. If a mismatch is detected, indicating a failure in the ECC logic, the event is reported to the device fault collection module.

34.5.16.2 Flash address generation check

Functional safety coverage of the address and data are handled by ECC performed within the flash and e2eECC performed at the master. Functional safety coverage of the address path and control within the flash memory controller rely on a feedback path between the flash controller and flash. Recall on a requested access to flash, the flash memory controller must decode the system AHB bus signals to generate the corresponding flash interface signals to invoke a flash lookup. In addition to providing the requested read data, the flash also provides output sidebands reflecting the encoded address and block selects used to perform the actual row lookup.

This sideband information is used by the flash memory controller to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and flash array, the event is forwarded to the device fault collection module and the corresponding buffer is invalidated.

34.5.16.2.1 On-Chip Overlay RAM Feedback Check

The integrity of the address and data on an overlay RAM transaction is covered by e2eECC check performed by the requesting master. Functional safety coverage of the address path and control within the flash memory controller is handled by a transaction monitor which verifies the integrity of the transactions between the flash memory controller and the on-chip overlay RAM. The function of the transaction monitor relies on a feedback path between the

flash memory controller and the on-chip overlay RAM, wherein the RAM provides latched address and control feedback outputs as an indication of received inputs when a RAM access is initiated. This feedback information is used by the flash memory controller transaction monitor to verify the expected transaction. If a mismatch is detected, indicating a failure in the address generation or control logic within the flash memory controller or the transmission path between the flash memory controller and on-chip overlay RAM array, the event is forwarded to the Fault Collection and Control Unit (FCCU).

34.5.16.2.2 e2eECC and Calibration Accesses

Because calibration write accesses are always presented with the physical, non-remapped system address, the write data checkbits presented by the master are calculated based on the physical overlay RAM system address. On a subsequent overlay read, the ECC checkbits must be manipulated to replace the physical overlay RAM address contribution with the logical flash address contribution. This is required to satisfy the e2eECC check at the originating master.

In addition, the flash memory controller can be configured to treat calibration RAM space as a safety-critical component. By programming `PFCRCR[SAFE_CAL]=1`, the flash memory controller treats the 32 available calibration region descriptors (CRD0-CRD31) as a replicated group of 16 region descriptors. More specifically, when N is the total number of region descriptors:

- The contents of CRD0 are expected to be redundantly defined in CRD[N/2]
- The contents of CRD1 are expected to be redundantly defined in CRD[(N/2)+1]
- The contents of CRD2 are expected to be redundantly defined in CRD[(N/2)+2]
- ...and so on
- The contents of CRD[(N/2)-1] are expected to be redundantly defined in CRD[N-1]

Note: It is the user's responsibility to establish redundant calibration region descriptors by programming the associated pairs of CRDs.

Incoming flash read requests are compared simultaneously against the calibration regions defined in CRD0 to CRD[(N/2)-1] and the calibration regions defined in CRD[N/2] to CRD[N-1]. Due to the enabled redundancy, the parallel overlay remap hardware structures should evaluate to symmetric results. If a mismatch is detected, the event is reported to the FCCU and calibration remapping is not performed. Instead, data is returned from the flash.

Figure 389. Safety-critical calibration remap datapath with redundancy

34.5.17 e2eECC and EEPROM accesses

ECC events detected on accesses to the EEPROM flash blocks are suppressed from being reported to the Memory Error Management Unit (MEMU).

In the event of a single-bit correction, the corrected data and checkbits are returned to the requesting master, and the single-bit correction event is suppressed from being reported to the MEMU.

In the event of a non-correctable error detection, a fixed, illegal opcode value is returned to the requesting master along with the associated ECC checkbits as determined by the requesting address, and the non-correctable error event is suppressed from being reported to the MEMU.

34.5.18 Array integrity considerations

During an array integrity sequence, the flash memory array ignores any incoming read requests. When a flash array integrity check is in progress, the flash memory controller terminates all flash access requests with an error.

35 Embedded Flash Memory (c55fmc)

35.1 Introduction

The primary function of the embedded flash memory is to serve as electrically programmable and erasable non-volatile memory (NVM) that may be used for instruction or data storage.

Figure 390 shows the top-level diagram and functional organization of the flash memory unit.

Figure 390. Block diagram of c55fmc

35.1.1 Overview

The embedded flash memory is addressable by word (32 bits) or double word (64 bits) for program operation, and page (256 bits) for read operation. Multiple word or double-word writes may be done to the flash memory to fill up the program page buffer (256 bits),

enabling page programming (256 bits, requiring 4 double-word writes) and quad-page programming (1024 bits, requiring 16 double-word writes). Flash memory reads always return 256 bits, although read page buffering may be performed by the Bus Interface Unit (BIU).

For more details on the embedded flash memory architecture and features, see [Section 35.3, “Functional Description”](#).

