- **Long(4bit Data Nibble):** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- "010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, X2", S, "X3, X4, X5", S, "D0, D1, D2", S, "D3, C2, C1", S, "C0" where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, "X0-X5" is the Range Address, "D0-D3" is the data and "C2-C0" is the CRC. Please refer [Figure 1188](#) for the frame structure.
 - The CRC polynomial used is $x^3 + x + 1$ with a binary initialization value of "111(C2:C0)".
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0..X5,D0...D3,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
 - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- **Long(8bit Data Word):** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - "010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, D0", S, "D1, D2, D3", S, "D4, D4, D6", S, "D7, C2, C1", S, "C0" where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is the sensor address, F0-F2 are the functional codes, "X0-X1" is the Range Address, "D0-D7" is the data and "C2-C0" is the CRC. Please refer [Figure 1188](#) for the frame structure.
 - The CRC polynomial used is $x^3 + x + 1$ with a binary initialization value of "111(C2:C0)".
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0..X1,D0...D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
 - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[15],000) with DPR[0] being fed first in the CRC calculator.
- **X-Long:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - "010", S, "A0, A1, A2", S, "F0, F1, F2", S, "X0, X1, X2", S, "X3, X4, X5", S, "X6, X7, D0", S, "D1, D2, D3", S, "D4, D5, D6", S, "D7, C2, C1", S, "C0" where "010" is the start sequence "S" is the stuff bit(1), A0-A2 is

the sensor address, F0-F2 are the functional codes, "X0-X5" is the Range Address, "D0-D3" is the data and "C2-C0" is the CRC. Please refer [Figure 1188](#) for the frame structure.

- The CRC polynomial used is $x^3 + x + 1$ with a binary initialization value of "111(C2:C0)".
- The transmitter extends the data bits by three zeros (as MSBs).
- The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0...X7,D0...D7,"000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
- When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[21],000) with DPR[0] being fed first in the CRC calculator.
- **XX-Long:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - "011111110", "A0, A1, A2", "C", "D0, D1", S, "D2, D3, D4" D5, D6, D7, S, "D8, D9, D10, D11, D12, D13", S,"D14, D15, D16, D17, D18, D19", S, "C0, C1, C2, C3, C4, C5" where "011111110" is the start sequence "S" is the stuff bit(0), A0-A2 is the sensor address, "C" is the configuration bit, "D0-D19" is the data and "C0-C5" is the CRC. Please refer [Figure 1188](#) for the frame structure.
 - The CRC polynomial used is $x^6 + x^4 + x^3 + 1$ with a binary CRC initialization value 010101(C5:C0).
 - The transmitter extends the data bits by six zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,D0..D19,"000000"] with "A0" being given first and "0" as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
 - When mapping this sequence to the DPR register bits for calculating the CRC; then it becomes (DPR[0],DPR[1]....DPR[23],000000) with DPR[0] being fed first in the CRC calculator.

53.4.3.4.1 Transmission Data Framing

The output data transmission block is constructed of seven sub-blocks:

- Data preparation register
- Buffer register
- Data shift register
- Periodic Sync Pulse Trigger Generator
- "GTM driven" sync pulse trigger input (GTM external to PSI5)
- Pulse length modulation block
- OR gate

Figure 1189. Data Transmission Block

53.4.3.4.2 Data Preparation Register (64-bit register, DPRH + DPRL, DPRH is fixed at 0)

- Up to 24 bits of this register can be written by the CPU. These register bits contain the ECU to sensor command that needs to be transmitted after being appended with the CRC, start bits and stuff bits. The hardware automatically calculates the CRC, adds the start and the stuff bits, before transferring the command to DBR. When `DPR_RDY == 1`, the data to be transmitted to sensors is written to this register via system bus with order data bit to be transmitted first at LSB and furthest on MSB. This register can only be used for writing standard length data frames. Data to this register can be written only when `PSI5_DOBCR[CMD_TYPE] != 7`. When `PSI5_DOBCR[CMD_TYPE] == 7` then `DPR_RDY` remains at "0" and the commands cannot be written to this register. Bits writable in different settings of the `PSI5_DOBCR[CMD_TYPE]` can be seen in [Section 53.3.2.36, Data Preparation Register Low \(PSI5_DPRL\)](#). Note that `PSI5_DPRH` is always = 0.
- Having written the data to the DPR, the `DPR_RDY` bit has to be cleared with a w1c. This indicates to the internal logic that the data in the DPR is valid and is to be processed.
- If `DPR_RDY = 0` and a new command is written to the DPR then the command is rejected and `GISR[IS_PROW]` is set.
- If the CRC or parity bit calculation is finished, then the data is shifted to the Buffer register with the start bits and the sync bits appended as well. This transfer is done to the Buffer register only if the Buffer register is ready for new data, which is indicated by `GISR[DBR_RDY] == 1`.
- As mentioned above, once this transfer is done, the `DPR_RDY` becomes 1 and a new command can be written to it.

53.4.3.4.3 Data Buffer Register (64-bit register)

- This register has two subregisters `DBRH` (higher register) and `DBRL` (lower register). Both of them are collectively referred to as `DBR`. `DBR` is of length 64 bits `DBR[63:0]`
- The bits accessible for functionality are dependent on the value of `PSI5_DOBCR[CMD_TYPE]`. For the writable bits corresponding to different setting of the `PSI5_DOBCR[CMD_TYPE]` field please refer bit description in `CMD_TYPE[2:0]`
- When `DPR_RDY == 0` and `DBR_RDY` goes to 1 then internal logic automatically transfers the data from the DPR (with CRC + stuff bits + sync bits) to the DBR. `DBR_RDY` goes low and `DPR_RDY` goes 1. In order to check the calculation of the DPR, register `DBR` can be read at this stage, i.e., when `DPR_RDY` becomes "1".
- If `DBR_RDY == 1` AND `DPR_RDY == 1`, then the data to be transmitted to sensors can be written to this register directly via system bus skipping preparation register in case application includes the start and sync bits and calculates the CRC/Parity itself. If the CPU writes to the DBR when `DBR_RDY == 1` but `DPR_RDY == 0` and

PSI5_DOBCR[CMD_TYPE] != 7, then the results can be unpredictable since the DPR has a pending data that needs to be transferred to DBR.

- If the CPU is writing to the DBR as mentioned above, then the DBR_RDY bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DBR is valid and is to be used for the shift operation.
- If while DBR_RDY == 0, and a new command is directly written to the DBR then the command is rejected and GISR[IS_BROW] bit is set.
- If while DBR_RDY == 0 a new command HAS to be written in the DBR then DOBCR[DBR_RST] has to be written to 1. Writing a 1 to DBR_RST will reject the current command in the DBR and generate DBR_RDY = 1.
- If the Data Shift Register signals that it is ready for new data (PSI5_GISR[DSR_RDY] == 1), the data of the Buffer register is shifted into the data shift register provided PSI5_DOBCR[SW_READY] is 1.
- If PSI5_DOBCR[SW_READY] == 0 then the data from the DBR is NOT transferred to the DSR automatically even if the DSR_RDY goes as 1. In such a case the IP waits for the software to make the PSI5_DOBCR[SW_READY] bit as 1; only then does it transfer the contents to the DSR.

53.4.3.4.4 Data Shift Register (64-bit register)

- This register has two subregisters DSRH (higher register) and DSRL (lower register). Both of them are collectively referred to as DSR. DSR is of length 64 bits DSR[63:0]. This register has a 1-1 correspondence with the bits in the DBR register when this register is updated automatically by the hardware.
- The bits accessible for functionality are dependent on the value of PSI5_DOBCR[CMD_TYPE]. For the writable bits corresponding to different setting of the PSI5_DOBCR[CMD_TYPE] field please refer bit description in CMD_TYPE[2:0].
- When DBR_RDY == 0 and DSR_RDY goes to 1 then internal logic automatically transfers the data from the DBR to the DSR provided PSI5_DOBCR[SW_READY] == 1'b1, else this transfer remains pending until PSI5_DOBCR[SW_READY] is '0'. Once the transfer is complete, DSR_RDY goes low and DBR_RDY goes 1. DSR contents that would finally get transferred, can be read at this stage, i.e., when DBR_RDY becomes "1".
- Making PSI5_DOBCR[SW_READY] now as '0' will not interrupt the ongoing transfer in the DSR.
- If DPR_RDY == 1 AND DBR_RDY == 1 AND DSR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when DSR_RDY == 1 but DBR_RDY == 0 then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.
- When PSI5_DOBCR[CMD_TYPE] == 7 and If DBR_RDY == 1 AND DSR_RDY == 1, then the data to be transmitted to sensors can be written to this register directly via system bus skipping Buffer register. If the CPU writes to the DSR when DSR_RDY ==

1 but `DBR_RDY == 0` then the results can be unpredictable since the DBR has a pending data that needs to be transferred to DSR.

- If the CPU is writing to the DSR as mentioned above then the `DSR_RDY` bit has to be cleared by a w1c. This indicates to the internal logic that the data in the DSR is valid and is to be used for the shift operation.
- If while `DSR_RDY == 0`, and a new command is directly written to the DSR then the command is rejected and `GISR[IS_DSROW]` is set.
- If while `DSR_RDY == 0` a new command HAS to be written in the DSR then `DOBCR[DSR_RST]` has to be written to 1. Writing a 1 to `DSR_RST` will reject the current command in the DSR and generate `DSR_RDY = 1`.
- This register is clocked by the ISPG pulses or the GTM pulses, as described in [Section 53.4.3.4.5, Sync Pulse Trigger Generation](#).
- Once the shift operation is complete in the DSR then `DSR_RDY` becomes 1.

53.4.3.4.5 Sync Pulse Trigger Generation

The sync pulse trigger can be used to generate the timing pulses or the data pulses.

The sync pulse can be generated based on triggers from two different sources:

- **ISPG (Internal Sync Pulse Generator):** Composed of CTPR, CIPR and Channel Target Counter (per channel). The internal sync pulse generator is clocked by either the GTM clock (max frequency is 3.9Mhz) or the internal 1 MHz clock. The Channel Target Counter operates with a 1 μ s resolution (when using the 1Mhz clock) or GTM clock resolution (when using the GTM clock). The ISPG is implemented to allow generation of internal periodic trigger. Please Refer [Figure 1196](#) for the ISPG structure and [Figure 1194](#) for the CTPR and CIPR explanation. The ISPG uses the Channel Target Counters (CTCs) for generating the sync pulse. The CTCs can be triggered globally (simultaneous for all channels) or locally (individual to each channel). The `CTC_GED` bit in the Global Control Register (GCR) ensures that all the CTCs start/stop simultaneously. The individual target values when the trigger pulse is generated are set in the Counter Target Pulse Register (CTPR) and the Channel Initial Pulse Register (CIPR). These registers are present for each channel. When staggering the channels, the `CTC_GED` bit should be used for providing a simultaneous trigger to the staggered channels. It is also possible for a subset of channels to work on the above arrangement while the remaining channels independently generate trigger pulses for which start/stop is controlled locally to the channels.
 - For each channel, it is possible to configure the trigger period by software using sync pulse generator control/configuration register and setting compare values in Counter Target Pulse Register(s). The Counter Initial Pulse Register (CIPR) can be used to provide the initial offset between various channels.
 - It is possible to deactivate each channel separately for the purpose of sync pulse generation.
 - The periodic pulses can be used to synchronize sensor-to-ECU communication (synchronization timing pulses) [State 1 of [Section 53.8.2, Valid states for integrated sync pulse generator](#)] or can be used as data pulse during ECU-to-sensor communication (through the DOBCR) [State 2 of [Section 53.8.2, Valid states for integrated sync pulse generator](#)].
 - When programming the CTPR, the Tsync period should be programmed ≥ 6 `SP_TS_CLK` cycles (For details of `SP_TS_CLK`, refer to Bit 23 of

Section 53.3.2.2, PSI5 Channel Control Register (PSI5_PCCR).

- **GTM event controlled:** Generation of sync trigger/pulse can be done based on events (for example, crank angle or software) through **general timer module (GTM)** output to the PSI5 interface.
 - Here the sync trigger pulses come from an external GTM module routed through a full XBAR, which is programmable at the system level.
 - The sync pulse programming (period, and so on) is done inside the GTM.
 - In [Figure 1189](#), if DOBCR[gtm_trig_sel] == 1, DOBCR[SPULSE_sel] == 0 and DOBCR[OP_sel] == 1 then the GTM trigger is used for data pulse generation (data pulses for ECU-to-sensor communication). [State 4 of [Section 53.8.2, Valid states for integrated sync pulse generator](#)]
 - In [Figure 1189](#), if DOBCR[gtm_trig_sel] == 1, DOBCR[SPULSE_sel] == 1 and DOBCR[OP_sel] == 1 the GTM trigger is used for timing pulse generation (synchronization pulse for sensor-to-ECU communication). [State 3 of [Section 53.8.2, Valid states for integrated sync pulse generator](#)]
 - In [Figure 1189](#), if DOBCR[gtm_trig_sel] == 1, DOBCR[SPULSE_sel] == "x" and DOBCR[OP_sel] == 0 the GTM trigger is passed directly to data sync port without pulse length modulation. In this case, the sync pulse length is defined by the GTM pulse length. [State 5 of [Section 53.8.2, Valid states for integrated sync pulse generator](#)]
- **Programming and control:** For achieving the various states of ISPG control or the GTM control, the 3 equivalent bits (GTM_TRIG_SEL, SPULSE_SEL and OP_SEL) belonging to the DOBCR, can be programmed, as shown in [Figure 1189](#) and [Figure 1190](#). The programming of various states mentioned above, with reference to the [Section 53.8.2, Valid states for integrated sync pulse generator](#) can be seen in [Table 1162](#) and also shown in [Figure 1197](#). The sending of the ECU to sensor commands, can be controlled by PSI5_GISR[DPR_RDY, DBR_RDY, DSR_RDY] bits and the PSI5_DOBCR register bits.

53.4.3.4.5.1 Timing Pulses

Timing pulses can also be produced without pulse width modulation also. These timing pulses can be generated through two sources:

- Periodic sync pulse from ISPG. In this case the synchro pulse from the internal sync pulse generator can be made available without any modulation. Referring [Figure 1190](#), in synchronous mode, if DOBCR[GTM_TRIG_SEL] == 0 and DOBCR[OP_SEL] == 0 then the internal sync pulse generator output can be made available without any modulation. The high time of this pulse is fixed at 4 μ s.
- Referring [Figure 1190](#), in synchronous mode, if DOBCR[GTM_TRIG_SEL] == 1 and DOBCR[OP_SEL] == 0, then the GTM trigger can be used for timing pulse generation without any Pulse Width Modulation.

53.4.3.4.5.2 Data pulse generation

Data pulses are produced by the Pulse Length Modulation Block based on triggers from one of the two selectable sources, the **ISPG** or the **GTM**, during ECU-to-sensor communication.

The two sync sources are selected by software programming of the Pulse Length Control/Configuration Register.

- A logical 1 in the Data Output Register LSB is coded as data sync pulse of width W1 {up to 127 μ s}.
- A logical 0 in the Data Output Register LSB is coded as data sync pulse of width W0 {up to 127 μ s}.
- The two widths are programmable in the Pulse Length Control/Configuration Register.
- The Data Shift Register is shifted right every time a bit is transmitted.

Figure 1189 shows the data transmission block.

Figure 1190. ECU-to-sensor communication registers (implementation of Figure 1189)

Figure 1190 details the implementation of Figure 1189 and shows how the various bits mentioned in Section 53.3.2.30, *Data Output Block Configuration Register (PSI5_DOBCR)* control the behavior of the Output Command path. Figure 1190 also shows the various clock sources to the Internal Sync Pulse Generator and the Time Stamp counter.

53.4.3.5 Response to ECU-to-sensor frames

The response to an ECU-to-sensor frame can be optionally transmitted in two ways:

- Out-of range values of data frame (as fast response coded as normal PSI5 payload region)
- Serial messaging channel (verification of the response frames must be handled by the software)

53.4.4 Tx/Rx scenario

The diagram below shows the communication scenario in synchronous modes. For asynchronous mode, sync pulses are not generated and sensor transmits data asynchronously.

Figure 1191. Synchronous mode communication scenarios

53.4.5 Interrupt handling

Configurable interrupts based on events (for example, reception of valid message), errors, DMA transfers, and so on are implemented. The following types of events can generate an interrupt:

- Reception of a new PSI5 message
- Reception of a new SMC message
- Unread SMC message overwritten in the SMC buffer area (PSI5_SFR)
- Unread PSI5 message overwritten in the PSI5 buffer area (PSI5_PMRH, PSI5_PMRL)
- Dedicated interrupts for selectable errors, mentioned below:
 - Bit C is set
 - Bit E and/or EM is set
 - Bit T is set
 - No PSI5 frame was received in a defined frame slot (Bit F is set)
- ECU-to-sensor communication-related interrupts
 - The application tries to load new data into the data preparation register before the register has signaled that it is ready for new data. (Note that the new command will be ignored in this case.)
 - The application loads new data into the data buffer register before the register has signaled that it is ready for new data. (Note that the new command will be ignored in this case.)
 - The application loads new data into the data shift register before the register has signaled that it is ready for new data. (Note that the new command will be ignored in this case.)
- DMA related interrupts (transfer finished/FIFO_FULL/underflow)
- Apart from this a single one sum interrupt OR-ing all the above events.

Various interrupt signals that represent the above events are:

- PSI5 new message arrival interrupt (**Status flags in PSI5_NDSR**) This is asserted when any of the programmed storage PSI5 locations (max 32) receive a new PSI5

message (error/error free). This interrupt also indicates that the PSI5 receive register (PMRRL/PMRRH) has been updated with a new PSI5 message.

- SMC message, ECU-to-sensor communication, and Time Stamp related interrupts (**All Status flags in PSI5_GISR**): This is asserted during following events:
 - When a new SMC message is received in its corresponding slot OR
 - When there is a CRC error in any SMC message OR
 - When an unread message in some corresponding SMC location (in PSI5_SFR) gets overwritten by a new SMC message OR
 - When DPR is ready for receiving a new data OR
 - When DBR is ready for receiving a new data OR
 - When DSR is ready for receiving a new data OR
 - When there is an attempt to write to DPR while it is NOT ready OR
 - When there is an attempt to write to DBR while it is NOT ready OR
 - When there is an attempt to write to DSR while it is NOT ready OR
 - When data time stamp register is updated with new time stamp value OR
 - When the sync time stamp read register is updated with a new time stamp.
- PSI5 Message Overwrite Interrupt (**Status Flags in PSI5_OWSR**): This is asserted when any of the programmed storage locations in the memory (max 32) have an unread PSI5 message that is overwritten by a new upcoming PSI5 message. Corresponds to OWSR.
- PSI5 Error interrupt (**Status Flags in PSI5_EISR**): This is asserted when any of the programmed storage locations in the memory (max32) have an error in the PSI5 message. It is used only for PSI5 messages.
- DMA Interrupt (**Status Flags in PSI5_DSR**):
 - When the DMA transfer corresponding to conf2, conf3 or conf4 finishes OR
 - When the DMA transfer corresponding to SMC message gets over OR
 - When there is an FIFO_FULL/Underflow in the PSI5 RAM register area OR
 - When there is an underflow in the SMC message area.
- Global Interrupt: Single interrupt ORing all above interrupt events.

53.4.5.1 Error conditions

- C: CRC/parity error on received data, evaluated after recalculating CRC on received data and comparing with received CRC or recalculating parity on received data and comparing with received parity.
- E: Electrical error during any Tbit period (excluding Messaging field M0M1) during frame reception (not applicable during Idle state); that is, if at least one bit is absent during its Tbit period.
- EM: Electrical error on M0M1 field.
- T: Timing error during frame reception violates the slot boundary. Here, all the corner cases and conditions are taken care of (for example, the isolation of correct slot to correct message if the message is too early or too late with respect to its expected position, the crossing of the slot boundary when one frame overlaps the other, and so on).
- F: No frame received during a particular slot time in case of sync mode.

53.4.6 DMA support

- The PSI5 module generates separate DMA transfer requests for PSI5 message/diagnostic status and SMC messages.
- A single DMA request is used for PSI5 messages and diagnostic data. The request is triggered based on the selected DMA configuration (either PSI5 message or diagnostic data or both). After choosing the configuration, data is available on respective DMA pop-up registers.
- DMA requests for PSI5 messages and diagnostic registers are based on the watermark level of message buffers (to be treated as FIFO for the DMA). PSI5 message buffer FIFOs get data from the PSI5 receiver in the order they are received.
- DMA requests for SMC messages are based on successful storage of each SMC frame to the message buffers. The SMC message buffers get data from SMC extraction logic in fixed round-robin arbitration sequence.
- Please see [Section 53.4.6.1, Single DMA request for PSI5/diagnostic message buffers](#) for PSI5 DMA handling and [Section 53.4.6.2, Single DMA request for SMC received messages](#) for SMC DMA handling

53.4.6.1 Single DMA request for PSI5/diagnostic message buffers

A common DMA request (per PSI5 block) is generated for PSI5 message/diagnostic buffers. The depth (up to 32 in present context) of the message buffer is programmable via the MEM_DEPTH filled in the PCCR. The width of each location of the PSI5 message buffer is 64 bits. When reading PSI5 message through the DMA, the 32-bit DPMR is sequenced with the data from the PSI5 message buffer. When reading the diagnostic registers through the DMA, the 32-bit DDSR is sequenced as NDSR followed by EISR. The DMA operation will happen as follows:

- Based on the DMA configuration chosen, one of the three DMA transfer sequence is initiated:
 - PSI5 buffer followed by diagnostic data sequenced to DPMR
 - PSI5 data sequenced to DPMR
 - Diagnostic buffer data sequenced to DDSR
- The DMA request is asserted when the number of messages stored in the buffer crosses the configured watermark number of messages.
- DMA request is deasserted once the “watermark” number of messages have been read.
- If the number of unread messages is still greater than the watermark programmed, then the DMA request is reasserted.
- The received message data is read from a common memory-mapped 32-bit DMA PSI5 message register (DPMR). Thus, a single PSI5 message (64 bits wide) will require two IPS read operations. The diagnostic data is read either through the DPMR or through the DDSR (single 32-bit register) by the DMA controller via the IPS interface.
- It is assumed that the DMA Controller's Transfer Control Descriptor (TCD) would be set to transfer bytes equal to the messages indicated by watermark level, as described in $\text{DMA_PM_DS_WM}[4:0]$ in [Section 53.3.2.3, DMA Control Register \(PSI5_DCR\)](#). It is assumed that when responding to a DMA request, the DMA controller will read faster

than the rate at which messages are received and stored in the buffer/FIFO, which will cause the DMA request to deassert.

- The next received message will be updated on the common memory map register once the previous message is read by the DMA (by the DMA sequencer).
- The store signal from the synchronization logic will push the message into the memory-mapped RAM registers and in parallel also into the PSI5 receive register. [Figure 1186](#) shows the format in which the messages will be stored in any message buffer (RAM registers) and finally when being read from DMA access register.
- For more details about DMA programming please refer to [Section 53.3.2.2, PSI5 Channel Control Register \(PSI5_PCCR\)](#), [Section 53.3.2.3, DMA Control Register \(PSI5_DCR\)](#), [Section 53.3.2.4, DMA Status Register \(PSI5_DSR\)](#), [Section 53.3.2.10, DMA PSI5 Message Register \(PSI5_DPMR\)](#) and [Section 53.3.2.12, DMA Diagnostic Status Register \(PSI5_DDSCR\)](#).

53.4.6.2 Single DMA request for SMC received messages

A separate DMA request (each channel) is generated for the SMC message buffer. Each SMC received messages would be stored in the internal registers and read out by DMA controller via a common memory-mapped DMA SMC Frame Register (DSFR) (single 32-bit register for each message buffer). The data flow will happen as follows:

- A request is asserted when the system buffer successfully receives one complete SMC message, and remains asserted until all complete messages have been read. Data is read from the DMA PSI5 Message Register in the memory map.
- It is the job of an internal sequencing logic to provide the next complete received message. The internal sequencer works in a round-robin fashion checking for the slot-specific registers for each SMC message. Thus the sequence will be slot1— slot2— slot3—slot4—slot5—slot6—slot1 and so on. In whichever slot it encounters the first complete SMC message, the DMA request is asserted and the sequencer will wait for this data to be read before moving on to the next slot in its loop. If a particular slot message remains unread and a new SMC message for the same slot comes in, then the previous message would be overwritten and the OW bit would be set.
- The DMA controller should be programmed to read only one message in one DMA transfer. Otherwise, if it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur. User software should ensure there is no overflow.
- For more details about DMA programming please refer “PCCR-PSI5 Channel Control Register” [on page 2137](#), “DCR-DMA Control Register” [on page 2143](#), “DSR-DMA Status Register” [on page 2146](#) and “DSFR-DMA SMC Frame Register” [on page 2155](#)

53.4.7 Message read through interrupt generation

There is a separate interrupt request for received messages for each PSI5 channel. Each PSI5 channel can be configured individually to generate an interrupt on reception of messages. An interrupt is asserted when the corresponding PSI5 channel has received a complete message (PSI5 or SMC). Please see [Section 53.4.5, Interrupt handling](#) for more details about interrupts. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing the corresponding PSI5 channel that is enabled to give out messages via interrupts through the IPS Interface. In response to these interrupts, the CPU is expected to read interrupt status register for

individual PSI5 Channel (depending on which interrupt was asserted) and store it in system memory.

53.5 Clock and Reset

The proposed clock scheme of the PSI5 block is shown in [Figure 1192](#). Global clock and clock divider are taken care of inside the CGM. Following is a brief description of these clocks with respect to the CGM:

- Global clock (please refer to [Figure 1192](#))
 - 1 Global clock generated from a single source but separately controllable for each PSI5 channel ("ipg_clk_psi5" for each channel that is generated from sys_clk).
 - It has a jitter of less than 5 ns at 1 MHz
 - 1 global clock, which is enabled during any register read/write from IPS interface. ("ipg_clk_s", which is common to all the PSI5 channels)
- Clock divider
 - Only one clock divider for all PSI5 interfaces (divider to generate 4 MHz/6.048 MHz from the system clock)
 - The clock divider generates all clocks that are needed for up to five interfaces
 - The clock divider is configurable by software
 - The output of the clock divider has a jitter of less than 5 ns at 1 MHz
- Separate GTM clock (not shown in [Figure 1192](#)) for each channel, which is available from at the system level. For reliable operation, the GTM clock should be limited in frequency to up to 3.9 MHz.

Figure 1192. PSI5 clock scheme

Note: Refer to the Device Configuration chapter for value of `PSI5_NUM_CH`.

53.5.1 Latency and Jitter related requirements

- Latency related
 - From the detection of the last bit of a frame (end of last CRC bit of message) at the input pin of the controller, up to provision of the data for the software (including CRC calculation): $\leq 3\mu\text{s}$.
 - From the sync pulse trigger output of the Sync Pulse Generator, up to the output of the sync pulse trigger at the data output pin of the controller: $\leq 2\mu\text{s}$.
- Jitter related
 - From the detection of the last bit of a frame (end of last CRC bit of message) at the input pin of the controller, up to provision of the data for the software (including CRC calculation): $\leq 1T_{\text{ipg_clk_psi5}}$
 - From the sync pulse trigger output of the Sync Pulse Generator, up to the output of the sync pulse trigger at the data output pin of the controller: $\leq 1\mu\text{s} + T_{\text{ipg_clk_psi5}}$

53.5.2 Reset

The device has a single global asynchronous reset input to the module that resets the whole module bringing it to an inactive state upon its assertion. The user software must program the module registers to bring up the receiver operations.

53.6 Initialization information

53.6.1 Initialization

53.6.1.1 Sensor startup and initialization

After each power-on or under-voltage reset, the sensor performs an internal initialization, which is divided into three phases:

- Initialization Phase1: No data transmission.
- Initialization Phase 2: Transmission of type code and serial number of sensor.
- Initialization Phase 3: Transmission of “Sensor Ready” or “Sensor Defect” or other sensor specific data.

As this PSI5 implementation is targeted towards powertrain devices/sensors the standard initialization phase is modified and tuned for those applications. The comparison of the original scheme and enhanced schemes are shown in [Figure 1193](#). [Figure 1193](#) also describes that the initialization content is the same as defined in V1.3, and the only modification is that it is transmitted using the SMC channel when a fast startup is required. “Fast Initialization Phase” below means that the sending of first sensor data is fast, but the sending of sensor initialization data will actually be much slower.

Figure 1193. Fast initialization phase

53.7 Design Assumptions and Limitations

53.7.1 Assumptions

- Slot Configuration Register would always be programmed with valid number of bits for frame configuration.
- There will be no Timing error bits (T) in async mode. Also, in this mode the IP waits indefinitely for the detection of a valid start sequence, hence the F bit (NFR) is not set in Async mode. Rest all of the errors are available (E, EM, and C).

53.7.2 Limitations

As this is a PSI5 receiver, designed primarily to only receive the PSI5/SMC data and store as it is into the RAM buffer. So, it would not be responsible neither to recognize the content of the received messages nor do any decision making based on the content. Similarly, for Command it would not recognize the content of command and would transmit as it is writing into corresponding DSR and reception of PSI5 messages would not in any way depend on the content of command as far as PSI receiver is concerned. Its the responsibility of SW to sequence the issue of commands across the PSI5 channels and thereby recognize the content of received message and infer it.

53.8 Miscellaneous descriptions

53.8.1 Internal SYNC Pulse generation and coordination across PSI5 channels

Each PSI5 channel has the Channel Target Pulse Registers (CTPR) and Channel Initialize Pulse Register (CIPR). The CTPR defines the period of the internal sync pulse generation and the CIPR defines the initial offset time with respect to the sync pulse trigger. The sync pulse trigger can be generated from either the PSI5_GCR[CTC_GED] global bit or the PSI5_PCCR[CTC_ED] channel specific bit.

When staggering of the channels is required then the PSI5_GCR[CTC_GED] global bit is used as a common trigger for all the PSI5 channels in which PSI5_PCCR[CTC_GED_SEL] bit is set to 1. Setting this bit to 1 triggers the internal sync pulse generators of all the PSI5 channels and the trigger of each channel is then automatically staggered with respect to the other channel, depending on the value of the CIPR.

When the specific PSI5 channel is not to be kept as a part of staggered channels, then the channel-specific PSI5_PCCR[CTC_GED_SEL] bit has to be kept as 0. The channel in this case, has to be triggered locally by writing a 1 to the PSI5_PCCR[CTC_ED] of that specific channel. This triggers the internal Sync Pulse Generator of that specific channel without affecting other channels.

Following is the procedure for starting the internal Sync Pulse Generators:

- If in Normal mode, then stop and reset all Channel Trigger Counters (CTCs) by setting the global PSI5_GCR[CTC_GED] bit to 0 or the channel specific PSI5_PCCR[CTC_ED] to 0.
- Enter Config mode.
- In Config mode, load all CTCs with the initialization value (offset) from CIPR.
- In Config mode, load all Counter Target Pulse Registers (CTPR) with the needed sync pulse period.
- Enter Normal mode.
- Send global start trigger (using PSI5_GCR[CTC_GED] bit) to all CTCs for synchronized start for the staggered channels OR send a local start trigger (by using the PSI5_PCCR[CTC_ED]) for channels not staggered.
- If the Compare Unit detects that the value in the CTC is equal to the value in CTPR, the CTC is automatically reset by hardware and restarts with 0.
- In Normal mode, if required, the CTC can be stopped and reset by writing a "0" to the PSI5_GCR[CTC_GED] or the PSI5_PCCR[CTC_ED] as the case may be.
- A sync pulse trigger is created. (See below.)

For the details about the operation of the below interface, please see [Section 53.3.2.34, Counter Target Pulse Register \(PSI5_CTPR\)](#), [Section 53.3.2.35, Counter Initialize Pulse Register \(PSI5_CIPR\)](#) and [Section 53.4.3.4.5, Sync Pulse Trigger Generation](#).

Figure 1194. CIPR and CTPR

[Figure 1194](#) shows the CIPR and the CTPR definition w.r.t the staggering of the channels. [Figure 1195](#) is a more detailed representation of these parameters along with the associated jitter, across different channels when these channels are staggered. (The figure also shows some other parameters, such as the modulated pulse width parameters and the Manchester decoder disable parameters.)

54 Peripheral Sensor Interface-Support Module (PSI5-S)

54.1 Introduction

The PSI5 support IP (PSI5-S) module is used to interface directly to a UART compatible PSI5 transceiver over a high speed UART link. The transceiver is required to implement a compliant PSI5 module for all vehicle applications as is currently defined in the PSI5 protocol specification V2.0.

PSI5 messages from sensors received by the transceiver are decomposed into UART bytes and sent to the PSI5-S which in turn reconstructs the PSI5 messages from the UART packet , and makes them available for the application in system RAM.

ECU-to-sensor commands are sent from the PSI5-S module to the transceiver, which in turn generates the appropriate logical 1's and 0's in the SYNC pulses sent on the bus. The PSI5-S supports all command formats of the PSI5 V2.0 including the "tooth gap" method and "variable length" pulses.

At the system level, the PSI5-S supports one transceiver with up to seven PSI5 channels. Apart from these seven channels, there is an eighth channel available for special purposes, including direct communication with the transceiver and storage of corrupt messages.

54.1.1 Overview

PSI5 is an interface for automotive sensor applications. PSI5 is an open standard based on existing sensor interfaces for peripheral airbag sensors, already proven in millions of safety airbag systems. The technical characteristics, the low implementation overhead, as well as the attractive cost make PSI5 also suitable for many other automotive sensor applications. The development goal of PSI5 is a flexible, reliable communication standard for automotive sensor applications that can be used and implemented license free.

The main features of PSI5 are high-speed and high-reliability data transfer at the lowest possible implementation overhead cost, offering a universal and flexible solution for multiple sensor applications. The main features of the PSI5 standard are:

- Two-wire current interface
- Manchester-coded digital data transmission from sensor to ECU
- High data transmission speed of 125 kbit/s or optional 189 kbit/s
- High EMC robustness and low emission
- Wide range of sensor supply current
- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

The PSI5-S module can be configured to support the following PSI5 features. :

- Configurable data word length (8 to 28 bits)
- Asynchronous or synchronous operation
- Bidirectional communication

The PSI5-S module requires the physical and data link layer of the PSI5 to be implemented outside its interface. It also requires the PSI5 information to be embedded in the form of UART packet, from where it reconstructs the PSI5 message.

The module receives PSI5 message, from up to seven PSI5 channels each with upto six sequential frames. This is achieved via the external UART compliant transceiver. The PSI5 message in each of these frames are decomposed into three-to-six UART bytes(depending on PSI5 data payload) and streamed on a UART link at up to 6.25 Mbit/s to the PSI5-S module. In addition, via the PSI5-S interface, the application sends commands to the transceiver. The transceiver interprets them as either SYNC pulse commands (which will result in short, long or no SYNC pulses on the PSI5 bus), configuration commands (which will result in updates to the transceiver configuration) or diagnostic commands (which will result in the transceiver responding directly over the UART connection). In addition to the seven channels above there is an additional Channel, known as Channel0, which is used for special purposes like storing the direct responses from the transceiver or storing the unrecoverable messages.

The PSI5-S consists of three main functional blocks.

1. UART front end - Used as PSI5-S front end. When PSI5 functionality is not required then it is possible to use this as a standard UART (without LIN) also.
2. Message Recovery Unit - consisting of two state machines.
 - The first state machine interprets the input UART data stream and rebuilds the PSI5 message contained in the up to six UART bytes and also checks for the status of the correct reception of PSI5 message.
 - The second state machine sends SYNC pulse commands via the UART TxBuffer, to the external UART compliant transceiver, which in turn outputs SYNC pulses (short, long, or no SYNC pulse) on the PSI5 bus used to synchronize sensor responses in a bus configuration, and where required, also sends commands to sensors as defined in the PSI5 protocols V2.0.
3. PSI5 message interface - It is composed of two MRU buffers, MRU buffer1 and MRU buffer2. Both of them are collectively referred to as MRU output buffer. The MRU buffer1 is internal to the IP and not accessible from outside the IP. It is three word deep. MRU buffer2 is accessible to the application and is 4 word deep. MRU buffer2 can be read by the DMA interface, to transfer the stored PSI5 messages, to Channel specific mailboxes in system RAM directly.

Note:

General Description

- *The location in system RAM where the messages are stored are referred to as the Mailbox . The mailbox is divided on the basis of channel and each channel is divided on the basis of slots on the PSI5 bus . Thus Mailbox1,location1 would mean Mailbox location for Channel1 and Slot No "1". This is also denoted by MBOX1,LOC1 or MBOX₁,LOC₁. This terminology would be followed in the subsequent sections of the doc.*
Each "location" of each mailbox channel is made up of 3x32 bits . The maximum size of each mailbox can be 6 "locations" . There are 8 such mailboxes . For channels operating in asynchronous mode , the whole of the Mailbox would act like a ring buffer and all the 6 locations would be filled in that manner.
Mailbox0 only has two locations MBOX0,LOC0 and MBOX0,LOC1. MBOX0,LOC0 is reserved for messages intended for Channel0(used for transceiver specific messages) while MBOX0,LOC1 contain "unrecoverable" messages for any channel . Other 4 locations of the MBOX0 are reserved.
- *Also a "UART byte" would mean the "byte" that is recieved by the UART reciever. "UART packet" would mean the group of UART bytes from which the PSI5 message would be extracted . "PSI5 message" means the message contained in the MRU*

buffers which contains the actual PSI5 message along with the timestamp and the error status bits.

Figure 1199 shows the block diagram of the PSI5-S module.

Figure 1199. PSI5-S digital interface block diagram

54.1.2 Features

- IPS interface for register read/write (big endian).
- Support for up to 7 PSI5 channels(Channel1 to Channel7) with each channel supporting up to 6 different Frame Streams (Slots). Each of the Frame Streams can be individually configured for Parity/CRC, payload Length, Synchronous/Asynchronous Operation, TimeStamp Capture event, Timestamp A or Timestamp B selection.
- Additional Channel0 for special functions.
- Supports bidirectional full duplex operations, via the UART Rx and Tx links.
- Provision of Extended CRC (XCRC) to check the coherence of the UART packet that comprise the PSI5 message.
- Message Reconstruction Unit (MRU) buffer2 (consisting of 4,32-bit words). Three of these words contain the PSI5 messages (PSI5 message payload, Message Status flags, Time Stamp) and the fourth one contains the mailbox address to which the three PSI5 words need to be transferred.
- A 24-bit time stamp register, clocked with either the module clock or the GTM clock(gtm_trig). The time stamp appended to the PSI5 message in the MRU, can be configured to be, either the one that is captured when a new PSI5 message is

- detected, or the one that is captured when the Output ECU to Sensor command is transferred from the UART TX buffer to the UART Tx Shift register.
- IPS interface DMA support, for transferring the data in the MRU output buffer to system memory.
 - Downstream Data Shift Register (DDSR) on per channel basis supporting the following :
 - Application can write the ECU to Sensor commands to the DDSR.
 - Supports automatic addition of the start bits/stuff bits /CRC calculation to the contents of DDSR.
 - Provision of resetting and rejecting the contents of DDSR at any stage of command transmission.
 - Support for conversion of the logic levels contained in the DDSR, to UART commands to be sent to the transceiver.
 - Provision of writing the Software calculated commands directly to the UART TX Buffer . This can be used for direct writing of the transceiver status and/or diagnostic commands.
 - Configurable UART message idle time counter, that indicates to the PSI5 MRU when an idle time at least as long as the configured length (number of bit times), has occurred on the Rx line.
 - Provision of configuring the PSI5-S front-end as a standalone UART module, when the PSI5-S module is disabled. In this mode the module, does not have any relation with the PSI5 protocol.
 - Support of up to 6.25 Mbit/s UART Rx Baud Rate.
 - An output clock for the PSI5 transceiver UART interface.

54.1.3 PSI5-S Global Modes of operation

The PSI5-S module can be configured in 4 different global modes of operation . These are UART_STDALONE,PS_DISABLE,PS_CONFIG and PS_NORMAL . These global modes can be entered by programming the PS_GLCR[GLOBAL_MODE] bits appropriately . [Figure 1200](#) shows the state transition diagram for these bits.

The PS_NORMAL,PS_CONFIG and PS_DISABLE are collectively referred to as the “PSI5-S” modes. Please see [Figure 1200](#). Once the PS_GLCR[GLOBAL_MODE] bits are appropriately configured for the “PSI5-S” modes , the information that the intended mode of operation is fully achieved is reflected by the setting of the PS_GLSR[GL_MODETR_DONE] status bit . An interrupt can also be generated for this event , in case the PS_GLCR[GL_MODETR_DONE_EN] bit is set to “1” . Thus, only when PS_GLSR[GL_MODETR_DONE] goes to “1” it should be considered that the IP has entered the desired “PSI5-S” mode.

This bit is reset to “0” when the mode is changed from any of the PSI5-S modes to the UART_STDALONE mode .

Following are the descriptions of the different global modes .

54.1.3.1 Standalone UART mode (UART_STDALONE mode)

This is the default state after the module reset. In this mode, only the PS_GLCR[GLOBAL_MODE] register bits and the registers of the UART module are accessible for writing. This is the mode which is to be used when the PSI5-S front end has

to be used as a standalone UART . This state indicates that the UART will now function as a standard UART and the PSI5-S core will be disabled. In this state, the PSI5-S register space is not accessible (except PS_GLCR[GLOBAL_MODE] registers) and any access to the registers of PSI5-S module (except PS_GLCR[GLOBAL_MODE] registers and UART specific registers) will generate transfer error.

54.1.3.2 Disable mode(PS_DISABLE)

PS_Disable mode in the PSI5 reduces power consumption. In this mode the RX, TX and common time base counters are disabled for any operation. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Please see [Table 1177](#) for the details of these bits. Note that when entering PS_Disable mode from any other mode, the register contents are retained and are not changed. The time stamp counter is however reset when entering Disable mode.

In “PS_Disable” mode, only PS_GLCR[GLOBAL_MODE] register bits are accessible for read/write. Accessing any other register bits will generate transfer error.

There is no software reset bit in the PSI5 module. The same has to be managed outside the IP at the system level. Channels will enter “Configuration/Normal mode” based on the value of the PS_GLCR[GLOBAL_MODE] bits.

54.1.3.3 Configuration mode (PS_CONFIG mode)

In the configuration mode all PSI5 global, channel specific configuration/control registers and UART registers can be written. The receiver and transmitter sub-blocks remain disabled in this mode. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Please see [Table 1177](#) for the details of these bits.

54.1.3.4 Normal mode (PS_NORMAL mode)

In PS_NORMAL mode, the receiver and the transmitter blocks become active, error handling is enabled, UART starts its operation and all the PSI5 protocol functions are also enabled. In this mode, all the PSI5 global and channel-specific configuration registers are locked for writing, although these registers can still be read. This mode is entered by the specific combination of PS_GLCR[GLOBAL_MODE] bits. Please see [Table 1177](#) for the details of these bits. Note that there are still some register bits that can be written in this mode also. Please refer to the detailed register description.

Figure 1200. Operating modes

1. PSI5-S module can be configured in 4 different Global modes of operation . These are UART_STDALONE , PS_NORMAL,PS_CONFIG and PS_DISABLE . The PS_NORMAL,PS_CONFIG and PS_DISABLE are collectively referred to as "PSI5-S" modes.
2. PS_GLSR[GL_MODETR_DONE] status bit is reset to "0" when the transition occurs from PS_DISABLE to UART_STDALONE mode .

Table 1177. State transition Table

Present State	PS_GLCR (State Variables)			Next State
	PS_GLCR[GLOBAL_MODE(2)]	PS_GLCR[GLOBAL_MODE(1)]	PS_GLCR[GLOBAL_MODE(0)]	
UART_STDALONE	1	1	1	PS_Disable
PS_Disable	0	0	0	UART_STDALONE
PS_Disable	0	0	1	PS_Normal
PS_Disable	1	0	0	PS_Config
PS_Config	1	1	1	PS_Disable
PS_Config	0	1	0	PS_Normal
PS_Normal	1	1	1	PS_Disable

54.1.4 PSI5-S System Modes of operation

54.1.4.1 Stop mode

For PSI5-S modes:

In this mode , upon the STOP request from the system level the IP generates a system level acknowledgement with the information that the clocks to the IP can be switched off. The process of the same is as described below.

At the PSI5-S Rx side, as soon as stop mode request is recieved by the IP then the current PSI5 message under construction (in the internal PSI5 message extraction logic) is immediately saved to the MRU output buffer1 . Thus the assertion of the stop mode acts like a “forced” flushing for the current PSI5 message completion. Depending on the state of the PSI5 message under construction, the resultant PSI5 message might or might not have errors. Any byte that is being recieved by the UART is henceforth rejected. The internal PSI5 message extraction logic goes back to an “idle” state and remains so till the STOP mode request remains asserted.

At the PSI5-S Tx side , on the reception of the stop mode request , the internal sync pulse generation counters are stopped immediately(DDSR trigger counters) and no further command bits are shifted onto the UART Tx side . The UART Tx completes the current byte that is being transmitted and enters the idle state . No further transmissions take place.On deassertion of the stop mode , once the clocks restarts, the transmission of the commands resumes from where they had halted.

Once both the above processes are complete the IP generates acknowledgement for switching of the clocks to the PSI5-S IP.

For UART STDALONE mode:

For this please refer to the separate documentation describing the standalone LINFLEX module.

54.1.4.2 Debug mode

The IP enters this mode on system request. Any register can be read or written to by the debugger. The IP can enter the debug mode in addition to it being in any of the other modes (Uart Standalone/Disable/Normal/Config). In this mode the hardware clearing of the register PS_WDGTSSR remains disabled and any read of this register has no effect on the contents of this register. Apart from this there is no other difference as to whether the IP is in debug mode or not in the debug mode of operation.