35.1.2 Features

The embedded flash memory includes these distinct features:

- Test information stored in a dedicated nonvolatile block (referred to as the UTest block)
- OTP space made available in the UTest block
- Read page size of 256 bits (8 words)
- ECC with single-bit correction, double-bit detection (all 1's valid)
- Quad Page programming (64-bit granularity)
- Software programmable block program/erase restriction control
- Erasing of selected block(s)
- Independent programming of the UTest NVM block
- Embedded hardware program and erase algorithms
- Support for reading while writing when the accesses are to different partitions
- Erase suspend, program suspend, and erase-suspended program
- UTest mode (user-accessible test modes) including Array Integrity and Margin Read
- Triple Voted Flops for safety critical flash functions

35.1.3 Modes of operation

Here is a brief description of the embedded flash memory operating modes.

- *User mode* is the default operating mode of the embedded flash memory. In this mode, it is possible to read and write registers, read and interlock write the memory array, program the memory array, and erase the memory array. In this mode program and erase operations are initiated by doing array and register writes, and are controlled by an internal state machine.
- *Low power mode* turns off all DC current sources within the embedded flash memory on the Vflash domain, and enables VDDF to be power gated. The embedded flash memory is not accessible for read, write, program, or erase when in low power mode. This is the lowest current draw the embedded flash memory can achieve.
- *UTest mode* is a tiered test mode strategy in which a portion of the factory test modes are made available. This mode is protected but accessible.

35.2 Memory map and register definition

The embedded flash memory map consists of a flash memory array (which includes main array space and UTest NVM space) as well as a second region of registers associated with the programming model that enable flash memory array operation and modification.

35.2.1 Memory map

The address space consists of 16 KB, 32 KB, 64 KB, and 256 KB blocks.

Table 456. Block Memory Map

1. Note that R/W registers may contain some read-only or write-only bits.
2. Alternate Interface registers may be re-mapped to a different base address.
3. Note that R/W registers may contain some read-only or write-only bits.
4. Note that R/W registers may contain some read-only or write-only bits.
5. # stands for configuration-dependent reset value.
6. Alternate Interface registers may be re-mapped to a different base address.
7. Alternate Interface registers may be re-mapped to a different base address.
8. # stands for configuration-dependent reset value.
9. # stands for configuration-dependent reset value.
10. # stands for configuration-dependent reset value.
11. # stands for configuration-dependent reset value.
12. Maximum address for flash register space is 0x1FC.

35.2.1.1 UTest NVM block

The UTest NVM block may be enabled by the BIU — this is device-specific. When the UTest NVM space is enabled, all operations are mapped to the UTest NVM block. User-mode programming of the UTest NVM block is enabled only when MCR[PEAS] is high. The UTest NVM block is an OTP block (assuming Test Mode Disable Seal is written) — thus erase is not allowed.

The UTest NVM block supports RWW, and is grouped with the blocks in partition 0.

The UTest NVM block may be locked against program by using the lock registers.

Programming of the UTest NVM space has restrictions that are similar to those of the main space in terms of how ECC is calculated. Only one program operation is allowed per 64-bit ECC segment.

The UTest NVM block contains specified data that is needed for embedded flash memory or SoC features.

35.2.1.2 Test Mode Disable Seal

Also included in the UTest NVM block is a mechanism to disable factory entry into Test mode. Extreme care must be taken when using this feature, as blocks that are selected to be protected in this method will not be able to have possible failures analyzed by factory failure analysts. Once sealed, the Utest block becomes OTP (Erase Locked, and Over Program Protection enabled). The Utest Block also is not accessible in Test Mode.

Protection of this sort prevents all high-voltage operations to the flash executed by the internal state-machine, as well as reads through this state machine, and reads through the Array Integrity state machine when using Test mode interfaces.

Utest operations Margin Read and Array Integrity are also protected by preventing MISR updates on blocks selected for protection, although reads will still be done and Single Bit Corrections and Double Bit Detections will be logged. Protection through other interfaces is protected by normal User mode protection mechanisms, and are device-specific.

The method to disable factory entry into Test mode is to first program the Test Mode Disable Seal location to be 0x2D3C_4B5A. Once the next reset is asserted, Test mode will be disabled.

It is possible to create a password to enable factory entry into test mode. This can be programmed into the Test Mode Disable Override Passcode. The passcode may not be 0x0000_0000, 0xFFFF_FFFF, or 0x5555_5555. These are all invalid passcodes and will not be accepted to override. If it is desired by the customer that override never be possible, one of the three invalid passcodes should be put into this location. Passcode may be entered to authenticate entry (if enabled) by doing a 32-bit register write to register address 0x90. The UTest NVM block is always protected even if the Test Mode Disable Seal password is written.