54.2 External signal description

Table 1178. External signal description

S.No	Name	Function	I/O	Pull-up
Signals to/from pads				
1.	ipp_ind_linrx	LINUART receive pin. Used for Receiving UART bytes from transceiver which contain information to enable the rebuilding of the PSI5 message within the packet of between three and six UART bytes	I	Active
2.	ipp_do_lintx	LINUART transmit pin. Used for transmitting command bytes from TxFIFO to transceiver for generation of SYNC pulses (long, short or no) on the PSI5 bus or direct diagnostic/status commands for the transceiver itself	O	Passive
3.	ipp_port_en_tx	LINUART transmission port enable : Connected to the enable pin of of the pad which is to be used for "LINTX" functionality. When "1" it indicates that the IP is doing transmit of data.	O	Passive
4.	ipp_psi5_uart_tclk	Transceiver clock output, which drives the UART interface on the transceiver. The clock output frequency is configurable between 4 and 8 x UART baud rate on the interface between PSI5-S and transceiver.Frequency can be controlled at the system level through the Clock Generator Module(MC_CGM). The duty cycle of the transceiver clock is between 40% and 60%	O	Passive
IPS Interface

1. In this column, R/W = Read/Write, R = Read-only, W = Write-only, W1C = write-1-to-clear and W1S = "write-to-1-shot" wherein writing a 1 causes an effect on the register bit while writing a 0 has no effect; a read always returning a 0, D = Disable mode, C = Config mode, N = Normal mode. All 32-bit registers are word/half word/byte addressable for write. Read is always word addressable. Trying to access any register space of PSI5-S, other than those mentioned in the memory map i.e. trying to access any "RESERVED" register in the memory space, results in the generation of transfer error. Note that the generation of transfer error is confined to this scenario only.
2. Locations from 0x0000 to 0x005C are for UART registers.
3. PS_NOUSE_REG : Stands for register NOT REQUIRED in PSI5-S modes. It will be required in UART STANDLONE mode.

4. Register has significance in UART STANDLONE mode. This document would only mention the bit field names in the corresponding register description. For detailed bit description and the functioning of this register in UART modes(sleep,init and normal) belonging to UART STANDLONE mode, please refer to the separate documentation describing the standalone LINFLEX module.
5. Not all register bits are of this type. Please see the register bit description for more details.
6. Register Bits are automatically hardware cleared on read of any bit of this register.

54.3.2 UART register configuration

This section contains information of the UART registers that are specifically required for correct functioning of the IP in the “PSI5-S” modes.

In order to operate the PSI5-S module, the UART configuration registers need to be programmed with appropriate values. The values that are required for different register fields are defined in the following register descriptions . Some bits have to be programmed with definite values of “1” or “0” only .

In the following UART register description “PS_NOUSE_BIT” against a bit name and bit description, means that the specific register bit is present in the UART module but it is NOT REQUIRED in the PSI5-S modes of operation. For correct operation in the PSI5-S modes , the corresponding register bit might be required to be programmed as “1” or a “0” ; the same would be mentioned in the bit description .

Note that a bit with “PS_NOUSE_BIT” against its description would still be required in the UART STANDALONE mode . For detailed information of the UART register bit functioning in the UART STANDLONE mode, please refer to the separate document describing the standalone LINUART module. There are some other register bits which dont have a “PS_NOUSE_BIT” against them . These can be programmed as required. A bit mentioned as “Reserved” would mean that neither it is available in the UART STANDLONE mode nor in the PSI5-S modes.

54.3.2.1 PSI5-S LIN Control Register 1 (PS_LINCR1)

The PS_LINCR1 register contains control bits used to configure features of the PSI5-S UART Front end.

Table 1180. PS_LINCR1 field descriptions

Field	Description
Reserved	Reserved Read returns 0
Reserved	Reserved
Reserved	Reserved
Reserved	Reserved
AUTOWU	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.
Reserved	Reserved
Reserved	Reserved
SLFM	Self test mode 0 Self test mode disabled 1 Self test mode enabled To be used along with the LBKM bit . When this bit is set then in addition to the Loop Back mode; the “ipp_do_lintx” is driven to “1” .
LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Programmed in PS_CONFIG mode. When set then then the “ipp_do_lintx” output is internally looped back and connected to “ipp_ind_linrx” pin .
Reserved	Reserved Read Only bit . Always read as “1”.
Reserved	Reserved
RBLM	PS_NOUSE_BIT Always program as 0 in PSI5-S modes.
SLEEP	PS_NOUSE_BIT Read Only Bit in PSI5-S modes. R/W in UART Standlone mode.
INIT	PS_NOUSE_BIT Read Only Bit in PSI5-S modes. R/W in UART Standlone mode.

54.3.2.2 PSI5-S LIN Interrupt enable register (PS_LINIER)

FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (FEF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose . It is not necessary to enable this interrupt for the correct operation of the PSI5-S core
BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose . It is not necessary to enable this interrupt for the correct operation of the PSI5-S core

Table 1181. PS_LINIER field descriptions (continued)

Field	Description
Reserved	Reserved. Always keep as 0.
WUIE	PS_NOUSE_BIT Always program as 0 in PSI5-S modes.
Reserved	Reserved
TOIE	Timeout Interrupt Enable 0 No interrupt 1 Interrupt generation enabled. An interrupt is generated if this bit is set and the Timeout Flag (TO) in PS_UARTSR is set. This interrupt can be used for monitoring purpose . It is not necessary to enable this interrupt for the correct operation of the PSI5-S core
DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated if this bit is set and the Data Recieved Flag (DRF) in PS_UARTSR is set. This interrupt can be used for monitoring purpose . It is not necessary to enable this interrupt for the correct operation of the PSI5-S core
DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt generation enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in PS_UARTSR is set. This interrupt can be used by the Application to check when the UART buffer is ready to accept the next byte. This is used by the application when it wants to write a transceiver command directly to the UART Tx buffer.
Reserved	Reserved Always read as "0".

54.3.2.3 PSI5-S LIN Status Register (PS_LINSR)

This register is used only in the UART STANDALONE mode and has no significance in the PSI5-S modes

Table 1183. PS_UARTCR field descriptions

Field	Description										
MIS	PS_NOUSE_BIT Always program as “1” in PSI5-S modes.										
CSP	Configurable Sample Point These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: <table border="1"> <thead> <tr> <th>OSR</th><th>CSP</th></tr> </thead> <tbody> <tr> <td>4</td><td>2, 3</td></tr> <tr> <td>5</td><td>2, 3, 4</td></tr> <tr> <td>6</td><td>3, 4, 5</td></tr> <tr> <td>8</td><td>NA</td></tr> </tbody> </table> For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.	OSR	CSP	4	2, 3	5	2, 3, 4	6	3, 4, 5	8	NA
OSR	CSP										
4	2, 3										
5	2, 3, 4										
6	3, 4, 5										
8	NA										
OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6 and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.										
ROSE	Reduced Over Sampling Enable 0 Each bit is over sampled sixteen times. 1 OSR bits decide the over sampling rate. The default value of this bit is 0.										
NEF	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.										
PCE_Tx/DTU	In PSI5-S mode Parity Control Enable for Tx path(In UART STANDLONE mode used to disable UART timeout-Refer to LINUART standalone documentation for more details) 1: Parity generation for Tx path enabled. 0: Parity generation for Tx path disabled. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[] == 1. When programmed as “1” then a 1 bit additional parity bit is added to the transmitted 8 bits of UART data, so a total of 9 bits including parity are present between a start and a stop bit , in the transmitted data When programmed as “0” then total of 8bits data is present between a start and a stop bit in the transmitted data.										
SBUR	PS_NOUSE_BIT Always program as “00” in PSI5-S modes.										
WLS	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.										
TDFL/TFC	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.										

Table 1183. PS_UARTCR field descriptions (continued)

Field	Description
RDFL/RFC	PS_NOUSE_BIT Always program as “000” in PSI5-S modes.
RFBM	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
TFBM	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
WL1	PS_NOUSE_BIT Always program as “0” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1
PC1	Parity Control {PC1,PC0} 00 Parity is Even for both the Rx/Tx paths 01 Parity is Odd for both the Rx/Tx paths. 10 A logical 0 is taken as parity bit for both the Rx and the Tx paths 11 A logical 1 is taken as parity bit for both the Rx and the Tx paths. Can be programmed only in the PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
RxEn	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when PS_UARTCR[] == 1.
TxEn	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when when PS_UARTCR[UART] == 1
PC0	Parity Control {PC1,PC0} 00 Parity is Even for both the Rx/Tx paths 01 Parity is Odd for both the Rx/Tx paths. 10 A logical 0 is taken as parity bit for both the Rx and the Tx paths 11 A logical 1 is taken as parity bit for both the Rx and the Tx paths. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1.
PCE_Rx	Recieve Parity check enable . 1 : Enable the parity checking on the Rx path 0: Disable the parity checking on the Rx path Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1. When programmed as “1” then a 1 bit additional parity bit is expected along with the recieved 8 bits of UART data, so a total of 9 bits including partity are expected between a start and a stop bit , in the recieved data. When programmed as “0” then total of 8bits data is expected between a start and a stop bit in the recieved data.

Table 1183. PS_UARTCR field descriptions (continued)

Field	Description
WL0	PS_NOUSE_BIT Always program as “1” in PSI5-S modes. Can be programmed in PS_CONFIG mode only and when PS_UARTCR[UART] == 1.

Table 1184. PS_UARTSR field descriptions

Field	Description
Reserved	Reserved Read returns 0
SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated on the UART interrupt lines if the SZIE bit in PS_LINIER is set.
OCF	PS_NOUSE_BIT Read Only Bit.
PE[3:1]	PS_NOUSE_BIT Read Only Bit.

Table 1184. PS_UARTSR field descriptions (continued)

Field	Description
PE0	Parity Error flag for Data0 byte These bits indicate if there is a Parity Error in the recieved byte. No interrupt is generated if this error occurs. 0 No parity error 1 Parity error in the corresponding received byte This flag is automatically cleared by hardware. The software can poll this flag for debugging purposes.
RMB	PS_NOUSE_BIT Read Only Bit.
FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). FEF is automatically cleared by hardware. An interrupt is generated if this bit is set and the FEIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose . It is not necessary to enable this interrupt for the correct operation of the PSI5-S core
BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and the previous byte has not yet been read from the UART Rx buffer due to some fault in PSI5-S core reading logic. It is automatically cleared by hardware . An interrupt is generated if this bit is set and the BOIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose . It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
WUF	PS_NOUSE_BIT Read Only Bit.
RFNE	PS_NOUSE_BIT Read Only Bit.
TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO is automatically cleared by hardware. An interrupt is generated if this bit is set and the TOIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose . It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.
DRF	Data Reception Completed Flag DRF is set by hardware in UART buffer mode and indicates that one byte has been recieved and is ready for being read. DRF is automatically cleared by hardware . An interrupt is generated if this bit is set and the DRIE bit of PS_LINIER is set. This interrupt can be used for monitoring purpose . It is not necessary to enable this interrupt for the correct operation of the PSI5-S core.

Table 1184. PS_UARTSR field descriptions (continued)

Field	Description
DTF	Data Transmission Completed Flag DTF is set by hardware in UART buffer mode and indicates that data transmission is completed. DTF is automatically cleared by hardware. When the SW desires to write the commands directly to the UART Tx buffer for transmission then it can monitor this bit for an indication of when the UART Tx buffer is ready to accept the next 8 bits of the data. An interrupt will be generated if the DTIE bit in PS_LINIER is set.
NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

54.3.2.6 PSI5-S LIN Fractional Baud Rate Register (PS_LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

00000h	LIN clock disabled												
00001h	1												
...	...												
FFFFEh	1048574												
FFFFFh	1048575												

Note: *UART baud rate*

The UART baud rate is programmed in two registers: the LIN Integer Baud Rate register(PS_LINIBRR) and the LIN Fraction Baud Rate register(PS_LINFBRR). The baud rate registers can be programmed only during the PS_CONFIG mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

$$Tx_{BR} = Rx_{BR} = ipg_baud_clk / (16 \times LDIV) \quad (\text{when } UARTCR[ROSE] == 0)$$

$$Tx_{BR} = Rx_{BR} = ipg_baud_clk / (UARTCR[OSR] \times LDIV) \quad (\text{when } UARTCR[ROSE] == 1)$$

LDIV is an unsigned fixed point number which comprises of the mantissa and the fraction . The mantissa is coded into 20 bits of LINIBRR, and the fraction is coded on 4 bits of LINFBRR.

When reduced oversampling is enabled($UARTCR[ROSE] == 1$) then PS_LINFBRR is not used . Hence LDIV contains only the integer part programmed in LINIBRR. Following are 2 examples for two different baud rate calculations.

Example 1:

With $UARTCR[ROSE] = 0$.

$LDIV = 1041.67$, $ipg_baud_clk = 80$ MHz

$LINIBRR = 1041d = 411$ h

$LINFBRR = 11d = B$ h

$$Tx_{BR} = Rx_{BR} = 80 \text{ Mhz} / (16 \times 1041,67) = 4.8 \text{ Kbit/s}$$

Example 2:

When $UARTCR[ROSE] = 1$:

$LDIV = 10$ d, $LIN_CLK = 80$ MHz

$LINIBRR = 10$ d, $UARTCR[OSR] = 4$

$$Tx_{BR} = Rx_{BR} = ipg_baud_clk / (UART[OSR] \times LDIV) = 80 \text{ MHz} / (4 \times 10) = 2 \text{ Mbit/s}$$

54.3.2.8 PSI5-S LIN Control Register 2 (PS_LINCR2)

1. Register bit can be read in any mode, written only in PS_CONFIG mode.
2. Register bit can be written only by software in PS_CONFIG mode. Bit is always read 0 by software.

Table 1190. PS_GCR field descriptions

Field	Description
Reserved	Reserved Forced to 0 by hardware
TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB: 0 The first bit of transmitted data is LSB — in other words, the first bit received is mapped on LSB bit (of DATA_TX in PS_BDRL register) 1 The first bit of received data is MSB — in other words, first bit received is mapped on MSB bit (of DATA_TX in PS_BDRL register)
RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB: 0 The first bit of transmitted data is LSB — in other words, the first bit received is mapped on LSB bit (of DATA_RX in PS_BDRM register) 1 The first bit of received data is MSB — in other words, first bit received is mapped on MSB bit (of DATA_RX in PS_BDRM register)
TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) . 0 Transmitted data is not inverted 1 Transmitted data is inverted
RD LIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) . 0 Received data is not inverted 1 Received data is inverted

Table 1190. PS_GCR field descriptions (continued)

Field	Description
STOP	PS_NOUSE_BIT Always program as “0” in PSI5-S modes.
SR	Soft reset SR executes a soft reset of the UART controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0.

54.3.2.12 PSI5-S UART Preset Timeout Register (PS_UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed to monitor the idle state of the reception line. This register can be written by software any time.

Figure 1212. PSI5-S UART Preset Timeout Register (PS_UARTPTO)

Address: 0x0050

Access: User read/write

1.

Table 1191. PS_UARTPTO field descriptions

Field	Description
Reserved	Reserved Read returns 0.
PTO[11:0]	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. The register must be programmed to a value of “Idle Timeout required in terms of number of bits recieved ” at that particular baud rate. Refers also to register UARTCTO.

54.3.2.13 PSI5-S UART Current Timeout Register (PS_UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see [Section 54.3.2.12, PSI5-S UART Preset Timeout Register \(PS_UARTPTO\)](#)) to monitor the idle state of the reception line.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with baud clock frequency of T_{xBR}/R_{xBR} . Also refer ^(Note:) which follows [Section 54.3.2.7, LIN Integer Baud Rate Register \(PS_LINIBRR\)](#).
- Is automatically enabled when UARTCR[RXEN] = 1

Note: Due to internal synchronization there is a delay between 4 to 6 clock cycles of "ipg_clk_ps", for the internal counter's value (which is clocked with baud frequency of T_{xBR}/R_{xBR}) to reflect on to UARTCTO.

UARTCTO is reset when :

- UARTCTO becomes equal to UARTPTO
- Whenever UARTPTO is written.
- When the PSI5-S goes in PS_DISABLE mode.

54.3.3 PSI5-S Register description

Unless specifically stated, the register bits are readable in all modes, but writable only in Config mode. Trying to write to any register outside its intended mode of write (Normal/config) will be ignored without the generation of any transfer error. PS_GLCR[GLOBAL_MODE] are the only register bits that can be written in the PS_DISABLE mode. In PS_DISABLE mode, accessing any other register bits will generate transfer error.

Note that, an access (read/write) to any register in the unimplemented register space will result in the generation of transfer error. All word locations are byte/half word/word accessible for write. Read is always a word access. Trying to write to "read only" bits of implemented register space, will be ignored without the generation of any error.

54.3.3.1 PSI5-S Global Control Register (PS_GLCR)

The Global Control Register (PS_GLCR) provides control functions for all the PSI5-S channels simultaneously.

Figure 1216. PSI5-S Global Control Register (PS_GLCR)

Address: 0x00B4

Access: User read/write

Table 1195. PS_GLCR bit field details

Field	Description
Reserved	Reserved
GL_DDSR_TRIG	This is the global shift trigger of all the DDSRs of each channel. When the corresponding PS_E2SCR_CH[n][GL_TRIG_SEL] == 1 , only then is this bit effective, else this bit has no effect. 1 The shift triggers of all the DDSR's start synchronously. 0 Shift triggers of all the DDSR registers are halted (default state). If bit is cleared during runtime, PS_DDTRIG_PERR and PS_DDTRIG_OFFR counters are reset. <i>Note: If bit is subsequently set after being cleared , then the counters will restart and the offsets in PS_DDTRIG_PERR and PS_DDTRIG_OFFR registers will be applied again.</i> This bit is also writable in PS_NORMAL mode
GL_MODETR_DONE_EN	Interrupt enable for PS_GLSR[GL_MODETR_DONE] bit. 1: Generates the interrupt when PS_GLSR[GL_MODETR_DONE] bit is set. 0 : No interrupt is generated on setting of the PS_GLSR[GL_MODETR_DONE] bit This bit is also writable in PS_NORMAL and PS_DISABLE modes.
MRU_ERR_EN	Enables the interrupt for MRU overwrite when the unread contents of MRU Buffer1 are overwritten by a new message 0 MRU overwrite error is not enabled 1 MRU overwrite error is enabled <i>Note: This bit is also writable in ps_normal mode</i>

Table 1195. PS_GLCR bit field details (continued)

Field	Description
TSCS_B	This bit controls the selection of clock input to timestamp counter B, either by the external periodic clock or by the GTM module 1 gtm_trig is selected as the clock. 0 External clock(ipg_clk_ps_ts) is selected
TSCS_A	This bit controls the selection of clock input to timestamp counter A, either by the external periodic clock or by the GTM module 1 gtm_trig is selected as the clock . 0 External clock(ipg_clk_ps_ts) is selected
CLR_CNTR_B	This bit will reset timestamp counter B when PS_GLCR[CLRTSCNT_G] is not set 1 Timestamp counter B is reset This bit is a one shot and is always read as 0. <i>Note: This bit is also writable in ps_normal mode</i>
CLR_CNTR_A	This bit will reset timestamp counter A when PS_GLCR[CLRTSCNT_G] is not set 1 Timestamp counter A is reset This bit is a one shot and is always read as 0. <i>Note: This bit is also writable in ps_normal mode</i>
CLRTSCNT_G	This bit controls the global clearing of the TimeStamp counters A and B when CLRTSCNT_G_L == 1. When CLRTSCNT_G_L == 0 then this bit has no effect. 1 Both time stamp counter are cleared at the same time. This bit is a one shot and is always read as 0. <i>Note: This bit is also writable in ps_normal mode</i>
CLRTSCNT_G_L	This bit control whether the timestamp counters counter A and B are cleared simultaneously or independently: 0 Timestamp counters A and B are cleared independently. When PS_GLCR[CLR_CNTR_A] == 1 timestamp counter A is cleared. When PS_GLCR[CLR_CNTR_A]== 1 timestamp counter B is cleared. 1 Both timestamp counter are cleared simultaneously as soon as CLRTSCNT_G== 1.
TSCNT_EN_B	This bit controls enabling of timestamp counter A when PS_GLCR[TSCNTEN_G] is not set 0 Timestamp counter A not enabled 1 Timestamp counter B is enabled Note: This bit is also writable in ps_normal mode
TSCNT_EN_A	This bit controls enabling of timestamp counter A when PS_GLCR[TSCNTEN_G] is not set 0 Timestamp counter A not enabled 1 Timestamp counter A is enabled <i>Note: This bit is also writable in ps_normal mode</i>
TSCNTEN_G	This bit controls the global trigger of the TimeStamp counters A and B when TSCNTEN_G_L == 1. When TSCNTEN_G_ == 0 then this bit has no effect. 0 Both time stamp counters are disabled simultaneously 1 Both time stamp counter start simultaneously. <i>Note: This bit is also writable in ps_normal mode</i>

Table 1195. PS_GLCR bit field details (continued)

Field	Description
TSCNTEN_G_L	This bit control whether the timestamp counters counter A and B are started simultaneously or independently 0 Timestamp counters A and B are started independently. When PS_GLCR[TSCNT_A_EN] == 1 timestamp counter A starts. When PS_GLCR[TSCNT_B_EN] == 1 timestamp counter B starts. 1 Both timestamp counter are triggered simultaneously as soon as TSCNTEN_G == 1.
GLOBAL_MODE	These are the bits which decide Global Mode of the IP. There are 4 modes, UART_STDALONE, PS_DISABLE, PS_CONFIG and PS_NORMAL. For the details of modes related to the bit setting of GLOBAL_MODE, please refer Table 1177 . <i>Note: This bits are writable in all modes</i>

54.3.3.2 PSI5-S Global Status Register (PS_GLSR)

Table 1198. PS_MRU_BUF2_REG0 bit field details

Field	Description
CHANNEL SPECIFIC MAILBOX ADDR	This register will provide the channel specific mailbox address corresponding to channel and slot for which data has been received. This value is computed by the IP based on the PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR] and FID, CID. Following is the formula used to calculate this address: - For messages with CID==0 in the header byte, destined for Channel0 location0, the value is: $\text{PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR]}$ - For “unrecoverable” messages destined for Channel0, location1, the value is: $\text{PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR]} + 0xC$ - For other messages with CID = 1 to 7 the value can be calculated as: $(\text{PS_CH_BASE_ADDR[MAILBOX_BASE_ADDR]} + (6 * 4 * 3 (\text{MSG_CH_ID}) + (\text{MSG_FRAME_ID}) * 4 * 3))$ When using the DMA for reading the MRU buffer, this register forms the Access1 of the DMA transfer.

Table 1199. PS_MRU_BUF2_REG1 bit field details

Field	Description
DCI[3:0]	To ensure that the Application reads the PSI5 message and its timestamp consistently, Data Consistency Indicator (DCI) is added to each word of the Message Reconstruction Unit Output buffer and subsequently is transferred to the PSI5 Mailbox in system RAM
Reserved	Reserved
R_UVL_ERR	Message underflow. It is set when less than three UART bytes are received in the UART packet . In case of XCRC error the message is treated as unrecoverable and written in mail box location1 of channel 0 1 error occurred 0 no error occurred Please refer to Section 54.4.2.1, PSI5-S Message extraction for more details.
N_ERR	Indicates that the number of UART bytes in the recieved UART packet does not match the number specified in Channel Configuration Register A indicated by CID and FID i.e. the number of UART bytes does not match the value programmed in PS_MSGA_CH_CID[FID_bytes]. Also please see Fn_byte recalculation . 1 error occurred 0 no error occurred Please refer to Section 54.4.2.1, PSI5-S Message extraction for more details.
CHID[2:0]	Indicates Channel id of PSI5 message present in the UART header byte.
FID[2:0]	Indicates Frame ID of PSI5 message present in the UART header byte.

Table 1199. PS_MRUF2_BUF2_REG1 bit field details (continued)

Field	Description
R_OVL_ERR	Message overflow. It is set when more than six UART bytes are received in the UART packet. The message may be recoverable (XCRC_ERR == 0) or unrecoverable (XCRC_ERR == 1). Please refer to Section 54.4.2.1, PSI5-S Message extraction for more details. 1 error occurred 0 no error occurred
F_WD_ERR	Frame watchdog error in the received PSI5 message. This will be the F_WD_ERR of the specific channel indicated by the "CID", or it will be the logical OR of the F_WD_ERR of all the channels depending on the XCRC error status of the UART bytes. Please see Section 54.4.5, PSI5-S Watchdog Operation , Section 54.3.3.21, PSI5-S channel message configuration register B (PS_MSGB_CHn)[n=1..7] and Section 54.3.3.16, PSI5-S Watchdog Error Status and Watchdog Timestamp status register (PS_WDGTSSR) for more details. 1 error occurred 0 no error occurred
SCI_O_ERR	UART overrun error has occurred in at least one UART byte of the received UART packet, due to which some UART byte has been lost. 1 error occurred 0 no error occurred
SCI_F_ERR	UART framing error has occurred in the current received UART packet. 1 error occurred 0 no error occurred
SCI_P_ERR	UART message parity error has occurred in at least one UART byte of the received UART packet. 1 error occurred 0 no error occurred
HD_ERR	This bit is set when any of the ERR[1:0] is "1" and indicates a transceiver error. 1 error occurred 0 no error occurred
ERR[1:0]	Transceiver error flags received in the Message header byte of the UART packet indicated by CID and FID
CRC_ERR/ P_ERR	Indicates whether "PSI5 message" crc_err or the parity error in the PSI5 message indicated by CID and FID has occurred. The Parity is taken as even for PSI5 calculation: 1 indicates crc_error/Parity Error has occurred 0 no crc_error/parity error has occurred <i>Note: This bit always remains "0" for messages having CID and FID both as "0".</i>
CRC[2:0]	Contains the received CRC or Parity Bits of the PSI5 message, of indicated by CID and FID
XCRC_ERR	Indicates xcrc_err in the received UART packet: 1 indicates xcrc_error occurred 0 no xcrc_error occurred
XCRC[5:0]	This is the value of xcrc received in the last six bits of the UART byte, which occurs just before the information of a "new UART packet received" has been generated. Please refer to Section 54.4.1, PSI5-S UART Message Structure and Section 54.4.2.5, PSI5-S XCRC handling for more details.

54.3.3.6 PSI5-S MRU OUTPUT BUFFER2 REGISTER2 (PS_MRU_BUF2_REG2)

Field	Description
DCI[3:0]	To ensure that the Application reads the PSI5 message and its timestamp consistently, Data Consistency Indicator (DCI) is added to each word of the Message Reconstruction Unit Output buffer and subsequently is transferred to the PSI5 Mailbox in system RAM
Reserved	Reserved
TIMESTAMP[23:0]	Time stamp value appended based on the various timestamp bit settings in the PS_GLCR register, PS_PCCR_CH[n] register and the errors occurred. For more details please refer to Section 54.4.4, TimeStamp .

54.3.3.8 PSI5-S Clock Divider “0” for WatchDog and DownStream Data Shift Register Trigger Counters . Used for Channel1 and Channel2 (PS_WD_DDTRIG_CLKDIV0)

Figure 1223. PSI5-S Clock Divider “0” for WD and DDSR trigger counters (PS_WD_DDTRIG_CLKDIV0)

Table 1202. PS_WD_DDTRIG_CLKDIV0 bit field details

Field	Description
WD_CLKDIV0[9:0]	Clock Divider for watchdog clock . This register controls the division factor of the watchdog clock (ipg_clk_ps_wd, please see Figure 1258) in steps of 1us . This register controls the watchdog clock for Channel 1 and Channel2. Also please see Figure 1262 .
DDTRIG_CLKDIV0[9:0]	Clock Divider for DDSR shift trigger generation counters which in turn are used for sync pulse generation . This register controls the division factor of the DDSR trigger clock (ipg_clk_ps_ddtrig , please see Figure 1253) in steps of 1us . This register controls this clock for Channel 1 and Channel 2. Also please see Figure 1262 .

54.3.3.9 PSI5-S Clock Divider “1” for WatchDog and DownStream Data Shift Register Trigger Counters . Used for Channel3 and Channel4 (PS_WD_DDTRIG_CLKDIV1)

Figure 1224. PSI5-S Clock Divider “1” for WD and DDSR trigger counters (PS_WD_DDTRIG_CLKDIV1)

Table 1203. PS_WD_DDTRIG_CLKDIV1 bit field details

Field	Description
WD_CLKDIV1[9:0]	Clock Divider for watchdog clock . This register controls the division factor of the watchdog clock (ipg_clk_ps_wd, please see Figure 1258) in steps of 1us . This register controls the watchdog clock for Channel 3 and Channel 4. Also please see Figure 1262 .
DDTRIG_CLKDIV1[9:0]	Clock Divider for DDSR shift trigger generation counters which in turn are used for sync pulse generation . This register controls the division factor of the DDSR trigger clock(ipg_clk_ps_ddtrig , please see Figure 1253) in steps of 1us . This register controls this clock for Channel 3 and Channel 4. Also please see Figure 1262 .

54.3.3.10 PSI5-S Clock Divider “2” for WatchDog and DownStream Data Shift Register Trigger Counters . Used for Channel5 and Channel6 (PS_WD_DDTRIG_CLKDIV2)

Figure 1225. PSI5-S Clock Divider “2” for WD and DDSR trigger counters (PS_WD_DDTRIG_CLKDIV2)

Table 1204. PS_WD_DDTRIG_CLKDIV2 bit field details

Field	Description
WD_CLKDIV2[9:0]	Clock Divider for watchdog clock . This register controls the division factor of the watchdog clock (ipg_clk_ps_wd, please see Figure 1258) in steps of 1us . This register controls the watchdog clock for Channel 5 and Channel 6. Also please see Figure 1262 .
DDTRIG_CLKDIV2[9:0]	Clock Divider for DDSR shift trigger generation counters which in turn are used for sync pulse generation . This register controls the division factor of the DDSR trigger clock(ipg_clk_ps_ddtrig , please see Figure 1253) in steps of 1us . This register controls this clock for Channel 5 and Channel 6. Also please see Figure 1262 .

54.3.3.11 PSI5-S Clock Divider “3” for WatchDog and DownStream Data Shift Register Trigger Counters . Used for Channel7 (PS_WD_DDTRIG_CLKDIV3)

Figure 1226. PSI5-S Clock Divider “3” for WD and DDSR trigger counters (PS_WD_DDTRIG_CLKDIV3)

Table 1205. PS_WD_DDTRIG_CLKDIV2 bit field details

Field	Description
WD_CLKDIV3[9:0]	Clock Divider for watchdog clock . This register controls the division factor of the watchdog clock (ipg_clk_ps_wd, please see Figure 1258) in steps of 1us . This register controls the watchdog clock for Channel 7. Also please see Figure 1262 .
DDTRIG_CLKDIV3[9:0]	Clock Divider for DDSR shift trigger generation counters, which in turn are used for sync pulse generation . This register controls the division factor of the DDSR trigger clock(ipg_clk_ps_ddtrig , please see Figure 1253) in steps of 1us . This register controls this clock for Channel 7 . Also please see Figure 1262 .

54.3.3.12 PSI5-S Mbox Status Irq (PS_MBOX_SR_IRQ)

Figure 1227. PSI5-S Mbox Status Irq (PS_MBOX_SR_IRQ)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1206. PS_MBOX_SR_IRQ bit field details⁽¹⁾

Field	Description
Reserved	Reserved
MBOX_CH7	When set it Indicates at least one message in mailbox 7 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH7[F(0-5)_READ] bits i.e. MBOX_CH7 = F0_READ OR F1_READ ORF5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel7 are cleared.
MBOX_CH6	When set it Indicates at least one message in mailbox 6 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH6[F(0-5)_READ] bits i.e. MBOX_CH6 = F0_READ OR F1_READ ORF5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel6 are cleared.
MBOX_CH5	When set it Indicates at least one message in mailbox 5 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH5[F(0-5)_READ] bits i.e. MBOX_CH5 = F0_READ OR F1_READ ORF5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel5 are cleared.
MBOX_CH4	When set it Indicates at least one message in mailbox 4 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH4[F(0-5)_READ] bits i.e. MBOX_CH4 = F0_READ OR F1_READ ORF5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel4 are cleared.

Table 1206. PS_MBOX_SR_IRQ bit field details⁽¹⁾

Field	Description
MBOX_CH3	When set it Indicates at least one message in mailbox 3 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH3[F(0-5)_READ] bits i.e. MBOX_CH3 = F0_READ OR F1_READ ORF5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel3 are cleared.
MBOX_CH2	When set it Indicates at least one message in mailbox 2 is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH2[F(0-5)_READ] bits i.e. MBOX_CH2 = F0_READ OR F1_READ ORF5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel2 are cleared.
MBOX_CH1	When set it Indicates at least one message in mailbox 1is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH1[F(0-5)_READ] bits i.e. MBOX_CH1 = F0_READ OR F1_READ ORF5_READ. Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel1 are cleared.
0 MBOX_CH0	When set it Indicates at least one message in mailbox 0is pending for read by the application. This bit is a “read status” of the OR of PS_MBOX_SR_CH0[F(0-1)_READ] bits i.e. MBOX_CH0 = F0_READ OR F1_READ . Hence this bit is cleared when all of the corresponding Fn_READ bits of Channel0 are cleared.

1. Also please see [Figure 1259](#).

54.3.3.13 PSI5-S Error Status Irq (PS_ERR_SR_IRQ)

Table 1207. PS_ERR_SR_IRQ bit field details⁽¹⁾

Field	Description
Reserved	Reserved
R_UVL_ERR	When set indicates that message underflow error(number of UART bytes recieved are less than 3) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[R_UVL_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[R_UVL_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.
N_ERR	When set indicates that N_ERR (Number of UART bytes are not equal to PS_MSGA_CHn[Fn_byte]) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[N_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[N_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.
R_OVL_ERR	When set indicates that message Overflow error(number of UART bytes recieved have exceeded 6) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[R_OVL_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[R_OVL_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.

Table 1207. PS_ERR_SR_IRQ bit field details⁽¹⁾

Field	Description
F_WD_ERR	When set indicates that Frame Watchdog error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[F_WD_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[F_WD_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.
SCI_O_ERR	When set indicates that UART Overrun error(from the UART side) is present in the message currently present in MRU buf2. When "1", then this bit indicates that some UART byte belonging to the concerned UART packet, has been overwritten by another UART byte and is lost. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_O_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_O_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.
SCI_F_ERR	When set indicates that UART Framing error is present in the message currently present in MRU buf2. If this bit is set then it indicates to the application that the synchronisation of the UART module is lost and any subsequent UART bytes recieved will be error prone. In this case the application is required to reset the UART module by using the PS_GCR[SR] bit. Subsequently it should restart the transmission. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_F_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_F_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.

Table 1207. PS_ERR_SR_IRQ bit field details⁽¹⁾

Field	Description
SCI_P_ERR	When set indicates that UART parity error is present in the message currently present in MRU buf2. This bit will be set when there is a parity error in any UART byte using which the concerned UART packet was formed. This bit is the reflection of PS_MRU_BUF2_REG1[SCI_P_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[SCI_P_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.
HD_ERR	When set indicates that Header error(E0/E1) is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[HD_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[HD_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.

Table 1207. PS_ERR_SR_IRQ bit field details⁽¹⁾

Field	Description
CRC_ERR/P_ERR	When set indicates that PSI5 CRC/Parity error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[CRC_ERR/P_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[CRC_ERR/P_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode. <i>Note: This bit always remains "0" for messages having CID and FID both as "0".</i>
XCRC_ERR	When set indicates that XCRC error is present in the message currently present in MRU buf2. This bit is the reflection of PS_MRU_BUF2_REG1[XCRC_ERR] bit. This bit is cleared by w1c. Clearing this bit would also clear the PS_MRU_BUF2_REG1[XCRC_ERR] bit. Correspondingly when a new message arrives in MRU_BUF2 then this bit is updated accordingly. Please see ^(Note:) below. The bit is also writable in PS_NORMAL mode.

1. Also please see [Figure 1259](#).

Note: *.If an interrupt is triggered by this bit it cannot be guaranteed that the message containing this error flag is still in MRU_BUF2, in case the DMA is being used to transfer messages to the mailbox. The subsequent message in MRU_BUF2 may not have this flag set, in which case it will no longer be visible to an ISR triggered by the previous message. The error flags are stored with the message in the mailbox and can be checked when reading the message.*

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1210. PS_WDGTSSR bit field details

Field	Description
F_WD_ERR_STATUS[7:1]	These bits give the watchdog error status for the watchdog of each corresponding channel . Thus F_WD_ERR_STATUS[1] will give the watchdog error status for watchdog of channel1 . Similarly F_WD_ERR_STATUS[2] will give the watchdog error status for watchdog of channel2 and so on till F_WD_ERR_STATUS[7] , which gives the watchdog error status for watchdog of channel7. As soon as the watchdog of the corresponding channel has a watchdog overrun error, the error status is latched in the corresponding bits of this register. <i>Note: These bits are automatically cleared by the hardware when any of the bits of PS_WDGTSSR is read by the application.</i>
WDTS_STATUS[23:0]	Timestamp value of that specific channel , the timestamp of which is captured when the watchdog error of that specific channel has occurred. This register always contains the timestamp value corresponding to the last occurring Watch Dog error. If due to bad programming watchdog error of more than one channel happen simultaneously then this register contains the timestamp value of the highest channel. For each channel , whether Time Stamp A or B is captured depends on the value of PS_MSGA_CHn[TIMESTAMP_A_B_SEL] register bit. <i>Note: These bits are automatically cleared by the hardware when any of the bits of PS_WDGTSSR is read by the application.</i>

Note: All bits of PS_WDGTSSR register are self clearing on read . This implies that in case this register is read by the application before the corresponding PS_WDGTSSR[F_WD_ERR_STATUS[CHn]] has had a chance to be sent in the next upcoming PSI5 message, then this bit would be sent as a “0” in this upcoming PSI5 message.

Table 1211. PS_MSGA_CH0 bit field details

Field	Description
Reserved	Reserved
F0_BYTE[2:0]	Number of UART bytes comprising one UART packet. Applicable only to special messages having CID = 0 in their Message Header. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled and a message with the corresponding frame ID is not expected to occur. Please see Fn_byte recalculation that explains the recalculation of Fn_bytes.
Reserved	Reserved
TIMESTAMP_A_B_SEL	Whether the Timestamp corresponding to TimeStamp Counter A or B, is appended to messages targetted for Channel0: 0 Timestamp counter A 1 Timestamp counter B
Reserved	Reserved
TSBUF_CLR	This bit is used to clear the local timestamp buffer for the respective channel. Once cleared the buffer remains clear till the event to capture time stamp is triggered. 1 Timestamp buffer is cleared. This bit is one shot and is always read as "0".
TSBUF_EN	This bit controls whether timestamp buffer maintains a value "0" or is refreshed on a timestamp "capture event" 0 Timestamp buffer maintains value "0" 1 Timestamp buffer responds to a "capture event" and captures the respective timestamp value.
Reserved	Reserved

Table 1212. PS_MSGB_CH0 bit field details

Field	Description
Reserved	Reserved
F0_payload[4:0]	Number of bits in payload region of the message (only for channels having CID as "0" in the message header). This channel is always asynchronous. Legal values are between 8 and 28 . Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.

Table 1213. PS_MBOX_SR_CH0 bit field details

Field	Description
Reserved	Reserved
F1_ERR ⁽¹⁾	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0,LOC1) by the DMA , has one or more _ERR bits set . 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0,LOC1) by the DMA , has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register . It is updated when an unrecoverable message(with the CID = 0 and FID=1) is read from the MRU_BUF2 . It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC1. This bit is also writeable in ps_normal mode.

Table 1213. PS_MBOX_SR_CH0 bit field details (continued)

Field	Description
F1_OV	1 Indicates that there is an unread message stored in MBOX0,LOC1 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX0,LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC1. This bit is also writeable in ps_normal mode.
F1_READ	MBOX0,LOC1 is reserved for any unrecoverable message(XCRC_ERR has occurred or it is an "illegal message") . It can correspond to any channel from 1 to 7 . 1It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX0,LOC1 by the DMA. 0 No unread message in MBOX0,LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC1. This bit is also writeable in ps_normal mode.
F0_ERR ⁽¹⁾	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0,LOC0) by the DMA , has one or more _ERR bits set . 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX0,LOC0) by the DMA , has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register . It is updated when a transceiver message(with the CID = 0 and FID=0) is read from the MRU_BUF2 . It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC0. This bit is also writeable in ps_normal mode.
F0_OV	1 Indicates that there is an unread message stored in MBOX0,LOC0 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA . 0 No overwrite of unread message in MBOX0,LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC0. This bit is also writeable in ps_normal mode.
F0_READ	MBOX0,LOC0 is reserved for a transceiver message . 1It indicates that the message that has just been read from PS_MRU_BUF2 will be stored in MBOX0,LOC0 by the DMA . 0 No unread message in MBOX0,LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX0,LOC0. This bit is also writeable in ps_normal mode.

1. Also please see [Figure 1259](#).

Table 1214. PS_MSGA_CHn bit field details

Field	Description
L_PC_EN	Selects whether the parity/CRC selection for a PSI5 message is to be controlled globally on a channel basis (through the G_PC bits) or locally on a per frame basis (through the L_PC[frame] bits) 0 Parity/CRC option controlled globally through the G_PC bit 1 Parity/CRC option controlled locally through the L_PC[frame] bits individually for message of each frame.
F5_BYTE[2:0]	Number of bytes in UART packet for message corresponding to frame 5. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F5_payload] is immaterial. Please see Fn_byte recalculation that explains the recalculation of Fn_bytes.
L_PC5	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame5 1 CRC selected for PSI5 message for frame5.
F4_BYTE[2:0]	Number of bytes in UART packet for message corresponding to frame 4. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F4_payload] is immaterial. Please see Fn_byte recalculation that explains the recalculation of Fn_bytes.
L_PC4	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame4 1 CRC selected for PSI5 message for frame4

Table 1214. PS_MSGA_CHn bit field details (continued)

Field	Description
F3_BYTE[2:0]	Number of bytes in UART packet for message corresponding to frame 3. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F3_payload] is immaterial. Please see Fn_byte recalculation that explains the recalculation of Fn_bytes.
L_PC3	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame3 1 CRC selected for PSI5 message for frame3.
F2_BYTE[2:0]	Number of bytes in UART packet for message corresponding to frame 2. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F2_payload] is immaterial. Please see Fn_byte recalculation that explains the recalculation of Fn_bytes.
L_PC2	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame2 1 CRC selected for PSI5 message for frame2.
F1_BYTE[2:0]	Number of bytes in UART packet for message corresponding to frame 1. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled (unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F1_payload] is immaterial. Please see Fn_byte recalculation that explains the recalculation of Fn_bytes.
L_PC1	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame1 1 CRC selected for PSI5 message for frame1
F0_BYTE[2:0]	Number of bytes in UART packet for message corresponding to frame 0. Legal values are 0 or between 3 and 6. Value of 0 means that the slot is not enabled(unconfigured) and a message with the corresponding frame ID is not expected to occur. In this case the value programmed in PS_MSGB_CHn[F0_payload] is immaterial. Please see Fn_byte recalculation that explains the recalculation of Fn_bytes.
L_PC0	Effective when L_PC_EN == 1. Controls the local parity/CRC option for the message 0 Parity selected for message for frame0 1 CRC selected for PSI5 message for frame0.
MODE	This bit selects the operating modes between sync and async for the channel. 1 Asynchronous 0 Synchronous
TIME_STAMP_A_B_SEL	Decides whether Timestamp Counter A or B, value is captured in the local timestamp buffer, whenever a "capture event" occurs: 0 Timestamp counter A 1 Timestamp counter B.

Table 1214. PS_MSGA_CHn bit field details (continued)

Field	Description
TMSG_TCMD	Whether the timestamp is recorded when the message is received or when the channel command is moved from the TxFIFO to the UART Tx register (emulates a sync pulse) 1 Timestamp recorded based on message header byte received 0 Timestamp recorded based on “emulated” sync pulse.
TSBUF_CLR	This bit is used to clear the local timestamp buffer for the respective channel. Once cleared the buffer remains clear till the event to capture time stamp is triggered. 1 TimeStamp buffer is cleared. This bit is one shot and is always read as “0”.
TSBUF_EN	This bit controls whether timestamp buffer maintains a value “0” or is refreshed on a timestamp “capture event” 0 Timestamp buffer maintains value “0” 1 Timestamp buffer responds to a “capture event” and captures the respective timestamp value.
G_PC	This bit globally selects the Parity or the CRC option for all the Frames of that particular channel provided L_PC_EN is set “0” 0 Parity option selected globally for messages of all frames. 1 CRC option selected globally for messages of all frames.
CH_EN	PSI5 Channel Enable. This bit decides if the IP takes the data belonging to the specific channel as “legal” or “illegal”. 0: Concerned PSI5 channel is disabled. Any data occurring with a CID value of a disabled channel is treated as an “illegal message” and send to Channel 0 unrecoverable message area (MBOX ₀ , LOC ₁) 1: Concerned PSI5 channel is enabled. Any data occurring with a CID value of an enabled channel can either be treated as “legal” or “illegal”. Please see Section 54.4.2.1, PSI5-S Message extraction for the definition of legal and illegal messages. Legal messages are sent to MBOX _{CID} , LOC _{FID} while illegal messages are sent to MBOX ₀ , LOC ₁

Table 1215. PS_MSGB_CHn bit field details

Field	Description
Reserved	Reserved
F5_payload[4:0]	Number of bits in the Payload region of the PSI5 message corresponding to frame 5. Legal values are between 8 and 28 . Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
F4_payload[4:0]	Number of bits in the Payload region of the PSI5 message corresponding to frame 4. Legal values are between 8 and 28 . Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
F3_payload[4:0]	Number of bits in the Payload region of the PSI5 message corresponding to frame 3. Legal values are between 8 and 28 . Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
F2_payload[4:0]	Number of bits in the Payload region of the PSI5 message corresponding to frame 2. Legal values are between 8 and 28 . Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
F1_payload[4:0]	Number of bits in the Payload region of the PSI5 message corresponding to frame 1. Legal values are between 8 and 28 . Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28.This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.
F0_payload[4:0]	Number of bits in the Payload region of the PSI5 message corresponding to frame 0. Legal values are between 8 and 28 . Any value programmed as less than 8 is defaulted to 8 and any value programmed as greater than 28 is defaulted to 28This updation occurs in the NORMAL mode and when read back the register will be read with the updated value.

Note: *Fn_byte recalculation. The IP expects legal values to be programmed for Fn_byte field. If this is not followed then the IP reprogrammes the registers with default values. Whenever the value of “Fn_byte” field becomes 1 or 2 it is defaulted to 3 and value of 7 is defaulted to 6. This updation happens once the IP enters the PS_NORMAL mode.*

In addition to the above , the following checks are also performed.

By default the IP will expect that there is coherence between the expected number of bytes calculated through the “minUARTbytes” and the number of bytes in the “Fn_byte” field . Please see [Figure 1246](#) for definition of “minUARTbytes”. If there is no coherence (i.e. the above two calculations do not match) then the IP does the following recalculation :

When Programmed Fn_byte > “minUARTbytes” , then the IP will expect that the additional extra bytes would be stuffed with 0s from the transceiver. Rest of the checking will be done

as described in [Section 54.4.2.2, PSI5-S “Recoverable and Unrecoverable” Messages](#).

When $F_n_byte < \text{“minUARTbytes”}$ then the “ F_n_bytes ” is internally “increased” such that the expanded “ F_n_bytes ” is now equal to minUARTbytes . Please see [Figure 1246](#) for definition of “ minUARTbytes ”. Using this expanded “ F_n_bytes ” value the message that would be arriving is analyzed. This would mean that no data bits are lost. Rest of the checking will be done as described in [Section 54.4.2.2, PSI5-S “Recoverable and Unrecoverable” Messages](#).

The “recalculated” F_n_byte field is automatically updated by the IP once the IP enters the NORMAL mode of operation. For the subsequent occurrence in the document, all references to “ F_n_byte ” would mean the recalculated value of “ F_n_byte ”.

Table 1216. PS_MBOX_SR_CHn bit field details

Field	Description
Reserved	Reserved
F5_ERR ⁽¹⁾	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC5) by the DMA, has one or more _ERR bits set . 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC5) by the DMA, has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register . It is updated when the corresponding message(with the CID = n and FID=5) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC5. This bit is also writeable in ps_normal mode.
F5_OV	1 Indicates that there is an unread message stored in MBOX[n],LOC5 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n],LOC5. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC5. This bit is also writeable in ps_normal mode.
F5_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC5. 0 No unread message in MBOX[n],LOC5. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC5. This bit is also writeable in ps_normal mode.
F4_ERR ⁽¹⁾	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC4) by the DMA , has one or more _ERR bits set . 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC4) by the DMA , has ALL the "_ERR" bits as "0". This bit is the "OR" of the contents of the PS_MBOX_SR_IRQ register . It is updated when the corresponding message(with the CID = n and FID=4) is read from the MRU_BUF2 by the DMA . It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC4. This bit is also writeable in ps_normal mode.
F4_OV	1 Indicates that there is an unread message stored in MBOX[n],LOC4 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA. 0 No overwrite of unread message in MBOX[n],LOC4. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC4. This bit is also writeable in ps_normal mode.

Table 1216. PS_MBOX_SR_CHn bit field details (continued)

Field	Description
F4_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC4. 0 No unread message in MBOX[n],LOC4. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC4. This bit is also writeable in ps_normal mode.
F3_ERR ⁽¹⁾	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC3) by the DMA, has one or more _ERR bits set . 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC3) by the DMA, has ALL the “_ERR” bits as “0”. This bit is the “OR” of the contents of the PS_MBOX_SR_IRQ register . It is updated when the corresponding message(with the CID = n and FID=3) is read from the MRU_BUF2 by the DMA. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC3. This bit is also writeable in ps_normal mode.
F3_OV	1 Indicates that there is an unread message stored in MBOX[n],LOC3 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA . 0 No overwrite of unread message in MBOX[n],LOC3. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC3. This bit is also writeable in ps_normal mode.
F3_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC3 by the DMA . 0 No unread message in MBOX[n],LOC3. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC3. This bit is also writeable in ps_normal mode.
F2_ERR ⁽¹⁾	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC2) by the DMA , has one or more _ERR bits set . 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC2) by the DMA, has ALL the “_ERR” bits as “0”. This bit is the “OR” of the contents of the PS_MBOX_SR_IRQ register . It is updated when the corresponding message(with the CID = n and FID=2) is read from the MRU_BUF2 by the DMA . It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC2. This bit is also writeable in ps_normal mode.

Table 1216. PS_MBOX_SR_CHn bit field details (continued)

Field	Description
F2_OV	1 Indicates that there is an unread message stored in MBOX[n],LOC2 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA . 0 No overwrite of unread message in MBOX[n],LOC2. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC2. This bit is also writeable in ps_normal mode.
F2_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC2. 0 No unread message in MBOX[n],LOC2. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC2. This bit is also writeable in ps_normal mode.
F1_ERR ⁽¹⁾	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC1) by the DMA, has one or more _ERR bits set . 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC1) by the DMA, has ALL the “_ERR” bits as “0”. This bit is the “OR” of the contents of the PS_MBOX_SR_IRQ register . It is updated when the corresponding message(with the CID = n and FID=1) is read from the MRU_BUF2 by the DMA . It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC1. This bit is also writeable in ps_normal mode.
F1_OV	1 Indicates that there is an unread message stored in MBOX[n],LOC1 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA . 0 No overwrite of unread message in MBOX[n],LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC1. This bit is also writeable in ps_normal mode.
F1_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC1. 0 No unread message in MBOX[n],LOC1. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC1. This bit is also writeable in ps_normal mode.

Table 1216. PS_MBOX_SR_CHn bit field details (continued)

Field	Description
F0_ERR ⁽¹⁾	1 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC0) by the DMA , has one or more _ERR bits set . 0 Indicates that the message that has just been read from the PS_MRU_BUF2 and is to be stored in (MBOX[n],LOC0) by the DMA , has ALL the “_ERR” bits as “0”. This bit is the “OR” of the contents of the PS_MBOX_SR_IRQ register . It is updated when the corresponding message(with the CID = n and FID=0) is read from the MRU_BUF2 by the DMA . It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC0. This bit is also writeable in ps_normal mode.
F0_OV	1 Indicates that there is an unread message stored in MBOX[n],LOC0 which will be overwritten with the new message, that has just been read from the PS_MRU_BUF2 by the DMA . 0 No overwrite of unread message in MBOX[n],LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC0. This bit is also writeable in ps_normal mode.
F0_READ	1 It indicates that the message that has just been read from PS_MRU_BUF2 , will be stored in MBOX[n],LOC0. 0 No unread message in MBOX[n],LOC0. It is a w1c and software should clear it whenever it reads the message from the MBOX[n],LOC0. This bit is also writeable in ps_normal mode.

1. Also please see [Figure 1259](#).

54.3.3.23 PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn) [n==1..7]

Figure 1238. PSI5-S channel watchdog configuration register (PS_WD_CFGR_CHn)

Address: 0x01A0 + hex([n-1]*0x3C) where "n" is Channel Number

Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1217. PS_WD_CFGR_CHn bit field details

Field	Description
WDRST	Resets watchdog counter for the channel This bit is one shot and is also writable in ps_normal mode. It is always read as 0. It will reset the watchdog counter and the counter will be reloaded with the value of WD_TO and automatically start counting again.
WDCS	This will select either GTM or module clock for watchdog counter of the channel. Please see Figure 1262 . 0 ipg_clk_ps_wd Clock 1 gtm_trig is selected as the clock.
WDEN	The watchdog counter for each channel can be started, stopped. 1 watchdog counter started 0 watchdog counter stopped. It maintains its value. This bit is also writable in ps_normal mode

Table 1217. PS_WD_CFGR_CHn bit field details (continued)

Field	Description
Reserved	Reserved
WD_TO[23:0]	This indicates the watchdog time out value . The watchdog generates an overrun error, in case the watchdog is not refreshed before the watchdog counter reached the WD_TO value. The Watchdog is refreshed in a different manner depending on whether the PSI5-S channel is in asynchronous mode or synchronous mode as described below : In Asynchronous mode : Whether the WD has to be “refreshed” or “not to be refreshed” is analyzed when the XCRC is calculated . In case the XCRC is correct the watchdog is refreshed(It is not STOPPED) , else the WD counter keeps on running normally eventually leading to a watchdog overrun error. In Synchronous Mode: The watchdog is ALWAYS refreshed on the occurrence of the internal sync pulse and keeps on counting thereafter. However, it is stopped when the “Packet_counter” reaches the count of “total number of configured slots”. The “Packet_counter” here is a counter that keeps track of the number of configured(enabled) slots. It is incremented on the reception of each UART packet with a “CID” and “FID” such that PS_MSGA_CH_CID[FID_byte] is not equal to “0” . The packet counter is however incremented ONLY if the XCRC of the received UART packet is correct else it is not incremented. In case the “Packet Counter” does not reach the “expected packet count” within the “WD timeout configured “ , the WD overrun error is generated. In both the above modes , the watchdog is always refreshed on the occurrence of Watchdog overrun error (F_WD_ERR) or a software reload . <i>Note: The watchdog counter is enabled ONLY if the channel is enabled.</i>

54.3.3.24 PSI5-S DDSR Trigger offset register channel(PS_DDTRIG_OFFR_CHn)[n=1..7]

Figure 1239. PSI5-S DDSR Trigger offset register channel (PS_DDTRIG_OFFR_CHn)

Table 1218. PS_DDTRIG_OFFR_CHn

Field	Description
Reserved	Reserved
DDTRIG_OFFR[15:0]	These bits configure the delay between the “shift trigger” of the various DDSRs across different channels. The value in this register governs the delay after which the specific DDSR would be triggered once the Global Shift trigger (PS_GLCR[GL_DDSR_TRIG]) is written to “1” and the corresponding PS_E2SCR_CH[n][GL_TRIG_SEL] is set to “1” for that channel. There is an internal counter which is clocked on the “ipg_clk_ps_ddtrig” clock . The counters count up to the value as programmed in the PS_DDTRIG_PERR_CH[n] registers after which they are reset. At each reset a shift trigger is generated for the DDSR. The “start” of these counters is delayed based on the value programmed in the PS_DDTRIG_OFFR_CH[n] register

54.3.3.25 PSI5-S DDSR Trigger period register channel(PS_DDTRIG_PERR_CHn)[n=1..7]

Table 1219. PS_DDTRIG_PERR_CHn

Field	Description
Reserved	Reserved
DDTRIG_PERR[15:0]	These bits configure the “shift trigger” period for the DDSR of that specific channel. The value in this register governs the period with which the data for the DDSR of that particular channel would be shifted out. There is an internal counter which is clocked on the “ipg_clk_ps_ddtrig” clock . The counters count up to the value as programmed in the PS_DDTRIG_PERR_CH[n] registers after which they are reset. At each reset a shift trigger is generated for the DDSR. The “start” of these counters is delayed based on the value programmed in the PS_DDTRIG_OFFR_CH[n] register

54.3.3.26 PSI5-S ECU to Sensor Control Register (PS_E2SCR_CHn)[n=1..7]

Figure 1241. PSI5-S ECU to Sensor Control Register (PS_E2SCR_CHn)

Address: 0x01AC + hex([n-1]*0x3C) where "n" is Channel Number

Access: User read/write

Table 1220. PS_E2SCR_CHn bit details

Field	Description
Reserved	Reserved Always read as 0
CMD[4:0]	Bits for the ECU-to-sensor "CMD" format. They refer to the command send to the UART Tx logic, when a "1" is shifted from the DDSR register <i>Note: This bit is writable only in PS_CONFIG mode.</i>
Reserved	Reserved Always read as 0
ACMD[4:0]	Bits for the ECU-to-sensor "ACMD" format. They refer to the command send to the UART Tx logic, when a "0" is shifted from the DDSR register. <i>Note: This bit is writable only in PS_CONFIG mode.</i>
Reserved	Reserved Always read as 0
CH_TRIG	This controls that the DDSR of the specific channel is triggered locally. This bit controls the shifting when PS_E2SCR_CHn[GL_TRIG_SEL] is 0. 1 Start the "shift trigger" of the DDSR. 0 Stop the DDSR from shifting the commands. The counters corresponding to DDTRIG_PERR and the DDTRIG_OFFR are reset. <i>Note: This bit is also writable in PS_NORMAL mode.</i>

Table 1220. PS_E2SCR_CHn bit details (continued)

Field	Description
GL_TRIG_SEL	This bit controls whether the DDSR shift trigger is a global trigger or a local channel trigger. 1 The DDSR shift trigger is a global trigger dependent on PS_GLCR[GL_DDSR_TRIG] . 0 The DDSR shift trigger is a local channel trigger dependent on the bit CH_TRIG. <i>Note: This bit is writable only in PS_CONFIG mode.</i>
DEFAULT_SYNC	Decides the value to which the DDSR should default to when PS_E2SSR_CHn[DDSR_RDY] == 1. When DDSR_RDY == 1 then the default shift (whether it is CMD or ACMD) is based on the value of this bit. <i>Note: This bit is writable only in PS_CONFIG mode</i>
Reserved	Reserved Always read as 0
DDSR_CLR	Used for rejecting the contents of the DDSR register. As soon as this bit is written to “1” the contents of DDSR are immediately rejected and defaulted to “0” after the completion of the current ACMD or the CMD transmission. PS_E2SSR_CHn[DDSR_RDY] goes to 1 and value of PS_E2SCR_CHn[DEFAULT_SYNC] starts getting shifted. This bit is one shot (W1S). <i>Note: This bit is also writable in PS_NORMAL mode.</i>
DDSR_CLK_SEL	Selects which clock clocks shift logic of the DDSR, for shifting the bits for command transmission: 0 ipg_clk_ps_ddtrig Clock 1 gtm_trig is selected as the clock.
CMDTR_SW_CTRL	This bit decides that once the command is ready for transmission (indicated by the setting PS_E2SSR_CHn[CMDPR_BZY] to 1), then when should the actual transmission start: 0 The actual transmission of command remains suspended, even though the command is ready in the DDSR. 1 The command transmission starts once the PS_E2SSR_CHn[CMDPR_BZY] becomes 1, and the internal shift logic is available. <i>Note: This bit is also writable in PS_NORMAL mode.</i>
Reserved	Reserved Always read as 0
CMDTR_NWRT_IE	Interrupt Enable for DDSR being attempted to be written when it is still not empty i.e PS_E2SSR_CHn[DDSR_RDY] == 0 yet an attempt to write to DDSR is made. 1: Enable the interrupt 0: Disable the interrupt <i>Note: This bit is also writable in PS_NORMAL mode.</i>
CMDPR_BZY_IE	Interrupt Enable for DDSR getting updated with the internally processed complete command (with CRC, stuff bits, start bits getting appended) 1: Enable the interrupt 0: Disable the interrupt <i>Note: This bit is also writable in PS_NORMAL mode.</i>

Table 1220. PS_E2SCR_CHn bit details (continued)

Field	Description																											
DDSR_RDY_IE	Interrupt Enable for DDSR getting empty and ready for receiving new command. 1: Enable the interrupt 0: Disable the interrupt <i>Note: This bit is also writable in PS_NORMAL mode</i>

Table 1222. PS_DDSR_H_CHn bit details

Field	Description
Reserved	Reserved Always read as 0
DDSR_H	Upper High bits of the 43 bit complete DDSR register. These bits are updated by the hardware and software cannot write to these bits. They can be read by the software to check for the processed command after the command is written to the DDSR by the application , the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to "1".

54.3.3.29 PSI5-S channel1 ECU to Sensor Downstream Data Shift Register Low (PS_DDSR_L_CHn)[n=1..7]

Figure 1244. PSI5-S channel1 ECU to Sensor Upstream Data Shift Register Low (PS_DDSR_L_CHn)

Table 1223. PS_DDSR_L_CHn bit field details

Field	Description
DDSR_L	8 bits of the DDSR_L that can only be read by the Application. These 8 bits are automatically updated by the hardware . They can be read by the software to check for the processed command after the command is written to the DDSR by the application , the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to "1".
DDSR_L	Lower 24 bits of the DDSR register that are written by the Application as well as updated by the hardware once the command processing is over. Though all the 24 bits can be written by the software , yet only those number of bits as governed by PS_E2SSR_CHn[CMD_TYPE] are actually taken for processing. This register can be read by the software to check for the processed command, after the command is written to the DDSR by the application , the DDSR_RDY is cleared and the PS_E2SSR_CHn[CMDPR_BZY] goes to "1". <i>Note: These bits are also writable in the PS_NORMAL mode.</i>

54.4 Functional description

The PSI5 is a communication protocol for peripheral inertial, pressure, temperature, and position sensors. These sensors are connected to the ECU by just two wires, using the same lines for power supply and data transmission. The UART compatible transceiver (present externally) provides a pre-regulated voltage to the sensors and reads in the transmitted sensor data. [Figure 1245](#) shows a point-to-point connection for sensors 1 and 2 and bus configuration for sensors 3 and 4.

Figure 1245. System setup (peripheral sensor connected to device)

ECU (Electronic Control Unit) is comprised of PSI5-S digital interface and the UART compatible PSI5 transceiver (present externally). The PSI5-S digital interface communicates with the PSI5 Transceiver through the UART interface as shown in [Figure 1245](#). When conducting the Sensor To ECU communication, the external transceiver converts the sensor data to the UART packet format before sending it to the PSI5-S module. The IP extracts the PSI5 Frames from the input UART Packet.

54.4.1 PSI5-S UART Message Structure

The transceiver sends a UART message packet consisting of between three to six UART bytes which contains information to allow rebuilding of the PSI5 message as well as the message itself and has a CRC which protects the complete packet (XCRC).

Each byte is made up of one start bit, eight data bits and one stop bit - no parity is included in the UART byte. [Figure 1246](#) shows the PSI5-S UART packet structure.

Figure 1246. PSI5-S Packet Structure

Total Message Payload(TMPL) = header_bits(8)+PSI5_payload(8-28bits) +CRC/P(3/1 bit)+XCRC(6bits)

minUARTbytes=CEIL(TMPL/8) where CEIL gives the largest integer greater than or equal to TMPL/8

PSI5_payload is the value obtained from PS_MSGA_CHn[Fn_payload] register bits.

XCRC(Extended CRC) can occupy any byte from UART3 to UART6 depending on the number of bytes received.

The UART packet is made up of the following:

- **MSGnHEADER:** This is the message header byte which includes the indication of which channel the PSI5 message was received on (3-bit CID), the slot on that channel in which the message was received (3-bit FID) and transceiver error indication bits (2-bit E)
- **PSI5 DATA bytes** - minimum one, maximum four, depending on the data payload region of the PSI5 message (8 - 28 bits) and whether parity (1-bit) or CRC (3-bit) is configured for the PSI5 message. In the above example shown in [Figure 1246](#) it is taken as 28 bits and 4 UART bytes are shown (UART2-UART5). Messages having CID and FID both as "0s" do not have the CRC/Parity field in them. Such messages only have the message header, payload and the xcrc fields.
- **XCRC- 6-bits** - This is the extended CRC which protects the UART packet. Note that any bits between the end of the PSI5 message payload and the XCRC are 'stuffed' with '0's. This can also be seen in [Figure 1246](#). For details about XCRC handling please refer [Section 54.4.2.5, PSI5-S XCRC handling](#).
- Example to calculate the minUARTbytes (for messages NOT having CID and FID both as 0):
 - $F_n_payload = 14$ with PSI5 CRC option : $TMPL = 8+14+3+6=31$,
 $minUARTbytes=CEIL(3.8)=4$.
 These input data stream is interpreted as
UART1(header),**UART2**(D[0:7]),**UART3**(D[8:13],CRC[2:1]),
UART4(CRC[0],0,XCRC[0:5]).
 - $F_n_payload = 13$ with PSI5 Parity option :
 $TMPL=8+13+1+6=28$, $minUARTbytes=CEIL(3.5)=4$.
 These input data stream is interpreted as
UART1(header),**UART2**(D[0:7]),**UART3**(D[8:12],Paritybit,00),
UART4(00,XCRC[0:5]). Note the "0" stuffing between the parity bit and the XCRC.
 The XCRC is always in the last 6 bits of the last byte.
- Example to calculate the minUARTbytes (for messages having CID and FID both as 0):
 - $F_0_payload = 8$: $TMPL = 8+8+0+6=22$, $minUARTbytes=CEIL(2.75)=3$
 These input data stream is interpreted as
UART1(header),**UART2**(D[0:7]), **UART3**(00,XCRC[0:5]).
 - $F_0_payload = 10$: $TMPL = 8+10+0+6=24$, $minUARTbytes=CEIL(3)=3$
 These input data stream is interpreted as
UART1(header),**UART2**(D[0:7]), **UART3**(D[8:9],XCRC[0:5]).

54.4.2 PSI5-S Received Message handling

The message handling in the IP can be divided in three parts:

- PSI5 message extraction:
This decides when a UART packet has been received with the correct header byte, and then how to extract the information from this UART packet form a complete PSI5 message .
- PSI5 “recoverable” and “unrecoverable messages”:
This differentiates the PSI5 messages received above, into “recoverable” and “unrecoverable” messages.
- PSI5 message storage and Mailbox transfer:
This ensures the transfer of the PSI5 message to the correct location in the system RAM, once the PSI5 message has been correctly differentiated into “recoverable” and “unrecoverable” messages.

Following sections detail the above 3 parts:

54.4.2.1 PSI5-S Message extraction

Once a UART start bit is detected after the idle timeout(the idle time between message packets on the UART interface i.e. the number of bit times between message packets in the range of at least 1 to 16 , configurable in the UART module through the PS_UARTPTO register) has occurred , the UART bytes are subsequently sampled . They are being received by an internal state machine in the MRU, which checks for the formation of a complete UART packet, its coherence and extraction of the PSI5 message from the UART packet . Also please see [Figure 1247](#) for further understanding of this section.Each UART packet that is received can be considered as “recoverable” or “unrecoverable”. Demarcation between the two is explained subsequently. Following are the sequence of steps performed as each UART byte is being received:

1. There is a 6 byte UART message input buffer into which the UART bytes from the UART Rx register are written as they are received. A 3-bit UART message counter is incremented on the reception of each byte in UART message packet i.e. each UART byte received between idle time counter indications .
2. All the subsequent UART bytes in the UART packet are stored internally till any of the following events occurs :
 - UART Timeout i.e. bus idle time is detected.
 - Framing Error from the UART.
 - Number of UART bytes that are received as reported through the UART message counter described in “⁽¹⁾” above exceed 6.
 - STOP mode request mode is asserted. Please see [Section 54.1.4.1, Stop mode](#) for further details.
3. As soon as any of the events described in ⁽²⁾ above occur, it is assumed that a complete UART packet has been received. The XCRC is then calculated immediately on the received UART packet. Please see [Section 54.4.2.5, PSI5-S XCRC handling](#) for details about XCRC. If there is an XCRC error the message is assumed to be “unrecoverable” and it is sent to MBOX₀,LOC₁.The timestamp of the message is captured as is described in [Section 54.4.4, TimeStamp](#) .The watchdog error is captured

as is described in [Section 54.4.5, PSI5-S Watchdog Operation](#).

4. If there is NO XCRC error, then the CID and FID are extracted from the header byte, and the configured length of the message is determined from the configuration in PSI5 Channel n Message Configuration Register A. Following steps are performed .
 - The FID and the CID from the header byte is transferred directly to the PSI5 Frame status word.
 - The transceiver error flags (E0,E1) are transferred directly to the PSI5 Frame status word
 - The message is then analysed to see whether it is “LEGAL” or “ILLEGAL”.
 - Following are the conditions for a “LEGAL” message :

When the CID and the FID of the received message are both “0s” and PS_MSGA_CH0[F0_byte] is NOT “0” OR

When the data of an Asynchronous Enabled channel is received with FID = 0 and PS_MSGA_CHCID[F0_byte] is NOT “0” OR

When the data of a Synchronous Enabled channel is received with legal FIDs(0 to 5) and if the recieved FID is such that the corresponding PS_MSGA_CHCID[F_FID_byte] is NOT 0
 - Any recieved message that does not satisfy the above condition is considered as “ILLEGAL”. Illegal Messages are also treated as “unrecoverable” messages and are sent to MBOX₀,LOC₁.

Example can be a message with CID as 0 but FID as 1(illegal because Channel0 is asynchronous and can only have FID equal to 0 messages) or a message recieved for an enabled synchronous channel but having an FID equal to 7(illegal because FID as 7 is not a legal Frame ID) etc.
 - The timestamp of a Legal/Illegal message is captured as is described in [Section 54.4.4, TimeStamp](#) . The watchdog error is captured as is described in [Section 54.4.5, PSI5-S Watchdog Operation](#).
 - The number of UART bytes received in the UART message packet is compared with the number specified in Message Configuration Register A for the channel indicated by CID and FID in the header byte. If the number of bytes indicated by the message counter does not match PS_MSGA_CHCID[F_FID_byte] field , then the status bit N_Err within the PSI5 Frame status word is set. The above “number of bytes recieved” check is not carried out for an “illegal message”.
5. The PSI5 message payload is checked using the PSI5 CRC or parity as per the configuration. Whether the CRC or parity check is correct or not, the PSI5 message payload is written to the PSI5 Sensor Data word and the CRC or parity is written to the PSI5 Frame Status word. Note that the messages which have CID and FID both as “0”, are not checked for CRC or parity error . The CRC/Parity error status bits remain “0” for such messages.This above check is NOT done for “illegal messages”.

54.4.2.2 PSI5-S “Recoverable and Unrecoverable” Messages

Based on [Section 54.4.2.1, PSI5-S Message extraction](#), a message is considered “unrecoverable”, if the XCRC is incorrect or it is an “illegal message”, else the message is considered “recoverable”. “Unrecoverable” message indicates that an error has been detected during the assembling phase of the UART packet i.e., during the formation of the UART packet from the individual UART bytes . “Unrecoverable” messages are always stored in PSI5 mailbox MBOX₀,LOC₁ in system RAM. “Recoverable” messages are always stored in the Mailbox location pointed out by the CID n and the corresponding FID fields.

[Figure 1247](#) describes the treatment of the “Recoverable” and “Unrecoverable” messages. It also details the setting of the various error flags. Note that a stop mode entry (please see [Section 54.1.4.1, Stop mode](#)) also causes the flushing of the internal PSI5 message buffer and this event is treated like a new message completion. This is however not shown in [Figure 1247](#).

Figure 1247. PSI5-S message handling and Error Flags

Once the message has been correctly deciphered as “Recoverable” or “Unrecoverable” and the various error flags have been set then the Message is finally transferred to the MRU buf2. Once the corresponding message has been read from the MRU buf2 the bits in the “PS_MBOX_SR_CH[n]” register are set appropriately. This aids the application to correctly read the concerned message from the Mailbox. [Section 54.4.2.3, PSI5-S Message Storage and Mailbox Transfer](#) describes the PSI5 Message Storage and detection in detail.

54.4.2.3 PSI5-S Message Storage and Mailbox Transfer

Once the message has been correctly deciphered as “recoverable” or “unrecoverable” and the various status bits are set, it is then transferred to the MRU output buffer. The MRU output buffer is a 2 stage buffer differentiated as MRU Buf1 and MRU Buf2. The MRU buf1 is composed of 3, 32 bit registers while the MRU buf2 is composed of 4, 32bit registers. *Figure 1248* shows the structure of MRU buf1. It is composed of three internal registers. These registers are not in the addressable space of the IP. When the internal state machine has correctly decoded the PSI5 message, it is transferred to MRU buffer1. It serves to hold the PSI5 message until it is transferred to MRU buf2.

Figure 1248. MRU buf1 structure

Figure 1249 shows the structure of MRU buf2. MRU buf2 has one extra location as compared to MRU buf1. This extra location (MRU buf2 Reg0) contains the address of the Mailbox location, where the message contained in the rest of the three locations of MRU buffer2 is to be placed. This specific MRU buf2 structure aids the DMA to perform linked scatter-gather data transfer from the IP. The extra location in the MRU buf2 is automatically updated by the hardware and provides the destination address for the message. This destination is the Mailbox Address at which the message (stored in MRU buf2 (Reg1-Reg3)) is to be transferred by the DMA. This destination address is calculated by the IP based on ChID in the message header (or ChID0 in the case of an unrecoverable message), the FID in the message header and Base address of the mailbox in system RAM (provided by CH_BASE_ADDR) register.

Figure 1249. MRU buf2 structure

MRU buf2 is in the addressable space of the IP and is read by the DMA when the corresponding DMA request is asserted. The PSI5 message is transferred from the MRU buf1 to the MRU buf2 only when the MRU buf2 has been read completely by the DMA, i.e., all the 4 locations of the MRU buffer2 have been read by the DMA, for the corresponding PSI5 message.

Following are the sequence of operations that are performed, before the message in MRU buf2, gets ready to be accessed by the DMA:

1. The IP decodes the message as detailed in [Section 54.4.2.1, PSI5-S Message extraction](#) and [Section 54.4.2.2, PSI5-S “Recoverable and Unrecoverable” Messages](#).
2. The corresponding message is available in MRU buf1 along with the various status bits latched internally in the IP. Externally, no interrupt is generated and neither are any status bit updated, when the message is transferred to MRU buf1. When the message is transferred to MRU buf1 a 3 bit DCI (data consistency indicator) is added. The DCI is a 3-bit counter that is counted on a reception of each new message in MRU buf1.
3. The IP checks whether MRU buf2 is empty. If it is empty, then the MRU buf1 “Reg1 to Reg3” contents are transferred to the MRU buf2 “Reg1 to Reg3”. The corresponding interrupts (except the Message Read from MRU) are also asserted based on the Interrupt Enable settings. Based on the PSI_CH_BASE_ADDR, the CID, FID values and whether an “unrecoverable message” has been received, the IP calculates the contents of MRU buf2 Reg0 register.
 - If CID == 0 then the “MRU buf2 Reg0” contains the Mailbox Location corresponding to MBOX0,LOC0.
 - If “unrecoverable message” is received then “MRU buf2 Reg0” contains the Mailbox Location corresponding to MBOX0,LOC1.
 - In all other cases “MRU buf2 Reg0” contains the Mailbox location corresponding to the MBOX_{CID},LOC_{FID}.
4. Once the calculations in ⁽³⁾, are done the IP asserts the DMA request for Access1. In DMA Access 1, the DMA reads the first location (MRU buf2 Reg0) of the MRU buf2. This single 32-bit access writes the content of MRU buf2 Reg0 into the destination address for the DMA channel performing the second access (Access 2). Access 2 is initiated by the DMA once the Access1 transfer is complete. Access 2 is composed of 3,32-bit accesses of MRU buf2 and it writes the reconstructed PSI5 message along with its status and timestamp to the mailbox, starting at the destination address provided by Access 1. In Access2 the DMA reads the MRU buf2 Reg1,Reg2 and Reg3 in that order.
5. The application can read the PS_MBOX_SR_CH[n] register to get an indication to which mailbox location (or locations) the DMA would transfer the message. Note that “DMA transfer complete” bit/interrupt of the DMA indicates to the application, that the message read by the DMA from the IP has actually been written to the Mailbox.
6. The application should clear the corresponding “Fn_read” bits in the PS_MBOX_SR_CH[n] register once the application has read the corresponding message from the Mailbox. If a PSI5 message gets written to a Mailbox location, with “Fn_read” bit still set at the time at which the DMA has started the Access1, then the corresponding “Fn_OV” bits are set in the PS_MBOX_SR_CH[n] register.
7. Reference to ⁽³⁾ above, if the MRU buf2 has a pending message and the MRU buf1 also has a message that is ready to be transferred to the MRU buf2 and then a new message gets ready to be written to MRU buf1, then the previous message in MRU buf1 gets overwritten by the new message. The MRU overwrite interrupt is also generated with the setting of the corresponding register bit in the PS_GLSR register. PS_GLSR register contains the CID and the FID of the message that got overwritten by the new message in MRU buf1.
8. When writing an unrecoverable message to the PSI5 mailbox CID0, with the XCRC_ERR bit set, the timestamp that will be used will be the one which is captured at the time XCRC_ERR bit is set. When the unrecoverable message is due to an “illegal message”, then the timestamp used would be the one which is captured on the

reception of any message i.e., always captured at the end of the header byte of every message.

9. In Asynchronous mode, FID will always be configured to be “0” and the module will use the PSI5 Mailbox for the channel (identified by CID in header) as a ring buffer, incrementing the destination address for each message received and saving up to the last six messages received. The bits of the PS_MBOX_SR_CH[n] register will still indicate the status of each location of the Ring Buffer. The software has to still clear the six bits of this register when it reads the Mailbox location else the overwrite bits would be set in the PS_MBOX_SR_CH[n] register. The message identification mechanism allows software to identify the latest message received

54.4.2.4 PSI5-S Data Payload CRC Recalculation

Error detection is realized by a single bit even parity (recommended for 10 or fewer bits) or a 3-bit CRC (recommended for long data words). The transmission error detection is selectable (by frame configuration register) as:

- 1-bit even parity
- 3-bit CRC

The generator polynomial of the CRC is $g(x)=1+x+x^3$ with a binary CRC initialization value of 111. The transmitter extends the data bits by three 0s (as MSBs). This augmented data word is fed (LSB first) into the shift registers of the CRC check. Start bits are ignored in this check. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the buffer registers contain the CRC checksum. These three check bits are transmitted in reverse order (MSB first: C2, C1, C0).

Figure 1250. CRC calculation scheme

Table 1224. CRC Calculation (at transmitter side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	0	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	1	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	1	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	1

Table 1225. Transmitted and Received Sensor Data

Transmitted Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0
Received Sensor Data	S0	S1	D0	D1	D2	D3	D4	D5	D6	D7	D8	D9	C2	C1	C0
	0	0	0	1	1	1	0	1	1	1	0	0	1	0	0

Table 1226. CRC Re-Calculation (At Receiver Side)

Sensor Data (LSB first)		0	1	1	1	0	1	1	1	0	0	1	0	0
C0	1	1	0	1	1	0	0	0	0	1	1	0	0	0
C1	1	0	0	0	1	1	1	1	1	1	0	0	0	0
C2	1	1	0	0	0	1	1	1	1	1	1	0	0	0

Syndrome = 000 → Transmission successful

The correct transmission is checked by the PSI5 receiver by comparing the syndrome (content of the shift register after reception of both data bits and CRC bits) with the zero vector. For error free reception, all shift registers have to be zero.

54.4.2.5 PSI5-S XCRC handling

The XCRC calculation is triggered on any of the following events(which also indicate the reception of a new UART packet):

- UART idle timeout
- number of UART bytes exceed 6
- UART Framing error
- STOP mode assertion. Please see [Section 54.1.4.1, Stop mode](#).

When any of the above events occur , the internal XCRC calculator becomes active. Each UART byte that is received, passes through the XCRC calculator on a bit by bit basis, starting from the header byte to the expected XCRC byte. The XCRC is assumed to be the last 6 bits of the last UART byte that is recieved before the occurrence of any of the above events. [Figure 1251](#) shows the XCRC calculation algorithm.

Figure 1251. XCRC calculation

The UART bytes are shifted starting from the received header to data packets to the XCRC packet. Each of these UART bytes is shifted LSB first into this XCRC calculator. Once all the bytes as denoted by the Fn bytes have been received and the Fnth packet (XCRC) has been shifted completely through this XCRC calculator and if XCRC[5:0] is equal to "0" then it denotes that the XCRC check has passed else there is an XCRC error and the XCRC_ERR bit is set.

The CRC polynomial used is " $x^6+x^4+x^3+1$ " with a binary initialization value of XCRC[5:0] = "010101".

54.4.3 ECU-to-sensor communication

The IP send the commands for the ECU to Sensor communication in terms of UART bytes. It expects the external transceiver to correctly interpret the commands and then generate the appropriate logic 0 or logic 1 on the PSI5 bus. Following are the various PSI5-S ECU to Sensor commands supported by the IP, as shown in [Figure 1252](#).

Figure 1252. Standard Frame Formats Supported

- Short:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- **"010",S, "A0,A1,A2",S, "F0,F1,F2",S, "C2,C1,C0"** where "010" is the start sequence "S" is the stuff bit(1),A0-A2 is the sensor address,F0-F2 are the functional codes and "C2-C0" is the CRC. Please refer [Figure 1252](#) for the frame structure.
 - The CRC polynomial used is $x^3 + x + 1$ with a binary initialization value of "111(C2:C0)".
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,"000"] with "A0" being given first and "0" as the last. When the

last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.

- When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]....PS_DDSR[5],000) with PS_DDSR[0] being fed first in the CRC calculator.
- **Long(4bit Data Nibble):** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) -- “010”,S, “A0,A1,A2”,S, “F0,F1,F2”,S, “X0,X1,X2”,S, “X3,X4,X5”,S, “D0,D1,D2”,S, “D3,C2,C1”,S, “C0” where “010” is the start sequence “S” is the stuff bit(1),A0-A2 is the sensor address,F0-F2 are the functional codes,”X0-X5” is the Range Address, “D0-D3” is the data and “C2-C0” is the CRC. Please refer [Figure 1252](#) for the frame structure.
 - The CRC polynomial used is $x^3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0..X5,D0...D3,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
 - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]....PS_DDSR[15],000) with PS_DDSR[0] being fed first in the CRC calculator.
- **Long(8bit Data Word):** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”,S, “A0,A1,A2”,S, “F0,F1,F2”,S, “X0,X1,D0”,S, “D1,D2,D3”,S, “D4,D4,D6”,S, “D7,C2,C1”,S, “C0” where “010” is the start sequence “S” is the stuff bit(1),A0-A2 is the sensor address,F0-F2 are the functional codes,”X0-X1” is the Range Address, “D0-D7” is the data and “C2-C0” is the CRC.Please refer [Figure 1252](#) for the frame structure.
 - The CRC polynomial used is $x^3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0..X1,D0...D7,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
 - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]....PS_DDSR[15],000) with PS_DDSR[0] being fed first in the CRC calculator.
- **X-Long:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C0 comes out Last) Data Stream - “010”,S, “A0,A1,A2”,S, “F0,F1,F2”,S, “X0,X1,X2”,S, “X3,X4,X5”,S, “X6,X7,D0”,S, “D1,D2,D3”,S, “D4,D5,D6”,S, “D7,C2,C1”,S, “C0” where “010” is the start sequence “S” is the stuff bit(1),A0-A2 is the sensor address,F0-F2 are the functional codes,”X0-X5” is the Range Address, “D0-D3” is the data and “C2-C0” is the CRC. Please refer [Figure 1252](#) for the

frame structure.

- The CRC polynomial used is $x^3 + x + 1$ with a binary initialization value of “111(C2:C0)”.
 - The transmitter extends the data bits by three zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,F0..F2,X0...X7,D0...D7,”000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
 - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]....PS_DDSR[21],000) with PS_DDSR[0] being fed first in the CRC calculator.
- **XX-Long:** It consists of the following data stream (Order of transmission from IP is Left to Right. Thus C5 comes Last) Data Stream - “01111110”, “A0,A1,A2”, “C”, “D0,D1”,S, “D2,D3,D4” D5,D6,D7, S, “D8,D9,D10,D11,D12,D13”, S, “D14,D15,D16,D17,D18,D19”,S, “C0,C1,C2,C3,C4,C5” where “01111110” is the start sequence “S” is the stuff bit(0),A0-A2 is the sensor address, “C” is the configuration bit, “D0-D19” is the data and “C0-C5” is the CRC. Please refer [Figure 1252](#) for the frame structure.
 - The CRC polynomial used is $x^6 + x^4 + x^3 + 1$ with a binary CRC initialization value 010101(C5:C0).
 - The transmitter extends the data bits by six zeros (as MSBs).
 - The CRC calculator is fed LSB first. Thus for CRC calculation the sequence given is [A0...A2,D0..D19,”000000”] with “A0” being given first and “0” as the last. When the last zero of the augmentation is calculated on the input adder and the result is shifted, the CRC calculation has been achieved.
 - When mapping this sequence to the DDSR register bits for calculating the CRC; then it becomes (PS_DDSR[0],PS_DDSR[1]....PS_DDSR[23],000000) with PS_DDSR[0] being fed first in the CRC calculator.

54.4.3.1 PSI5-S ECU to Sensor Command Handling

The ECU-to-Sensor commands can be written to the PSI5 IP in two ways:

1. Direct writing to the UART Tx Buffer : This can be used by the software to directly write the transceiver/diagnostic commands to the UART Tx buffer . In case there is a simultaneous UART access also by the PSI5-S core then the priority is given to the system(software) . The pending command from the PSI5-S core is then buffered internally and is transmitted when the system is no longer accessing the UART core. The system can write to the UART Tx buffer when the PS_UARTSR[DTF] flag goes to “1”. Setting of this bit indicates that the UART Tx buffer is ready for accepting a new byte.Interrupt can also be generated by setting the corresponding interrupt enable bit to “1” .
2. Writing to the DDSR (Downstream Data Shift Register): In this case the application writes the basic command to the DDSR_L and the IP will add the start bits/start condition/CRC/stuff bits before sending this command to the UART Tx FIFO. Following are the details:
 - There is one DDSR per channel. The default value of DDSR is dependent on the PS_E2SCR[CMD_TYPE] value. DDSR is composed of two sub registers DDSR_H (Higher) and DDSR_L (Lower). The application can only write to DDSR_L. The number of bits that can be written in the DDSR_L is dependent on

- the value of PS_E2SCR[CMD_TYPE] bit values. Note that Channel0 does not have any DDSR, as it does not support any ECU-to-Sensor communication.
- The “shift trigger” of the DDSR is governed by the values programmed in the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] register and the frequency of ipg_clk_ps_ddtrig clock .
 - Once the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] are correctly programmed and each channel is programmed to respond to the selected shift trigger (local trigger or global trigger is decided via the bit PS_E2SCR[GL_TRIG_SEL]) the software has to write to the Global DDSR trigger bit, PS_GLCR[GL_DDSR_TRIG] or the PS_E2CR[CH_TRIG] bit, so as to synchronously start the DDSR triggers of each channel or locally start the DDSR shift triggers of each channel. The DDSR trigger logic gets the trigger signal immediately but it responds after a delay as programmed in the PS_DDTRIG_OFFR_CH[n] register. The shift trigger period is governed by the value programmed in the PS_DDTRIG_PERR_CH[n] register. Please see [Figure 1253](#) for the structure of the logic that generates the internal DDSR shift triggers.

Figure 1253. DDSR internal shift trigger generator

Note : This structure is replicated for each channel except Channel0, in which this structure is not present.

- The number of bits of DDSR_L that can be written by the application, is dependent on the value of PS_E2SCR[CMD_TYPE] value.
- When PS_E2SSR[DDSR_RDY] == 1, then it indicates that the DDSR is empty and is ready to accept a new command. If the PS_E2SCR[DDSR_RDY_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line.
- Attempting to write to DDSR while PS_E2SSR[DDSR_RDY] == 0 results in the rejection of the new command and setting of the PS_E2SSR[CMD_NWRT] bit. If the PS_E2SCR[CMDTR_NWRT_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line.
- The application then writes the command to the DDSR and writes a “0” to the PS_E2SCR[DDSR_RDY]. This indicates to the internal logic that the command is

now ready for further processing. The clock that is used for shifting the contents of the DDSR can be configured through the PS_E2SCR[DDSR_CLK_SEL] register.

- Depending on the value of PS_E2SCR[CMD_TYPE], the internal logic adds the start bits/start condition/CRC/bit stuffing and updates the DDSR with the complete command, ready for transmission.
- Once this happens the PS_E2SSR[CMDPR_BZY] becomes “1”. If the PS_E2SCR[CMDPR_BZY_IE] == 1 then this results in the generation of interrupt on the “ipi_ps_e2s_ch[n]” line. If PS_E2SCR[CMDTR_SW_CTRL] == 0 then the application can check the final value of the command in DDSR, that would actually be transmitted. Once the checking is complete it can put the PS_E2SCR[CMDTR_SW_CTRL] to “1”, to start the actual transmission. By default PS_E2SCR[CMDTR_SW_CTRL] is set to “1”. Note that the start condition is not a part of the DDSR and its transmission is dependent on the value of the PS_E2SCR[CMD_TYPE] and is automatically taken care by the IP.
- Each bit of the command in DDSR, if it is “1”, results in PS_E2SCR[CMD] being transferred to the UARTTX buffer or if it is “0” results in PS_E2SCR[ACMD] being transmitted to the UART-TX buffer. The “CMD” and the “ACMD” governs as to how the transceiver has to respond when it receives these values. These will specify to the transceiver whether it should send a short or long SYNC pulse on the PSI5 bus when the application wishes to write to the sensors
- Once the complete command has been transmitted the PS_E2SSR[DDSR_RDY] goes to “1” while PS_E2SSR[CMDPR_BZY] goes to “0”.
- Once the PS_E2SSR[DDSR_RDY] goes to “1” then default “1s” or default “0s” are transmitted, depending on the value of PS_E2SCR[CMD_TYPE].
- When PS_E2SSR[DDSR_RDY] == 1, then it is possible to abort the current transmission by doing a “W1C” of the PS_E2SCR[DDSR_CLR] bit. As soon as this is done the DDSR is reset to “0”, PS_E2SSR[DDSR_RDY] goes to “1” while PS_E2SSR[CMDPR_BZY] goes to “0”. Once the PS_E2SSR[DDSR_RDY] goes to “1” then default “1s” or default “0s” are transmitted, depending on the value of PS_E2SCR[CMD_TYPE]. Note that doing this “W1C” does not have any effect on the CMD/ACMD transmission that is already under progress in the UART.

Figure 1254. PS_DDSR Sensor Command (Ex: XXLong Frame)

Figure 1255. PS_DD SR Sensor Command (Ex: PSI5 LONG format)

Figure 1256. CMD and ACMD

- The logic for processing the DDSR contents is shared among all the 7 channels. It has to be ensured by the software to correctly program the PS_DDTRIG_OFFR_CH[n] and the PS_DDTRIG_PERR_CH[n] register contents so that the none of the bits in the command get missed. Also since ⁽¹⁾ is possible, it is up to the application to ensure that the UART TX_BUFFER does not remain busy to the extent that some particular DDSR bit does not get the chance to be shifted out before it gets overwritten by some new DDSR bit.
- The approximate maximum time, beginning from when PS_E2SCR[DDSR_RDY] is made "0", to the time when the command is available for transmission is less than 1us, provided no other channel has an active command processing ongoing. If commands are written to multiple DDSR registers one after the other, then the time after which the particular channel will again get an access will

increase. Note that the irrespective of the sequence in which the PS_E2SCR[DDSR_RDY] of the channels are cleared, the channels are always searched in a round robin fashion for the status of the respective DDSR_RDY bits. When the internal sequencer find the respective DDSR_RDY as "0" it starts the processing of the corresponding DDSR. The sequencer always goes as Channel1->Channel2->Channel3...Channel7->Channel1...

- The logic that shifts each bit of the DDSRs of each channel is shared among all the channels. When the shift trigger of a particular DDSR is received and if the UART TX Buffer is empty then the particular command bit is transmitted to the UART TX by the appropriate CMD/ACMD. It is possible that at one point of time , CMD/ACMD of more than one channel are pending to be transmitted to the UART TX . In this case the channel with a higher channel number will be given a priority . Thus if channel2 and channel1 , both have a pending CMD/ACMD shift, then channel2 would be the first to get an access .Each pending channel would queue up for transmission . It has to be ensured by the software that the internal shift triggers generated through the PS_DDTRIG_PERR_CHn and PS_DDTRIG_OFFR_CHn registers are correctly spaced so that all the channels get an access to transmit their DDSR bits. If a command bit that is desired to be shifted encounters more than one shift triggers (because it did not get shifted on the previous shift trigger) then there is no indication for this loss of synchronisation . In general , if the if PS_DDTRIG_PERR is programmed to be greater than 500us(which is a practical PSI5 sync pulse period) then it would be ensured that the bits are correctly transmitted even if all the channels simultaneously transmit their command bits.