Only blocks selected in the Test Mode Disable Block Select field are controlled by the Test Mode Disable feature. Thus it is possible for customers to selectively pick blocks that have this type of protection, and will not be eligible for factory failure analysis. Bits programmed to 0 in the Test Mode Disable Block Select field(s) will designate blocks that are controlled by the Test Mode Disable feature. If either Test Mode Disable Block Select - 0 or Test Mode Disable Block Select - 1 have a 0 programmed, that block will be protected. In order to let two opportunities to select blocks for the Test Mode Disable, two regions are available, Test Mode Disable Block Select - 0 and Test Mode Disable Block Select - 1. The bit of these two regions are logically ANDed, to define which blocks are effectively selected for the Test Mode Disable feature. The Block Select field is organized as follows, and aligns with how blocks are defined in the LOCK registers.

Table 457. Test mode disable block select

Block	Bits used to select blocks
Low Block Disable	Data[13:0]
Unused	Data[15:14]

Table 457. Test mode disable block select (continued)

Block	Bits used to select blocks
Mid Block Disable	Data[31:16]
High Block Disable	Data[47:32]
256K Block Disable	Data[95:48]

35.2.2 Register Summary

[Table 458](#) provides a key for register figures and tables.

Table 458. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writeable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register field types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but it always reads as zero (previously designated slfclr).
Reset Values	
0	Resets to zero.
1	Resets to one.
1*	Resets to one based on UTest NVM block being erased. If UTest NVM block is not erased, than value is determined by value programmed in UTest NVM block.
—	Undefined at reset.
u	Unaffected by reset.
[signal_name]	Reset value is determined by polarity of indicated signal.

[Table 459](#) is the register summary table for embedded flash memory. These registers are associated with the programming model that enables flash memory array operation and modification. Reset values for these registers can be found in [Table 456](#).

35.2.3 Register descriptions

This section consists of descriptions of the user mode registers.

35.2.3.1 Module Configuration Register (MCR)

The following field and bit descriptions fully define the MCR register ([Figure 391](#)).

Note: A number of Module Configuration Register (MCR) bits are locked against write by other bits. These locks are discussed in relationship to each bit in this section. Simultaneously writing bits which lock each other out is also discussed in [Section 35.3, "Functional Description"](#).

Figure 391. MCR Register

Offset 0x0000												Access: User read/write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	RVE	RRE	AEE	EEE	0	0	0	0	0	0	0	0	0	0	0	0
W	w1c	w1c	w1c	w1c												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
R	EER	RWE	SBC	0	PEAS	DONE	PEG	PECIE	FERS	0	0	PGM	PSUS	ERS	ESUS	EHV
W	w1c	w1c	w1c													
Reset	0	0	0	0	0	0/1	1	0	0	0	0	0	0	0	0	0

MCR register functions are as shown in [Table 460](#).

Table 460. MCR field descriptions

Field	Description
0 RVE	Read Voltage Error RVE provides information on previous reads monitoring the read pump voltage. If the read voltage is detected to be out of range, this bit will set to signify that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without voltage issues 1 A previous read may have been corrupted due to read voltage being out of range
1 RRE	Read Reference Error RRE provides information on previous reads monitoring the read reference. If the read reference is detected to be out of range, this bit will set to signify that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without reference issues 1 A previous read may have been corrupted due to read reference being out of range

Table 460. MCR field descriptions (continued)

Field	Description
2 AEE	Address Encode Error AEE provides information on previous reads monitoring the address encode feature. On every read request to the flash, the incoming address is compared to an encoded address (row, column, and block) coming back from the memory array using the read data sense amp timing. If these two values do not match (zero selected, multiple selected, wrong selected), or the timing is incorrect, an address encode error will be recorded. If an address encode mismatch is detected, this bit will set to signify that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without address encode mismatches 1 A previous read may be corrupted based on address encode mismatch
3 EEE	ECC after ECC Error EEE provides information on previous reads monitoring the ECC after ECC feature. On every read request to the flash, ECC is recalculated serially, and if there is a mismatch between the ECC calculations (taking into account corrections or detections) a late error will be reported. If an ECC after ECC mismatch is detected, this bit will set to signify that previous reads requested may have been corrupted. Since this bit is a status flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring without ECC after ECC mismatches 1 A previous read may be corrupted based on ECC calculation errors
4–15	Reserved, reset to 0.
16 EER	ECC Event Error This bit provides information on previous reads. If a double bit detection occurred, the EER bit is set to a 1. This bit must then be cleared, or a reset must occur before it returns to a 0 state. This bit may not be set by software. In the event of a single bit detection and correction, this bit is not set. If EER is not set, or remains 0, this indicates that all previous reads (from the last reset, or clearing of EER) are correct. Since this bit is an error flag, it must be cleared to a 0 by writing a 1 to the register location. A write of 0 has no effect. 0 Reads are occurring normally 1 An ECC Error occurred during a previous read