54.4.4 TimeStamp

The IP provides for two global 24-bit timestamp counters. Each can be clocked by either the module clock or the GTM trigger. The two timestamp counters are detailed as TimeStamp Counter A and B. Please see [Figure 1257](#). Following are the details:

1. Each channel has an internal TimeStamp buffer that can be configured to capture either the TS counter A or B when it encounters the "capture event". Provided there is no XCRC error in the message, then this Timestamp buffer is appended to the message when it is written to MRU buf1 . When there is an XCRC error in the message, then Channel0 timestamp is appended. Please see point number ⁽⁷⁾ below.
2. The "captured event" for the timestamp buffer of each channel can either be when a "a valid message header is detected" or when "a Command (or Alternate Command) is moved from the UART Tx Buffer to the UART Tx shift register" corresponding to the channel for which this command is being shifted to the UART .
3. The TimeStamp Buffer can be enabled or disabled through the PS_MSGA_CHn[TSBUF_EN] bit . When the TimeStamp buffer is disabled then it no longer responds to "capture events" and always contains the value "0".
4. It is possible to reset each TimeStamp buffer by using the PS_MSGA_CHn[TSBUF_CLR] bit . As soon as this bit is written to "1" the TimeStamp buffer is reset to all "0s" and it remains in this state till it encounters a "capture event".
5. In the case when the reception of message is chosen as the trigger, the time stamp will be captured immediately after the header byte of the UART message packet has been received.
6. In the case when the move of CMD or ACMD from the internal UART Tx Buffer to the UART Tx shift register in the UART module is chosen as the trigger, the timestamp for the intended channel (indicated in the CIDn fields of CMD or ACMD) is valid for all

- frames received on a channel between moves of CMD or ACMD from the UART Tx Buffer to the UART Tx Register (i.e., for a PSI5 SYNC period).
7. When a XCRC error is detected in any message then the timestamp that is appended with the message is the Channel0 timestamp which is captured at the time when XCRC_ERR has been detected.
 8. For “illegal messages”, the timestamp value that is captured is the Channel0 Timestamp value, which is captured whenever “a valid message header for that illegal message is detected”. Note that the definition of a “legal” or a “illegal” message applies to a PSI5 message only when the concerned UART packet has no XCRC error.
 9. In addition to the timestamp buffers described in point number ⁽¹⁾ above, there is a separate timestamp capture that occurs in case of a watchdog error. This timestamp is captured in the PS_WDGTSSR[WDGTS_STATUS] bits. The TimeStamp A or B (as programmed in the PS_MSGA_CHn[TIMESTAMP_A_B_SEL]) is captured as soon as the watchdog overrun error occurs for that channel. Please see [Section 54.3.16, PSI5-S Watchdog Error Status and Watchdog Timestamp status register \(PS_WDGTSSR\)](#) for more details.

Figure 1257. TimeStamp Capture

54.4.5 PSI5-S Watchdog Operation

The IP provides a watchdog to keep track of a number of reception parameters. The watchdog counter is a 24 bit down counter. Each channel, except Channel0, contains a watchdog counter. The refresh event for the watchdog is automatically chosen depending on whether the channels mode is synchronous or asynchronous. The watchdog timeout

value can be configured in the “WD_TO” bits in the PS_WD_CFGR_CH[n] register. The refresh event for the watchdog are different in the synchronous and asynchronous modes as mentioned below :

- In Asynchronous mode :

Whether the WD has to be “refreshed” or “not to be refreshed” is analyzed when the XCRC is calculated . In case the XCRC is correct the watchdog is refreshed (It is not STOPPED) , else the WD counter keeps on running normally eventually leading to a watchdog overrun error.

- In Synchronous Mode:

The watchdog is ALWAYS refreshed on the occurrence of the internal sync pulse and keeps on counting thereafter. However, it is stopped when the “Packet_counter” reaches the count of “total number of configured slots”. The “Packet_counter” here is a counter that keeps track of the number of configured(enabled) slots. It is incremented on the reception of each UART packet with a “CID” and “FID” such that PS_MSGA_CH_CID[FID_byte] is not equal to “0” . The packet counter is however incremented ONLY if the XCRC of the received UART packet is correct else it is not incremented. In case the “Packet Counter” does not reach the “expected packet count” within the “WD timeout configured “ , the WD overrun error is generated.

In both the above modes , the watchdog is always refreshed on the occurrence of Watchdog overrun error (F_WD_ERR) or a software reload . Also please refer to [Section 54.3.3.23, PSI5-S channel watchdog configuration register \(PS_WD_CFGR_CHn\) \[n==1..7\]](#)

The watchdog can be started in the NORMAL mode by writing a “1” to the WDEN bit in the PSI5_WD_CFGR_CH[n]. If the watchdog counter is not refreshed by its event and the watchdog counter becomes equal to “0”; the F_WD_ERR flag is set in the PSI5_IRQ_ERR_SR register and the same is also reflected in the PS_MRU_BUF2_REG1 register. An interrupt can also be generated on any of the “ipi_ps_irq[irq_n]” lines depending on the configuration. Note that writing a “0” to WDEN bit disables the watchdog checking mechanism. [Figure 1258](#) shows the watchdog counter.

Figure 1258. Watchdog Counter

As soon as the watchdog overrun error for a particular channel occurs , the status of the watchdog error is immediately latched in the register described in [Section 54.3.3.16, PSI5-S](#)

Watchdog Error Status and Watchdog Timestamp status register (PS_WDGTSSR). This watchdog error status(PS_WDGTSSR[F_WD_ERR_STATUS[CHn]]) is also sent to the MRU registers(as F_WD_ERR) as shown in the PSI5 frame status word (shown in [Figure 1248](#) and [Figure 1249](#)) . However this information is sent in the next upcoming PSI5 message packet that occurs for that particular channel , provided this upcoming PSI5 message has no XCRC error. In case the upcoming UART packet has an XCRC error then the Frame watchdog error field in this PSI5 message packet is the “OR” of the F_WD_ERR status of all the channels i.e. OR of all the fields of PS_WDGTSSR[F_WD_ERR_STATUS] bits.

54.4.6 Interrupt handling

Following are the various interrupt signals that represent the various events:

1. PSI5-S general interrupt request (**Status flags in PS_MBOX_SR_IRQ and PS_ERR_SR_IRQ**)/ipi_ps_irq[irq_n] where irq_n = 0 to 7 and denotes the irq number. There are 8 such interrupts in the IP. Each of these “irq” lines can be configured to respond to any or all of the following events:
 - At least one message of the specific channel has been read by the DMA from the MRU buffer. (The interrupt is configurable to respond to any channel through the corresponding PS_MBOX_SEL_IRQ[irq_n] register)
 - When there is a XCRC error in a new packet that is transferred to MRU buffer2 OR
 - When there is a CRC or parity error in a new packet that is transferred to MRU buffer2 OR
 - When the watchdog Error has been detected in the message just written to MRU buf2 OR
 - When the message header has been detected with transceiver error flags OR
 - When the PSI5 state machine detects in the UART, the message parity error, the overflow error or the framing error and the corresponding frame is transferred to MRU buffer 2.
 - When the “R_OVL_ERR” error occurs in the new packet that is transferred to MRU buffer 2 OR
 - When the “R_UVL_ERR” error occurs in the new packet that is transferred to MRU buffer 2 OR
 - When the number of bytes received does not match the expected Fn bytes (N_ERR == 1)

Each of the “ipi_ps_irq[irq_n]” lines can be configured to be asserted on any of the above events by correctly programming the registers PS_MBOX_SEL_IRQ[irq_n] and PS_ERR_SEL_IRQ[irq_n].

This interrupt is cleared when the corresponding bits in PS_MBOX_SR_IRQ and PS_ERR_SR_IRQ are cleared. It is assumed that one event would not be mapped on more than one “irq” lines. If the same event is mapped on more than one “irq” lines then clearing the corresponding status bit in the PS_MBOX_SR_IRQ or PS_ERR_SR_IRQ will clear all the interrupt requests related to that same event. [Figure 1259](#) shows the interrupt structure for IRQ interrupts.

Figure 1259. IRQ[n] interrupts

2. PSI5-S ECU-to-Sensor interrupt (**Status Flags in PSI5_E2SSR**)/ipi_ps_e2s_ch[n] where n = 1 to 7:

This interrupt is used for the ECU to Sensor Communications and is generated in the following cases:

- When the DDSR is empty and is ready to accept a new command new from the application. In this case the PS_E2SSR[DDSR_RDY] bit is set to "1".
- When the DDSR is still busy (PS_E2SSR[DDSR_RDY] bit is set to "0") and the application attempts to write a new command to the DDSR. The new command is rejected and the PS_E2SSR[CMD_NWRT] bit is set to "1".
- When the command that is written to the DDSR has finished calculating the CRC/stuff bits/start bits and is ready for transmission the PS_E2SSR[CMDPR_BZY] goes to "1" leading to the generation of this interrupt.

Figure 1260. ECU to Sensor interrupts

3. Global interrupt (**Status Flags in PS_GLSR**) /ipi_ps_glbl:

This interrupt is a single interrupt for the whole IP and is generated in the following cases.

- When the DMA has not completed reading the MRU buffer2; simultaneously there is a pending data in MRU buffer1 that needs to be offloaded to the MRU buffer2 and a new message comes, that overwrites the contents of MRU buffer 1. The channel ID and the Frame ID of the overwritten message can be read from the PS_GLSR registers.
- When there is any change in the “PSI5-S” global modes of the IP . Thus it is asserted during the following transitions UART_STDALONE to PS_DISABLE , PS_DISABLE to PS_CONFIG , PS_DISABLE to PS_NORMAL and PS_CONFIG to PS_NORMAL . Assertion of this interrupt indicates that the desired mode has been accomplished by the IP.

Figure 1261. Global Interrupts

54.5 PSI5-S Clock and Reset

Figure 1262. Clock distribution in PSI5-S

[Figure 1262](#) shows the clocking scheme for the PSI5-S IP. It also shows the distribution of various clocks on the basis of channels .

The divider and the control of clock “ipg_clk_ps_ts” is outside the IP , while for the clocks “ipg_clk_ps_wd” , “ipg_clk_ps_ddtrig” and “ipg_clk_ps_uart_tclk” , though the frequency divider is placed outside the IP yet the value of this divider is controlled from inside IP using the “*_clkdivN” signals which are in turn driven by IPS registers of the IP.

For the safe operation of the UART module , the following relation should be satisfied between the “ipg_baud_clk” and “ipg_clk_ps” :

$$\text{ipg_baud_clk} > \text{ipg_clk_ps} > \text{ipg_baud_clk}/3$$

55 SENT Receiver (SRX)

55.1 Introduction

The Single Edge Nibble Transmission (SENT) Receiver (SRX) module is a multi-channel receiver for receiving serial data frames which are being transmitted by a sensor implementing the SENT encoding scheme and present them to the CPU for further processing.

This module is based on the SAE J2716 information report titled "SENT - Single Edge Nibble Transmission for Automotive Applications" and released on January 27, 2010 (<http://www.sae.org>), Apr2007 and Feb2008. As per this standard, the SENT protocol is intended for use in applications where high resolution sensor data needs to be communicated from a sensor to an Engine Control Unit (ECU). It is intended as a replacement for the lower resolution methods of 10 bit A/Ds and PWM and as a simpler low-cost alternative to CAN or LIN. The implementation assumes that the sensor is a smart sensor containing a microprocessor or dedicated logic device (ASIC) to create the signal.

The SENT encoding scheme is a unidirectional communications scheme from the sensor / transmitting device to the controller /receiving device which does not include a coordination signal from the controller/receiving device. The sensor signal is transmitted as a series of pulses with data encoded as falling to falling edge periods.

55.1.1 Features

The SENT receiver module has the following features:

- The number of SENT channels supported are device-specific. See [Section 7.8.8, SENT receiver \(SRX\) configuration](#) for details.
- Unified message read logic to transfer all messages received to system memory via interrupts or DMA
 - Programmable option per channel to support reading of messages via DMA or Interrupt
 - Internal round robin arbitration sequencer to loop across channels to read messages from each channel leaving CPU/DMA transparent to this process
 - All received messages are stored excluding the synchronization pulse (for Fast messages) and identifiers (for Slow Serial Messages)
 - Separate buffers for storing Fast and Slow Serial Messages
 - Separate DMA and Interrupts generated for Fast and Slow Serial Messages
- Supports compensation for variation in SENT Tx Clock up to $\pm 25\%$ and adjusts its measurement for drift and jitter in the Transmitter and Receiver clocks per channel
 - Calibration pulse correction factor per channel is available for use by software
- Implements for each channel all receiver diagnostics as specified by the SAE Specifications
- Internal 4-bit CRC calculator that can be configured to compute CRC in both Legacy and Recommended method (as given in SAE SENT Specification) for both Fast and Short Serial Message per channel
- Internal 6-bit CRC calculator for Enhanced Serial Messages per channel
- Supports all bit rates by having per channel configurable Rx clock periods from 3 μs to 90 μs

- Support for configurable number of data nibbles per channel
- Option to disable individual channel via programmable control bit
- Time stamping on start of each valid message (i.e. without errors) across all channels. This time stamp is appended to each message for synchronization of messages and for application to understand how much time has elapsed between successive sensor readings
- Support for pause pulse per channel. This can be enabled by programming a bit in the control register for that channel
- Input Programmable Filter on each channel to filter any glitches on input. This filter duration is programmable by the user software.
- 32-bit register interface for programming the module's registers and reading the received messages
- Works on two clocks, one for accurate receive operations (high frequency receiver clock or protocol clock) and other for message read logic (system bus clock) and the module can work irrespective of the frequency relationship between the two clocks. See [Section 55.5, "Clocks and resets"](#) for more details on the clocks.

55.1.2 Modes of operation

55.1.2.1 Debug mode

In debug mode, message reception will be halted and all existing status and messages will be retained. DBG_FRZ bit is required to be set for this mode. On debug exit, a calibration length error (CAL_LEN_ERR) can be reported and the channels will start receiving messages from a valid calibration pulse.

55.1.2.2 Low power modes

SENT Receiver behavior is affected by chip-specific low power modes (for example, STOP or WAIT modes). These low power modes should either gate-off both the system bus clock and the protocol clocks or reduce their frequencies, depending on the application.

On exiting from these low power modes, calibration length error (CAL_LEN_ERR) can get set in channel status registers as the SENT sensor (transmitter) could be in the middle of a message transmission at that point. Thus, software should clear all error status bits after exiting the low power modes.

Modes where both system bus clock and protocol clock are gated: In this case, both message reception and interrupt / DMA request generation will halt. The internal receiver channels will freeze (since clock is not there) and will not receive any messages. Messages which are completely received before entering the low power mode can be read after the low power mode exit.

Modes where frequency of system bus clock is changed: For reduced power consumption the system bus clock can be reduced but not below a minimum value (See [Section 55.5.2, "System bus clock requirements"](#)) to avoid overflow of received messages. Protocol clock should not go below the minimum value (See [Section 55.5.3, "High frequency receiver clock \(protocol clock\) requirements"](#)) for accurate receive operations.

Note: Gating of clocks in the low power mode is chip-specific, see the chapter that refers how the modules behave in low power modes.

55.1.3 Block diagram

Figure 1263. SENT block diagram

55.1.4 Design overview

The SENT Receiver Module is a unified receiver module comprising of a number of receiver channels and a unified DMA and Register Space for accessing the messages from each channel. [Figure 1263](#) shows the top level block diagram for the SENT Receiver module.

Each channel of the SENT Receiver is composed of a Clock Generation and Adjustment block to generate the receiver clock and adjust it for frequency variation in the transmitter clock. This block also detects the synchronization/calibration pulse which is present in every SENT message.

The SENT Receiver State Machine controls the sequencing of decoding the messages and combining the information as nibbles. In parallel a diagnostic block is running that monitors the incoming messages for any errors and also verifies the CRC of the received messages. The fast and serial message extractors collate the message nibbles and add the channel number and time stamp information to the messages. A free running time stamp counter is used to add the time stamp value to each message received. The value of this counter is input to each channel and the channel logic appends the time stamp to each message. These messages are then formatted to be stored in the corresponding message read buffer. Only the messages that pass the diagnostics checks are forwarded to be stored in the buffers.

The SENT Receiver provides two mechanisms for reading the received messages, which are via DMA transfers and via Interrupts. Based on the control bit settings in the control registers, a DMA request or Interrupt is asserted to signal the DMA controller or CPU that messages are available to be read.

The free running time stamp counter, register block and DMA interface are common for all channels configured. The register space contains all the necessary registers for all channels. The register space is 32-bit aligned and accessible via 8-/16-/32-bit accesses. The registers for all un-configured channels are marked as reserved.

55.1.4.1 Functional overview

After reset, the SENT module comes up in the disabled state. All channel enable bits and the global enable bit are set to 0 and the user software must program the SENT module parameters correctly before enabling it. The user software must correctly configure all parameters to avoid any underflow or overflow in the message buffers.

Once enabled, the Receiver Clock Generation and Adjustment block detects the synchronization pulse. Until then, the state machine blocks all subsequent operations of the receiver. Once the synchronization pulse is detected, the receiver clock tick period is compensated for variation in transmitter clock tick period and the state machine then waits for the reception of data nibbles. The adjusted receiver clock is used to sample the data nibbles from the incoming serial message. The state machine waits until the status and communication nibble and configured number of data nibbles are received. The state machine then waits for the pause pulse (if configured to receive a pause pulse). The fast and serial message extractor block provides the state machine with the information on how many nibbles have been received. All diagnostics checks are computed in parallel. Once all required data nibbles are received, the CRC is checked, time stamp and channel number is added to the message. The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer along with the message. This final message is stored in the message buffer as described in the

subsequent sections. Any error detected during the receive process causes the status bits in the corresponding channel's status register to be set.

The above process repeats across each enabled channel in parallel and keeps pushing error free messages into the buffers on high frequency receiver clock. The module's message read logic synchronizes all these messages on the bus clock and pops out these messages on any DMA or CPU read access. Any DMA underflow errors are stored in the global status register while the overflow errors are stored in the corresponding channel's status register. In case of an overflow in Fast Messages, the newer messages received will overwrite the previous message.

For detailed description on the complete functionality of each block, see [Section 55.4](#), "[Functional description](#)".

55.2 External signal description

This section lists all inputs to the SENT block.

55.2.1 SENT_RX [(CH-1):0]

These pins serve as the serial data input for each of the SENT channel. There is one bit per channel supported by the device. The SENT sensor input pads on the device using this module should have pull-up enabled to ensure a 1'b1 is seen at the module input when SENT sensor is not driving any data.

Note: The value of the CH is device-specific. See [Section 7.8.8, SENT receiver \(SRX\) configuration](#) for details.

55.3 Memory map and register definition

This section provides a detailed description of all registers accessible in the SENT block.

55.3.1 Memory map

[Table 1227](#) gives an overview on all SENT registers. The memory map comprises of 32-bit aligned registers which can be accessed via 8-bit, 16-bit, or 32-bit accesses. Write access to reserved locations will generate transfer error. Read access to reserved locations will also generate transfer error and the read data bus will show all 0s. The Memory Map and complete module is in Big Endian Format.

The module will not check for correctness of programmed values in Register Space and software must ensure that correct values are being written.

Note: $\text{Register Address} = \text{Base Address} + \text{Address Offset}$, where the Base Address is defined at the MCU level and the Address Offset is defined at the module level. The number of registers are device specific. See the Device Configuration chapter for details.

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

Table 1228. GBL_CTRL field descriptions

Field	Description
0:7 TSPRSC	Time Stamp Prescaler Value. Value in number of clock cycles of high frequency receiver clock set in order to obtain a clock frequency for the time stamp counter block. 0 – Prescaler Bypassed. Time Stamp Clock = High Frequency Receiver Clock 1 to 255 – Value set by user software to obtain a clock period of at least 1μs for the time stamp counter. If the high frequency clock input is 75 MHz, then the value set in this field would be 0x4B (or 75) to obtain a 1μs clock. Note: Since the time stamp clock is common for all channels, the timestamp clock frequency must be at least twice the fastest receiver channel in the application. This is to ensure that the time stamp clock is fast enough to show change in timestamp from message to message.
8:15	Reserved. Read returns zero
16:21	Reserved. Read returns zero

Table 1228. GBL_CTRL field descriptions (continued)

Field	Description
22 FMDUIE	Fast Message DMA Underflow Interrupt Enable: Enables interrupt assertion when there is an underflow condition on Fast Message DMA registers. Default value is 0. 0 – Interrupt is disabled 1 – Interrupt is enabled
23 SMDUIE	Slow Serial Message DMA Underflow Interrupt Enable: Enables interrupt assertion when there is an underflow condition on Slow Message DMA registers. Default value is 0. 0 – Interrupt is disabled 1 – Interrupt is enabled
24	Reserved. Read returns zero
25	Reserved. Read returns zero
26	Reserved. Read returns zero
27 FAST_CLR	Fast Clearing Enable bit. Enables clearing of ready status (for both fast and slow) bit automatically when corresponding message is read. Default value is 1. See Fast Message Ready Status Register (FMSG_RDY) and Slow Serial Message Ready Status Register (SMSG_RDY) for details on the ready status bits. 0 – Fast Clearing is disabled. Bits will be cleared by writing 1 1 – Fast Clearing is enabled
28	Reserved. Read returns zero
29 DBG_FRZ	Debug Freeze. This bit will enable the debug mode support. SENT Module will freeze in debug mode if this bit is set. Default is 0. 0 – No effect in debug mode 1 – Freeze in debug mode
30	Reserved. Read returns zero
31 SENT_EN	SENT Receiver Global Enable. This bit enables or disables the complete receiver module irrespective of the setting of individual channel enable bits. User software must program all channel parameters before setting this bit. Default is 0. 0 – Entire module is disabled 1 – Module is enabled

55.3.2.2 Channel Enable Register (CHNL_EN)

This register is used to enable individual SENT Receiver channels in the module. The user software must ensure all channel parameters and control settings have been programmed before writing to this bit. In case these parameters are changed while the channel is enabled, normal operation is not guaranteed.

Note: The following register figure and table shows the maximum possible configuration but the exact number of valid register bits are dependent on supported SENT channels on the device. Please see Device Configuration chapter for number of support SENT channels. Reads of bits beyond the supported number of channels should be ignored and these bits must be written to 0.

Table 1230. GBL_STATUS field descriptions

Field	Description
0:21	Reserved. Read returns zero
22 FMDU	Fast Message DMA Underflow: Interrupt Status bit that indicates when there is an underflow in Fast Message buffers in any channel which has DMA enabled. This bit is set when there is no message in the DMA buffers for read and the software still reads the Fast Message DMA register. Default value is 0. 0 – No underflow 1 – Underflow occurred

Table 1230. GBL_STATUS field descriptions (continued)

Field	Description
23 SMDU	Slow Serial Message DMA Underflow: Interrupt Status bit that indicates when there is an Underflow in Slow Serial Message DMA buffers on channel which has DMA enabled. The bit is set when there is no message in the DMA buffers for read and the software still reads the Slow Serial Message registers. Default value is 0. 0 – No underflow 1 – Underflow occurred
24:31	Reserved. Read returns zero

55.3.2.4 Fast Message Ready Status Register (FMSG_RDY)

The bits of this register are asserted when a Fast Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via [Fast Message DMA Control Register \(FDMA_CTRL\)](#)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via [Fast Message Ready Interrupt Control Register \(FRDY_IE\)](#)) and the channel is enabled, the message ready status bit in this register will get asserted on Fast Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Proper flow cannot be guaranteed if neither is selected.

These bits can be configured to be cleared via “Write 1 to Clear” or “Fast Clearing Mechanism”. The configuration is done by writing to the FAST_CLR bit in the [Global Control Register \(GBL_CTRL\)](#).

Note: The following register figure and table shows the maximum possible configuration but the exact number of valid register bits are dependent on supported SENT channels on the device. Please see the Device Configuration chapter for number of support SENT channels. Reads of bits beyond the supported number of channels should be ignored and writes to these bits are inadvisable and may cause unexpected behavior.

W	*(1)	*(1)	*(1)	*(1)	*(1)	*(1)	*(1)	*(1)
Reset	0	0	0	0	0	0	0	0

1. This bit is either “write 1 to clear” (w1c) or self-clearing depending on the value of the FAST_CLR bit in the [Global Control Register \(GBL_CTRL\)](#).

Table 1231. FMSG_RDY field descriptions

Field	Description
0:15	Reserved. Read returns zero
16:31 F_RDYn (n = 15 to 0)	Fast Message Data Ready Status Bit. Indicates that a Fast Message is ready to be read by CPU from that specific channel. This bit is asserted only when DMA is NOT enabled for that channel (from the DMA Control Register) and an error free message is received, irrespective of the value of corresponding enable bit in Message Ready Interrupt Control Register. Reading the message from the corresponding memory-mapped Fast Message Read Registers would automatically clear this bit (Fast Clearing Mechanism). 0 – No Fast Message is available to be read out via Interrupt 1 – Fast Message is available to be read out via Interrupt The clearing mechanism is selected by user by programming the FAST_CLR bit in the Global Control register. See Section Global Control Register (GBL_CTRL) for details on FAST_CLR bit. <i>Note: When using the fast clearing option, these bits will not clear till the complete message is read out which requires the CPU to read all 3 fast message registers via 32-bit read accesses. For 8/16-bit accesses fast clearing mechanism should not be used as it is not supported.</i> <i>Note: When the fast clearing option is not configured, the bits will be cleared only if 1 is written to those bits.</i>

55.3.2.5 Slow Serial Message Ready Status Register (SMSG_RDY)

The bits of this register are asserted when a Slow Serial Message arrives on a corresponding channel that is not configured to be read via DMA. If a channel is not configured for DMA (via [Fast Message DMA Control Register \(FDMA_CTRL\)](#) and [Slow Serial Message DMA Control Register \(SDMA_CTRL\)](#)), it is assumed to be read via Interrupt or Polling this status bit. Even if the Interrupt Enable bit for that channel is not set (via [Fast Message Ready Interrupt Control Register \(FRDY_IE\)](#) and [Slow Serial Message Ready Interrupt Enable Register \(SRDY_IE\)](#)) and the channel is enabled, the message ready status bit in this register will get asserted on Slow Message reception. Software must ensure that if a channel is enabled; either DMA or Interrupt must be enabled for that channel. Erroneous flow can happen if neither is selected.

These bits can be configured to be cleared via “Write 1 to Clear” or “Fast Clearing Mechanism”. The configuration is done by writing to the FAST_CLR bit in the [Global Status Register \(GBL_STATUS\)](#).

Note: The following register figure and table shows the maximum possible configuration but the exact number of valid register bits are dependent on supported SENT channels on the device. Please see Device Configuration chapter for number of support SENT channels. Reads of bits beyond the supported number of channels should be ignored and writes to these bits are inadvisable and may cause unexpected behavior.

Table 1240. DMA_FMSG_CRC field descriptions

Field	Description
0:11	Reserved. Read returns zeros.
12:15 CRC4b	4-bit CRC value of the message.
16:31	Reserved. Read returns zeros.

55.3.2.14 DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the [Global Control Register \(GBL_CTRL\)](#) register. DMA Source Size must be set to 32 bits when reading this register (DMA_FMSG_TS) via DMA.

Figure 1277. DMA Fast Message Time Stamp Read Register (DMA_FMSG_TS)

Table 1241. DMA_FMSG_TS field descriptions

Field	Description
0:31 TS	Time Stamp for received message. Indicates the relative time when the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) was detected

55.3.2.15 DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)

The above register (DMA_SMSG_BIT3) is common for all types of slow serial messages. Bit C defines the type of enhanced packet and bit TYPE defines whether it is short serial or enhanced serial message. Since this register is used to read both Short and Enhanced Serial Messages, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in [Figure 1286](#), [Figure 1287](#) and [Figure 1288](#). [Figure 1286](#) and [Figure 1287](#) shows the enhanced serial messages format to be used when reading this register for these two types of messages. [Figure 1288](#) shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Figure 1278. DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3)

Address Offset = 0x0050

Table 1242. DMA_SMSG_BIT3 Field Descriptions

Field	Description
0:3 CHNUM	Channel Number. Indicates the channel number of the received message being read by DMA. Valid values are 0 to '15'
4 TYPE	Serial Message Type. Indicates the type of Serial Message received 0 – Short Serial Message 1 – Enhanced Serial Message
5:19	Reserved. Read returns zeros
20	Placed as 0 by Specification
21 CFG	Configuration bit 'C'. Indicates the type of Enhanced Serial message 0 – Enhanced Serial Message with 8-bit ID field 1 – Enhanced Serial Message with 4-bit ID field
22:25 ID[7:4]/ID[3:0]	ID Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[7:4] and if the 'C' bit is 1, this field is ID[3:0]
26	0 as per SAE Specification
7:30 ID[3:0]/DATA[15:12]	ID or Data Field. Value depends on setting of 'C' bit. If 'C' bit is 0, this field is ID[3:0] and if the 'C' bit is 1, this field is Data[15:12]
31	0 as per SAE Specification

Note: *If the TYPE bit in the register reads '0', then remainder bits (for CFG, ID & DATA) will be redundant and read zeros. The short serial message will be located in DMA_SMSG_BIT2 register fields. If TYPE bit is '1', then the message in register is Enhanced Serial Message and using CFG bit, software can decode the ID & DATA fields.*

55.3.2.16 DMA Slow Serial Message Bit2 Read Register (DMA_SMSG_BIT2)

This register (DMA_SMSG_BIT2) is common for all types of slow serial messages. Hence, the register fields have been placed in such a way to match the bit positions in actual message defined by SAE Specification as shown in [Figure 1286](#), [Figure 1287](#) and [Figure 1288](#). [Figure 1286](#) and [Figure 1287](#) shows the enhanced serial messages format to be used when reading this register for these two types of messages. [Figure 1288](#) shows the short serial message.

DMA Source Size must be set to 32 bits when reading this register via DMA.

Table 1243. DMA_SMSG_BIT2 field descriptions

Field	Description
0:9	Reserved. Read returns zeros.
10:15 SMCRC	6-bit CRC value of the message. When TYPE bit in DMA Slow Serial Message Bit3 Read Register (DMA_SMSG_BIT3) is set to 0, this CRC is of 4-bits for Short Serial Messages and when TYPE bit is set to 1, this CRC is of 6-bits for Enhanced Serial Messages.
16:19	Reserved. Read returns zeros.
20:31 DATA[11:0]	12-bit Data Value

55.3.2.17 DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)

The resolution of the time stamp is set by programming the Time Stamp Prescaler Value in the [Global Control Register \(GBL_CTRL\)](#) register.

DMA Source Size must be set to 32 bits when reading this register (DMA_SMSG_TS) via DMA.

Figure 1280. DMA Slow Serial Message Time Stamp Read Register (DMA_SMSG_TS)

Address Offset: 0x0058

Access: R

**Table 1244. DMA_SMSG_TS field descriptions**

Field	Description
0:31 TS	Time Stamp for the received message. Indicates the relative time of detection of the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) of the last Fast Message that completed the Serial Message. Time Stamp for Slow Serial Messages is not latched when the Slow Serial Message starts but when the Slow Serial Message is completely received.

55.3.2.18 Channel 'n' Clock Control Register (n = 0 to (CH-1)) (CHn_CLK_CTRL)

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

The SENT module generates the Receiver Sensor Clock (or simply Receiver Clock) internally to sample the incoming filtered sensor data. The user software must program the prescaler value (for Receiver Clock) to match the ideal Sensor Tx Clock period. The generated Receiver Clock is compensated for variations, clock drift and jitter that might occur in the Sensor Tx Clock. See [Section 55.4.5, "Adjustment for variation in sensor \(Tx\) clock"](#) for more details.

This register configures the generation and subsequent compensation logic of the Receiver Clock. User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the [Channel Enable Register \(CHNL_EN\)](#).

Figure 1281. Channel 'n' Clock Control Register (CHn_CLK_CTRL)

Address Offset = $0x0060 + n \times 0x10$

Access: RW

Table 1245. CHn_CLK_CTRL field descriptions

Field	Description
0	Reserved. Read returns zero
1:15 CM_PRSC	Compensated Prescaler Value. This is the compensated prescaler value calculated by Clock Compensation logic and this value is used to compensate for sensor Tx clock variation. This value is indicated as a read only field for use by user software, if needed. This is a 15-bit value. '= Rx Prescaler Value' – No variation, hence no compensation or Compensation is disabled '< Rx Prescaler Value' – Tx Clock is SLOWER than the programmed receive clock '> Rx Prescaler Value' – Tx Clock is FASTER than the programmed receive clock Thus, the new Receiver Clock Tick Period can be computed by software as <i>Compensated Prescaler Value</i> × <i>High Frequency Receiver Clock Period</i>

Table 1245. CHn_CLK_CTRL field descriptions (continued)

Field	Description
16 COMP_EN	Compensation Enable. To enable compensation logic to adjust the receiver clock against variation in Tx clock on this channel. User must set the Prescaler Value before enabling this bit. 0 – Compensation is disabled 1 – Compensation is enabled
17	Reserved. Read returns zero
18:31 PRSC	Rx Prescaler Value. This factor is required to generate required Receiver Clock tick from the High Frequency Receiver Clock. This value can only be written when Channel Enable bit is Zero. Hence this value must be programmed before enabling the channel. If required receiver clock tick period (T_{rx_clk}) is not divisible by the high frequency receiver clock (protocol clock) period (T_{hf_clk}), the required prescaler value will have a fractional part which cannot be programmed. In this case then user is advised to program the prescaler value to the lower integer value. 0 – Prescaler is bypassed. Should not be used. Non-Zero Value – Enables Prescaler The required value is computed by software as follows: Equation 81 $\text{Prescaler_value} = \text{floor}\left(\frac{T_{rx_clk}}{T_{hf_clk}}\right)$ (both clock periods taken in μs). Please see Section 55.5.3, “High frequency receiver clock (protocol clock) requirements before setting this value. For example, if the required receiver clock tick period is 43 μs and the High Frequency Receiver clock is selected to be 62.5 MHz (or 0.016 μs) then, Prescaler Value = 43/0.016 = 2687.5. Hence user must program 2687 in this register.

55.3.2.19 Channel ‘n’ Status Register (n = 0 to (CH-1)) (CHn_STATUS)

This registers stores information about certain events and error conditions that occur in the channel during the message reception process. The assertion of these bit is not linked to any message but it is a general alert to the CPU that a particular condition (error or normal event) happened in the recent past. Messages are automatically discarded when an error is detected.

User software can clear these bit at any time by writing 1 to them. This register can be updated at any time irrespective of the setting in the [Channel Enable Register \(CHNL_EN\)](#) bit for the corresponding channel.

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

Table 1246. CHn_STATUS field descriptions

Field	Description
0 BUS_IDLE	Bus Idle Status. This bit indicates that the sensor interface has been idle for more than the period defined by the programmed Bus Idle Count value (in Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)). CPU should write 1 to this clear this bit once it is read. 0 – Bus is not idle 1 – Channel has been idle for more than the allowed value
1:3	Reserved. Read returns zero
4 CAL_RESYNC	Successive Calibration Check (Option 2 of SAE SENT Spec) Resynchronized. This bit indicates that Successive Calibration Check (Option 2 of SAE Spec) has failed three times and has resynchronized to assume 3rd message to be correct and will be received. The successive calibration check error will also be asserted during re-synchronization (to indicate the 3rd error being detected). 0 – No interrupt 1 – Interrupt Status condition has occurred
5 CAL_20_25	Calibration Variation 20 – 25% Interrupt Status. This bit indicates that the calibration pulse received on this channel has variation in between $\pm 20\%$ to $\pm 25\%$ from 56 ticks. 0 – No Interrupt 1 – Interrupt Status condition has occurred
6 MSG_OFLW	Slow Serial Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow will cause the older messages (which are not read out) to be overwritten with newly received messages. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 – No Interrupt 1 – Interrupt Status condition has occurred
7 FMSG_OFLW	Fast Message Overflow Status. This bit indicates overflow occurred on this channel. Overflow happens when effective data read rate by CPU is slower than data receive rate on channel. On overflow, new incoming messages will overwrite the previous messages (that are not read out) stored in the receiver buffers. However, any message that is currently being read out by DMA or CPU will not get over-written. 0 – No Interrupt 1 – Interrupt Status condition has occurred
8	Reserved. Read returns zero

Table 1246. CHn_STATUS field descriptions (continued)

Field	Description
9:15	Diagnostic Checks Status bits. These bits indicate which diagnostic has failed or passed on this channel. These bits are cleared by writing 1 to them. NUM_EDGES_ERR: Not the expected number of negative edges between calibration pulse. This bit will not set in case of “Option 2” for successive calibration pulse check is selected. This error will only set when “Option 1” for successive calibration check is selected (SUCC_CAL_CHK). FMSG_CRC_ERR: Checksum error in Fast Message SMSG_CRC_ERR: Checksum error in Slow Serial Message NIB_VAL_ERR: Any nibble data value <0 or >15 CAL_DIAG_ERR: Successive Calibration pulses differ by $\pm 1.56\%$. SAE spec defines it be 1.5625% but the accuracy of this check depends on the frequency of protocol clock (See Section 55.5.3, “High frequency receiver clock (protocol clock) requirements). CAL_LEN_ERR: This bit indicates that Calibration pulse is more than 56 ticks $\pm 25\%$. PP_DIAG_ERR: This bit indicates that the ratio of calibration pulse length to overall message length (with pause pulse) is more than $\pm 1.5625\%$ between two messages. This check is valid only for messages with pause pulse. 0 – Error Check has passed 1 – Error Check has failed
15:016:31	Reserved. Read returns zero

55.3.2.20 Channel ‘n’ Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)

This register (CHn_CONFIG) provides the configurability for interrupt assertion for various events and error as explained in [Channel ‘n’ Status Register \(n = 0 to \(CH-1\)\) \(CHn_STATUS\)](#) and control bits for selection of various receive options that might be required by the user software. This register also configures the width of noise glitches (on the sensor input) to be filtered out by the input programmable filter.

User must program the contents of this register before enabling the channel by writing to the corresponding channel enable bit in the [Channel Enable Register \(CHNL_EN\)](#).

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

Table 1247. CHn_CONFIG field descriptions

Field	Description
0:3 BUS_IDEL_CNT	Bus Idle Count: This register value defines the maximum allowable idle period on the sensor interface of this channel. The value is defined as follows: 0000: Disabled. 0001: 127*2 Receiver Clock Tick Counts 0010: 127*4 Receiver Clock Tick Counts 0100: 127*8 Receiver Clock Tick Counts 1000: 127*16 Receiver Clock Tick Counts
4 IE_CAL_RESYNC	Successive Calibration Check Resynchronized Interrupt Enable: This bit enables interrupt assertion when Successive Calibration diagnosis has failed three times in case of "Option 2" being selected for Successive Calibration Check Method and the check resynchronizes the take the third message to be correct. 0 – Interrupt is disabled 1 – Interrupt is enabled
5 IE_CAL_20_25	Calibration Variation 20 - 25% Interrupt Enable. This bit enables interrupt assertion when corresponding status bit is set. 0 – Interrupt is disabled 1 – Interrupt is enabled
6 IE_SMSG_OFLW	Slow Serial Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Slow Serial Messages in corresponding channel 0 – Interrupt is disabled 1 – Interrupt is enabled
7 IE_FMSG_OFLW	Fast Message Overflow Interrupt Enable. This bit enables interrupt assertion when overflow occurs on reception of Fast Messages in corresponding channel. 0 – Interrupt is disabled 1 – Interrupt is enabled
8 FCRC_CHK_OFF	Fast Message CRC Check Off: This bit can be used to switch off CRC check in Fast Message 0 – Check is enabled 1 – Check is disabled/off

Table 1247. CHn_CONFIG field descriptions (continued)

Field	Description
9:15	Diagnostic Checks Interrupt Enable bits. These bits enables interrupts assertion when respective diagnostic checks fail on corresponding channel. IE_NUM_EDGES_ERR: Not the expected number of negative edges between calibration pulse IE_FMSG_CRC_ERR: Checksum error in Fast Message IE_SMSG_CRC_ERR: Checksum error in Slow Serial Message IE_NIB_VAL_ERR: Any nibble data value <0 or >15 IE_CAL_DIAG_ERR: Successive Calibration pulses differ by more than $\pm 1.56\%$. SAE spec defines it be 1.5625% but the accuracy of this check depends on the protocol clock. For instance for 62.5 MHz, this check will fail for 1.56% and passes for 1.55% IE_CAL_LEN_ERR: Calibration pulse is wider than 56 ticks $\pm 25\%$ IE_PP_DIAG_ERR: Ratio of calibration pulse length to message length varies by more than $\pm 1.5625\%$ between two frames. Valid for messages with pause pulse. Configuration option for each bit as below: 0 – Interrupt is disabled 1 – Interrupt is enabled
16 DCHNG_INT	Enable for Interrupt on Reception of Fast Message with Changed Data: This bit is used to enable storing and generating corresponding DMA or Message Ready Interrupt Request for Fast Message only when any of the data nibbles after different from previously received Fast Message on that channel. If a new Fast Message is received that has same values for all data nibbles as that of previous message then the current message will be discarded and will not be stored in the buffer, and neither Fast Message Ready Interrupt nor DMA request will be generated. 0 – All Fast Messages will be received even if data nibbles are same 1 – Only Fast Messages with differing values of data nibbles will be received
17 CAL_RNG	Valid Calibration Pulse Range Selection: This bit is used to control whether 20% variation or 25% variation in Calibration Pulse will be tolerated when detecting a Calibration Pulse 0 – 20% variation is acceptable 1 – 25% variation is acceptable
18 PP_CHKSEL	Pause Pulse Diagnostic Check Selection: This bit controls which diagnostic checks to run when messages are enabled to be received with pause pulses. 0 – Both Successive Calibration Pulse Check and Pause Pulse Diagnostic are run 1 – Only Pause Pulse Diagnostic is run. Successive Calibration Pulse Check is disabled.
19 FCRC_TYPE	Fast Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received fast messages 0 – XOR based implementation (Recommended by SAE Specification) 1 – Legacy LUT based implementation

Table 1247. CHn_CONFIG field descriptions (continued)

Field	Description
20 FCRC_SC_EN	Fast Message CRC Status and Communication Nibble Enable. This bit enables the inclusion of Status and Communication Nibble when CRC is calculated for Fast Messages. 0 – Status and Communication Nibble <u>not</u> included in CRC calculation 1 – Status and Communication Nibble is included in CRC calculation
21 SCRC_TYPE	Slow Serial Message CRC Type. This indicates the type of CRC method to be used for CRC Diagnostic Check on the received slow serial messages. 0 – XOR based implementation (Recommended by SAE Specification) 1 – Legacy LUT based implementation
22 PAUSE_EN	Pause Pulse Enable. Enables the channel receiver to detect a pause pulse. 0 – Detection of Pause Pulse is disabled 1 – Detection of Pause Pulse enabled
23 SUCC_CAL_CHK	Successive Calibration Pulse Check Method. This bit indicates the method to be used for performing the successive calibration pulse check. Default value is 1. 0 – Option 2 i.e. Low Latency Option as per SAE Specification 1 – Option 1 i.e. Preferred but High Latency Option as per SAE Specification
24:31 FIL_CNT	Input Filter Sample Count. This indicates the number of Protocol Clock (of High Frequency Receiver Clock) cycles required for channel input from device's pad to remain stable before it is sampled as 0 or 1. This field defines the width of glitches to be filtered out by the input programmable filter on that channel. Only one bit should be set in this field and the output of filter will be offset by twice the same number of clocks plus additional 3 clocks due to synchronization. Default value is '4'. 0 – No filtering. Input from device's pad is only synchronized Non-Zero – Filtering is enabled

55.3.2.21 Channel 'n' Fast Message Data Read Register (n = 0 to (CH-1)) (CHn_FMSG_DATA)

Address offset: $0x0160 + 0x18 \times n$

This is register CHn_FMSG_DATA. The contents of this register are same as [DMA Fast Message Data Read Register \(DMA_FMSG_DATA\)](#).

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

55.3.2.22 Channel 'n' Fast Message CRC Read Register (n = 0 to (CH-1)) (CHn_FMSG_CRC)

Address offset: $0x0164 + 0x18 \times n$

This is register CHn_FMSG_CRC. The contents of this register are same as [DMA Fast Message CRC Read Register \(DMA_FMSG_CRC\)](#).

55.3.2.23 Channel 'n' Fast Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_FMSG_TS)

Address offset: $0x0168 + 0x18 \times n$

This is register CHn_FMSG_TS. The contents of this register are same as [DMA Fast Message Time Stamp Read Register \(DMA_FMSG_TS\)](#).

55.3.2.24 Channel 'n' Serial Message Read Register (Bit 3) (n = 0 to (CH-1)) (CHn_SMSG_BIT3)

Address offset: $0x016C + 0x18 \times n$

This is register CHn_SMSG_BIT3. The contents of this register are same as [DMA Slow Serial Message Bit3 Read Register \(DMA_SMSG_BIT3\)](#).

Note: The value of the CH is device-specific. See the Device Configuration chapter for details.

55.3.2.25 Channel 'n' Serial Message Read Register (Bit 2) (n = 0 to (CH-1)) (CHn_SMSG_BIT2)

Address offset: $0x0170 + 0x18 \times n$

This is register CHn_SMSG_BIT2. The contents of this register are same as [DMA Slow Serial Message Bit2 Read Register \(DMA_SMSG_BIT2\)](#).

55.3.2.26 Channel 'n' Serial Message Time Stamp Read Register (n = 0 to (CH-1)) (CHn_SMSG_TS)

Address offset: $0x0174 + 0x18 \times n$

This is register CHn_SMSG_TS. The contents of this register are same as [DMA Slow Serial Message Time Stamp Read Register \(DMA_SMSG_TS\)](#).

55.3.3 Register Classification for Safety

The registers of this module are classified as per Safety Requirements as follows:

Safety Critical: There are no safety critical registers in this module.

Safety Relevant: The register bits/fields in this category are safety relevant as any random error in these bits will lead to unwanted interference to CPU/DMA. The registers containing these bits must be protected by periodic CRC or equivalent check implemented at SoC Level. The following register bits/fields are classified in this category:

- [Global Control Register \(GBL_CTRL\)](#)
- [Channel Enable Register \(CHNL_EN\)](#)
- [Fast Message Ready Status Register \(FMSG_RDY\)](#)
- [Slow Serial Message Ready Status Register \(SMSG_RDY\)](#)
- [Data Control Register 1 \(DATA_CTRL1\)](#) and [Data Control Register 2 \(DATA_CTRL2\)](#)
- [Fast Message DMA Control Register \(FDMA_CTRL\)](#)
- [Slow Serial Message DMA Control Register \(SDMA_CTRL\)](#)
- [Fast Message Ready Interrupt Control Register \(FRDY_IE\)](#)
- [Slow Serial Message Ready Interrupt Enable Register \(SRDY_IE\)](#)
- Fast Message DMA Read Register Set and Slow Message DMA Read Register Set

Safety Latent: The register bits/fields in this category should be protected by LBIST at SoC level. The following register bits/fields are classified in this category:

- [Global Status Register \(GBL_STATUS\)](#)
- [Channel 'n' Status Register \(n = 0 to \(CH-1\)\) \(CHn_STATUS\)](#)
- [Channel 'n' Configuration Register \(n = 0 to \(CH-1\)\) \(CHn_CONFIG\)](#)

Non-Safety: The following register bits are classified in this category:

- All other registers and bits fall in this category

55.4 Functional description

55.4.1 Initialization sequence

All the channels are required to be configured before enabling them by writing into corresponding channel enable bit in the [Channel Enable Register \(CHNL_EN\)](#). There are some registers which must be configured and some which are to be changed if reset value is not as required for that channel. After enabling the channel, no configuration should be changed and if required to be changed, the user needs to first disable the channel and then reconfigure the channel parameters. The following must to be configured before enabling the corresponding channel:

- Time Stamp Prescaler Value in [Global Control Register \(GBL_CTRL\)](#) to generate the time stamping clock
- Rx Prescaler Value in [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(CHn_CLK_CTRL\)](#) to generate the channel's receiver clock
- Compensation enable in [Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(CHn_CLK_CTRL\)](#)
- Channel Configuration settings in the [Channel 'n' Configuration Register \(n = 0 to \(CH-1\)\) \(CHn_CONFIG\)](#)
- Number of Data Nibbles in Channel in the [Data Control Register 1 \(DATA_CTRL1\)](#) and [Data Control Register 2 \(DATA_CTRL2\)](#)
- Control bits that control whether messages received in channel are to read by interrupt or DMA in [Fast Message DMA Control Register \(FDMA_CTRL\)](#), [Slow Serial Message DMA Control Register \(SDMA_CTRL\)](#), [Fast Message Ready Interrupt Control Register \(FRDY_IE\)](#) and [Slow Serial Message DMA Control Register \(SDMA_CTRL\)](#)

55.4.2 DMA read logic

The SENT module generates separate DMA requests for all Fast Messages and Slow Serial Messages received. The DMA requests are common for all channels. Each packet stored in the channels' buffers are appended with a time stamp taken from a free running time keeping counter and the channel number on which it was received. Details on this time stamp counter can be found in [Section 55.4.8, "Time stamp logic"](#).

55.4.2.1 DMA request for Fast Message reading

Fast Messages received are stored in a single system bus clock domain buffer to be read out by the DMA Controller via the DMA Fast Message Read register set. Note the DMA

Controller must read all 3 DMA Read Registers to obtain the complete message. The data flow will happen as follows:

- A DMA request will be asserted when any of the DMA enabled channels has successfully received one complete Fast Message. The request is kept asserted till all messages (across DMA enabled channels) have been read out.
- DMA Controller should read the complete message by accessing each register of the DMA Fast Message Read register set, the registers being:
 - [DMA Fast Message Data Read Register \(DMA_FMSG_DATA\)](#)
 - [DMA Fast Message CRC Read Register \(DMA_FMSG_CRC\)](#)
 - [DMA Fast Message Time Stamp Read Register \(DMA_FMSG_TS\)](#)
- A fixed round robin sequencing runs, as shown in [Figure 1284](#), and this logic checks for messages in sequence 0→1→3→5→7 and back to channel 0 and so on. Channel 2 is skipped as it's not DMA enabled) and channel 4 and 6 are skipped as message is not received completely. This sequence continues like this.
- The sequence in which messages are read through DMA interface is not deterministic and depends on the sequence in which they are completely received.
- When the sequencing logic detects a message ready to be read, it will update the DMA Fast Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 read accesses to the above mentioned registers)
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- User software should ensure there is no overflow in channels. In case overflow occurs, the message in the channel buffer will get overwritten by the newly received message. However, when a DMA read is in progress, the buffers will not be overwritten if overflow occurs to maintain data integrity.
- The Round Robin sequencing logic loops through each DMA enabled channel and halts at any channel having data till it is read out by the DMA Controller.

Figure 1284. Fast Message DMA read logic

55.4.2.2 DMA request for Slow Serial Message reading

A separate DMA request (different from DMA request for Fast Message) is generated for all slow serial messages received on all channels. The data flow will happen as follows:

- Request will be asserted when any of the DMA enabled channels has successfully received one complete serial message (short or enhanced) and kept asserted till all messages have been read from their respective memory-mapped registers
- Similar to DMA read for Fast Messages, data for slow serial messages will be read from DMA Slow Serial Message Read register set in memory map, the register set comprising of:
 - [DMA Slow Serial Message Bit3 Read Register \(DMA_SMSG_BIT3\)](#)
 - [DMA Slow Serial Message Bit2 Read Register \(DMA_SMSG_BIT2\)](#)
 - [DMA Slow Serial Message Time Stamp Read Register \(DMA_SMSG_TS\)](#)
- A fixed round robin sequencing logic will be running and it will update the DMA Slow Serial Message Read register set for DMA read and move to the next channel when this message is read out completely (i.e., 3 DMA read accesses to the above mentioned registers)
- The channel number and time stamp will also be appended for every message
- A message type bit (TYPE) will also be appended to distinguish between short and enhanced serial messages
- The DMA controller should be programmed to read only one message in one DMA transfer (i.e. 12 bytes). If it is programmed to read more than one message in one DMA transfer, underflow in buffers might occur
- Since serial messages receive rate is very slow, user software should ensure there is no overflow
- The fixed round robin sequence logic for DMA read is the same as that used for Fast Messages (see [Section 55.4.2.1, DMA request for Fast Message reading](#))

[Figure 1285](#) shows the sequencing of channels for serial messages to be read when DMA read is done on DMA Slow Serial Message Read register set.

Figure 1285. Slow Serial Message DMA read logic

Note: The arrows in the figure indicate next DMA transfer. One DMA Read Register set (3 registers) will be read in

The formats in which the 3 types of Serial Messages will be stored in the buffers are shown in figures below.

Figure 1286. Enhanced Serial Message with 8-bit ID field

Figure 1287. Enhanced Serial Message with 4-bit ID field

Figure 1286 and Figure 1287 shows the enhanced serial messages. Bit C (shown in figure) or bit CFG (as shown in [DMA Slow Serial Message Bit3 Read Register \(DMA_SMSG_BIT3\)](#) description) defines the type of enhanced packet and bit P (shown in figure) or bit TYPE (shown in [DMA Slow Serial Message Bit3 Read Register \(DMA_SMSG_BIT3\)](#) description) defines whether it is short serial or enhanced serial message. CRC, ID and Data fields are stored in format as received and shown in SAE specification with just one exception that CRC is shifted to align with 16-bit boundary.

Figure 1288 shows the short serial message. Field locations have been placed in such a way to allow a common register to read all the slow serial messages and also match the bit positions in actual message defined by SAE Specification.

Figure 1288. Short serial message

Again, three 32-bit accesses to be made by DMA to get one complete message with time stamp.

55.4.3 Message reading via interrupts

There is one interrupt request per channel for a Fast message received and one for a serial message received. Each channel is individually configurable to enable or disable interrupt on reception of Fast or Slow Serial messages separately. In case of interrupt request of Fast Message, an interrupt will be asserted when any of the channels has received a complete Fast Message without errors and that channel is not configured for DMA Reads. The interrupt routine should be coded in such a way to take the least amount of overhead (in CPU cycles) while entering the routine and start reading the available messages. The routine should be capable of accessing all channels that are enabled to give out messages via interrupts through the Register Interface.

In response to these interrupts, the CPU is expected to read interrupt status register for fast or Slow Messages (depending on which interrupt was asserted) and store it in system memory. Using this status register value, the interrupt routine can decide from which channels the message is to be read. For instance if bit corresponding to channel 0 is set then routine should read from the address location corresponding to Channel 0 Fast Message Read registers and move onto the next asserted bit. The interrupt routine should scan through all the bits of this stored interrupt status register value and read corresponding channel's fast or Slow Message registers. In this manner all available messages can be read. After scanning through all the bits of status register stored in system memory, routine can read again the message ready interrupt status register to find out if any other channel has received in the mean time. This will save another interrupt routine time mainly from stacking/unstacking delay.

It is assumed that the interrupt controller will be able to respond fast enough to avoid any overflow as only one message per channel will be stored and the system bus clock frequency is sufficient to avoid this.

55.4.3.1 Suggested software interrupt service routine steps

These are suggested step to have an interrupt routine that can read all messages quickly and avoid any underflow/overflow. Actual implementations can vary.

When separate Fast Message and Slow Serial Message Interrupts are used:

The Fast Message Interrupt should have higher priority than Slow Serial Message Interrupt. The suggested ISR steps for a Fast Message Interrupts can be

- Read the Fast Message Ready Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register set (3 registers). Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Fast Message Status Registers again to ensure no new message has arrived during the ISR.
- If there are no bits set, exit the ISR, else repeat this process.

The ISR steps for Slow Serial Message Interrupt can be same as for Fast Message ISR.

When common Fast Message and Slow Serial Message Interrupts are used:

The suggested ISR steps can be

- Read the Fast Message Status Register and store it in a variable
- Shift out bits starting from MSB from this variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Fast Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, read the Slow Serial Message Status Register into a new variable
- Shift out bits starting from MSB from this new variable
- If bit is 1, perform read operation on corresponding channel's memory-mapped Slow Serial Message Read Register. Three read accesses will fetch complete message. Shift out new bit. Repeat Step.
- Else if bit is 0, shift out new bit
- When all bits are shifted out, software can again check both Fast and Slow Serial Message Ready register to ready any message that might have been received while the routine was being serviced, or can choose to exit the routine.

55.4.4 Overflow behavior

This section describes the overflow behavior.

55.4.4.1 Fast messages buffers

Overflow in Fast Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, the newly received message overwrite the previously stored message and the overflow status bit is set. However, if overflow asserts while CPU/DMA is reading that channel (i.e. all 3 read registers have not yet been read), then that message is not overwritten. While messages are being overwritten, the slow message reception is not hampered.

55.4.4.2 Slow message buffers

Overflow in Slow Message buffers can occur when the CPU or DMA does not read messages from that channel for a long period of time. The receiver channel stores two messages in its buffers and indicates an overflow when these buffers are full.

When an overflow event occurs, further reception of slow messages is halted until the buffers are read out by CPU or DMA. Since it is less likely that CPU or DMA do not read the read registers for 32 or 36 fast message length duration, an overflow in slow messages would not be as frequent as in fast messages.

55.4.5 Adjustment for variation in sensor (Tx) clock

The clock used by the Channel Receiver (referred to as Receiver Clock, or Rx_CLK) to sample the message nibbles is generated from a High Frequency Receiver Clock or Protocol Clock. This high frequency receiver clock is divided using a prescaler counter which generates a tick when it rollovers on reaching a count equal to the Prescaler Value programmed in the channel's clock control register. The receive clock is generated separately for each channel. By varying this Prescaler Factor, we can control the period of the receive clock and make it close to the Transmitter clock used by the sensor for the particular channel.

After reset and once channel is enabled, the compensated prescaler value is set to Zero and the user software programs the Prescaler Value to obtain the desired receiver clock frequency for the particular channel. Thus, the receiver starts working by assuming that the transmitter is sending messages on the frequency that is programmed in its channel clock control register. The channel's input after filtering is continuously measured by the Prescaler Counter. The compensation logic checks each pulse length and determines the calibration pulse from them. When a calibration pulse is detected, the compensated prescaler value is computed and stored in the Channel's Clock Control Register ([Channel 'n' Clock Control Register \(n = 0 to \(CH-1\)\) \(CHn_CLK_CTRL\)](#)). Software can use this value to determine the variation in Tx Clock.

Note: A pause pulse may incidentally be detected as a synchronization/calibration pulse during start up after reset. The correction value would be computed on the pause pulse too but since the next synchronization pulse would follow, the logic would again detect the falling edge on the synchronization pulse and the correction value would now be correctly computed on the correct synchronization pulse.

The Clock Compensation or Correction happens for every messages that is received and the compensated prescaler value remains constant for that message.

55.4.5.1 Adjustment for nibble length variation

Section 6.2 of SAE Specifications specifies the maximum allowable limits for clock drift and jitter for the transmitter and receiver separately. This can cause the length of nibbles to vary and can cause incorrect sampling of data nibbles. This variation is adjusted by the SENT Receiver when nibbles are being sampled.

55.4.6 Input programmable filter

The Input Programmable Filter ensures that only valid input pin transitions are received by the SENT Receiver module. The input programmable filter is an 8-bit programmable up counter that increments on the high frequency receiver clock. The sensor input signal from device's pad is synchronized by high frequency receiver clock. When a state change occurs

in the sensor input signal, the 8-bit counter resets and starts counting up on the high frequency receiver clock. As long as the new state is stable on the pin, the counter remains incrementing. If a counter overflow occurs, the new pin value (i.e. sensor input) is validated and latched in the filtered output flop (also running on high frequency receiver clock). If the opposite edge appears on the sensor input before validation (i.e. overflow), the counter is reset and the input is not passed onto the filtered output. At the next pin transition, the counter starts counting again. Any pulse that is shorter than a full range of the masked counter is regarded as a glitch and it is not passed on to the filter output. The number of samples (or the match value of the up counter) is programmable by the user in the channel's configuration register (*Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)*). When zero is programmed into the registers, it bypasses the filter and the synchronized input is output as the filtered output. A non-zero value delays the filtered output by the number of clocks proportional to the programmed value in the Channel Configuration Register (*Channel 'n' Configuration Register (n = 0 to (CH-1)) (CHn_CONFIG)*). A timing diagram of the input filter is shown in *Figure 1289*.

Figure 1289. Input programmable filter timing diagram

55.4.7 Receiver diagnostics

Most of the receiver diagnostics are controlled by the Fast Message State Machine. The following checks are conducted by the receiver in each channel

- Calibration pulse length < 56 clock ticks – 25% or > 56 clock ticks + 25%
- Not the expected number of falling edges between calibration pulses. (Message length is pre-defined by each sensor device and programmed by user for each channel)
- Checksum error. Two 4-bit CRC checks and one 6-bit CRC check according to the message type. User has a programmable option to select the method of CRC to use i.e. Legacy or XOR-based.
- Any nibble data values measured as < 0 or > 15
- Successive calibration pulses differ by > +1.5625% (1/64) or < -1.5625%. The accuracy of this check will depend on the frequency of the protocol clock used.
- For messages with pause pulse, an additional diagnostic is done; however, this diagnostic will not fail any message (to reduce latency in message reception) but the failure of this diagnostic will be indicated in the channel's status register.

On detection of any of the above errors, the receiver rejects the current packet until a new calibration pulse is detected. Occurrence of an error is flagged in the respective channel's status register (*Channel 'n' Status Register (n = 0 to (CH-1)) (CHn_STATUS)*). If error interrupt is enabled, an error interrupt will be generated. There is a single error interrupt generated for all errors, so the CPU must read the status register to find out which error occurred. Once error condition is flagged, subsequent errors (except NUM_EDGES_ERR)

are automatically masked out until a valid calibration pulse is detected, after which all checks are automatically enabled. This is done to avoid multiple assertions of the interrupt to CPU in case the channel become unstable and send wrong data continuously.

55.4.7.1 Calibration pulse length check

The calibration pulse length check happens in conjunction with Clock Compensation Logic since current calibration pulse is detected in this block. The Clock Compensation Logic detects a calibration pulse of length between 42 and 70 tick counts. This check will assert the CAL_LEN_ERR status bit on failure.

55.4.7.2 Successive calibration pulse check

The successive calibration pulse check checks if successive calibration pulses differ by $> +1.5625\%$ ($1/64$) or $< -1.5625\%$. The accuracy of this check will depend on the frequency of the protocol clock used. Specifically, the higher the frequency, the closer the check will be to 1.5625% . So if protocol clock is T_{HF_CLK} and channel tick period is T_{TX_CLK} then the check will be of $1.5625\% \pm \{100 \times (4 \times T_{HF_CLK}) / (42 \times T_{TX_CLK})\}$. So it won't allow variance in clock of a channel by $1.5625\% - \{100 \times (4 \times T_{HF_CLK}) / (42 \times T_{TX_CLK})\}$. This check will assert the CAL_DIAG_ERR status bit on failure.

When Option 2 of successive calibration pulse check is enabled, the CAL_RESYNC bit will be asserted on every third successive error detected by this check.

55.4.7.3 Not the expected number of edges check

The number of negative edges between two successive calibration pulses is counted and compared with expected number of edges in case of preferred option of successive calibration pulse check. The expected number of nibbles is the sum of following:

- Status and Communication nibble (1 No.)
- Data nibbles (Programmable as per user software)
- CRC nibble (1 No.)
- Pause Pulse, if configured (1 No.)

This check ("Not the expected number of edges check") will assert the NUM_EDGES_ERR status bit on failure. The check does not run when Option 2 (low latency) of successive calibration pulse check is enabled. This check is not masked after any other error is detected so it could be redundant if it is flagged along with CAL_DIAG_ERR and CAL_LEN_ERR. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

55.4.7.4 Nibble value check

As part of this check, the lengths of the following nibbles are checked to remain in between 0 and 15 ticks:

- Status and Communication nibble
- all Data nibbles
- CRC nibble

The nibble value check will assert the NIB_VAL_ERR status bit on failure. This error can be flagged along with NUM_EDGES_ERR in which case the former can be ignored as the number of pulses in the message is incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. In case, errors are accumulated, the above cannot be deduced.

55.4.7.5 CRC check

The CRC check will compute both 4-bit and 6-bit CRC as requested by State Machine control logic. Two 4-bit CRCs and one 6-bit CRC are supported to compute the CRC on Fast/Slow Serial Message (4-bit CRC) and Enhanced Serial Message (6-bit CRC) respectively. The SENT Receiver Module allows the user to calculate the 4-bit CRC using either the legacy CRC implementation method or the new XOR-based CRC implementation via a control bit in the channel's corresponding control register. Please refer to SAE SENT Specification for details on CRC algorithm.

Asserting the CHn_CONFIG_REG[11] bit, causes the Status and Communication nibble to be included in the 4-bit CRC calculation for Fast Serial Messages. De-asserting this bit enables normal operation as described above.

This check will assert the FMSG_CRC_ERR or SMSG_CRC_ERR status bit on failure, depending on whether the check is run for Fast Message or Slow Message.

The FMSG_CRC_ERR can be flagged along with the NUM_EDGES_ERR, in which case the CRC error can be ignored as the number of pulses in the message was incorrect. However, this is true only when CPU is clearing error status bits as and when they are asserted. If errors are accumulated, the above cannot be deduced.

55.4.7.6 Pause pulse diagnostic

The pause pulse diagnostic checks whether the ratio of calibration pulse length to full message length (including pause pulse) varies from one message to another by less than 1.5625% (as per spec). In order to have reduced latency of operation, message reception is not gated due to this check and no messages are discarded. However, when this check fails, a status bit is asserted to let the software know of this condition. The successive calibration pulse check can be configured to operate along with this check. This configurability is added to avoid conflicting results from the two checks.

There can be some inaccuracy in measuring pause pulse length as SAE specification specifies maximum clock drift/jitter up to maximum nibble length only and the frequency of high frequency receiver clock (protocol clock) used, allows clock compensation logic to ensure accuracy up to maximum nibble length. Hence there could be some inaccuracy in this check when sampling pause pulses that are larger than the maximum nibble pulse length.

This check will assert the PP_DIAG_ERR status bit on failure. This check does not run when reception of pause pulse is disabled.

55.4.8 Time stamp logic

A single counter maintains the time stamp for all channels which can be used by the software to determine the relative time of arrival of the messages for each channel. The time stamp counter is a 32-bit counter.

The clock for this counter is derived from the high frequency receiver clock using a Time Stamp Prescaler Counter that divides the high frequency receiver clock to generate the clock of required resolution. The user must program the time stamp prescaler value (in [Global Control Register \(GBL_CTRL\)](#)) in order to generate the time stamp clock. The period of the time stamp clock must be less than that of the fastest receiver channel being used, or it can be set at some fixed value determined by application, such as 1 μ s. For example, if the high frequency receiver clock is 60 MHz, the required prescaler value to generate a time stamp clock of 1 μ s resolution is 60.

Note: The rollover of time stamp values should be determined in user software, by comparing the time stamp values in previous and current messages that are read out. User software should adjust the time stamp values in these messages accordingly, after reading them.

The time stamp for a Fast Message is sampled at the falling edge that comes at the end of the calibration pulse (which is also the start of the status and communication nibble pulse) and is stored in the message read buffer. However, if the current message is found to be in error, the message buffer is discarded. Thus, the time stamp will be available to user software for only those messages which do not have any error.

The time stamp for a serial message is sampled at the end of the message i.e. when the serial message is completely received and when the message is found to have no errors. the time stamp is stored in the message read buffer to be read by the user software. Again, for messages with error the message and time stamp are discarded.

55.4.8.1 Limitation

Since the same counter is used for all channels, it may happen that more than 1 message is received within the same time stamp across different channels. Hence the software would not be able to determine the sequence of arrival of messages which have the same time stamp value.

55.4.9 Bus Idle Diagnostic

This diagnostic checks the connected sensors for inactivity. SENT module can indicate if the idle period on a particular channel has crossed the period defined by the programmed value in Bus Idle Count (in [Channel 'n' Configuration Register \(n = 0 to \(CH-1\)\) \(CHn_CONFIG\)](#)). Status bit (bus_idle in [Channel 'n' Status Register \(n = 0 to \(CH-1\)\) \(CHn_STATUS\)](#)) will be set when idle period crosses the allowed value. CPU should write 1 to this clear this bit once it is read.

55.5 Clocks and resets

The SENT Receiver works on two clocks. First is the System Bus Clock that is used to program the registers and read messages via DMA or Interrupt from the module's Register Interface. Second is the High Frequency Receiver Clock or Protocol Clock that is used for accurate message receiving operations. There is a single asynchronous reset which is the system asynchronous reset and one internal reset for each of the channel logic.

55.5.1 Clocking strategy

[Figure 1290](#) shows the clock domain in which each module is functioning.

Figure 1290. SENT Receiver module clock domains

55.5.2 System bus clock requirements

Since all the received messages are read on the System Bus Clock it is necessary that both the interrupt service routine and the DMA controller must be able to access all channels with messages ready to be read within a time to prevent overflow in any channel. The minimum time available to the CPU or DMA is the case when the smallest Fast Message is received back to back on all channels while working on the smallest receive clock tick period.

Now, the smallest Fast Message size with valid checksum as per SAE Specifications is 154 ticks. At 3 μ s receive clock tick with a -20% variation in the transmitter clock tick, the effective receiver clock tick is 2.4 μ s (after compensation). This gives us the time in which the minimum size Fast Message is received in any channel as $154 \times 2.4 = 369.6 \mu$ s. Now since messages are arriving in parallel, 369.6 μ s is the time available for CPU or DMA to access all channels to prevent an overflow in the channel that received the very first message.

Thus, if assume that ' N_{CHNL} ' channels are being used and all channels have messages ready to be read together from either DMA or CPU then the time available to read a message in one channel will be $369.6/N_{CHNL} \mu$ s or $\sim 370/N_{CHNL} \mu$ s. Since the CPU or the

DMA needs to make three 32-bit accesses in order to read a complete message and taking the time required for one 32-bit read access as ' T_{RD} ' (assuming it to be same for DMA and CPU); we can determine the minimum frequency for the System Bus Clock as:

For CPU,

$$\text{Equation 82} \quad 3 \times T_{RD} + T_{ISR} + T_{WAKUP} < 370/N_{CHNL}$$

where T_{ISR} is the overhead in initiating an ISR and T_{WAKUP} is the time to wakeup from low power mode

For DMA,

$$\text{Equation 83} \quad 3 \times T_{RD} + T_{WAKUP} < 370/N_{CHNL}$$

Replacing $T_{RD} = N_{RD} \times T_{SYS_CLK}$ and $T_{ISR} = N_{ISR} \times T_{SYS_CLK}$, where N_{RD} is the number of System Bus Clock cycles in one 32-bit read access, N_{ISR} is the number of System Bus Clock Cycles in initiating an interrupt service routine and T_{SYS_CLK} is the period of the same clock, we get

For CPU,

$$\text{Equation 84} \quad (3 \times N_{RD} + N_{ISR}) \times T_{SYS_CLK} + T_{WAKUP} < 370/N_{CHNL}$$

(all units is μs)

For DMA,

$$\text{Equation 85} \quad 3 \times N_{RD} \times T_{SYS_CLK} + T_{WAKUP} < 370/N_{CHNL}$$

(all units is μs)

55.5.3 High frequency receiver clock (protocol clock) requirements

For accurate receive operations, the protocol is required to satisfy a minimum frequency defined as per formula below.

$$\text{Equation 86} \quad F_{HF_CLK} > 332 / (3 \times T_{TX_CLK})$$

where F_{HF_CLK} is the High Frequency Receiver Clock or Protocol Clock in MHz and T_{TX_CLK} is the Transmitter or Sensor Clock Frequency in μs .

Note: T_{TX_CLK} in the above equation should be chosen based on the fastest sensor clock among all channels in the device.

56 LINFlexD

56.1 Introduction

The LINFlexD controller is designed to manage a high number of LIN messages efficiently with a minimum of CPU load. To reduce the CPU loading in Master mode, LINFlexD autonomously handles the LIN messages once software has triggered the header transmission, until the next header transmission request in transmitter mode or until checksum reception in the receiver mode.

The LINFlexD supports LIN protocol version 1.3, 2.0, and 2.1. It also consists of an 8-byte buffer for transmission/reception data.

The LINFlexD also provides support for some of the basic UART transfers of 8-bit, 9-bit, 16-bit, and 17-bit frames and also 12-bit data frame + parity reception in UART mode for MSC support.

The LINFlexD supports multi-channels and parametric DMA Tx/Rx interface in LIN/UART operating mode.

Figure 1291. Block diagram

1. The value of n depends on the no_of_filters. Refer to the device configuration chapter to see the number of filters used in this device.
2. For LIN mode N = 16 and N is programmable by user in UART mode.
3. FBRR is not usable when reduced over-sampling is enabled in UART mode.

56.2 Main features

The LINFlexD controller can operate in several modes, each of which has a distinct set of features which are described in the following sections. In addition, the LINFlexD controller has several features common to all modes:

- Fractional baud rate generator
- 3 operating modes for power saving and configuration registers lock
 - Initialization
 - Normal
 - Sleep
- Test Mode: Loop Back
- Maskable interrupts
- A maximum of 16 possible identifiers can be programmed into the identifier list

56.2.1 LIN mode features

- Supports LIN protocol version 1.3, 2.0, and 2.1
- Bit rates up to 20 Kbit/s (LIN protocol)
- Master/Slave mode
- Classic and Enhanced Checksum calculation and check
- Single 8-byte buffer or FIFO for Transmission/Reception
- Timeout management
- Identifier filters
- DMA interface
- Supports a maximum of 16 possible identifiers
- Master mode with autonomous message handling
- Extended frame mode for in-application programming purposes
- Wakeup event on dominant bit detection
- True LIN field state machine
- Advanced LIN error detection
- Header, response, and frame timeout
- Slave mode
 - Autonomous header handling
 - Autonomous transmit/receive data handling
- Identifier filters for autonomous message handling in Slave mode
- Separate clock for baud rate calculation (The relationship “ $\text{LIN_CLK} > \text{PBRIDGE_CLK} \geq 1/3 * \text{LIN_CLK}$ ” should be maintained.)

56.2.2 UART mode features

- Full-duplex communication
- Baud rate is a function of baud clock, LINIBRR and LINFBR registers — see [Section 56.3.2.8, Baud rate generation](#)
- Separate clock for baud rate calculation (The relationship “ $LIN_CLK > PBRIDGE_CLK \geq 1/3 * LIN_CLK$ ” should be maintained)
- 15/16/7/8 bits data, parity
- 1/2/3 stop bits
- 12-bit + parity reception
- 4-byte buffer for reception, 4-byte buffer for transmission
- 12-bit counter for timeout management
- The maximum baud rate achievable is 25 Mbit/s.
- For bit rate ≤ 6.25 Mbit/s
 - Sixteen times oversampling
 - 3:1 majority voting
- For 6.25 Mbit/s $<$ bit rate ≤ 12.5 Mbit/s
 - Reduced over sampling programmable by the user
 - 3:1 majority voting for reduced over sampling of 8
- For 12.5 Mbit/s $<$ bit rate ≤ 25 Mbit/s
 - Reduced over sampling programmable by the user
 - 1:1 voting for all reduced over sampling of 4, 5 and 6

56.2.3 Standard features

DMA2x bus interface

56.3 Functional description

56.3.1 LIN protocol

The LIN (Local Interconnect Network) is a serial communication protocol. A LIN cluster consists of one master task and several slave tasks. A master node contains the master task as well as a slave task — all other nodes contain a slave task only. The master node decides when and which frame is transferred on the bus. The slave task provides the data to be transported by the frame.

56.3.1.1 Frames

A frame consists of a header provided by the master task and a response provided by the slave task. The header consists of a break, a sync pattern, and an identifier. The break is followed by the sync pattern and the sync pattern is followed by the identifier. The slave task associated with the identifier provides the response. The response consists of a data field and checksum. The slave task designated to receive the data associated with the identifier receives the response and verifies the checksum.

Figure 1292. Frames

Figure 1293. Structure of LIN frame

56.3.1.2 Data field

Each byte is transmitted as shown in [Figure 1294](#). The LSB of the data is sent first and the MSB is sent last. The start bit is encoded as a bit with value zero (dominant) and stop bit is encoded as bit value one (recessive).

Figure 1294. Structure of byte field

56.3.1.3 Break

The break symbol is used to signal the beginning of a new frame. It is the only field that does not comply with the above figure. The break is always generated by the master and shall be at least 13 bits of dominant value including the start bit, followed by a break delimiter as shown in [Figure 1295](#). The break delimiter must be of two-bit duration (to be compliant with LIN protocol 2.1).

Figure 1295. Break field

56.3.1.4 Sync byte

Sync is a byte field with the data value of 0x55.

Figure 1296. Sync byte field

56.3.1.5 Identifier

The Identifier field consists of two sub-fields, the identifier and the identifier parity. Bits 0 to 5 are the identifier and bits 6 and 7 indicate the parity.

Figure 1297. Identifier field

$$P0 = ID0 \text{ XOR } ID1 \text{ XOR } ID2 \text{ XOR } ID4$$

$$P1 = \text{NOT } (ID1 \text{ XOR } ID3 \text{ XOR } ID4 \text{ XOR } ID5)$$

56.3.1.6 Checksum

The last field of a frame is the checksum. The checksum contains the inverted 8-bit sum with carryover of all data bytes or all data bytes and the identifier. Checksum calculation over the data bytes only is called classic checksum and is used for communication with LIN 1.3 slaves. Checksum calculation over the data bytes and the protected identifier byte is called enhanced checksum, and it is used for communication with LIN 2.0 slaves.

56.3.2 LINFlexD features

56.3.2.1 Operating modes

The LINFlexD has three operating modes: **Initialization**, **Normal**, and **Sleep** modes. After hardware reset, the LINFlexD enters sleep mode to reduce power consumption.

Initialization mode (INIT)

To enter this mode, software sets the INIT bit in the LINC1R1. To exit the initialization mode, software should reset the INIT bit.

When in initialization mode, all message transfers to and from the LIN bus are stopped and the status of LIN bus output LINTX is recessive (high). If software invokes the initialization mode when a bus transfer is in progress, the transfer is aborted. The software should therefore check the LIN state before setting this bit.

To initialize the LINFlexD controller, software must:

1. set up the baud rate registers
2. reset the UART bit
3. select the mode (Master or Slave)
4. configure checksum control bits
5. initialize the identifier list (Slave mode)

Normal mode (NM)

Once software has completed initialization of the LINFlexD controller, it can enter Normal mode by clearing the INIT bit.

Sleep mode (SM)

Sleep mode in LINFlexD reduces power consumption. This mode is entered by setting the SLEEP bit in LINC1. In this mode the LINFlexD clock is stopped. LINFlexD can be woken from Sleep mode by clearing the SLEEP bit.

If software detects a wakeup pulse of 150 μ s on the LIN Bus, it can request LINFlexD to wake up from Sleep mode. Refer to [Section 56.3.2.10, Wakeup management](#).

Figure 1298. Operating modes

56.3.2.2 Test mode

Loop Back mode

This mode is entered by setting the LBKM bit in LINC1. In this mode, the LINFlexD receives the Identifier and Data transmitted by itself and writes the same in the BIDR and Data buffers respectively. This mode is provided for selftest functions. Bit error is checked in this mode.

The LINFlexD ignores the LINRX signal. There is internal feedback from its TX output to its RX input. The TX pin can be disconnected from LINTX pin by SIUL2 setting.

56.3.2.3 Master mode

Master mode is selected by means of the MME bit in LINCR1 register.

Header transmission

According to the LIN protocol any communication on the LIN bus is triggered by the master sending a header. The header is transmitted by the master task of a node while the response is transmitted by the slave task of a node.

To transmit the header, first program the Identifier, data field length, message direction and checksum enable in the BIDR register; then set the HTRQ bit in LINCR2. Once header transmission starts, the user should not modify BIDR register bits until the current frame is complete. The transmitted ID is also received by the master node and copied to BIDR.

Data transmission

When the master node is the publisher of the data corresponding to the Identifier sent by the master, then the slave task of the node should send the data in the response part of the frame. Hence software must provide the data to the LINFlexD before the header transmission is requested. The data to be transmitted is stored in the message buffer BDR[0:7]. The number of bytes to be transmitted depends on the Data Field length in BIDR. The software uses the BIDR[CCS] bit to configure the checksum type (classic or enhanced) for each message.

If the response has been sent successfully, LINSR[DTF] is set. In case of error, the DTF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, LINSR[DBEF] is set once the first eight bytes have been transmitted. The application has to update the buffer BDR before resetting the DBEF bit. The transmission of the next bytes starts when the DBEF bit is reset. Once the last data byte (or the checksum byte) has been sent, the DTF flag is set.

The direction of the message buffer is decided by the DIR bit in the BIDR. The transmitted data is also received by the same node and copied to the buffer.

Data reception

To receive data from a slave node, the master sends a header with the corresponding Identifier. The data received from the slave is stored in the message buffer and the status of the message is stored in the LINSR.

If the response has been received successfully, the LINSR (DRF) bit is set. In case of error, the DRF flag is not set and the corresponding error flag is set in the LINESR (refer to error handling). It is possible to handle frames with a Response size larger than eight bytes of data (extended frames). If the data field length in the BIDR is configured with a value higher than eight data bytes, the LINSR (DBFF) bit is set once the first eight bytes have been received. The application has to read the buffer BDR before resetting the DBFF bit. Once the last data byte (or the checksum byte) has been received, the DRF flag is set.

Data Discard

If the user wants to discard the data after header transmission, then the DDRQ bit in LINCR2 should be set.

56.3.2.4 Slave mode

This mode is selected when the MME bit of the LINCR1 register is cleared.

Data transmission

On header reception, the HRF bit is set and an RX interrupt is generated. The software must then:

1. read the received ID in the BIDR register
2. fill the BDR[0:x] register
3. program the CCS and DIR bits in the BIDR register
4. specify the data field length DFL[5:0] bits in the BIDR register
5. trigger the data transmission by setting the DTRQ bit

Note that the HRF bit should be reset only after the DTRQ bit is set. For the DTRQ to be effective, the HRF bit must be set. This is to ensure that DTRQ is not set randomly, but only after a header reception. It must be noted that you cannot set the DIR and DTRQ bits once RXbusy is asserted in LINSR.

Alternately, one or more Identifier filters are configured for transmission by setting the DIR bit and activated by setting the enable bits in IFER. When at least one Identifier filter is active and configured for transmission and the received ID matches the filter, a TX interrupt is generated. The software can use the index in the IFMI register to point directly to the corresponding data array in the RAM and copy this data to the BDR[0:7]. The use of a filter saves software the processing time required to read the ID value in the BIDR, match it, and configure the data field length and checksum type.

If the number of filters provided by LINFlexD are not sufficient for the application, mask mode can be used for the filters.

The transmitted data is also received by the same node and copied to the buffer.

Data reception

When LINFlexD is the subscriber of the data of the received identifier, then on header reception the HRF flag is set and an RX interrupt is generated. The software must read the received ID from the BIDR register and specify the data field length before the reception of the stop bit of the first data byte. When the checksum is received, an RX interrupt is generated for software to read the received data from BDR[0:7] and the RMB bit is set. Software must then release the data buffer by resetting the RMB bit in the LINSR.

When at least one identifier filter is active and configured for reception, an RX interrupt is generated only after the checksum reception. No interrupt request is generated on reception of the ID.

If the Identifier is filtered by software, you can discard the data by setting the DDRQ bit in the LINCR2, while HRF is set.

Note that for software filtering, software must decide the type of checksum (configure the CCS bit of the BDR register) before reception of data. Otherwise the previous value of the CCS bit is considered while calculating checksum.

56.3.2.5 Errors

56.3.2.5.1 Header error

A header error is an error during header reception. The types are:

- Sync Del error (SDEF)
- Sync field error (SFEF)
- Identifier Parity error (IDPEF)

1. Sync Delimiter too short

The delimiter should be 1 for at least one bit time, otherwise it is considered short and consequently the receiver discards synchronization on the current header. Hence the frame is discarded. An interrupt is generated if the HEIE bit of LINEIER is set.

2. Inconsistent Sync field

This error condition is monitored differently depending on whether autosynchronization is ON or OFF.

Case 1: Autosynchronization ON (LASE bit of LINCR1 = 1):

When Autosynchronization is enabled, the inconsistent Sync Field informs:

- that the deviation error on the Sync Field is outside the LIN specification, which allows up to 14% of period deviation between the slave and master oscillators,
or
- An overflow has occurred during the Sync Field Measurement, which leads to an overflow of the divider registers.

Deviation error on the Sync Field

The deviation error is checked by comparing the current baud rate (relative to the slave oscillator) with the received LIN Sync Field (relative to the master oscillator). Two checks are performed in parallel:

1. The first check is based on a measurement between the first falling edge and the last falling edge of the Sync Field. Let's refer to this period deviation as D.

If there is an inconsistent Sync Field error, it means that:

$$D > 14.0625\%$$

If there is no error, it means that:

$$D < 14.84375\%$$

If $14.0625\% < D < 14.84375\%$, then the Sync Field could be either consistent or inconsistent depending on dephasing between the signal on the RDI line and the LIN_CLK.

2. The second check is based on the measurement of each bit time between both edges of the Sync Field. This checks that each of these bit times is large enough (more than 12 samples) compared to the bit time of the current baud rate.

Case 2: Autosynchronization OFF (LASE bit of LINCR1 = 1)

In this case the Sync character is received as a normal character. If the received character is 0x55, then the Sync Field is OK.

On any occurrence of an inconsistent Sync Field, the receiver immediately exits from Sync_Field state and the frame is consequently discarded. The SFEF bit of LINESR is set.

3. Identifier Parity error

There are two parity bits in the identifier field. These bits are checked against the hardware-calculated parity over the other six bits of identifier, according to the formula:

$$P0 = ID0 \text{ XOR } ID1 \text{ XOR } ID2 \text{ XOR } ID4$$

$$P1 = \text{NOT } (ID1 \text{ XOR } ID3 \text{ XOR } ID4 \text{ XOR } ID5)$$

This parity is checked after the ID is transferred to the BIDR register (after stop of ID has been detected properly) and upon parity mismatch, the receiver state machine exits from Identifier state immediately if the IOPE bit of LINCR2 is set.

56.3.2.5.2 Bit error

This error is flagged in transmission mode when the value read back from the bus is different from the value transmitted. Bit error checking on each bit is guaranteed if transceiver delay is less than one bit time minus 6 LIN_CLK cycles.

Example 17

1-bit time at 20 Kbit/s = 50 μ s

6 LIN_CLK cycles at 80 MHz = 75 ns

Thus, (1-bit time) – (6 LIN_CLK cycles) = 49.925 μ s

Transmission of the frame is stopped after the corrupted bit if the IOBE bit in LINCR2 is set. If IOBE is reset, the transmitter continues to transmit in spite of the bit error. An interrupt is generated if the BEIER bit is set in LINIER.

Note: *If the break delimiter is not detected by the master within one bit time after delimiter transmission due to transceiver delay or error on the bus, then a train of bit error interrupts are generated. In this case, the Identifier may not be replaced in the BIDR.*

Similarly, if the start of a falling edge of data is not detected by the transmitter node within one bit time after start bit transmission, then a train of bit error interrupts are generated. In

this case also, data and checksum replacements in the BDR and CFR respectively are not guaranteed.

56.3.2.5.3 Framing error

This error is flagged when a dominant state is sampled on the stop bit of the current received character (sync field, identifier field, data field, checksum field). LINFlexD discards the current frame and returns to Idle state. An interrupt is generated if the FEIE bit is set in LINEIER.

The byte that caused framing error is also shifted to the buffer but DRF or DBFF is never set in this case.

56.3.2.5.4 Checksum error

This error is flagged when the checksum computed by hardware does not match the received checksum.

LINFlexD discards the received frame and returns to Idle state. An interrupt is generated if the CEIE bit is set in LINEIER.

56.3.2.5.5 Overrun error

Once the message buffer is full (RMB is set), the next valid message reception will lead to an overrun and the message will be lost. The hardware signals the overrun condition by setting the BOF bit. Which message is lost depends on the buffer lock function control bit RBLM.

If RBLM is cleared, the old message in the buffer is overwritten by the most recent message. If RBLM bit is set, the most recent message is discarded and the oldest message is available to the software. In the case of a slave, if the buffer is not released (RMB is not reset) before reception of the next Identifier and if RBLM is set, then the ID along with the data is discarded.

56.3.2.5.6 Timeout error

Figure 1299. Incomplete response (for example, missing checksum)

Figure 1300. No response

Response timeout mechanism

- Master mode
 - ocr_l is loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = $1.4 \times ((DFL + 2) \times 10 \text{ bit time})$).
 - The change with respect to earlier implementation is that this loading takes place at the end of the ID field (and not at the beginning of the data field). Moreover, the correct value, which depends on DFL, is loaded immediately. No further ocr_l update is required.
 - In case of no response at all within this time (in other words, start of data is not received), timeout takes place when the counter reaches the ocr_l value (no change compared to earlier implementation).
 - In case of an incomplete response, timeout also occurs when the counter reaches the ocr_l value (no change compared to earlier implementation).
- Slave mode
 - **Case 1:** The received identifier is managed by a filter. The implementation can be similar to the master mode, because the DFL value is loaded by hardware. Thus, ocr_l can be loaded with Nominal_time_out-Correction_factor at the end of the stop bit of the Identifier field (where nominal_time_out = $1.4 \times ((DFL + 2) \times 10 \text{ bit time})$).
 - **Case 2:** The received identifier is not managed by a filter. As the DFL value needs to be updated by software after the identifier field has been received, the previous strategy cannot be used as the DFL value is not yet available. The earlier implementation loaded the maximum value = $1.4 \times (9 \times 10 \text{ bit time})$ and then updated it according to DFL after the first data byte reception. This was not acceptable if no data byte was received at all, as timeout expired too late. The proposed implementation is the following:
 - At the end of the ID, ocr_l is loaded with 36 (maximum possible response space)
 - At the end of the first_data_byte it is reloaded again according to DFL
 - Before reloading, LINFlexD checks the count_val. If count value is higher than the value to be reloaded, timeout takes place immediately and no reloading occurs.

Header timeout mechanism

- Master mode: As the header is generated by the LINFlexD, there are only two cases:
 - no error on the bus and timing is correct (nominal header length)
 - an error occurs on the bus and LINFlexD flags it in LINESR register (typically a bit error)

Therefore there is no meaning of header timeout in master mode, so it is disabled

- Slave mode
 - $\text{header_nominal} = 13 + 2 + 10 + 10 = 35 \text{ Tbit}$
 - $\text{header_max} = 1.4 \times \text{Header_nominal} = 49 \text{ Tbit}$
 - taking into account a possible 14% clock deviation, header_max seen by LINFlexD is $49 \times 1.14 = 56 \text{ Tbit}$.
 - If the counter starts after 11 Tbit, the HTO value is $56 - 11 = 45 \text{ Tbit}$

The reset value of HTO is 45 and this register can only be programmed in slave mode.

As response space is not included in the response, frame timeout is no longer needed and is removed completely. Indeed, header timeout and response timeout cover all cases.

The timeout counter can be used to detect other timeouts. In this case, the MODE bit must be set and the output compare value can be updated in the LINTOCR register by software.

Stuck at zero timeout error

If the dominant pulse lasts for a time of at least 100 bits, the SZF bit in LINESR is set. If the same dominant pulse prolongs, the subsequent SZF setting will be 87 bit times apart (instead of 100 bit times).

56.3.2.5.7 Noise

During reception each bit is sampled 16 times and the value of the bit is obtained by taking the majority value of the 8th, 9th, and 10th samples. If any one of these three samples has a value different from the other two, this error is flagged.

When OSR = 8, majority of 2nd, 3rd, and 4th samples are taken into account to determine noise. Noise checking is disabled for all OSR less than eight.

This error is flagged when there is noise detected in the start bit (see [Section 56.4.2.4, LIN Error Status Register \(LINESR\)](#)).

56.3.2.6 Identifier filtering

In LIN protocol the identifier of a message is not associated with the address of a node but is related to the content of the message. A transmitter broadcasts its message to all the receivers. Based on the header received, the receiver decides whether to receive or transmit a response (depending on the identifier value). If the message does not target the node, it should be discarded.

To fulfill this requirement, the LINFlexD provides configurable filters in order to eliminate software intervention. This hardware filtering saves CPU resources that would otherwise be required to perform filtering by software.

There are a maximum of 16 filters (depending on the generic no_of_filters) in the LINFlexD, which can be programmed by the user only during Initialization mode. In order to activate a

filter the corresponding FACT bit in IFER needs to be set. There are two modes possible for each identifier depending on the corresponding IFM bit of IFMR.

Identifier list mode

If the n^{th} bit of IFMR is cleared, then filter number $2n$ and $2n+1$ is in identifier list mode. In this mode, the maximum number of filters that can be configured for transmission/reception equals `no_of_filters`, depending on the FACT bit of IFER. In this mode the identifier received should match bit by bit to the ID field of IFCR $2n$ or IFCR $2n+1$ (if the corresponding FACT bit is set).

Identifier mask mode

If the number of filters required is more than `no_of_filters`, then filters should be configured in Mask mode. If the n^{th} bit of IFMR is set, then filter number $2n$ is the filter and $2n+1$ acts as a mask for it. The FACT bit for filter $2n+1$ has no effect in this case. In this mode, if the x^{th} bit of the mask is set, then the x^{th} bit of the received identifier must match the x^{th} bit of filter.

If there is a match of identifier with the m^{th} filter in any mode, then $m+1$ is loaded in the IFMI register by hardware. No match condition is denoted by IFMI = 0.

Upon matching DFL (2:0), the CCS and DIR bits of the BIDR register are copied from the filter by hardware and from then on, the BIDR register is read-only until the end of the frame. Now if the DIR bit of BIDR is set, then a TXI interrupt is generated if the HRIE bit of LINIER is set. In this case, software uses the IFMI register to transfer the relevant data from the RAM area to BDR, and after a complete transfer the DTRQ bit of LINCR2 is set to start the transmission. If the DIR bit is cleared then an RXI interrupt is generated (provided DRIE bit of LINIER is set) when the checksum has been received and there is no checksum error.

In case of no filter match condition (IFMI = 0) and if the BF bit of LINCR1 is set, then an RXI is generated. Now it is the responsibility of software to configure BIDR and start transmission (by loading the BDR buffer and setting the DTRQ bit of LINCR2) or discard reception (by setting the DDRQ bit of LINCR2). If the BF bit is reset, then the receiver discards the received identifier and turns to Idle state in search of a new break.

Note: *If one identifier matches with two filters (one is in the list and the other in Mask mode) then List mode prevails over Mask mode. In Mask mode, if two filters match with the identifier then the filter having the lower number prevails.*

Figure 1301. Identifier List mode

Figure 1302. Identifier Mask mode

56.3.2.7 Start detection and delimiter detection in receiver

There is a 10-bit-shift-register sample register in the receiver that shifts signal data to the next less significant bit on each incoming sample.

Table 1248. 10-bit-shift-register sample register

Sample register bit number										Counter
9	8	7	6	5	4	3	2	1	0	
—	—	—	—	—	—	—	—	—	RT1	counter = 0
—	—	—	—	—	—	—	—	RT1	RT2	counter = 1
—	—	—	—	—	—	—	RT1	RT2	RT3	counter = 2
—	—	—	—	—	—	RT1	RT2	RT3	RT4	counter = 3
—	—	—	—	—	RT1	RT2	RT3	RT4	RT5	counter = 4
—	—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	counter = 5
—	—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	counter = 6
—	—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	counter = 7
—	RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	counter = 8
RT1	RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	counter = 9
RT2	RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	counter = 10
RT3	RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	counter = 11
RT4	RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	counter = 12
RT5	RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	counter = 13
RT6	RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	counter = 14
RT7	RT8	RT9	RT10	RT11	RT12	RT13	RT14	RT15	RT16	counter = 15
1	1	1	0	x ⁽¹⁾	0	x	0	x	0	Start detection
1	1	1	0	x	0	x	0	x	1	
1	1	1	0	x	0	x	1	x	0	
1	1	1	0	x	1	x	0	x	0	
0	0	0	1	x	1	x	1	x	1	Delimiter detection
0	0	0	1	x	1	x	1	x	0	
0	0	0	1	x	1	x	0	x	1	
0	0	0	1	x	0	x	1	x	1	

1. x: Due to sampling during transition of the bit, the bit value might be sampled as a '0' or '1' depending on the rise/fall time. So 'x' refers to an indeterministic value.

56.3.2.7.1 Start detection mechanism

The following steps are followed for detecting a start bit:

1. Refer to [Table 1248](#) for the status of the sample register (shift register) when count = 6
2. At this point, if RT1 (the first incoming sample) = 0 and the previous three samples already received are all ones, then it might be a start bit.
3. To make sure it is indeed a start bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to '0', then start bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the "verification samples" which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called "qualification samples" which are checked at count = 6.
7. At count = 9, if majority value of RT8, RT9, and RT10 is not equal to '0' then Noise flag is set.

56.3.2.7.2 Delimiter detection mechanism

The following steps are followed for detecting a delimiter bit:

1. Refer to [Table 1248](#) for the status of the sample register (shift register) when count = 6
2. At this point, if RT1(the first incoming sample) = 1 and the previous three samples already received are all zeros, then it might be a delimiter bit.
3. To make sure it is indeed a delimiter bit, the incoming data samples in the sample register (4), sample register (2) and sample register (0) which correspond to RT3, RT5, and RT7 is verified using the steps mentioned below.
4. If the majority (i.e., 2) out of these 3 samples are equal to '1', then delimiter bit is said to be detected.
5. These three samples RT3, RT5, and RT7 are called the "verification samples" which are checked at count = 6.
6. The sample register bits 9, 8, 7, and 6 are called "qualification samples" which are checked at count = 6.

Hence, a start is detected as soon as it is qualified with 1110 in the sample register and verified with at least two out of three predefined verification samples being zero. Similarly for delimiter detection, qualification samples are 0001 and at least two out of the three verification samples are one. The Noise Flag is set if the start is verified with only two valid samples.

Figure 1303. Start detection and sampling for over sampling rate = 4 (Case 1)

Figure 1304. Start detection and sampling for over sampling rate = 4 (Case 2a)

The choice of the correct sample points depends on the external Rx signal quality. During the application development process, the error information indicated by the parity error can help to find the best setting for an application-specific hardware signal.

To sample at the correct point therefore, CSP has to be changed to two; resulting in the following situation:

Figure 1305. Start detection and sampling for over sampling rate = 4 (Case 2b)

Figure 1306. Start detection and sampling for over sampling rate = 4 (Case 3)

Figure 1307. Start detection and sampling for over sampling rate = 4 (Case 4)

Figure 1308. Start detection and sampling for over sampling rate = 4 (Case 5)

56.3.2.8 Baud rate generation

The LIN baud rate is programmed in two registers: the LIN Integer Baud Rate register and the LIN Fraction Baud Rate register. The baud rate registers can be programmed only during Initialization mode.

The baud rate is calculated with the following formula for both receiver and transmitter:

$$\text{Equation 87} \quad T_x = R_x = \text{LIN_CLK} / (16 \times \text{LDIV})$$

Where LIN_CLK is the frequency of the baud clock (ipg_baud_clk).

LDIV is an unsigned fixed point number. The mantissa is coded into 20 bits of LINIBRR and the fraction is coded on 4 bits of LINFBR.

When reduced oversampling is enabled LINFBR is not used and LDIV contains only the integer part of LINIBRR.

Example 18

When ROSE = 0 (For LIN and UART mode):

LDIV = 1041.67, LIN_CLK = 80 MHz

LINIBRR = 1041d = 411 h

LINFBR = 11d = B h

Baud rate = 80 MHz / (16 × 1041.67) = 4.8 Kbit/s

Example 19

When ROSE = 1 (Only for UART mode):

LDIV = 10 d, LIN_CLK = 80 MHz

LINIBRR = 10 d, OSR = 4

Baud rate = LIN_CLK / (OSR × LDIV) = 80 MHz / (4 × 10) = 2 Mbit/s

Note:

Due to design constraints the maximum baud rate achievable is 25 Mbit/s.

The relationship "LIN_CLK > PBRIDGEx_CLK ≥ 1/3 × LIN_CLK" should also be maintained.

56.3.2.9 Automatic resynchronization

To automatically adjust the baud rate based on measurement of the LIN sync field, write the nominal Prescaler value (nominal baud rate) in LINIBRR and LINFBRR, then set the LASE bit in LINCR1 to enable automatic synchronization.

When automatic synchronization is enabled, after each LIN Sync Del, the time duration between five falling edges on RDI is sampled on LIN_CLK.

56.3.2.10 Wakeup management

Any node in a sleeping LIN cluster may request a wakeup. The wakeup request is issued by forcing the bus to the dominant state for 250 μ s to 5 ms. Every slave node should detect the wakeup request (a dominant pulse longer than 150 μ s) and be ready to listen to bus commands within 100 ms, measured from the ending edge of the dominant pulse. The master also wakes on detecting a wakeup request and when the slaves are ready, starts sending frame headers to find out the cause of the wakeup. If the master does not issue a frame header within 150 ms from the wakeup request, then the node issuing a request may try issuing a new wakeup request.

In LINFlexD, a wakeup request can be generated by writing the wakeup character in BDR0 and setting the WURQ bit in LINCR2. On setting the WURQ bit, the character in BDR0 is transmitted. For LIN 2.0, character 0xF0 is sent as the wakeup character.

In LINFlexD, wakeup can be detected in two ways.

1. AUTOWU = 1

On detecting a falling edge in sleep mode, the SLEEP bit is cleared by hardware, the WUF flag is set, and an interrupt is generated (if WUPIE is set). LINFlexD is now in normal mode and ready to receive frames.

2. AUTOWU = 0

On detecting a falling edge the WUF flag is set and an interrupt is generated (if WUPIE is set). It is then up to the software to clear the SLEEP bit.

Figure 1309. Wakeup sequence

56.3.3 Timer

There is an 8-bit counter that is free-running (even in Sleep and Initialization modes) if it is configured in Output Compare mode. There are two software-configurable output compare registers that, upon match with the counter value, generate an output compare interrupt provided the TOCE bit in LINTCSR is set.

If this timer is configured in LIN mode, then software has no control over the TOCE bit and output compare registers are utilized for generation of LIN timeout interrupts (header, frame, response times out). In this case, if LIN moves to Sleep or Init state, then this counter

remains in Reset state. LIN mode has no meaning if UART is enabled — hence the counter will remain in Reset state.

56.3.4 UART mode

The main features in UART mode are:

- Full duplex communication
- 8-bit frames, 9-bit frames, 16-bit frames, 17-bit frames
- Even/Odd/0/1 Parity
- User programmable over sampling rate to obtain the baud rate of up to 25 Mbit/s

56.3.4.1 8-bit data frames

The eighth bit can be a data bit or a parity bit. Even/Odd/0/1 parity can be selected by the PC[1:0] bit in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case.

Figure 1310. UART mode 8-bit data frame

56.3.4.2 9-bit frames

The ninth bit should be a parity bit. Even/Odd/0/1 Parity can be selected by the PC[1:0] field in the same register. An even parity will be set if the modulo-2 sum of the seven data bits is one. An odd parity will be cleared in this case. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

Figure 1311. UART mode 9-bit data frame

56.3.4.3 16-bit data frames

The sixteenth bit can be a data or parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

Figure 1312. UART mode 16-bit data frame

56.3.4.4 17-bit frames

The seventeenth bit is the parity bit. Even/Odd/0/1 Parity bit can be selected by the PC[1:0] bit in the same register. Parity 0 forces a zero logical value. Parity 1 forces a high logical value.

Figure 1313. UART mode 17-bit data frame

56.3.4.5 13-bit frames

Whenever WLS is one, special word length is selected in UART mode. This bit enables 12-bit + parity bit reception.

Figure 1314. UART mode 13-bit data frame

56.3.4.6 Buffer in UART mode

The 8-byte buffer is divided into two parts: one for receiver and one for transmitter, as shown in [Figure 1315](#).

Figure 1315. Structure of 8-byte buffer

For 16-bit frames, the lower eight bits are written in BDR0 and the upper eight bits in BDR1. The same applies for reception.

56.3.4.7 UART transmitter

In order to start transmission in UART mode, the UART bit should be set and the transmitter enable bit should be set. Transmission starts when the BDR0 (least significant data byte) is programmed and continues until the number of bytes/halfwords transmitted is equal to the value in the TDFL bits in UARTCR.

The transmit buffer is four bytes (when UARTCR[WL1] = 0) or two halfwords (when UARTCR[WL1] = 1), hence a maximum of four bytes (two halfwords) transmission can be triggered. Once the programmed number of bytes (halfwords) has been transmitted, the DTF flag is set in UARTSR. If the Txen bit of UART is reset in the middle of a transmission, then the current transmission is completed and no further transmissions can be invoked.

The buffer can be configured in FIFO mode (mandatory when the DMA Tx is enabled) by setting the control bit UARTCR[TFBM].

Note: If TFF bit is set and a write is performed to the FIFO, the data transmitted may be erroneous.

Table 1249. BDRL access in UART mode

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Write byte0	BDRL	FIFO	Byte	OK
Write byte1-2-3	BDRL	FIFO	Byte	IPS transfer error
Write halfword0-1	BDRL	FIFO	Byte	IPS transfer error
Write word	BDRL	FIFO	Byte	IPS transfer error
Write byte0-1-2-3	BDRL	FIFO	Halfword	IPS transfer error
Write halfword0	BDRL	FIFO	Halfword	OK
Write halfword1	BDRL	FIFO	Halfword	IPS transfer error
Write word	BDRL	FIFO	Halfword	IPS transfer error
Read byte0-1-2-3	BDRL	FIFO	Byte/halfword	IPS transfer error
Read halfword0-1	BDRL	FIFO	Byte/halfword	IPS transfer error

Table 1249. BDRL access in UART mode (continued)

IPS operation	Register	Mode (UARTCR[TFBM])	Word length (UARTCR:WL)	IPS operation result
Read word	BDRL	FIFO	Byte/halfword	IPS transfer error
Write byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Write halfword0-1	BDRL	Buffer	Byte/halfword	OK
Write word	BDRL	Buffer	Byte/halfword	OK
Read byte0-1-2-3	BDRL	Buffer	Byte/halfword	OK
Read halfword0-1	BDRL	Buffer	Byte/halfword	OK
Read word	BDRL	Buffer	Byte/halfword	OK

In UART FIFO mode (UARTCR[TFBM] = 1), any read operation causes an IPS transfer error.

56.3.4.8 UART receiver

The reception of a data byte is started as soon as the user exits Initialization mode, sets the Rxen bit, and detects the start bit. There is a dedicated 4-byte (if UARTCR[WL1] = 0) or 2-halfword (if UARTCR[WL1] = 1) data buffer for received data. Once the programmed number (RDFL bits) of bytes have been received, the DRF flag is set in UARTSR and the current reception gets completed. Rxen bit needs to be set only to start the reception. The reception is automatically completed as soon as the programmed number (RDFL bits) of bytes have been received.

The buffer can be configured in FIFO mode (mandatory when the DMA Rx is enabled) by setting the control bit UARTCR[RFBM].

Table 1250. BDRM access in UART mode⁽¹⁾

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read byte4	BDRM	FIFO	Byte	OK
Read byte5-6-7	BDRM	FIFO	Byte	IPS transfer error
Read halfword2-3	BDRM	FIFO	Byte	IPS transfer error
Read word	BDRM	FIFO	Byte	IPS transfer error
Read byte4-5-6-7	BDRM	FIFO	Halfword	IPS transfer error
Read halfword2	BDRM	FIFO	Halfword	OK
Read halfword3	BDRM	FIFO	Halfword	IPS transfer error
Read word	BDRM	FIFO	Halfword	IPS transfer error
Write byte4-5-6-7	BDRM	FIFO	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	FIFO	Byte/halfword	IPS transfer error
Write word	BDRM	FIFO	Byte/halfword	IPS transfer error
Read byte4-5-6-7	BDRM	Buffer	Byte/halfword	OK

Table 1250. BDRM access in UART mode⁽¹⁾ (continued)

IPS operation	Register	Mode (UARTCR[RFBM])	Word length (UARTCR:WL)	IPS operation result
Read halfword2-3	BDRM	Buffer	Byte/halfword	OK
Read word	BDRM	Buffer	Byte/halfword	OK
Write byte4-5-6-7	BDRM	Buffer	Byte/halfword	IPS transfer error
Write halfword2-3	BDRM	Buffer	Byte/halfword	IPS transfer error
Write word	BDRM	Buffer	Byte/halfword	IPS transfer error

1. Refer to the layout of the registers BDRL and BDRM to identify the mapping between byte x and the data bits of the BDRL and BDRM registers.

Note:

- If the user does not know in advance how many bytes are to be received, RDFL should not be programmed in advance. The reset value of RDFL is zero. This will ensure that the reception will happen byte by byte. The state machine will move to the Idle state after each byte reception.
- If RDFL is programmed for a certain value but that number bytes are not received, then reception will hang. In that case, software needs to take care of timeout by seeing the flag. Software has to set the sleep bit to move to the Idle state.
- If a STOP request arrives in the middle of a reception, it is only acknowledged after all the programmed number of data bytes have been received; it is not served immediately. If the programmed number of data bytes are not received, then software has to take care of timeout; when the state machine moves to Idle state, then only a stop request is served.
- If during reception of any byte a parity error occurs, then the corresponding PEx bit in UARTSR is set. No interrupt is generated in this case. If a framing error occurs in any byte (FE bit in UARTSR is set) then an interrupt is generated if the FEIE bit in LINIER is set. As there is only one register bit for a framing error, this interrupt will be helpful in identifying which byte has the framing error.
- If the last received frame has not been read from the buffer (in other words, RMB is not reset by the user), then upon reception of the next byte, an overrun error occurs (BOF bit in UARTSR will be set) and one message is lost depending on the RBLM bit of LINCR1. An interrupt is generated if the BOIE bit in LINIER is set.
- When WLS bit = 1, BDRM access depends on WL bit setting.
- When IPG_STOP is requested, for UART in FIFO mode, SW has to set the INIT bit in order to send the receiver to idle. This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

56.3.5 DMA interface

56.3.5.1 Main features

The LINFlexD DMA offers a parametric and programmable solution with the following distinctive features:

- LIN Master node, TX mode: single DMA channel
- LIN Master node, RX mode: single DMA channel
- LIN Slave node, TX mode: 1 to N DMA channel where N = max number of ID filters
- LIN Slave node, RX mode: 1 to N DMA channel where N = max number of ID filters
- UART node, TX mode: single DMA channel
- UART node, RX mode: single DMA channel + time-out

This release is backwards-compatible with the existing LINFlexD release if the new features are not enabled.

56.3.5.2 Definitions

Control/status register fields of the LINFlexD macrocell are described in [Table 1251](#) and [Table 1252](#).

Table 1251. LINFlexD control/status fields description

Register	Field	Level	Description
LINC2	DDRQ	High	Data discard request in reception mode
	DTRQ	High	Data transmission request (slave mode) of the LIN data field stored in BDRL/BDRM
	HTRQ	High	Header transmission request (master mode)
BIDR	DFL[5:0]	—	Data field length: – 1–8 bytes: normal frames – 1–64 bytes: extended frames
	DIR	—	Direction of the data field: 0 Reception 1 Transmission
	CCS	—	Checksum type: 0 Enhanced 1 Classic
	ID[5:0]	—	Identifier

Table 1251. LINFlexD control/status fields description (continued)

Register	Field	Level	Description
LINSR	RMB	—	Buffer data ready to be read via CPU/DMA 0 Buffer data is free 1 Buffer data is ready
	DBFF	High	Data buffer full (8 bytes received) and DFL > 7 Used for extended frames.
	DBEF	High	Data buffer empty (8 bytes have been transmitted) and DFL > 7 Used for extended frames.
	DRF	High	Data reception completed
	DTF	High	Data transmission completed
	HRF	High	Header received Used in slave mode in case of Tx filter match.
IFMI	IFMIx	!= zero	Filter match index (slave mode)
UARTCR	FBM	—	FIFO/Buffer mode 0 Buffer mode 1 FIFO mode (mandatory in DMA mode)
UARTSR	RFE	—	Rx FIFO empty 0 Rx FIFO not empty 1 Rx FIFO empty
	TFF	—	Tx FIFO full 0 Tx FIFO not full 1 Tx FIFO full
DMATXE[2**TX_CH_NUM] (1)		High	DMA Tx channel enable (read/write) In UART or LIN master mode only channel 0 can be programmed. In LIN slave mode: # DMA TX channel = IFMI[3:0] – 1. DMATXE[x] = 0b → TX channel x disabled DMATXE[x] = 1b → TX channel x enabled
DMARXE[2**RX_CH_NUM] (1)		High	DMA Rx channel enable (read/write) In UART or LIN master mode only the channel 0 can be programmed. In LIN slave mode: # DMA RX channel = IFMI[3:0] – 1. DMARXE[x] = 0b → RX channel x disabled DMARXE[x] = 1b → RX channel x enabled

1. ** stands for exponentiation

Table 1252. LINFlexD DMA control fields description

Field	Mode	Value	Level	Description
DMA_TEN	LIN master Tx or UART Tx	DMATXE[0] & dma_enb_req_tx[0]	High	Logical AND between the two DMA enable bits (LINFlexD and eDMA)
DMA_TEN	LIN slave Tx	DMATXE[x] & dma_enb_req_tx[x] x = IFMI – 1	High	
DMA_REN	LIN master Rx or UART Rx	DMARXE[0] & dma_enb_req_rx[0]	High	
DMA_REN	LIN slave Rx	DMARXE[x] & dma_enb_req_rx[x] x = IFMI – 1	High	

Control/status fields of the TCD descriptors referred to in this document are described in [Table 1253](#).

Table 1253. TCD control fields description

TCD field	Level	Description
CITER[14:0]	—	Current major iteration count
BITER[14:0]	—	Beginning major iteration count
NBYTES[31:0]	—	Inner minor byte transfer count Number of bytes to be transferred in each service request of the channel.
SADDR[31:0]	—	Source address
SOFF[15:0]	—	Source address signed offset Applied to the current source address as each source read is completed.
SSIZE[2:0]	—	Source data transfer size 000 → 8-bit 001 → 16-bit 010 → 32-bit 011 → 64-bit
SLAST[31:0]	—	Last source address adjustment
DADDR[31:0]	—	Destination address
DOFF[15:0]	—	Destination address signed offset Applied to the current destination address as each destination write is completed.
DSIZE[2:0]	—	Destination data transfer size 000 → 8-bit 001 → 16-bit 010 → 32-bit 011 → 64-bit

Table 1253. TCD control fields description (continued)

TCD field	Level	Description
DLAST_SGA[31:0]	—	Last destination address adjustment or the memory address for the next TCD to be loaded into this channel (scatter/gather)
INT_MAJ	High	Enable an interrupt when major iteration count completes
START	High	The channel is explicitly started via a software initiated service request
DONE	High	Channel done (the DMA has completed the outer major loop)
D_REQ	High	Disable request If this flag is set the DMA hardware automatically clears the corresponding DMAERQ bit when the current major iteration count reaches zero.

56.3.5.3 Master node — TX mode

On a master node, in TX mode the DMA interface requires a single TX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in [Figure 1316](#).

Figure 1316. Master node — TX memory map

The TCD chain of the DMA Tx channel on a master node supports:

- Master to Slave: transmission of the entire frame (header + data)
- Slave to Master: transmission of the header; the data reception is controlled by the Rx channel on the master node
- Slave to Slave: transmission of the header

[Table 1254](#) provides the register settings of the LINC2 and BIDR for each class of LIN frame.

Table 1254. Master node — Tx mode — Register setting

LIN frame	LINC2	BIDR
Master to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)
Slave to Master	DDRQ = 0 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)
Slave to Slave	DDRQ = 1 DTRQ = 0 HTRQ = 0	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Tx interface is given in [Figure 1317](#). DMA TX FSM moves to Idle state immediately at next clock edge if DMATXE[0] = 0. The TCD setting (word transfer) is given in [Table 1255](#). All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1255. TCD setting — Master node — Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	$[4 + 4] + 0/4/8 = N$	Data buffer is filled with dummy bytes if length is not word-aligned LINC2 + BIDR + BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	LINC2 address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 1317. Master node — DMA Tx FSM (concept scheme)

56.3.5.4 Master node — RX mode

On a master node in RX mode, the DMA interface requires a single RX channel. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in [Figure 1318](#).

Figure 1318. Master node — RX memory map

The TCD chain of the DMA Rx channel on a master node supports Slave to Master: reception of the data field of the header.

The BIDR register is optionally copied into the RAM area. This BIDR field (part of FIFO data) contains the ID of each message, which only allows the CPU to figure out which ID the LINFlexD DMA received if the single DMA channel setup is used.

The concept FSM to control the DMA Rx interface is given in [Figure 1319](#). DMA RX FSM moves to Idle state immediately at the next clock edge if DMARXE[0] = 0. The TCD setting (word transfer) is given in [Table 1256](#). All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1256. TCD setting — Master node — Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	[4] + 4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing

Table 1256. TCD setting — Master node — Rx mode (continued)

TCD field	Value	Description
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 1319. Master node — DMA Rx FSM (concept scheme)

56.3.5.5 Slave node — TX mode

On a slave node in TX mode, the DMA interface requires a DMA TX channel for each ID filter programmed in TX mode. In case a single DMA TX channel is available, a single ID field filter must be programmed in TX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in [Figure 1320](#).

Figure 1320. Slave node — TX memory map

The TCD chain of the DMA Tx channel on a slave node supports:

- Slave to Master: transmission of the data field
- Slave to Slave: transmission of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in [Table 1257](#).

Table 1257. Slave node — Tx mode — Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Slave to Master or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Tx mode) for each DMA TX channel	– Identifier list mode – Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 1 (TX)

The concept FSM to control the DMA Tx interface is given in [Figure 1321](#). DMA TX FSM moves to Idle state if $DMATXE[x] = 0$ where $x = IFMI - 1$. The TCD setting (word transfer) is given in [Table 1258](#). All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1258. TCD setting — Slave node — Tx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	4/8 = N	Data buffer is filled with dummy bytes if length is not word-aligned BDRL + BDRM
SADDR[31:0]	—	RAM address
SOFF[15:0]	4	Word increment

Table 1258. TCD setting — Slave node — Tx mode (continued)

INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 1321. Slave node — DMA Tx FSM (concept scheme)

56.3.5.6 Slave node — RX mode

On a slave node in RX mode, the DMA interface requires a DMA RX channel for each ID filter programmed in RX mode. In case a single DMA RX channel is available, a single ID field filter must be programmed in RX mode. Each TCD controls a single frame, except for the extended frames (multiple TCDs). The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in [Figure 1322](#).

Figure 1322. Slave node — RX memory map

The TCD chain of the DMA Rx channel on a slave node supports:

- Master to Slave: reception of the data field
- Slave to Slave: reception of the data field

The register setting of the LINCR2, IFER, IFMR, and IFCR registers is given in [Table 1259](#).

Table 1259. Slave node – Rx mode — Register setting

LIN frame	LINCR2	IFER	IFMR	IFCR
Master to Slave or Slave to Slave	DDRQ = 0 DTRQ = 0 HTRQ = 0	To enable an ID filter (Rx mode) for each DMA RX channel	– Identifier list mode – Identifier mask mode	DFL = payload size ID = address CCS = checksum DIR = 0 (RX)

The concept FSM to control the DMA Rx interface is given in [Figure 1323](#). DMA Rx FSM moves to Idle state if DMARXE[x] = 0 where x = IFMI – 1. The TCD setting (word transfer) is given in [Table 1260](#). All other TCD fields = 0. TCD settings based on halfword or byte transfer are allowed.

Table 1260. TCD setting — Slave node — Rx mode

TCD field	Value	Description
CITER[14:0]	1	Single iteration for the major loop
BITER[14:0]	1	Single iteration for the major loop
NBYTES[31:0]	$[4] + 4/8 = N$	Data buffer is filled with dummy bytes if length is not word-aligned BIDR + BDRL + BDRM
SADDR[31:0]	—	BIDR address
SOFF[15:0]	4	Word increment
SSIZE[2:0]	2	Word transfer
SLAST[31:0]	–N	—
DADDR[31:0]	—	RAM address
DOFF[15:0]	4	Word increment
DSIZE[2:0]	2	Word transfer
DLAST_SGA[31:0]	–N	No scatter/gather processing
INT_MAJ	0/1	Interrupt disabled/enabled
D_REQ	1	Only on the last TCD of the chain
START	0	No software request

Figure 1323. Slave node — DMA Rx FSM (concept scheme)

56.3.5.7 UART — TX mode

In UART TX mode, the DMA interface requires a DMA TX channel. A single TCD can control the transmission of an entire Tx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in [Figure 1324](#).

Figure 1324. UART — TX memory map

The UART TX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the RAM to the FIFO
- Use low priority DMA channels

The Tx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

A DMA request is triggered by FIFO-not-full (TX) status signals.

The concept FSM to control the DMA Tx interface is given in [Figure 1325](#). DMA Tx FSM will move to Idle state if DMATXE[0] = 0. The TCD setting (typical case) is given in [Table 1261](#). All other TCD fields = 0. The minor loop transfers a single byte/halfword as soon as a free entry is available in the Tx FIFO.

Table 1261. TCD setting — UART — Tx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0]	—		RAM address
SOFF[15:0]	1	2	Byte/halfword increment
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	–M	–M × 2	—
DADDR[31:0] ⁽¹⁾	—		BDRL address
DOFF[15:0]	0		No increment (FIFO)
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	0		No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. DADDR[31:0] = BDRL + 0x3 for byte transfer — DADDR [31:0] = BDRL + 0x2 for halfword transfer.

Figure 1325. UART — DMA Tx FSM (concept scheme)

56.3.5.8 UART — RX mode

In UART RX mode, the DMA interface requires a DMA RX channel. A single TCD can control the reception of an entire Rx buffer. The memory map associated with the TCD chain (RAM area and LINFlexD registers) is given in [Table 1262](#).

Figure 1326. UART — RX memory map

The UART RX buffer must be configured in FIFO mode in order to:

- Allow the transfer of large data buffer by a single TCD
- Adsorb the latency, following a DMA request (due to the DMA arbitration), to move data from the FIFO to the RAM
- Use low priority DMA channels

The Rx FIFO size is:

- 4 bytes in 8-bit data format
- 2 halfwords in 16-bit data format

This will be sufficient because just one byte allows a reaction time of about 3.8 μ s (at 2 Mbit/s) (~450 clock cycles at 120 MHz) before the transmission is affected. A DMA request is triggered by FIFO and not by empty (Rx) status signals.

The concept FSM to control the DMA Rx interface is given in [Figure 1327](#). DMA Rx FSM will move to Idle state if DMARXE[0] = 0. The TCD setting (typical case) is given in the next table. All other TCD fields equal zero. The minor loop transfers a single byte/halfword as soon an entry is available in the Rx FIFO. A new software reset bit is required that allows the LINFlexD FSMs to be reset in case this timeout state is reached or in any other case. The timeout counter can be re-written by software at any time to extend the timeout period.

Table 1262. TCD setting – UART – Rx mode

TCD field	Value		Description
	8 bits data	16 bits data	
CITER[14:0]	M		Multiple iterations for the major loop
BITER[14:0]	M		Multiple iterations for the major loop
NBYTES[31:0]	1	2	Minor loop transfer = 1 or 2 bytes
SADDR[31:0] ⁽¹⁾	—		BDRM address
SOFF[15:0]	0		No increment (FIFO)
SSIZE[2:0]	0	1	Byte/halfword transfer
SLAST[31:0]	0		—
DADDR[31:0]	—		RAM address
DOFF[15:0]	1	2	Byte/halfword increment
DSIZE[2:0]	0	1	Byte/halfword transfer
DLAST_SGA[31:0]	–M	–M × 2	No scatter/gather processing
INT_MAJ	0/1		Interrupt disabled/enabled
D_REQ	1		Only on the last TCD of the chain
START	0		No software request

1. SADDR = BDRM + 0x3 for byte transfer; SADDR[31:0] = BDRM + 0x2 for halfword transfer.

Figure 1327. UART — DMA Rx FSM (concept scheme)

56.3.5.9 DMA interface timing

The LINFlexD DMA interface includes the following signals:

- **ipd_req**
DMA peripheral request, asserted until the DMA transfer has been completed
- **dma_done_lw**
DMA minor loop done. It indicates that the channel's data transfer of nbytes (the minor loop) has been completed. It is asserted for one cycle after the data phase of the channel's last AMBA AHB write access, or when an error condition is detected
- **dma_ipd_complete**
DMA major loop finished. It is asserted for one cycle after the data phase of the last write
- **dma_ipd_ack, dma_ipd_done**
Unused in this implementation

All signals of the DMA interface must be registered in order to meet timing requirements of the DMA engine.

Figure 1328. DMA interface (major loop — single iteration)

Figure 1329. DMA interface (major loop — N iteration)

56.3.5.10 Use cases and limitations

- In LIN slave mode, the DMA capability can be used only if the ID filtering mode is activated. The number of ID filters enabled must be equal to the number of DMA

channels enabled. The correspondence between channel number and ID filter is based on IFMI (identifier filter match index).

- In LIN master mode both the DMA channels (TX and RX) must be enabled in case the DMA capability is required.
- In UART mode the DMA capability can be used only if the UART Tx/Rx buffers are configured as FIFOs.
- DMA and CPU operating modes are mutually exclusive for the data/frame transfer on a UART or LIN node. Once a DMA transfer is finished the CPU can manage subsequent accesses.
- Error management must always be executed via the CPU enabling the related error interrupt sources. DMA capability does not provide support for error management. Error management means checking status bits, handling IRQs, and potentially canceling DMA transfers.
- The DMA programming model must be coherent with the TCD setting defined in this document
- When IPG_STOP is requested, SW has to first disable DMATXE/DMARXE channel registers, after the current minor loop finishes (indicated by the clearing of ACTIVE bit in DMA TCD register). This ensures that IPG_STOP_ACK is generated and IP enters STOP mode.

56.4 Memory map and register description

56.4.1 Memory map

[Table 1263](#) shows the LINFlexD memory/register map.

Note: In Master mode, the registers IFCR0 – IFCR15 are not present.

In Master Mode, read access to IFMI register and read/write access to IFER and IFMR registers would result in ips_xfr_err being flagged.

Table 1263. LINFlexD memory map

88	Identifier Filter Control registers (IFCR15)	Saf-Relv	on page 2476
8C ⁽²⁾	Global Control register (GCR)	Saf-Relv	on page 2478
90 ⁽²⁾	UART Preset Timeout register (UARTPTO)	Saf-Relv	on page 2480
94 ⁽²⁾	UART Current Timeout register (UARTCTO)	No-Saf	on page 2480
98 ⁽²⁾	DMA Tx Enable register (DMATXE)	Saf-Relv	on page 2482
9C ⁽²⁾	DMA Rx Enable register (DMARXE)	Saf-Relv	on page 2483

1. No-Saf = Not safety relevant, Saf-Lat = Safety Latent, Saf-Relv = Safety Relevant, Saf-Crit = Safety Critical.

2. The address offset depends on the no_of_filters and value of slave. Refer to the device configuration chapter for the number of filters and value of slave used in this device.

56.4.2 Register description

The following points should be considered for the below mentioned LINFlexD registers:

- Reset values are with-slave/without-slave (master only) format
- If not specified, then the bit can be configured for both master only and master/slave format; in other words, for both values of generic slave = 0 and slave = 1.

56.4.2.1 LIN Control Register 1 (LINC1)

LINC1 consists of control bits used to configure features of the LINFlexD.

Figure 1330. LIN Control Register 1 (LINC1)

W																
Reset	0	0	0	0	0	0	0	0	1	0	0	0/1 ⁽²⁾	0	0	1	0

1. Register bit can be read in any mode, written only in Initialization mode.

2. When slave = 0, then this bit will read a 1 always and cannot be programmed.

Table 1264. LINC1 field descriptions

Field	Description
0–15	Reserved Read returns 0
16 CCD	Checksum Calculation disable 0 Checksum calculation is done by hardware When this bit is reset the LINC1FR register is read-only. 1 Checksum calculation is disabled When this bit is set the LINC1FR register is read/write. User can program this register to send a software calculated checksum/CRC (provided CFD is reset). This bit can be written during Initialization mode only. It is read-only in Normal mode.
17 CFD	Checksum field disable 0 Checksum field is sent after the required number of data bytes are sent 1 No checksum field is sent in the frame This bit can be configured during Initialization mode only. It is read-only in Normal mode.

Table 1264. LINCR1 field descriptions (continued)

Field	Description																																		
18 LASE	LIN Auto Synchronization Enable 0 Auto synchronization disabled 1 Auto synchronization enabled This bit can be programmed in Initialization mode only. It is read-only in Normal mode. (Note: If generic auto_sync = 0, then this bit will always read a 0).																																		
19 AUTOWU	Auto Wakeup 0 Sleep bit is cleared by software only 1 Sleep bit gets cleared by hardware whenever WUF bit of LINSR is set This bit can be configured during Initialization mode only. This bit is utilized in UART mode also.																																		
20–23 MBL[3:0]	Master Break Length These bits choose the length of the Sync break to be generated by the master. <table border="1"> <thead> <tr> <th>MBL[3:0]</th><th>Break length</th></tr> </thead> <tbody> <tr><td>0</td><td>10-bit</td></tr> <tr><td>1</td><td>11-bit</td></tr> <tr><td>2</td><td>12-bit</td></tr> <tr><td>3</td><td>13-bit</td></tr> <tr><td>4</td><td>14-bit</td></tr> <tr><td>5</td><td>15-bit</td></tr> <tr><td>6</td><td>16-bit</td></tr> <tr><td>7</td><td>17-bit</td></tr> <tr><td>8</td><td>18-bit</td></tr> <tr><td>9</td><td>19-bit</td></tr> <tr><td>A</td><td>20-bit</td></tr> <tr><td>B</td><td>21-bit</td></tr> <tr><td>C</td><td>22-bit</td></tr> <tr><td>D</td><td>23-bit</td></tr> <tr><td>E</td><td>36-bit (cooling)</td></tr> <tr><td>F</td><td>50-bit</td></tr> </tbody> </table> These bits can be programmed in Initialization mode only. F	50-bit																																		
24 BF	By-pass filter 0 No IRQ if ID does not match any filter 1 A RX IRQ is generated on ID not matching any filter This bit can be programmed during Initialization mode only. <i>Note: If generic_slave = 0 or no_of_filters = 0, then this bit will always read a 1, and cannot be programmed.</i>																																		
25	Reserved																																		

Table 1264. LINCR1 field descriptions (continued)

Field	Description
26 LBKM	Loop Back mode 0 Loop Back Mode disabled 1 Loop Back mode enabled Refer to Section 56.3.2.2, Test mode. Note that this bit can be programmed only in Initialization mode. This bit is utilized in UART mode also.
27 MME	Master mode enable 0 Slave Mode 1 Master Mode This bit can be programmed in Initialization mode only. It is read-only in Normal mode. <i>Note: If generic slave = 0, then this bit will read a '1' always, and cannot be programmed.</i>
28 SSBL	Slave Mode Sync Break Length 0 11 bit break length 1 10 bit break length This bit can be programmed in Initialization mode only. It is read-only in Normal mode.
29 RBLM	Receiver Buffer Locked mode 0 Receiver Buffer not locked, next incoming message will overwrite the old one 1 Receiver buffer locked against overrun Once the buffer is full the next incoming message will be discarded if buffer is not released — in other words, RMB is not reset by software. This bit can be programmed in Initialization mode only. It is read-only in Normal mode. This bit is utilized in UART mode also.
30 SLEEP	Sleep Mode Request This bit is set by software to request LINFlexD to enter Sleep mode. This bit is cleared by software or hardware (if AUTOWU bit in LINCR1 and WUF bit in LINSR are set) to exit sleep mode. This bit is utilized in UART mode also. When in_ps_bit_remap is set, SLEEP bit can be set/cleared by in_ps_sleep signal only.
31 INIT	Initialization Mode Request The software sets this bit to switch the hardware into Initialization mode. On clearing this bit (and if SLEEP bit is also zero) LINFlexD enters normal mode. This bit is utilized in UART mode also. When in_ps_bit_remap is set, INIT bit can be set/cleared by in_ps_init signal only.

56.4.2.2 LIN Interrupt enable register (LINIER)

Figure 1331. LIN Interrupt enable register (LINIER)

Table 1265. LINIER field descriptions

Field	Description
0–15	Reserved Read returns 0
16 SZIE	Stuck at Zero Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Stuck at Zero Flag (SZF) in LINESR or UARTSR is set.
17 OCIE	Output Compare Interrupt Enable 0 No interrupt 1 Interrupt generated when OCF bit in LINESR or UARTSR is set
18 BEIE	Bit Error Interrupt Enable 0 No interrupt 1 Interrupt generated when BEF bit in LINESR is set
19 CEIE	Checksum Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Checksum Error Flag (CEF) is set in LINESR.
20 HEIE	Header Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and either of the following flags are set SFEF, SDEF, IDPEF in LINESR are set. <i>Note: If generic slave = 0, then this bit will always read a 0 and cannot be programmed.</i>
21–22	Reserved Read returns 0.

Table 1265. LINIER field descriptions (continued)

Field	Description
23 FEIE	Frame Error Interrupt Enable 0 No interrupt 1 Interrupt generated if Frame Error Flag (FEF) bit is set in LINESR or UARTSR
24 BOIE	Buffer Overrun Error Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the Buffer Overrun Flag (BOF) is set in LINESR or UARTSR.
25 LSIE	LIN state Interrupt enable 0 No interrupt 1 Interrupt generated on entering the following states: Sync Del, Sync Field, Identifier field, Checksum Interrupt is generated only when entering the above fields. This interrupt can mainly be used for debugging purposes. The interrupt has no status flag.
26 WUIE	Wakeup interrupt enable 0 No interrupt 1 Interrupt enabled If this bit is set and the WUF in LINSR or UARTSR is set then an interrupt is generated.
27 DBFIE	Data Buffer Full Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and the DBFF bit in LINSR is also set.
28 DBEIE/TOIE	Data Buffer Empty Interrupt enable/Timeout Interrupt Enable 0 No interrupt 1 Interrupt enabled An interrupt is generated if this bit is set and LINSR[DBEF] status bit is set (in LIN mode) or if this bit is set and UARTSR[TO] status bit is set (in UART mode).
29 DRIE	Data Reception complete Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Received flag (DRF) in LINSR or UARTSR is set.
30 DTIE	Data Transmitted Interrupt enable 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and Data Transmitted flag (DTF) in LINSR or UARTSR is set.
31 HRIE	Header Received Interrupt 0 No interrupt 1 Interrupt enabled An interrupt is generated when this bit is set and the Header Received flag (HRF) in LINSR is set. <i>Note: If generic slave = 0, then this bit will always read a 0, and cannot be programmed.</i>

56.4.2.3 LIN Status Register (LINSR)

This register consists of status bits indicating the state of the LINFlexD hardware.

Figure 1332. LIN Status Register (LINSR)

Address: 0x0008h

Access: User read/write

Table 1266. LINSR field description

Field	Description
0–11	Reserved Read returns 0
12 AUTOSYNC_C OMP	AUTOSYNC_COMP This bit is set after autosynchronization is complete and when the LASE bit in LINCR1 register is enabled. Only after this bit is set, the contents of LINIBRR and LINFBRR registers can be read in autosynchronization mode.
13–15 RDC	Receive Data Byte Count RDC contains the number of entries (bytes) in the Receive data buffer in LIN mode. RDCx is a read-only field available for debug purposes. 000 1 byte 001 2 bytes 010 3 bytes 011 4 bytes 100 5 bytes 101 6 bytes 110 7 bytes 111 8 bytes

Table 1266. LINSR field description (continued)

Field	Description
16–19 LINS[3:0]	LIN state 0: Sleep mode LINFlexD is in Sleep mode, to save power consumption. 1: Init, 2: Idle This mode is entered when: – SLEEP bit and INIT bit are reset by software. – Wakeup pulse has been received on RX pin (AUTOWU set). – Previous frame transmission/reception has been completed/aborted. 3: Sync Break In slave mode, a falling edge followed by a dominant state has been detected. Receiving sync break. In master mode, sync break transmission ongoing. <i>Note: In slave mode upon any error LIN state could be either Idle or Rec Break, depending on last bit detected on LIN_RX. If last bit detected is dominant then Rec_Break, otherwise Idle.</i> 4: Sync Del In Slave mode, valid Sync break has been detected (10 bit or 11 bit). Waiting for a rising edge. In Master mode, Sync break transmission has been completed, sync delimiter transmission is ongoing. 5: Sync Field In Slave mode, a valid sync Del has been detected (recessive state for at least one bit time). Receiving sync field. In Master mode, sync field transmission ongoing. 6: Identifier Field In Slave mode, a valid sync field has been received. Receiving ID field. In Master mode, identifier transmission is ongoing. 7: Header Reception/Transmission In Slave mode, a valid header has been received and Identifier field is available in the BIDR. In Master mode, header transmitted. 8: Data Reception/Data Transmission In Receiver mode, reception ongoing. In Transmitter mode, response transmission ongoing. 9: <i>Checksum</i> Data transmission/reception completed, checksum transmission/reception ongoing. In UART mode Idle, Init, Sleep, and Data Transmission/Reception states are flagged by the LIN status bits.
20–21	Reserved Read returns 0.
22 RMB	Release Message Buffer 0 Buffer data is free. Reset by hardware in when in Initialization mode 1 Buffer data ready to be read by software. This bit should be cleared by software after reading the data received in the buffer.

Table 1266. LINSR field description (continued)

Field	Description
23 DRBNE	Data Reception Buffer Not Empty Flag This bit is set by hardware as soon as the first byte of response has been received and stored in BDRL (when there is at least one data byte in reception buffer). Software should clear it after reading all the buffers. This bit is also reset by hardware in Initialization mode. This flag could be checked by software in case of a response timeout event.
24 RXbusy	Receiver Busy flag 0 Receiver is idle 1 Reception ongoing In Slave mode after header reception, if DIR bit is reset and reception starts, then this bit is set. In this case user cannot set the DTRQ bit.
25 RDI	LIN Receive signal This bit reflects the current status of the Rx pin. <i>Note: After reset is released, RDI reflects the actual value of Rx pin.</i>
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the Rx pin. 1. When slave is in Sleep mode 2. When master is in Sleep mode or Idle mode It can be cleared by software. It gets reset by hardware in Initialization mode.
27 DBFF	Data Buffer full flag This bit is set by hardware when the buffer is full (8 bytes received) and DFL > 7. It should be cleared by software. This bit is also reset by hardware in Initialization mode.
28 DBEF	Data Buffer empty flag This bit is set by hardware when the buffer is empty (8 bytes have been transmitted) and DFL > 7. It should be cleared by software after data buffer is refilled by software. Transmission of next 8 bytes will not start unless this bit is reset by software. This bit is also reset by hardware in Initialization mode.
29 DRF	Data Reception Completed flag This bit is set by hardware and indicates that data reception has been completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. <i>Note: In case framing error or checksum error occurs then this flag is not set.</i>

Table 1266. LINSR field description (continued)

Field	Description
30 DTF	Data Transmission Completed flag This bit is set by hardware and indicates that data transmission is completed. This flag should be cleared by software. This bit is also reset by hardware in Initialization mode. <i>Note: For LIN mode, in case a bit error occurs (and IOBE is reset) then this flag is not set.</i>
31 HRF	Header Received flag This bit is set when the header reception is completed. It should be cleared by software. This bit is set only when: a) All filters are inactive and Bypass filter (BF) bit is set b) No match in any filter and Bypass filter (BF) bit is set c) TX filter match At end of frame or frame aborted, if HRF is still set, it gets reset by hardware. This bit is also reset by hardware in Initialization mode. <i>Note: If generic slave = 0, then this bit will always read a 0, and cannot be programmed.</i>

56.4.2.4 LIN Error Status Register (LINESR)

Figure 1333. LIN error status register (LINESR)

Address: 000Ch

Access: User read/write

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Refer to [Section 56.3.2.5, Errors](#) for detailed description of all errors.

Table 1267. LINESR field descriptions

Field	Description
0–15	Reserved Read returns 0
16 SZF	Stuck at Zero flag This bit is set when there is a stuck-at-zero timeout error. It should be reset by software.

Table 1267. LINESR field descriptions (continued)

Field	Description
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of OCR1 or OCR2 This bit should be cleared by software. If this bit is set and the IOT bit of LINTCSR is set, then LINFlexD moves to Idle state. If the MODE bit in LINTCSR is clear, then OCF gets reset by hardware in Initialization mode; if the MODE bit is set, then OCF maintains its status irrespective of the LIN state.
18 BEF	Bit Error flag This bit is set by hardware when there is a bit error. It should be cleared by software. Reset by hardware in Initialization mode.
19 CEF	Checksum Error flag This bit is set by hardware if the received checksum does not match the hardware-calculated checksum. It should be cleared by software. This error will never occur if CCD or CFD bit of LINC1R1 is set. Reset by hardware in Initialization mode.
20 SFEF	Sync Field Error flag This bit is set by hardware when the received Sync Field is inconsistent. It should be cleared by software. Reset by hardware in Initialization mode. If generic <i>slave</i> = 0, then this bit will always read a 0, and cannot be programmed.
21 SDEF	Sync Delimiter Error flag This bit is set by hardware when the delimiter is too short (in other words, less than one bit time). It should be cleared by software. Reset by hardware in Initialization mode. <i>Note: If generic slave = 0, then this bit will always read a 0, and cannot be programmed.</i>
22 IDPEF	ID Parity Error flag This bit is set by hardware when there is an error in the ID parity. It should be cleared by software. <i>Note: Header Error Interrupt is triggered for SFEF or SDEF or IDPEF flag is set and HEIE is set.</i> If generic <i>slave</i> = 0, then this bit will always read a 0, and cannot be programmed. For generic <i>slave</i> = 1, this bit is reset by hardware in Initialization mode.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. Reset by hardware in initialization mode.
24 BOF	Buffer overrun flag This bit is set by hardware when there is a new byte received and RMB bit is not cleared. It can be cleared by software. Reset by hardware in initialization mode.

Table 1267. LINESR field descriptions (continued)

Field	Description
25–30	Reserved Read returns 0.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. Reset by hardware in Initialization mode.

56.4.2.5 UART Mode Control Register (UARTCR)

Figure 1334. UART Mode Control Register (UARTCR)

Address: 0010h

Access: User read/write

1. Register bit can be read in any mode, written only in Initialization mode.

2. Register bit is a read/write field.

3. Register bit is read-only field.

Table 1268. UARTCR field descriptions

Field	Description										
0 MIS	Monitor Idle State 1UARTCTO monitors the idle state of the reception line. 0UARTCTO monitors the number of bits to be received. The default value of this bit is 0.										
1–3 CSP	Configurable Sample Point (i) These bits will decide the sample point during reduced over sampling (ROSE=1). CSP can take the following range of values for a certain over sampling rate: <table border="1"> <thead> <tr> <th>OSR</th><th>CSP</th></tr> </thead> <tbody> <tr> <td>4</td><td>2, 3</td></tr> <tr> <td>5</td><td>2, 3, 4</td></tr> <tr> <td>6</td><td>3, 4, 5</td></tr> <tr> <td>8</td><td>NA</td></tr> </tbody> </table> For any values of CSP other than the ones mentioned in the above table, data sampled is erroneous.	OSR	CSP	4	2, 3	5	2, 3, 4	6	3, 4, 5	8	NA
OSR	CSP										
4	2, 3										
5	2, 3, 4										
6	3, 4, 5										
8	NA										
4–7 OSR	Over Sampling Rate These bits are programmable by the user to configure the number of samples taken for a bit when reduced over sampling is enabled (ROSE=1). For proper functionality, OSR can only take values 4, 5, 6, and 8. For any other values start bit of data is not detected by receiver and thus the reception will never start.										
8 ROSE	Reduced Over Sampling Enable 0Each bit is over sampled sixteen times. 1OSR bits decide the over sampling rate. The default value of this bit is 0.										
9–11 NEF	Number of expected frame These bits are used to configure the number of expected frames in UART reception mode. If the DTU bit is set, then the UART timeout counter will be reset after the configured number of frames have been received.										

Table 1268. UARTCR field descriptions (continued)

Field	Description
12 DTU/PCE_Tx	Disable Timeout in UART mode/Parity transmission and checking When in_ps_bit_remap is set: 0 Parity transmission and checking disabled 1 Parity transmission and checking enabled When in_ps_bit_remap is cleared: 0 Timeout has to be handled by software 1 Timeout in UART mode is disabled after the configured number of data frames are received This bit can be programmed in initialization mode only when the UART bit is set. There is an internal counter that gives the number of frames received. In Buffer mode: The timer gets reset whenever the number of bytes received (rec_byte_cnt) is equal to RDFL. At this point the DRF bit is also set and num_of_frames (number of frames received), rec_byte_cnt are reset. When num_of_frames equals NEF, Disable Timeout is generated. But this clears num_of_frames also. Thus the timer restarts again. The value of counter is 0 when it restarts. In FIFO mode: When num_of_frames equals NEF, Disable Timeout is generated which clears num_of_frames and causes the timer to restart again. The value of counter is 0 when it restarts. <i>Note:</i> – Disable Timeout causes only the Timer to restart which enables Timeout again – Timer reset means it resets and starts counting again and the Timeout is enabled.
13–14 SBUR	Stop bits in UART reception mode When the UART is used for transmission and reception we have to set the same number of stop bits in GCR and SBUR. When the UART is used only as receiver, it is enough to set SBUR bits only. 00 1 stop bit 01 2 stop bits 10 3 stop bits 11 Reserved This bit can be programmed in the initialization mode only, when the UART bit is set.
15 WLS	Special Word Length in UART mode 0 This bit is disabled. 1 This bit enables 12-bit + parity bit in reception (UART mode) for MSC (Micro Second Channel upstream frame) support. This bit can be programmed in initialization mode only when the UART bit is set. Parity check is enabled by default in this mode and PC0/1 bits can be used to select the parity control. This bit is given the highest priority in UART reception mode.

Table 1268. UARTCR field descriptions (continued)

Field	Description
16–18 TDFL/TFC	Transmitter Data Field Length/TX FIFO Counter TDFL defines the number of bytes to be transmitted in UART buffer mode (TFBM = 0). TDFL is a read/write field. Bit 15 is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations TDFL = x01 or TDFL = x11 are allowed. x00 1 byte x01 2 bytes x10 3 bytes x11 4 bytes TFC contains the number of entries (bytes) of the Tx FIFO in UART FIFO mode (TFBM = 1). TFCx is a read-only field available for debug purposes. 000 empty 001 1 byte 010 2 bytes 011 3 bytes 100 4 bytes Others: Reserved TDFL/TFC can be programmed and are significative only when the UART bit is set.
19–21 RDFL/RFC	Reception Data Field Length /RX FIFO Counter RDFL defines the number of bytes to be received in UART buffer mode (RFBM = 0). RDFL is a read/write field. Bit 19 is reserved and not implemented. When the UART data length is configured as a halfword (WL = 10 or WL = 11), only the configurations RDFL = x01 or RDFL = x11 are allowed. x00 1 byte x01 2 bytes x10 3 bytes x11 4 bytes RFC contains the number of entries (bytes) of the Rx FIFO in UART FIFO mode (RFBM = 1). RFCx is a read-only field available for debug purposes. 000 empty 001 1-byte 010 2 bytes/1.5 byte in case of WLS bit setting 011 3 bytes 100 4 bytes/2×1.5 byte in case of WLS bit setting Others: reserved RDFL/RFC can be programmed and are significative only when the UART bit is set. <i>Note: In buffer mode, RDFL should be programmed to be greater than or equal to NEF (number of expected frames). In FIFO mode, there is no such constraint.</i>
22 RFBM	RFBM Rx Fifo/Buffer mode 0 Rx Buffer mode enabled 1 Rx Fifo mode enabled (mandatory in DMA Rx mode) This bit can be programmed in Initialization mode, only when the UART bit is set.
23 TFBM	Tx Fifo/Buffer mode 0 Tx Buffer mode enabled 1 Tx Fifo mode enabled (mandatory in DMA Tx mode) This bit can be programmed in initialization mode, only when the UART bit is set.

Table 1268. UARTCR field descriptions (continued)

Field	Description
24 WL1	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when the UART bit is set.
25 PC1	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set.
26 RxEn	Receiver Enable 0 Receiver disabled 1 Receiver enabled This bit can be programmed only when the UART bit is set.
27 TxEn	Transmitter Enable 0 Transmitter disabled 1 Transmitter enabled, transmission starts only when this bit is set and Data byte 0 (DATA0) is programmed This bit can be programmed only when UART bit is set.
28 PC0	Parity Control 00 Parity sent is Even 01 Parity sent is Odd 10 A logical 0 is always transmitted/checked as parity bit 11 A logical 1 is always transmitted/checked as parity bit This bit can be programmed in Initialization mode, only when UART bit is set.
29 PCE	Parity Control Enable When in_ps_bit_remap is set: 0 Parity reception and checking disabled 1 Parity reception and checking enabled When in_ps_bit_remap is cleared: 0 Parity transmission, reception, and checking disabled 1 Parity transmission, reception, and checking enabled This bit can be programmed in Initialization mode only, when the UART bit is set.
30 WL0	Word Length in UART mode 00 7 bits data + parity 01 8 bits data when PCE = 0 or 8 bits data + parity when PCE = 1 10 15 bits data + parity 11 16 bits data when PCE = 0 or 16 bits data + parity when PCE = 1 This bit can be programmed in Initialization mode only, when UART bit is set.
31 UART	UART Mode 0 LIN mode 1 UART mode This bit can be programmed in Initialization mode only.

56.4.2.6 UART Mode Status Register (UARTSR)

Figure 1335. UART Mode Status Register (UARTSR)

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Register bit can be read/cleared by software. Writing 1 clears contents.
2. Register bit is read-only field.

Table 1269. UARTSR field descriptions

Field	Description
0–15	Reserved Read returns 0
16 SZF	Stuck at Zero flag This bit is set by hardware when 100 dominant bits are detected. It should be cleared by software. An interrupt will be generated if the SZIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
17 OCF	Output Compare Flag 0 No output compare event occurred 1 The content of the counter has matched the content of LINOCCR An interrupt will be generated if the OCIE bit in LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set. <i>Note: For Baud rate above 1 Mbit/s, this flag is not usable.</i>

Table 1269. UARTSR field descriptions (continued)

Field	Description
18—21 PE[0:3]	Parity Error flag These bits indicate if there is a Parity Error in the corresponding byte. No interrupt is generated if this error occurs. 0 No parity error 1 Parity error in the corresponding received byte This bit will reflect the same value as in LINESR, when in initialization mode and UART bit set. <i>Note: Parity is checked only after a complete frame is received.</i> When WL bits = 10 or 11, either PE0 or PE2 is only set. – When PE0 is set, it indicates Parity error in either first or second byte received – When PE2 is set, it indicates Parity error in either third or fourth byte received
22 RMB	Release Message Buffer 0 Buffer data is free 1 Buffer data ready to be read by software This bit should be cleared by software. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
23 FEF	Framing Error flag This bit is set by hardware when there is a framing error (invalid stop bit). It should be cleared by software. It will generate an interrupt if the FEIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
24 BOF	FIFO/Buffer overrun flag This bit is set by hardware when there is a new byte received and the RMB bit is not cleared in UART buffer mode. In UART FIFO mode this bit is set when there is a new byte and the Rx FIFO is full. In UART FIFO mode, once Rx FIFO is full, the new received message will be discarded irrespective of the value of the RBLM bit. In UART Rx Buffer mode, if RBLM is set then the new message received will be discarded; if RBLM is reset then the new message will overwrite the buffer. It can be cleared by software writing a 1. An interrupt is generated if the BOIE bit of LINIER is set. This bit will reflect the same value as in LINESR, when in Initialization mode and the UART bit is set.
25 RDI	Receiver Data Input signal This bit reflects the current status of the RX pin.
26 WUF	Wakeup flag This bit is set by hardware when a falling edge is detected on the RX pin in sleep mode. It should be cleared by software. An interrupt will be generated if the WUIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set.
27 RFNE	Receive FIFO Not Empty RFNE bit is set by hardware in UART FIFO mode (RFBM = 1), when there is at least one data byte present in the receive FIFO. RFNE is a read-only bit for debugging purposes. This flag can be used by software in case of a timeout event.

Table 1269. UARTSR field descriptions (continued)

Field	Description
28 TO	Timeout This bit is set by hardware when a UART timeout occurs — in other words, the value of UARTCTO becomes equal to the preset value of the timeout (UARTPTO register setting). TO should be cleared by software. The SR bit should be used to reset the receiver fsm to Idle state in case of UART TIMEOUT for UART reception, depending on the application, in both buffer and FIFO mode. An interrupt will be generated when LINIER.DBEIE/TOIE bit is set on the Error interrupt line in UART mode.
29 DRF/RFE	Data Reception Completed Flag /Rx FIFO Empty Flag DRF is set by hardware in UART buffer mode (RFBM = 0) and indicates that the number of bytes programmed in RDFL have been received. DRF should be cleared by software. An interrupt will be generated if the DRIE bit in LINIER is set. DRF bit is set only when the configured number of stop bits are received for the last frame (number of frames is configurable by RDFL bits). DRF is set irrespective of framing error, parity error or overrun error. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. RFE is set by hardware in UART FIFO mode (RFBM = 1) when the RX FIFO is empty. RFE is a read-only bit for debugging purposes. It is internally used by the DMA RX interface.
30 DTF/TFF	Data Transmission Completed Flag/ TX FIFO Full Flag DTF is set by hardware in UART buffer mode (TFBM = 0) and indicates that data transmission is completed. DTF should be cleared by software. An interrupt will be generated if the DTIE bit in LINIER is set. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. TFF is set by hardware in UART FIFO mode (TFBM = 1) when TX FIFO is full. TFF is a read-only bit for debugging purposes. It is internally used by the DMA TX interface.
31 NF	Noise flag This bit is set by hardware when noise is detected in the received character. It should be cleared by software. This bit will reflect the same value as in LINESR when in Initialization mode and the UART bit is set. During reduced oversampling (ROSE bit = 1), it is enabled only when OSR = 8.

56.4.2.7 LIN Time-Out Control Status Register (LINTCSR)

This register contains control and status bits for the timeout feature.

Figure 1336. LIN Time-Out Control Status Register (LINTCSR)

Address: 0018H

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Register bit can be read in any mode, written only in Initialization mode.

Table 1270. LINTCSR field descriptions

Field	Description
0–20	Reserved Read returns 0.
21 MODE	Time-out counter mode 0 LIN mode 1 Output compare mode This bit can be configured only during initialization.
22 IOT	Idle on timeout 0 LIN state machine does not reset to Idle on timeout 1 LIN state machine resets to Idle on timeout event
23 TOCE	Time-out counter enable 0 Time-out counter disable OCF flag is not set on an output compare event. 1 Time-out counter enable OCF flag is set if an output compare event occurs. TOCE is always configurable by software in Initialization mode. If LIN state is other than INIT and if timer is configured in LIN mode, then hardware takes control of TOCE.
24–31 CNT[0:7]	Counter Value These bits reflect the value of a free-running counter used for timeout.

56.4.2.8 LIN Output Compare Register (LINOCR)

This register contains the value to be compared to the LINTOCR value. This register is writable by software only in Output Compare Mode.

Figure 1337. LIN Output Compare Register (LINOCR)

Address: 001CH

Access: User read/write

1. These reset values are valid only for Master mode.

Table 1272. LINTOCR field descriptions

Field	Description
0–19	Reserved Read returns 0.
20–23 RTO[3:0]	Response timeout value This is the response timeout duration (in bit time) for 1 byte. The reset value is 0Eh = 14, corresponding to $T_{\text{Response_Maximum}} = 1.4 \times T_{\text{Response_Nominal}}$
24	Reserved Read returns 0.
25–31 HTO[6:0]	Header timeout value This register contains the header timeout duration (in bit time). This register can be written only for Slave mode. The reset value is the 2Dh = 45, corresponding to $T_{\text{Header_Maximum}}$ in the LIN specification. If Master mode is enabled then these bits will always reflect 28 (1.4×10 bits of sync + 1.4×10 bits of ID). For slave, these bits should be programmed without considering 11 bits of break.

56.4.2.10 LIN Fractional Baud Rate Register (LINFBRR)

This register consists of bits that decide the fractional part of the LIN Baud Rate. It can be programmed only in Initialization mode.

Note: When LASE bit is set, this register should be read only after AUTOSYNC_COMP bit in LINSR register is set to obtain the correct value.

This register cannot be used when reduced oversampling is enabled (ROSE bit = 1)

1. Register bit can be read in any mode, written only in Initialization mode.
2. Register bit can be read/set by software.
3. When slave = 0, then this bit will always read a 0, and cannot be programmed.

Table 1276. LINC2 field descriptions

Field	Description
0–15	Reserved Read returns 0.
16 TBDE	Two Bit delimiter bit 0 Delimiter length in break field is 1 bit 1 Delimiter length in break field is 2 bits This bit can be set in Initialization mode only.
17 IOBE	Idle on Bit Error 0 Bit Error does not reset LIN state machine 1 Bit Error resets LIN state machine This bit can be set in Initialization mode only.
18 IOPE	Idle on Identifier Parity Error 0 Parity Error does not reset LIN state machine 1 Parity Error resets LIN state machine This bit can be set in Initialization mode only. If generic <i>slave</i> = 0, then this bit will always read a 0, and cannot be programmed.
19 WURQ	Wakeup Generate Request Setting this bit will generate a wakeup pulse. It is reset by hardware when the wakeup character has been transmitted. The character sent during wakeup is copied from BDRL (DATA0). Note that this bit cannot be set in Sleep mode — software has to exit Sleep mode before setting this bit. Bit Error is not checked when transmitting the wakeup request.
20 DDRQ	Data Discard request Set by software to stop data reception if the frame does not concern the node. This bit is reset by hardware once LINFlexD ignores the response and moves to Idle state. For LIN slave this bit can be set only when HRF bit is set and Identifier is software-filtered.
21 DTRQ	Data Transmission Request Set by software in slave mode to request the transmission of the LIN Data field stored in the Buffer data register. This bit can be set only when the HRF bit is set (to ensure that data transmission is requested only after a header reception). Cleared by hardware when the request has been completed, or on abort request or error condition. In Master mode, this bit is set by hardware when the DIR bit is set and header transmission is complete.
22 ABRQ	Abort Request Set by software to abort the current transmission. Cleared by hardware when the transmission has been aborted. LINFlexD aborts the transmission at the end of the current bit. This bit can abort a wakeup request also and can be used in UART mode also.

Table 1276. LINCR2 field descriptions (continued)

Field	Description
23 HTRQ	Header Transmission Request Set by software to request the transmission of the LIN Header. Cleared by hardware when the request has been completed or on abort request. This bit has no effect in UART mode. <i>Note: In master mode, if both HTRQ and ABRQ are set at the same time then ABRQ has no effect. Similarly, in slave mode after header reception, if DTRQ and ABRQ are simultaneously set then ABRQ has no effect.</i>
24–31	Reserved Read returns 0.

56.4.2.14 Buffer Identifier Register (BIDR)

This register contains the bits which provide information about the identifier of the transaction and other related information.

Note: All the fields (ID, CSS, DIR, DFL) of the BIDR register must be updated when an ID filter (enabled) in Slave mode (Tx or Rx) matches the ID received.

Figure 1343. Buffer Identifier Register (BIDR)

2. Register bit can be written only by software in Initialization mode. Bit is always read 0 by software.
3. Refer to device configuration chapter to see the number of filters and value of slave used in the device.

Table 1285. GCR field descriptions

Field	Description
0–25	Reserved Forced to 0 by hardware
26 TDFBM	Transmit data first bit MSB This bit controls the first bit of transmit data (payload only) as MSB/LSB in both UART and LIN modes. 0 The first bit of transmitted data is LSB — in other words, the first bit transmitted is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of transmitted data is MSB — in other words, the first bit transmitted is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
27 RDFBM	Received data first bit MSB This bit controls the first bit of received data (payload only) as MSB/LSB both in UART and LIN modes. 0 The first bit of received data is LSB — in other words, the first bit received is mapped on LSB bit (BDR (0), BDR (8), BDR (16), BDR (24)) 1 The first bit of received data is MSB — in other words, first bit received is mapped on MSB bit (BDR (7), BDR (15), BDR (23), BDR (31))
28 TDLIS	Transmit data level inversion selection This bit controls the data inversion of transmitted data (payload only) in both UART and LIN modes. 0 Transmitted data is not inverted 1 Transmitted data is inverted

Table 1285. GCR field descriptions (continued)

Field	Description														
29 RDLIS	Received data level inversion selection This bit controls the data inversion of received data (payload only) in both UART and LIN modes. 0 Received data is not inverted 1 Received data is inverted														
30 STOP	1/2 stop bit configuration This bit controls the number of stop bit transmitted data in both UART and LIN modes. The stop bit is configured for all the fields (Delimiter, Sync, ID, Checksum, Payload). 0 1 stop bit 1 2 stop bits														
31 SR	Soft reset SR executes a soft reset of the LINFlexD controller (FSMs, FIFO pointers, counters, timers, status and error registers) without modifying the configuration registers when a 1 write operation is performed. This bit should be cleared by software to perform further operations (this bit is not cleared by hardware). This bit is always read as 0. The following table describes, the register fields reset by SR: <table> <tr> <th>Register</th><th>Comment</th></tr> <tr> <td>LINSR</td><td>All fields except RXbusy and AUTOSYNC_COMP are reset</td></tr> <tr> <td>LINESR</td><td>All fields are reset</td></tr> <tr> <td>LINTCSR</td><td>Only CNT[0:7] is reset</td></tr> <tr> <td>UARTSR</td><td>All fields except RFE & TFF are reset</td></tr> <tr> <td>UARTCR</td><td>Only TFC & RFC are reset</td></tr> <tr> <td>UARTCTO</td><td>All fields are reset</td></tr> </table>	Register	Comment	LINSR	All fields except RXbusy and AUTOSYNC_COMP are reset	LINESR	All fields are reset	LINTCSR	Only CNT[0:7] is reset	UARTSR	All fields except RFE & TFF are reset	UARTCR	Only TFC & RFC are reset	UARTCTO	All fields are reset
Register	Comment														
LINSR	All fields except RXbusy and AUTOSYNC_COMP are reset														
LINESR	All fields are reset														
LINTCSR	Only CNT[0:7] is reset														
UARTSR	All fields except RFE & TFF are reset														
UARTCR	Only TFC & RFC are reset														
UARTCTO	All fields are reset														

56.4.2.23 UART Preset Timeout Register (UARTPTO)

This register contains the preset value of the timeout register in UART mode and is programmed according to the number of bits to be received or to monitor the idle state of the reception line. This register can be written by software any time.

Figure 1352. UART Preset Timeout Register (UARTPTO)

Address: (GCR address)⁽¹⁾+04h

Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1

1. Depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Table 1286. UARTPTO field descriptions

Field	Description
0–19	Reserved Read returns 0.
20–31 PTO[11:0]	Preset Timeout PTO defines the preset value of timeout counter. A zero-value is forbidden, otherwise the UARTSR[TO] status bit is immediately set. Refer also to register UARTCTO.

56.4.2.24 UART Current Timeout Register (UARTCTO)

This register contains the current timeout value in UART mode, and is used in conjunction with the UARTPTO register (see [Section 56.4.2.23, UART Preset Timeout Register \(UARTPTO\)](#)) to monitor the number of bits received by UART or to monitor the idle state of the reception line. UART timeout works in both CPU and DMA modes.

The timeout counter:

- Starts at zero and counts upward
- Is clocked with LIN_CLK / (16 * LDIV) synchronized to PBRIDGE_{Ex}_CLK (when ROSE = 0)
- Is clocked with LIN_CLK / (OSR * IBRR) synchronized to PBRIDGE_{Ex}_CLK (when ROSE = 1)
- Is automatically enabled when UARTCR[RXEN] = 1

Note: Due to this synchronization there is a delay between 4 to 6 clock cycles of PBRIDGE_{Ex}_CLK for the internal counter's value (which is clocked with LIN_CLK/16 * LDIV when ROSE = 0 or LIN_CLK/OSR * IBRR when ROSE = 1) to reflect on UARTCTO.

It is reset when:

- Number of frames received is equal to NEF bits
- UARTCTO becomes equal to UARTPTO
- Whenever UARTPTO is written
- When DRF is set and DTU bit = 1

1. Depends on no_of_filters. Refer to device configuration chapter to see the number of filters used in the device.

Table 1287. UARTCTO field descriptions

Field	Description
0–19	Reserved Read returns 0.
20–31 CTO[11:0]	Current Timeout CTO defines the current value of the timeout counter. CTO is a read-only field. CTO is reset every time UARTPTO is re-initialized, or UARTCTO = UARTPTO, or by hard/soft reset. When the CTO value matches the preset value (UARTPTO), the status bit UARTSR[TO] is set.

56.4.2.25 DMA Tx Enable Register (DMATXE)

This register enables the DMA TX interface. This register can be written and read by software any time.

Figure 1354. DMA Tx Enable Register (DMATXE)

56.5 Programming considerations

The next subsections describe the various configurations in which the LINFlexD module can be used.

56.5.1 Master node

LINFlexD acts as Master when the MME bit is set.

56.5.1.1 Transmitter

Figure 1356. Master node — transmitter configuration

56.5.1.2 Receiver

Figure 1357. Master node — receiver configuration

56.5.1.3 Transmitter, Bit Error

Figure 1358. Master node — transmitter, bit error configuration

Figure 1359. Master node — transmitter, checksum error configuration

56.5.1.4 Receiver, Checksum Error

Figure 1360. Master node — receiver, checksum error configuration

56.5.2 Slave node

56.5.2.1 Transmitter (no identifier filters)

Figure 1361. Slave node — transmitter (no identifier filters) configuration

56.5.2.2 Receiver (no identifier filters)

Figure 1362. Slave node — receiver (no identifier filters) configuration

Figure 1363. Slave node — receiver (no identifier filters) configuration

56.5.2.3 No filters, transmitter, bit error

Figure 1364. Slave node — No filters, transmitter, bit error configuration

56.5.2.4 No filters, receiver, checksum error

Figure 1365. Slave node — No filters, receiver, checksum error configuration

56.5.2.5 At least one TX filter, BF is reset, ID matches filter

This configuration can be used in case slave never receives data, for example, sensor.

Figure 1366. Slave node — one TX filter configuration

56.5.2.6 At least one RX filter, BF reset, ID matches filter

Figure 1367. Slave node — one RX filter configuration

56.5.2.7 RX only, TX only, RX & TX filters, ID not matching filter, BF reset

Figure 1368. RX only, TX only, RX & TX filters configuration

56.5.2.8 TX filter, BF is set

This configuration is used when:

- All TX IDs are handled by filters.
- There are not enough other filters to handle all reception IDs.

Figure 1369. TX filter, BF is set configuration — ID has matched

Figure 1370. TX filter, BF is set configuration — ID not matched

56.5.2.9 RX filter, BF is set

Figure 1371. RX filter, BF is set configuration — ID matched

Figure 1372. RX filter, BF is set configuration — ID not matched (ID is Rx)

Figure 1373. RX filter, BF is set configuration — (ID is Tx)

56.5.2.10 TX filter, RX filter, BF set

This configuration is used when:

- There are not enough filters.
- The filters are used for most frequently used IDs to reduce CPU usage.

Figure 1374. TX filter, RX filter, BF set configuration — (ID matched)

Figure 1375. TX filter, RX filter, BF set configuration — (ID matched + 1)

Figure 1376. TX filter, RX filter, BF set configuration — (ID not matched, RX/TX Interrupt)

56.5.3 Extended frames

Figure 1377. Extended frames (TX Interrupt)

Figure 1378. Extended frames (RX Interrupt)

56.5.4 Timeout

Master Node: Response (during reception only) and frame timeout are checked.

Slave Node: Header, Response (during reception only), and frame timeout are checked.

Figure 1379. Response timeout

Figure 1380. Frame timeout

Figure 1381. Header timeout

56.5.5 UART mode

Figure 1382. UART mode configuration

56.5.6 Interrupts

Table 1291. Interrupts

Interrupt event	Event flag	Enable control bit	Interrupt vector
Stuck at zero	SZF	SZIE	Error
Output compare	OCF	OCIE	Error
Bit error	BEF	BEIE	Error
Checksum error	CEF	CEIE	Error

Table 1291. Interrupts (continued)

Interrupt event	Event flag	Enable control bit	Interrupt vector
Header error	SFEF or SDEF or IDPEF	HEIE	Error
Frame error	FEF	FEIE	Error
Buffer overrun error	BOF	BOIE	Error
UART timeout error	TO	TOIE	Error
LIN state	Sync Del, Sync Field, Identifier Field, or Checksum Field	LSIE	Rx
Wakeup	WUF	WUIE	Rx
Data buffer full	DBFF	DBFIE	Rx
Data buffer empty	DBEF	DBEIE	Tx
Data reception complete	DRF	DRIE	Rx
Data transmitted	DTF	DTIE	Tx
Header received	HRF	HRIE	Rx
Header received	HRF	HRIE	Tx (if there is a filter match for Tx identifier)

Figure 1383. Interrupt diagram

56.6 External signal description

56.6.1 Interface signals summary

Table 1292. Interface signals

Signal name	Active level	Reset value	In/Out	Description
IPS Bus Signals				
lps_module_en	High	0	In	Chip select
lpg_clk	—	—	In	PBRIDGE _{Ex} _CLK

Table 1292. Interface signals (continued)

Signal name	Active level	Reset value	In/Out	Description
ipg_baud_clk	—	—	In	LIN_CLK
ipg_hard_async_reset_b	High	—	In	System reset
ipg_baud_reset_b	High	—	In	Baud clock reset
ips_rwb	—	0	In	IPS read/write
ips_addr	—	—	In	IPS address
ips_wdata	—	—	In	Data write bus
ips_byte_31_24	—	—	In	Byte 24 to 31 bits select
ips_byte_23_16	High	—	In	Byte 16 to 23 bits select
ips_byte_15_8	—	—	In	Byte 8 to 15 bits select
ips_byte_7_0	High	—	In	Byte 0 to 7 bits select
ipg_stop	High	—	In	After the ongoing transaction is completed, the transmitter/receiver stay in idle mode till ipg_stop is high.
ipg_stop_ack	High	—	Out	Acknowledgement signal sent when transmitter/receiver go to idle mode when ipg_stop is asserted.
ips_rdata	—	—	Out	Data read bus
ips_xfr_err	High	—	Out	Error on accessing unused register address space and on writing read-only or reading write-only registers
DMA Tx signals				
ipd_req_tx[2**tx_ch_num-1:0]	High	—	Out	DMA Tx request
dma_ipd_complete_tx[2**tx_ch_num-1:0]	High	—	In	DMA Tx major loop done indicator
dma_done_lw_tx[2**tx_ch_num-1:0]	High	—	In	DMA Tx minor loop, last write address phase
dma_enb_req_tx[2**tx_ch_num-1:0]	High	—	In	DMA Tx enable request (content of the DMAERQ register)
DMA Rx Signals				
ipd_req_rx[2**rx_ch_num-1:0]	High	—	Out	DMA Rx request
dma_ipd_complete_rx[2**rx_ch_num-1:0]	High	—	In	DMA Rx major loop done indicator
dma_done_lw_rx[2**rx_ch_num-1:0]	High	—	In	DMA Rx minor loop, last write address phase
dma_enb_req_rx[2**rx_ch_num-1:0]	High	—	In	DMA Rx enable request (content of the DMAERQ register)
LIN signals				
ipp_ind_linrx	—	—	In	Receiver input for LIN

Table 1292. Interface signals (continued)

Signal name	Active level	Reset value	In/Out	Description
ipp_do_lintx	—	—	Out	Transmitter output for LIN
ipp_port_en_lintx	High	0	Out	Alternate function enable for TX
ipi_int_rx	High	0	Out	Receiver interrupt request
ipi_int_tx	High	0	Out	Transmitter interrupt request
ipi_int_err	High	0	Out	Error interrupt request
ipi_int_all	High	0	Out	All interrupt request for LIN
in_ps_clr_DRF ⁽¹⁾	High	0	In	These are added for PSI5-S UART interface. They are used to clear status bits.
in_ps_clr_DTF ¹	High	0	In	
in_ps_clr_PE[3:0] ¹	High	0	In	
in_ps_clr_FEF ¹	High	0	In	
in_ps_clr_BOF ¹	High	0	In	
in_ps_clr_TOF ¹	High	0	In	
in_ps_clr_RMB ¹	High	0	In	This is added for PSI5-S UART interface. This is used to clear status bit RMB.
in_ps_bit_remap ¹	High	0	In	This is added for PSI5-S UART interface. When this signal is set, it modifies the functionality of DTU, and PCE bits in Section 56.4.2.5, UART Mode Control Register (UARTCR) and SLEEP, and INIT bits in Section 56.4.2.1, LIN Control Register 1 (LINC1R)
in_ps_sleep ¹	High	1	In	When in_ps_bit_remap is set, the SLEEP bit in LINC1R is set/cleared by this signal only.
in_ps_init ¹	High	0	In	When in_ps_bit_remap is set, the INIT bit in LINC1R is set/cleared by this signal only.
out_ps_DRF ⁽²⁾	High	0	Out	These are added for PSI5-S UART interface. They reflect the value of corresponding status bits in UARTSR.
out_ps_DTF ²	High	0	Out	
out_ps_PE[3:0] ²	—	0	Out	
out_ps_FEF ²	High	0	Out	
out_ps_BOF ²	High	0	Out	
out_ps_TOF ²	High	0	Out	
out_ps_RMB ²	High	0	Out	This is added for PSI5-S UART interface. This reflects the value of status bit RMB.
out_bdr32b_rx[31:0] ²	—	0	Out	Added for PSI5-S UART interface. It reflects the value of receive buffer.

Table 1292. Interface signals (continued)

Signal name	Active level	Reset value	In/Out	Description
out_wr_tdsr ²	High	0	Out	Added for PSI5-S UART interface. It indicates the data from buffer has been moved to transmit shift register.
out_ps_mode[1:0] ²	—	0	Out	Added for PSI5-S UART interface. This signal indicates which mode LINFlexD is in. 00: SLEEP mode 01: INIT mode 10: Normal mode 11: Not applicable
Scan Inputs				
scan_mode	High	0	In	Scan enable signal
Generics				
slave	—	—	—	Note: Refer to device configuration chapter to see the value of slave used in the device.
addr_width	—	14	—	Address bus width
no_of_filters	—	—	—	Note: Refer to device configuration chapter to see the number of filters used in the device.
rx_ch_num	—	—	—	Note: Refer to device configuration chapter to see the number of rx_ch_num used in the device.
tx_ch_num	—	—	—	Note: Refer to device configuration chapter to see the number of tx_ch_num used in the device.
auto_sync	—	—	—	Note: Refer to device configuration chapter to see the value of auto_sync used in the device.

1. These inputs should be tied to '0' if PSI5-S interface is not used.
2. These outputs can be left unconnected if PSI5-S interface is not used.

- The total number of DMA channels (Tx + Rx) that can be used in SLAVE mode must be less than or equal to the number of ID filters.
- 2 DMA channels (Tx + Rx) are always required to support the DMA capability in LIN master/slave or UART mode.
- Number of Filters is independent of filtered IDs. Each filter supports more than just one ID. Wild cards are possible.
- To use only one DMA channel for Tx and one for Rx in LINFlexD mode, only two filters (one for Tx and one for Rx) have to be used in software. Wild cards are possible for more than one ID.

57 Reset Generation Module (MC_RGM)

57.1 Introduction

57.1.1 Overview

The reset generation module (MC_RGM) centralizes the different reset sources and manages the reset sequence of the chip. It provides a register interface and the reset sequencer. Various registers are available to monitor and control the chip reset sequence. The reset sequencer is a state machine which controls the different phases (PHASE0, PHASE1, PHASE2, PHASE3, and IDLE) of the reset sequence and controls the reset signals generated in the system.

[Figure 1384](#) shows the MC_RGM block diagram.

Figure 1384. MC_RGM block diagram

57.1.2 Features

The MC_RGM contains the functionality for the following features:

- 'destructive' resets management
- 'functional' resets management
- signalling of reset events after each reset sequence (reset status flags)
- conversion of reset events to SAFE mode or interrupt request events
- short reset sequence configuration
- bidirectional reset behavior configuration
- configurable escalation of recurring 'functional' resets to 'destructive' reset
- configurable escalation of recurring 'destructive' resets to keep chip in reset state until next power-on reset

57.1.3 Reset sources

The different reset sources are organized into two families: 'destructive' and 'functional'.

- A 'destructive' reset source is associated with an event related to a critical — usually hardware — error or dysfunction. When a 'destructive' reset event occurs, the full reset sequence is applied to the chip starting from PHASE0. This resets the full chip ensuring a safe start-up state for both digital and analog modules, and the memory content must be considered to be unknown except in the software 'destructive' reset and external power-on reset cases, which do preserve the system memory content if the chip is not configured to execute a self-test on power-on, 'destructive', and external resets. 'Destructive' resets are:
 - power-on reset
 - external power-on reset
 - software 'destructive' reset
 - FCCU failure to react reset
 - STCU2 unrecoverable fault
 - 'functional' reset escalation
 - flash memory initialization failure
 - JTAG 'destructive' reset request
 - HSM 'destructive' reset request
 - temperature sensor 'destructive' reset
 - voltage out of range 'destructive' reset
- A 'functional' reset source is associated with an event related to a less-critical — usually non-hardware — error or dysfunction. When a 'functional' reset event occurs, a partial reset sequence is applied to the chip starting from PHASE1. In this case, most digital modules are reset normally, while the state of analog modules or specific digital modules (e.g., debug modules, flash modules) as well as the system memory content is preserved, except on an external reset in the case where the chip is configured to execute a self-test on power-on, 'destructive', and external resets. 'Functional' resets are:
 - ESR0 external reset
 - ESR1 external reset
 - start-up self test completed

- software 'functional' reset
- FCCU hard reaction
- FCCU soft reaction
- JTAG 'functional' reset
- HSM 'functional' reset request
- temperature sensor 'functional' reset
- voltage out of range 'functional' reset

When a reset is triggered, the MC_RGM state machine is activated and proceeds through the different phases (i.e., PHASEn states). Each phase is associated with a particular chip reset being provided to the system. A phase is completed when all corresponding phase completion gates from either the system or internal to the MC_RGM are acknowledged. The chip reset associated with the phase is then released, and the state machine proceeds to the next phase up to entering the IDLE phase. During this entire process, the MC_ME state machine is held in RESET mode. Only at the end of the reset sequence, when the IDLE phase is reached, does the MC_ME enter the DRUN mode.

Alternatively, it is possible for software to configure some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt issued to the core (see [Section 57.3.1.2, 'Destructive' Event Reset Disable Register \(RGM_DERD\)](#) and [Section 57.3.1.3, 'Destructive' Event Alternate Request Register \(RGM_DEAR\)](#) for 'destructive' resets and [Section 57.3.1.6, 'Functional' Event Reset Disable Register \(RGM_FERD\)](#) and [Section 57.3.1.7, 'Functional' Event Alternate Request Register \(RGM_FEAR\)](#) for 'functional' resets).

57.2 External signal description

The MC_RGM interfaces to the bidirectional reset pin ESR0.

57.3.1 Register descriptions

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the RGM_DES[8:15] register bits may be accessed as a word at address offset 0x000, as a half-word at address offset 0x002, or as a byte at address offset 0x003.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

57.3.1.1 'Destructive' Event Status Register (RGM_DES)

This register contains the status of the 'destructive' reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on write '1'.

This register is reset only on power-on.

Figure 1385. 'Destructive' Event Status Register (RGM_DES)

Table 1295. RGM_DES field descriptions

Field	Description
F_VOR_DEST	Flag for voltage out of range 'destructive' reset 0 No voltage out of range 'destructive' reset event has occurred since the last clear 1 A voltage out of range 'destructive' reset event has occurred
F_TSR_DEST	Flag for temperature sensor 'destructive' reset 0 No temperature sensor 'destructive' reset event has occurred since the last clear 1 A temperature sensor 'destructive' reset event has occurred
F_HSM_DEST	Flag for HSM 'destructive' reset request 0 No HSM 'destructive' reset request event has occurred since the last clear 1 A HSM 'destructive' reset request event has occurred
F_JTAG_DEST	Flag for JTAG 'destructive' reset request 0 No JTAG 'destructive' reset request event has occurred since the last clear 1 A JTAG 'destructive' reset request event has occurred
F_FIF	Flag for flash memory initialization failure 0 No flash memory initialization failure event has occurred since the last clear 1 A flash memory initialization failure event has occurred
F_EDR	Flag for 'functional' reset escalation 0 No 'functional' reset escalation event has occurred since the last clear 1 A 'functional' reset escalation event has occurred

Table 1295. RGM_DES field descriptions (continued)

Field	Description
F_SUF	Flag for STCU2 unrecoverable fault 0 No STCU2 unrecoverable fault event has occurred since the last clear 1 A STCU2 unrecoverable fault event has occurred
F_FFRR	Flag for FCCU failure to react reset 0 No FCCU failure to react reset event has occurred since the last clear 1 A FCCU failure to react reset event has occurred
F_SOFT_DEST	Flag for software 'destructive' reset 0 No software 'destructive' reset event has occurred since the last clear 1 A software 'destructive' reset event has occurred
F_PORST	Flag for external power-on reset 0 No external power-on reset has occurred since the last clear 1 A external power-on reset event has occurred
F_POR	Flag for Power-On reset 0 No power-on event has occurred since the last clear 1 A power-on event has occurred

57.3.1.2 'Destructive' Event Reset Disable Register (RGM_DERD)

This register provides dedicated bits to disable particular 'destructive' reset sources. When a 'destructive' reset source is disabled, the associated 'destructive' event will trigger either a SAFE mode request or an interrupt request (see [Section 57.3.1.3, 'Destructive' Event Alternate Request Register \(RGM_DEAR\)](#)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after a 'destructive' or power-on reset.

This register is reset only on power-on.

Caution: It is important to clear the RGM_DES register before setting any of the bits in the RGM_DERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

Table 1296. RGM_DERD field descriptions

Field	Description
D_VOR_DEST	Disable voltage out of range 'destructive' reset 0 A voltage out of range 'destructive' reset event triggers a reset sequence
D_TSR_DEST	Disable temperature sensor 'destructive' reset 0 A temperature sensor 'destructive' reset event triggers a reset sequence 1 A temperature sensor 'destructive' reset event generates either a SAFE mode or an interrupt request depending on the values in RGM_DEAR
D_HSM_DEST	Disable HSM 'destructive' reset request 0 A HSM 'destructive' reset request event triggers a reset sequence
D_JTAG_DEST	Disable JTAG 'destructive' reset request 0 A JTAG 'destructive' reset request event triggers a reset sequence
D_FIF	Disable flash memory initialization failure 0 A flash memory initialization failure event triggers a reset sequence
D_EDR	Disable 'functional' reset escalation 0 A 'functional' reset escalation event triggers a reset sequence
D_SUF	Disable STCU2 unrecoverable fault 0 A STCU2 unrecoverable fault event triggers a reset sequence
D_FFRR	Disable FCCU failure to react reset 0 A FCCU failure to react reset event triggers a reset sequence

Table 1296. RGM_DERD field descriptions (continued)

Field	Description
D_SOFT_DEST	Disable software 'destructive' reset 0 A software 'destructive' reset triggers a reset sequence
D_PORST	Disable external power-on reset 0 An external power-on reset event triggers a reset sequence 1 An external power-on reset event generates either a SAFE mode or an interrupt request depending on the values in RGM_DEAR
D_POR	Disable Power-On reset 0 A power-on event triggers a reset sequence

57.3.1.3 'Destructive' Event Alternate Request Register (RGM_DEAR)

This register defines an alternate request to be generated when a reset on a 'destructive' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on.

BE_POR	Bidirectional Reset Enable for Power-On reset 0ESR0_B is asserted on a Power-On reset event

57.3.1.5 'Functional' Event Status Register (RGM_FES)

This register contains the status of the 'functional' reset sources, including those configured to not generate a reset sequence. It can be accessed in read/write on either supervisor mode or test mode. It can be accessed in read only in user mode. Register bits are cleared on write '1' if the triggering event has already been cleared at the source.

This register is reset only on power-on.

Note: *If a 'functional' reset source is configured to generate a SAFE mode request or an interrupt request, software needs to clear the event in the source module at least three system clock cycles before it clears the associated RGM_FES status bit in order to avoid multiple SAFE mode requests or interrupts for the same event. In order to avoid having to count cycles, it is good practice for software to check whether the RGM_FES has been properly cleared, and if not, clear it again.*

F_ESR0	Flag for ESR0 External Reset 0 No ESR0 external reset event has occurred since either the last clear or the last power-on reset assertion 1 An ESR0 external reset event has occurred

57.3.1.6 'Functional' Event Reset Disable Register (RGM_FERD)

This register provides dedicated bits to disable 'functional' reset sources. When a 'functional' reset source is disabled, the associated 'functional' event will trigger either a SAFE mode request or an interrupt request (see [Section 57.3.1.7, 'Functional' Event Alternate Request Register \(RGM_FEAR\)](#)). It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. Each byte can be written only once after power-on reset.

This register is reset only on power-on and any 'destructive' reset.

Caution: It is important to clear the RGM_FES register before setting any of the bits in the RGM_FERD register to '1'. Otherwise a redundant SAFE mode request or interrupt request may occur.

57.3.1.7 'Functional' Event Alternate Request Register (RGM_FEAR)

This register defines an alternate request to be generated when a reset on a 'functional' event has been disabled. The alternate request can be either a SAFE mode request to MC_ME or an interrupt request to the system. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

This register is reset only on power-on and any 'destructive' reset.

57.3.1.9 'Functional' Event Short Sequence Register (RGM_FESS)

This register defines which reset sequence will be done when a 'functional' reset sequence is triggered. The 'functional' reset sequence can either start from PHASE1 or from PHASE3, skipping PHASE1 and PHASE2.

Note: This could be useful for fast reset sequence, for example to skip flash memory reset.

It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read in user mode.

This register is reset only on power-on and any 'destructive' reset.

57.3.1.10 'Functional' Reset Escalation Threshold Register (RGM_FRET)

This register sets the threshold for 'functional' reset escalation to a 'destructive' reset. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the FRET field will enable the 'functional' reset escalation function. Writing any value to this register will reset the 'functional' reset counter. See [Section 57.4.6, 'Functional' reset escalation](#) for details on the 'functional' reset escalation function.

This register is reset only on power-on and any 'destructive' reset.

Figure 1394. 'Functional' Reset Escalation Threshold Register (RGM_FRET)

Table 1304. 'Functional' Reset Escalation Threshold Register (RGM_FRET) field descriptions

Field	Description
FRET	'Functional' Reset Escalation Threshold — If the value of this field is 0, the 'functional' reset escalation function is disabled. Any other value is the number of 'functional' resets which will cause a 'destructive' reset if the RGM_FRET register is not written to beforehand.

57.3.1.11 ‘Destructive’ Reset Escalation Threshold Register (RGM_DRET)

This register sets the threshold for ‘destructive’ reset escalation keeping the chip in the reset state until the next power-on reset triggers a new reset sequence. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode.

Writing a non-zero value to the DRET field will enable the ‘destructive’ reset software escalation function. Writing any value to this register will reset the ‘destructive’ reset counter. See [Section 57.4.7, ‘Destructive’ reset escalation](#), for details on the ‘destructive’ reset escalation function.

This register is reset only on power-on.

Field	Description
DRET	‘Destructive’ Reset Escalation Threshold — If the value of this field is 0, the ‘destructive’ reset escalation function is disabled. Any other value is the number of ‘destructive’ resets which will keep the chip in the reset state until the next power-on reset triggers a new reset sequence if the RGM_DRET register is not written to beforehand.

57.3.1.12 External Reset Output Extension Control Register (RGM_EROEC)

This register controls the assertion of the ESR0_B pin after the reset sequence has completed. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. The register bit is cleared on write ‘1’.

Clearing the EROEC bit will cause the MC_RGM to stop asserting the ESR0_B pin within two 16 MHz internal RC oscillator clock cycles. The ESR0_B pin cannot be asserted by writing to this register.

This register also provides the current value sampled on ESR0 via the ERIS bit. This is useful for software to poll if, for example, ESR0_B is used in the system to synchronize the application software with an external event.

This register is reset only on power-on.

57.3.1.15 Peripheral Reset Register 2 (RGM_PRST2)

This register provides individual resets for various peripherals. It can be accessed in read/write in either supervisor mode or test mode. It can be accessed in read only in user mode. See [Table 1307](#) for details.

In addition to resetting the CAN_RAM_CTR module, writing a '1' to the CAN_RAM_CTR_RST bit will also reset the M_CAN_1, M_CAN_2, and M_CAN_3 modules and keep them in reset until a '0' is written to this bit. M_CAN_1, M_CAN_2, and M_CAN_3 can still be reset individually via their individual bits.

Table 1308. Peripheral Reset Registers (RGM_STATn) field descriptions

Field	Description
<periph>_STAT	Peripheral reset status. 0 peripheral is not in reset 1 peripheral is in reset

57.4 Functional description

57.4.1 Reset state machine

The main role of the MC_RGM is the generation of the reset sequence which ensures that the correct parts of the chip are reset based on the reset source event. This is summarized in [Table 1309](#).

Table 1309. MC_RGM reset implications

Source	What Gets Reset	External Reset Assertion ⁽¹⁾
power-on reset	all - executes a start-up self test if enabled	yes
'destructive' resets	all except some clock/reset management - executes a start-up self test if enabled	yes
long external (ESR0) reset	all except some clock/reset management and debug - executes a start-up self test if enabled	programmable ⁽²⁾
long external (ESR0) and long 'functional' resets	all except some clock/reset management, STCU, FCCU, and debug	programmable ⁽²⁾
shortened 'functional' resets ⁽³⁾	flip-flops except some clock/reset management, STCU, FCCU, and debug	programmable ⁽²⁾

1. 'external reset assertion' means that the ESR0_B pin is asserted by the MC_RGM from the start of the reset sequence until the end of reset PHASE3
2. the assertion of the external reset is controlled via the RGM_FBRE register
3. the short sequence is enabled via the RGM_FESS register

Note: JTAG logic has its own independent reset control and is not controlled by the MC_RGM in any way.

The reset sequence is comprised of five phases managed by a state machine, which ensures that all phases are correctly processed through waiting for a minimum duration and until all processes that need to occur during that phase have been completed before proceeding to the next phase.

The state machine used to produce the reset sequence is shown in [Figure 1413](#).

Figure 1413. MC_RGM state machine

57.4.1.1 PHASE0 Phase

This phase is entered immediately from any phase on a power-on or enabled 'destructive' reset event. The reset state machine exits PHASE0 and enters PHASE1 on verification of the following:

- all enabled 'destructive' resets have been processed
- all processes that need to be done in PHASE0 are completed
 - PMC and 16 MHz internal RC oscillator stabilization
- a minimum of 3 16 MHz internal RC oscillator clock cycles have elapsed since power-up completion and the last enabled 'destructive' reset event
- the 'destructive' reset escalator counter has not reached the value in the RGM_DRET[DRET] field

57.4.1.2 PHASE1 phase

This phase is entered either on exit from PHASE0 or immediately from PHASE2, PHASE3, or IDLE on a non-masked external or 'functional' reset event if it has not been configured to trigger a 'short' sequence. The reset state machine exits PHASE1 and enters PHASE2 on verification of the following:

- all enabled, non-shortened 'functional' resets have been processed
- a minimum of 350 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled external or non-shortened 'functional' reset event

57.4.1.3 PHASE2 phase

This phase is entered on exit from PHASE1. The reset state machine exits PHASE2 and enters PHASE3 on verification of the following:

- all processes that need to be done in PHASE2 are completed
 - flash initialization
- a minimum of 8 16 MHz internal RC oscillator clock cycles have elapsed since entering PHASE2

57.4.1.4 PHASE3 phase

This phase is entered either on exit from PHASE2 or immediately from IDLE on an enabled, shortened 'functional' reset event. The reset state machine exits PHASE3 and enters IDLE on verification of the following:

- all processes that need to be done in PHASE3 are completed
 - trimming, start-up self test configuration, and FCCU initialization
- a minimum of 40 16 MHz internal RC oscillator clock cycles have elapsed since the last enabled, shortened 'functional' reset event
- ESR0 is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence or RGM_EROEC[EROEC] = 1
- PORST is not asserted, except if a start-up self test is to be executed on exit of the current reset sequence

57.4.1.5 IDLE phase

This is the final phase and is entered on exit from PHASE3. When this phase is reached, the MC_RGM releases control of the system to the platform and waits for new reset events that can trigger a reset sequence.

57.4.2 ‘Destructive’ resets

A ‘destructive’ reset indicates that an event has occurred after which critical register or memory content can no longer be guaranteed. Exceptions to the latter are the software ‘destructive’ reset and the external power-on reset which do allow the memory content to be preserved if the chip is configured to not execute a self-test on power-on, ‘destructive’, and external resets.

The status flag associated with a given ‘destructive’ reset event (RGM_DES.F_<destructive reset> bit) is set when the ‘destructive’ reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software’s responsibility to determine which reset source is the most critical for the application.

A given ‘destructive’ reset can be optionally disabled by writing bit RGM_DERD.D_<destructive reset>.

Note: The RGM_DERD register can be written only once between two ‘destructive’ reset events.

The chip’s low-voltage detector threshold ensures that, when ‘destructive’ voltage out of range (LVD and/or HVD) is enabled, the supply is sufficient to have the ‘destructive’ event correctly propagated through the digital logic. Therefore, if a given ‘destructive’ reset is enabled, the MC_RGM ensures that the associated reset event will be correctly triggered to the full system. However, if the given ‘destructive’ reset is disabled and the voltage goes below the digital functional threshold, functionality can no longer be ensured, and the reset may or may not be asserted.

An enabled ‘destructive’ reset will trigger a reset sequence starting from the beginning of PHASE0.

57.4.2.1 External power-on reset—PORST

The bidirectional external power-on reset pin PORST is a special case ‘destructive’ reset.

The detection of a falling edge on PORST will start the reset sequence.

The chip asserts PORST if the reset sequence was triggered by one of the following:

- a power-on reset
- a ‘destructive’ reset event

In this case, PORST is asserted until the end of PHASE0.

The PORST input is disabled immediately as of the PORST output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 µs after the PORST output stops being driven by the chip in order to allow the pull-up on the pin to take effect.

In addition, the reset sequence is not exited into application until PORST is no longer driven low from off-chip. In the case the chip is configured to execute a self-test on power-on, ‘destructive’, and external resets, this is the exit of PHASE3 after self test execution has completed.

57.4.3 External reset

The MC_RGM manages the external reset coming from ESR0. The detection of a falling edge on ESR0 will start the reset sequence.

The status flag associated with the external reset falling edge event (RGM_FES.F_ESR0 bit) is set when the external reset is asserted and the power-on reset is not asserted.

Note: The RGM_FERD register can be written only once between two 'destructive' reset events.

An enabled external reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by the external reset. When RGM_FESS.SS_ESR0 is set, the external reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially when an external reset should not reset the flash memory.

The MC_RGM may also assert the external reset if the reset sequence was triggered by one of the following:

- a power-on reset
- a 'destructive' reset event
- an external reset event if configured via the RGM_FBRE register to assert the external reset
- a 'functional' reset event configured via the RGM_FBRE register to assert the external reset

In this case, ESR0_B is asserted until all conditions for exiting PHASE3 have been met with the exception of the ESR0 assertion check. If the OPT_RGM_ESR0_HW bit of the "UTEST Miscellaneous" DCF client is set to '0', the MC_RGM continues to assert ESR0 until the RGM_EROEC[EROEC] bit has been cleared by software.

In addition, the MC_RGM asserts ESR0 while the start-up self test is being executed.

The ESR0 input is disabled immediately as of the ESR0 output being asserted in order to prevent a falling edge from being detected while the pin is being driven from the chip. The input is then re-enabled 4 μ s after the ESR0 output stops being driven by the chip in order to allow the pull-up on the pin to take effect. If ESR0_B is stopped being asserted by the MC_RGM and the 4 μ s input mask period expires during the reset IDLE phase (e.g., due to the EROEC bit being cleared by software), and now a low value is detected on ESR0, an external reset falling edge event will not occur, and no new reset sequence will be triggered. For a new reset sequence to trigger, ESR0 must first be deasserted.

57.4.4 Functional' resets

A 'functional' reset indicates that an event has occurred after which it can be guaranteed that critical register and memory content is still intact.

The status flag associated with a given 'functional' reset event (RGM_FES.F_<functional reset> bit) is set when the 'functional' reset is asserted and the power-on reset is not asserted. It is possible for multiple status bits to be set simultaneously, and it is software's responsibility to determine which reset source is the most critical for the application.

A given 'functional' reset can be optionally disabled by software writing bit RGM_FERD.D_<functional reset>.

Note: The RGM_FERD register can be written only once between two power-on reset events.

An enabled 'functional' reset will normally trigger a reset sequence starting from the beginning of PHASE1. Nevertheless, the RGM_FESS register enables the further configuring of the reset sequence triggered by a 'functional' reset. When

RGM_FESS.SS_<functional reset> is set, the associated 'functional' reset will trigger a reset sequence starting directly from the beginning of PHASE3, skipping PHASE1 and PHASE2. This can be useful especially in case a 'functional' reset should not reset the flash memory module.

See the MC_ME chapter for details on the STANDBY0 and DRUN modes.

57.4.5 Alternate event generation

The MC_RGM provides alternative events to be generated on reset source assertion. When a reset source is asserted, the MC_RGM normally enters the reset sequence. Alternatively, it is possible for some reset source events to be converted from a reset to either a SAFE mode request issued to the MC_ME or to an interrupt request issued to the core.

Alternate event selection for a given reset source is made via the RGM_D/FERD and RGM_D/FEAR registers as shown in [Table 1310](#).

Table 1310. MC_RGM alternate event selection

RGM_D/FERD bit value	RGM_D/FEAR bit value	Generated event
0	X	reset
1	0	SAFE mode request
1	1	interrupt request

The alternate event is cleared by deasserting the source of the request (i.e., at the reset source that caused the alternate request) and also clearing the appropriate RGM_D/FES status bit.

Note: SAFE mode requests are generated regardless of whether the system clock is running. Interrupt requests are generated with the system clock, and therefore, if the system clock was disabled at the time of the event, the interrupt request is not asserted until the system clock is re-enabled.

Note: If a masked 'destructive' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE0, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

Note: If a masked 'functional' reset event which is configured to generate a SAFE mode/interrupt request occurs during PHASE1, it is ignored, and the MC_RGM will not send any safe mode/interrupt request to the MC_ME.

57.4.6 'Functional' reset escalation

'Functional' reset escalation can be used to generate a 'destructive' reset if a number of 'functional' or external resets has occurred between software writes to the RGM_FRET register. This function is enabled by writing a non-zero value to the FRET field of this register.

Once 'functional' reset escalation has been enabled, the MC_RGM increases a counter on each 'functional' or external reset which causes a reset sequence to be initiated (i.e., entrance into PHASE1 or PHASE3 from the IDLE phase). This counter is cleared on a write of any value to the RGM_FRET register and on any power-on or 'destructive' reset. If the

counter reaches the value in the RGM_FRET register's FRET field, the MC_RGM starts a reset sequence at PHASE0 and asserts the F_EDR bit in the RGM_DES register.

57.4.7 'Destructive' reset escalation

'Destructive' reset escalation can be used to keep the chip in the reset state until a new power-on triggers a reset sequence if a number of 'destructive' resets has occurred between software writes to the RGM_DRET register. This function is enabled by writing a non-zero value to the DRET field of this register.

Once 'destructive' reset escalation has been enabled, the MC_RGM increases a counter on each 'destructive' reset which causes a reset sequence to be initiated (i.e., entrance into PHASE0 from the IDLE phase) or an ongoing reset sequence to restart (i.e., entrance into PHASE0 from PHASE1, PHASE2, or PHASE3). This counter is cleared on a write of any value to the RGM_DRET register and on any power-on reset. If the counter reaches the value in the RGM_DRET register's DRET field, the MC_RGM enters reset PHASE0 and stays there until the next power-on reset occurs.

57.4.8 Individual peripheral resets

A peripheral may be reset individually without resetting the rest of the chip by setting the appropriate bit in the RGM_PRSTn registers. However, in order to prevent unexpected behavior by the chip, the following sequence must be observed by software.

1. Disable the peripheral that is to be reset via the MC_ME (see the MC_ME chapter for details).
2. Wait for the mode change to complete.
3. Set the bit corresponding to the peripheral in the RGM_PRSTn registers.
4. Wait until the bit corresponding to the peripheral in the RGM_PSTATn registers is set.
5. Clear the bit corresponding to the peripheral in the RGM_PRSTn registers.
6. Wait until the bit corresponding to the peripheral in the RGM_PSTATn registers is cleared.

The peripheral can be kept in reset indefinitely by not executing steps ⁽⁵⁾ and ⁽⁶⁾. After the completion of step ⁽⁶⁾, the peripheral can be enabled again via the MC_ME.

58 Boot Assist Flash (BAF)

58.1 Introduction

The MCU is booted through a collaboration of several blocks, hardware, and firmware. The first boot phases are performed by a state machine inside the System Status and Configuration Module (SSCM). Once completed, the SSCM sends a reset vector to the boot core (the I/O Processor (IOP) on this device) pointing into the Boot Assist Flash (BAF).

The BAF code then checks the life cycle of the device. If it is “Failure Analysis”, BAF enters a loop in which it services the watchdog. BAF does not execute further since the read access to flash memory boot sectors for cores may be disabled if device life cycle is “Failure Analysis”. Otherwise, it searches for a boot header and boots the application code in internal flash memory.

If no boot header is found in internal flash memory, it downloads application code serially using the LINFlexD module. The package pins used by LINFlexD are the same pins used by the M_CAN module. Hence, the external PHY can be either LIN or CAN, allowing the “ASC@CAN” operation. See [Section 58.3.10, UART serial boot configuration](#) for configuration details.

58.2 Memory map

The BAF is located in a 16 KB block of flash that is mapped adjacent to the UTEST flash memory block. The BAF block base address is 0040_4000h. It is one time programmable (OTP) and is programmed during factory test. The address space and memory used by the BAF code are shown in [Table 1311](#).

Table 1311. BAF memory organization

BAF Component	Address
BAF version number	0040_4000h
BAF code entry point	0040_4100h
BAF data area and stack	5280_0000h – 5280_01FFh

58.2.1 BAF image header

BAF image contains a 256-byte header starting from address 0040_4000h. The header contains important information such as BAF version and production disable flag. The BAF header is explained in the following table.

Table 1312. BAF Image Header

Address Offset	Size (bits)	Field Description
0000h	32	BAF Image version
0004h	32	Reserved
0008h	32	Reserved (Part of clock Jitter Activation Constant)

Table 1312. BAF Image Header (continued)

Address Offset	Size (bits)	Field Description
000Ch	32	Clock Jitter Activation Constant
0010h-00FFh	Reserved	

58.2.1.1 BAF image version

The BAF version is a 32-bit field in the image header starting at address 0040_4000h. The 32-bit field is explained in the following table.

Table 1313. BAF image version

Field	Description
[0:7]	Major Number: This field contains the major version number for the BAF image
[8:15]	Minor Number: This field contains the minor version number for the BAF image
[16:23]	BAF Type: This field contains customer specific information.
[24:31]	Reserved

58.2.1.2 Clock Jitter Activation constant

The Clock Jitter Activation constant is a 32-bit flag, but the smallest element in flash that can be programmed is 64 bits, so the first 32 bits are reserved to allow programming of this constant. This 32-bit flag can be programmed by the customer and is used to activate the Clock Jitter feature that adds clock edge jitter to the baud rate clocks of several communications modules. As part of the BAF startup procedure, BAF copies this constant from flash to the PASS Clock Jitter Enable Register.

Table 1314. BAF Clock Jitter Activation Constant

Field	Description
[00:31]	Clock Jitter Activation Constant. The initial state of production disable flag is erased - FFFF_FFFFh. This equates to NO clock jitter.

58.3 Functional description

58.3.1 Boot modes

Depending on the state and the content of its flash memory, the device can enter one of three different boot modes.

- **Boot from internal flash**
If the internal flash contains application code with a valid boot header, the application is booted. The boot header contains flags that enable/disable individual cores and their reset vectors.
- **Serial boot**
If no valid boot header is found and the current lifecycle phase of the device is less than “In Field”, an attempt is made to download the application by a serial protocol using the LINFlexD module. The downloaded code is then executed by the initial boot core.
- **Static mode**
The device enters power safe mode and waits for an external reset.

58.3.2 Device initialization

The BAF performs a minimal initialization of core registers and clocks required to enter the above described boot modes, then attempts to interact with the buddy device^(v) and the Hardware Security Module (HSM) in the following way:

1. **Buddy device:** If the device is an emulation device (ED device, buddy device present) and the calibration RAM content is valid, then this RAM is automatically remapped over the calibration flash memory. This is intended to assist with cold-start calibration.
2. **HSM:** If the HSM is enabled and the “wait for HSM” flag is present, then the boot core waits for the HSM to become ready.
3. **BAF sets up the exception vector table** to catch machine check exceptions, which may occur if there are any uncorrectable ECC errors. In the event of an uncorrectable ECC error, BAF issues a destructive reset from the machine check exception handler. BAF programs the Mode Entry module's ME_MCTL[target mode] to issue a destructive reset.
4. **BAF uses 512 bytes of the IOP core's D-MEM area** from 5280_0000h to 5280_01FFh for its stack, data and any code that executes from volatile memory. During the BAF start up procedure, it initializes this section of memory so that there is no ECC error when BAF accesses this memory area.

58.3.3 Flow of control

[Figure 1414](#) shows the overall flow of control in the BAF. The individual steps are explained in the following sections.

v. “Buddy device” refers to a companion device that is used only for system development and debug activities. It is not used in production systems.

Figure 1414. Flow of control

58.3.4 Optionally remap calibration RAM

If the device is an ED device (buddy device present, `SIUL2_MIDR1[ED] = 1`), and the external overlay RAM has valid content, then this RAM is automatically remapped over selected flash memory regions. The details of the mapping are defined by a 400-byte configuration table at the beginning of the external overlay RAM (0C00_0000h - 0C00_0193h). The layout of the table is depicted in [Table 1315](#).

The content of the overlay RAM is assumed valid:

- if the BD_INIT flag in the initialization status register of the buddy device (BD_SIUL2_ISR) is set,
- and a CRC calculation over the configuration table yields the correct result,
- and the version of the calibration data matches the version of the application software in flash memory ($((\text{uint64_t})\text{ADDR_SWID}) = \text{DATID}$).

In this case, all 32 calibration remap descriptors (PFCRDs) are setup with the values contained in the configuration table. Finally, the PFCRDE field is copied to the enable register in the PFLASH controller.

Table 1315. Remap configuration table

Address Offset (hex)	Name	Contents
00	CRC_REF	CRC reference value
04	ADDR_SWID	Address of 64-bit ID value in SW FLASH
08	DATID	64-bit ID value of the calibration data
0C		
10	PFCRDE	CRD enable flags
14	LSTARTADDR0	PFCRD0, logical start address
18	PSTARTADDR0	PFCRD0, physical start address
1C	CRDSize0	PFCRD0, size
20	LSTARTADDR1	PFCRD1, logical start address
24	PSTARTADDR1	PFCRD1, physical start address
28	CRDSize1	PFCRD1, size
...	...	...
188	LSTARTADDR31	PFCRD31, logical start address
18C	PSTARTADDR31	PFCRD31, physical start address
190	CRDSize31	PFCRD31, size

The CRC calculation is performed using the CRC unit applying the CRC-32 (Ethernet protocol) polynomial. The calculation is initialized with a seed of 0000h. Then, the 100 32-bit words starting at table address offset 04h are moved to the CRC_INP register by the CPU. Finally, the content of the CRC_OUTP register is compared to the CRC_REF value.

58.3.5 Optionally wait for HSM

If the HSM is enabled (SSCM_UOPS[HSE] = 1), the boot core will need to wait for the HSM to become ready (SSCM_UOPS[HSB] = 1). The core then polls the HSM until a ready flag is set. Both SSCM registers can be set by a DCF record. The boot core polls the HSM to HOST FLAGS register (HSM_HSM2HTF) until its least significant bit is set. The boot core also services the watchdog while polling the HSM_HSM2HTF register. This is just in case the HSM is not ready in 16 ms, servicing the watchdog prevents the system going to reset.

58.3.6 Initialization of BAF DCF clients

58.3.6.1 'Soft' DCF clients

DCF clients are 32-bit hardware registers that are written by the SSCM during reset with data that is stored in DCF record format in UTEST region of flash memory. These DCF records are used to configure module registers, and select device operating modes.

The BAF extends the DCF record concept by implementing soft DCF clients. The 64-bit DCF records include:

- 32-bits of data
- 15-bit chip select field (selects the module which implements the DCF clients)
- 15-bit address field (selects a specific DCF client within the selected module)
- Parity bit (not used with UTEST DCF records)
- Stop bit (to indicate the end of DCF record has been reached)

As part of its execution flow, BAF searches through the list of DCF records in UTEST flash to determine if any of the records are to be processed by BAF.

The search starts at one of two addresses: either the start address of DCF records in UTEST (0040_0200h), or the address specified in UTEST at location 0040_00C0h. If either of the two least significant bits of the 32-bit address stored at 0040_00C0h is set, the default start address of 0040_0200h is used. If the two least significant bits are clear, this 32-bit value is assumed to be the start address of the search.

The default setting of the two least significant bits is 11b (erased value of flash memory is FFFF_FFFFh). A user may intentionally program a dummy address with the least two significant bits set in order to disable the search for an alternate address (as the UTEST block is OTP). Valid search start address must start on a 4-byte boundary.

The DCF record search finishes when a DCF record is read with a STOP bit set. The STOP bit may be set because that memory location is not programmed yet (so the list can be added to) or it can be intentionally programmed STOP record to indicate that no more records are added to the list. BAF does not execute the DCF record with STOP bit set. BAF parses the STOP bit before parsing the rest of the records.

BAF uses Chip Select 14 (CS14) for BAF DCF clients. For records with CS14 asserted, the BAF uses the address field (address[14:0]) in DCF records to determine how to process the 32-bits of data. The soft DCF clients programmed by BAF is listed in [Table 1316](#).

The DCF clients which are used for initialization of security watchdog are explained in [Section 58.3.6.2, Security watchdog configuration](#).

A group of four Soft DCF clients is used to provide a mechanism to write configuration information to address locations. The first DCF client receive 32-bit address information. The next three DCF Clients receive the data that is to be written to the address contained in the first client. The three data clients allow 32-, 16- and 8-bit data to be written to the address in the first client. These four clients can be accessed repeatedly to write whole string of data to memory.

Another soft DCF client as stated in [Table 1316](#) provides a simple callback feature. The soft DCF record data contains the start address of a subroutine that the BAF calls before it starts searching for the host boot header and exits to customer application code. The callback routine can reside anywhere in the CPU address space including the BAF code block or UTEST. The callback DCF client can be accessed repeatedly in order to execute a callback sequence.

The serial boot DCF client provides a mechanism using which application can inform BAF to perform serial boot or boot from internal flash. Details can be viewed in section [Section 58.3.6.6, BAF Serial Boot DCF Client -- SER_BOOT_CBACK](#).

Table 1316. BAF DCF client list

Address (hex)	Name	Label	Description
0000h	Security Watchdog Control Register	SEC_SWT_CR	Data to write to SWT Control Register
0001h	Security watchdog Time out register	SEC_SWT_TO	Security watchdog counter value
0002h	Security watchdog service address	SEC_IAC8	Instruction Address compare register value - Code present at this address services the watchdog.
0003h	Security watchdog CPU select	SEC_SWT_CPU	Determines which CPU is to use the security watchdog
0004h...01FFh	Reserved	—	Reserved for future use
0200h	Address	ADDR	The address to which DATA is written
0201h	32-bit Data	DATA32	The 32-bit data that is written to ADDR
0202h	16-bit Data	DATA16	The 16-bit data that is written to ADDR
0203h	8-bit Data	DATA8	The 8-bit data that is written to ADDR
0204h...020Fh	Reserved	—	Reserved for future use
0210h	Callback Address	CALLBACK	The address of a callback function
0211h	Serial boot Callback Address	SER_BOOT_CBACK	The address of serial boot callback function
0212h...7FFFh	Reserved	—	Reserved for future use.

58.3.6.2 Security watchdog configuration

BAF initializes the security watchdog before it jumps to the HOST CPU application. BAF implements four DCF clients for security watchdog initialization. BAF parses the DCF records and looks for configuration data to be used to program the security watchdog registers. BAF first collects all information required to program the security watchdog from DCF records and then program the security watchdog registers. BAF configures only SWT2 as security watchdog for the CPU2 (IOP) core. Configuration of the Security watchdog for other cores has to be performed by the application running on that core as BAF cannot program other core's IAC8 register. Security watchdog detailed configuration steps are explained in the section below.

58.3.6.2.1 Security Watchdog Control Register (SEC_SWT_CR)

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0000h while parsing, BAF programs the DCF client "Security watchdog control register" with the 32-bit value present in the DATA section of the DCF records. Once written, any subsequent writes to this DCF Client are ignored by BAF.

58.3.6.2.2 Security Watchdog Timeout (SEC_SWT_TO)

BAF parses the DCF records. While parsing, if BAF finds a DCF record with CS14 set and address field as 0001h, BAF programs the security watchdog timeout DCF Clients. This is the security watchdog timeout register. BAF checks the value obtained from DCF records. If the value yields a timeout greater than 30 seconds, then BAF changes this value to 30 seconds. Once written, any subsequent writes to this DCF client are ignored.

58.3.6.2.3 Security Watchdog Service Address (SEC_IAC8)

BAF configures the security watchdog in 'fixed address execution service mode'. In this mode, the watchdog is serviced by executing code at the address loaded into the designated IAC8 (Instruction Address Compare) register. If BAF finds a DCF record with CS14 set and address field as 0002h while parsing the DCF records, BAF programs the DCF clients for SEC_IAC8. This DCF client can only be written once. Subsequent writes are ignored.

Warning: To program the IOP core IAC8 special purpose register, the ownership of this register should be with software. If Hardware has its ownership software will not be able to write to it using mtspr instruction.

58.3.6.2.4 Security Watchdog CPU select (SEC_SWT_CPU)

This DCF client indicates to BAF which CPU will use the security watchdog. BAF parses the DCF record and if it finds a record with CS14 set and address field set as 0003h, BAF programs this DCF client. This means that BAF uses the two least significant bits out of the 32-bit data in the DCF record to find the CPU number which will use the security watchdog. [Figure 1415](#) and [Table 1317](#) indicate the data layout for this client in the DCF record. This client is written once during reset. Subsequent writes are ignored.

Note: Due to the limitation that only the IAC8 on the CPU running the BAF code can be accessed, the BAF can only configure the Security Watchdog to operate on CPU2. If another CPU is selected, the Security watchdog is NOT configured

Writing this client causes the BAF to configure the security watchdog based on data written to the three previous DCF clients. If any of the three previous DCF clients are not written, data is configured erroneously.

If security watchdog is assigned to CPU0 or CPU1, relevant CPU IAC8 register is programmed along with other debug configuration registers to enable IAC8 as watch point.

During normal BAF operation, SWT2 is configured to perform a conventional task watchdog function (cause reset if not regularly serviced). If the security watchdog is assigned to CPU2 (IOP), first SWT3 is configured to perform the watchdog function task. The timeout value, configuration, and current time is read from SWT2 and copied to SWT3. Then SWT2 is unlocked with current sequence and enabled as security watchdog.

58.3.6.3 BAF DCF client - ADDRESS

BAF parses the DCF records. If BAF finds a DCF record with CS14 set and Address field as 0200h while parsing, BAF programs this DCF client. This client is written with a 32-bit address from the Data section of DCF record. This 32-bit address is used in conjunction with any one of the DATA32, DATA16 or DATA8 DCF Data clients. BAF does not immediately use the ADDRESS information, but it is stored and used later in conjunction with a DATAX DCF client (DATA32, DATA16 or DATA8). Then BAF writes the data to the address in memory specified by this ADDRESS DCF client.

The user can create a series of data writes to memory by programming a series of DCF records consisting of pairs of records. The first DCF record of the pair writes to ADDR to provide the address. The second DCF record of the pair writes to the DATA client (DATAX) to provide the data. Subsequent pairs of DCF records can be programmed to write to more memory locations. The number of pairs of DCF records that can be programmed is only limited by the amount UTEST space set aside for DCF records.

Figure 1416. BAF DCF ADDR client configuration

Field	Description
ADDR[0:31]	32-Bit Address DCF client. This ADDRESS value is used in conjunction with a DATAX value. The BAF writes DATAX value to ADDRESS value in the memory space of the MCU

58.3.6.4 BAF DCF client - DATAX

58.3.6.4.1 DATA32 – 32-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0201h while parsing, BAF programs this 32-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant 2 bits to '0' (Only 32-bit aligned writes are supported) and writes this 32-bit data to the address.

Figure 1417. DATA32 DCF client configuration

58.3.6.4.2 DATA16 – 16-bit data DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0202h while parsing, BAF programs this 16-bit DCF client. BAF takes the memory address provided by the ADDR client, masks the least significant bits to '0' (Only 16-bit aligned writes are supported) and writes least significant 16-bit data to the address. Data in the 16 most significant bits are ignored.

Figure 1418. DATA16 DCF Client Configuration

58.3.6.4.3 DATA8 – 8-bit DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field set as 0203h while parsing, BAF programs this 8-bit DCF client. BAF takes the memory address provided by the ADDR client, and writes least significant 8-bit data to the address. Data in the 24 most significant bits are ignored.

RESERVED[16:23]								DATA[0:7]							

58.3.6.5 CALLBACK – BAF callback DCF client

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0210h while parsing, BAF programs this callback DCF client. This client is written with a 32-bit start address of a function which is invoked by BAF. The BAF code checks the start address is within the UTEST or within the BAF flash memory blocks, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory blocks, no function call is executed. The callback is aborted and BAF moves on to the next DCF records. The function that is called is expected to comply with power.org EABI and to terminate in an orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function and no return value is expected.

Warning: Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

BAF executes the callback function as the DCF records are parsed. Therefore several callback functions maybe executed by writing several DCF records that write to the callback DCF clients. The callback functions are executed in the same order as the DCF records.

58.3.6.6 BAF Serial Boot DCF Client -- SER_BOOT_CBACK

BAF parses the DCF records. If BAF finds a record with CS14 set and address field as 0211h while parsing, BAF programs this serial boot DCF client. This DCF client is written with a 32 bit start address of function which is invoked by BAF. The BAF code checks the start address is within UTEST or within the BAF flash memory block, and then passes program flow to this address. If the address is found to be outside the UTEST and BAF flash memory block, no function call is executed. The DCF client execution is aborted and BAF moves on to the next DCF record. The function that is called is expected to comply with power.org EABI and to terminate in orderly manner. An incorrectly written function causes unpredictable operations in BAF. No parameters are passed to this function.

Warning: Excessively long callback functions could cause the watchdog timer to time-out and cause a reset.

The serial boot callback function returns a char value. The returned value informs BAF if serial boot or normal internal flash boot should be executed. For detail regarding return

value of serial boot callback function refer [Table 1319](#).

Table 1319. Serial boot callback function return value definition

Return Values	Description
00h	Boot from internal flash using standard search for boot record. See section 58.3.7 for detail
01h	Serial boot using both CAN and Linflex(in UART mode). For detail see section serial boot
02h-FFh	Reserved

58.3.7 Search boot header and boot options

The BAF searches the flash memory for the boot header, checking the first word location of the 4 × 16 KB blocks and then the 4 × 256 KB blocks. The blocks are searched in the order shown in the following table and once a Boot Header is found, no further blocks are searched.

Table 1320. Locations of boot headers

Search Order	Block	Address
1st	16 KB Code flash memory block1	00FC_0000h
2nd	16 KB Code flash memory block2	00FC_4000h
3rd	16 KB Code flash memory block3	00FC_8000h
4th	16 KB Code flash memory block4	00FC_C000h
5th	256 KB Code flash memory block0	0100_0000h
6th	256 KB Code flash memory block1	0104_0000h
7th	256 KB Code flash memory block2	0108_0000h
8th	256 KB Code flash memory block3	010C_0000h

The first header found that contains the value 005Ah in the first half-word is valid for booting. The whole header structure is shown in [Table 1321](#).

Table 1321. Boot header structure

Address Offset	Contents
00h	Boot Header Configuration (see Figure 1420)
04h	CPU2 Reset Vector
08h	Configuration Bits
0Ch	Configuration Bits
10h	CPU0 Reset Vector
14h	CPU1 Reset Vector
18h	CPUC Reset Vector

Figure 1420. Boot header configuration

Offset 00h

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0				0				5				A			

16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
0				0				0				CPU1	CPUC	CPU0	CPU2

Table 1322. Boot header configuration field description

Field	Description
CPU1	CPU1 is enabled (starts execution at CPU1 Reset Vector)
CPUC	CPU0-Checker Core is enabled. (starts execution at CPUC Reset Vector. If this is different from CPU0 Reset Vector, then a lockstep error occurs as the CPU comes out of reset)
CPU0	CPU0 is enabled (starts execution at CPU0 Reset Vector)
CPU2 (IOP)	CPU2 (IOP) is enabled (starts execution at CPU2 Reset Vector)

The cores that are enabled in the boot header configuration field are enabled by programming ME_CCTLn[DRUN] register to run in all DRUN modes and their reset vector is set in register ME_CADDRn. Then, the memory area of the BAF is protected from execution for functional safety considerations. This is achieved by disabling BAF execution in PFLASH control register3 (PFLASHC_PFCR3[BAF_DIS]). Finally a mode change (from DRUN to DRUN again) is requested from Mode Entry module to activate the new core configuration and make the cores jump to their respective reset vectors. At this point the BAF has finished its operation.

58.3.8 Production disable activation protocol and implementation

Module failure analysis is a standard requirement. But some OEMs have an additional requirement that upon entering failure analysis mode, the MCU operation is modified in such a way that the MCU can never be used in production ECU. The chosen operational modification for production disable is to apply clock jitters to can modules so that it prevents active communications with another can device on a can network. For detail regarding production disable refer the PASS chapter.

BAF maintains a 64 bit flag in BAF code flash region as explained in [Section 58.2.1.2, Clock Jitter Activation constant](#). On every POR BAF copies the clock jitter activation constant from this flag to clock jitter enable register in PASS module to enable jitters on can baud clock. Default value of this flag is FFFF_FFFFh. Hence jitter on can baud clock is disabled. To enable jitter on can clock the value of this flag should be modified to 7FFF_FFFFh.

BAF flash is write protected and locked. To enable modification of this flag and activate production disable feature, BAF implements production disable activation protocol as explained in [Table 1324 \(Production Disable protocol description\)](#). BAF implements this protocol in a power.ORG EABI compliant callback routine. This callback routine can be invoked by programming a callback based soft DCF client as explained in [Section 58.3.6.5, "CALLBACK – BAF callback DCF client"](#). The callback function address is show in [Table 1323 \(Production Disable Callback routine entry point\)](#)

Table 1323. Production Disable Callback routine entry point

Description	Address
Production disable protocol callback function address	0040_40E0h

Table 1324. Production Disable protocol description

Step	Description	Tool Action/Response	MCU Action/Response
1	After power-on tool holds the MCU in reset and writes the activation code to JDC via JTAG interface. The tool pulls hardware interlock pin high, then releases reset.	Assert hardware interlock pin Write F5A0_AA55h to JDC	Starts production disable activation
2	The MCU responds by writing to the JDC an acknowledgment code and which of the 4 PASS passwords are required to unlock the BAF flash block		Write FA50_000nh to JDC if password for pass group n is required to unlock the BAF flash block. (n is either 0,1,2 or 3)
3	The tool reads the acknowledge from JDC module and writes the relevant password to the JDC module. MCU performs password comparison and writes error code to JDC module password provided by tool was incorrect.	Read JDC Write 256 bit password for pass group n to JDC in eight 32 bit words. (n is 0,1,2 or 3)	Write FA50_F00nh if password does NOT match. Once the status has been read by the tool then cause reset. (n is either 0,1,2 or 3)
4	If more than one password is required to unlock the BAF flash block step 2 and step 3 are repeated until all relevant password has been supplied.		If password matches step 2 and step 3 are repeated for the next pass group until all pass group that lock BAF flash has been processed.
5	The MCU then attempts to program the can jitter activation constant within the BAF flash block. The can jitter activation constant flag is a write once flag. Once written it cannot be re-programmed as BAF flash block is OTP. MCU write a code to JDC to signal success or failure of flash programming operation and issue reset.		Program can jitter activation constant in BAF flash block. If successful write FA51_0000h to JDC. If unsuccessful write FA51_F000h to JDC Issue reset.

Figure 1421. Production Disable callback function flow chart

58.3.9 Optionally perform a serial boot

If no boot header is found in one of the locations mentioned above or customer selects serial boot using serial boot DCF client, then BAF determines the lifecycle status of the device. If it is not in “In Field” lifecycle, it attempts a serial boot. Otherwise, the boot has failed and the BAF issues a destructive reset.

Figure 1422. Flow of control during serial boot

Serial boot allows the download of application to internal sram via linflexD_0 or MCAN_1 interface. After downloading the application image to sram, BAF jumps to the start address provided as part of download protocol mentioned below and executes the downloaded application.

At the start of the process both LinFlexD_0 and MCAN_1 is configured in passive listening mode, connected to the same pair of pads. As soon as either interface receives a valid message, the receiving interface is configured in full Tx and Rx mode. The non receiving interface is switched back to reset state and doesn't participate further in serial boot.

If a CAN message of 8 bytes with ID 11h is received on the MCAN_1 controller first, the BAF program

- Disables the LinFlexD_0.
- Configures LinflexD_0 RXD input mux back to reset state.
- Transitions to CAN serial download protocol routine.

If a CAN message not containing 8 bytes or NOT with ID 11h is received by MCAN controller or a MCAN controller generates a CAN error, it is probable that the tool is sending a Linflex frame. Under such circumstances BAF program

- Ignores the CAN message, if a message arrived.
- Clear any pending CAN error
- Continue monitoring for valid CAN messages.

If any byte from Linflex is received first the BAF program

- Checks if the first byte is FEh of the password. If not continue polling. The Data may be a valid CAN message.
- If it is first byte of the password (FEh) then disable MCAN_1 controller and restore to its reset state.
- Configures MCAN_1 pads to their reset state.
- Transition to Linflex (Uart mode) serial boot

58.3.9.1 Serial boot mode protocol

From a high-level perspective, the download protocol follows steps:

1. Host transmits the 64-bit password to MCU.
2. Host transmits start address, size of downloaded code in bytes and VLE bit^(w) to MCU.
3. Host transmits a sequence of data bytes that are to be executed.
4. CPU2 (IOP) executes code from start address provided in step 2.

Each step must be complete before the next step starts.

The exact protocol between LinFlex and CAN are slightly different.

Communication is performed in half-duplex mode, any transmission from the host is followed by the MCU transmission.

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received data to the host.
3. The host verifies whether the echo is correct.
 - If the data is correct, the host can send the next byte of data.
 - If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

w. Since this device supports only VLE code and no Book E code, this flag is used only for backward compatibility

58.3.9.2 Linflex download protocol

The communication is performed in half-duplex mode, Any transmission from the host is followed by the MCU transmission.

1. The host sends data to the MCU and starts waiting.
2. The MCU echoes the received data to the host.
3. The host verifies whether the echo is correct.
 - If the data is correct, the host can send the next byte of data.
 - If data is not correct, it is assumed the MCU has not correctly received the data and the only practical option is for the Host to reset the MCU and start again.

A more detailed description of these steps follows.

All multi-byte data structures are sent with MSB first.

The tool sends data in the following order:

1. 8 bytes that represent the password.
2. 4 bytes that represent the start address where the code is to be downloaded.
3. 4 bytes that represent the number of bytes to be downloaded and the VLE bit.
4. x bytes of code that is downloaded to SRAM and executed (x must match the value specified in step ⁽³⁾).

58.3.9.3 MCAN download protocol

The MCAN download protocol uses very similar structure to the LINFlex protocol, but it makes use of the message ID's provided by CAN.

The tool sends data packed into standard CAN message in the following manner:

1. A message with 11h as the ID and an 8-byte length to send the password. The MCU transmits the same message, but with an ID of 1h.
2. A message with 12h as the ID and an 8-byte length to send the start address, size of the code and VLE mode bit. The MCU transmits back the same data but with an ID of 2h.
3. A message with 13h as the ID is used to send data that is to be downloaded to SRAM. The MCU transmits the same data with an ID of 3h.

58.3.9.4 Download 64-bit password and password check

The first 64 bits received represent the password. The MCU only supports public passwords. The received password is always compared with the public password FEED_FACE_CAFE_BEEFh.

- If the correct password is received, BAF continues its task.
- If an incorrect password is supplied, BAF puts the device into static mode (low power safe mode).
- If 64 bits of password data is not received after approximately 30s, BAF causes a destructive reset of the MCU.

58.3.9.5 Download start address, VLE bit and code size

After the password, the next 8 bytes received by the MCU contains a 32-bit start address, the VLE mode bits, and 31-bit code length as shown in [Figure 1423](#) and [Figure 1424](#)

The VLE bit (Variable Length Encoding) is used to indicate for which instruction set the downloaded code is compiled. The UART serial boot protocol supports download of VLE Code (VLE = 1) and Book E Code (VLE = 0).

The MCU only supports VLE code. If the BAF detects that the host is sending Book E code, the BAF puts the device into static mode.

The start address defines where the received data is stored and where the MCU branches after the download is finished. The three LSB bits of the start address are ignored by BAF, such that the load address is 64-bit double-word aligned.

The length determines how many data bytes has to be loaded.

Figure 1423. Start address

Figure 1424. Download VLE bit and code size

58.3.9.6 Download data

Each byte of data received is downloaded into device SRAM starting from the address specified in the previous protocol step. It is not verified whether the provided address is a valid address in SRAM or is writable.

The address increments until a number of bytes of data received matches the code length specified in the previous protocol step.

Since the SRAM is protected by 64-bit wide Error Correction Code (ECC), BAF always writes to SRAM grouped in 64-bit double-words. If the last byte does not fall into a 64-Bit bounder, the BAF fills it with zero's and renders the data aligned on a 64-bit bounder. After the last data is written to SRAM, the BAF writes a dummy double-word (0000_0000_0000_0000h) to the next address location. This is written to avoid possible ECC error during core prefetch.

58.3.9.7 Execute code

The BAF program waits for the last echo message transmission to be completed. Then it restores the initial MCU configuration and jumps to the loaded code at Start Address which

was received in step 2 of the protocol. At this point the BAF has finished its tasks and the MCU is controlled by new code executing from SRAM.

58.3.10 UART serial boot configuration

58.3.10.1 Configuration

Boot using UART protocol is implemented by LINFlexD_0 module. The pins used are:

- LINFlexD_Tx, corresponding to pin PA[10]
- LINFlexD_Rx, corresponding to pin PA[11]

When Serial Boot mode is started, pin PA[11] (LINFlexD_Rx) is configured as an input and multiplexed to the LINFlexD_0 module. The pin PA[10] (LINFlexD_Tx) remains in a passive input state until the first byte of protocol is received. It is then configured as an output and multiplexed to LINFlexD_0 module. This is done because it is only certain that the application expects pin PA[10] to be an output when a serial message is received on pin PA[11]. The application may not be using the Serial Boot Mode function and may be using pin PA[10] as an input pin with some external hardware driving the pin. Inadvertently driving this pin as an output would cause contention and possible damage.

The LINFlexD module operates in half-duplex mode. The interface is either transmitting a byte or receiving a byte, but never both at the same time. It is expected that LINFlexD pins are connected to a physical layer bus driver/receiver (PHY). Many PHYs enforce half-duplex mode by using a single data channel for both transmitting and receiving data (e.g. LIN, CAN, FlexRay). The side effect of this is that all data transmitted on Tx pin is also received on Rx pin. To prevent the LINFlexD module receiving its own transmission, the Rx pin is blocked during Tx Pin transmission.

The LINFlexD controller is configured to operate at a baud rate of $f_{\text{xosc}} / 833$, using 8-bit data frame without parity bit and 1 stop bit.

Figure 1425. LINFlexD bit timing in UART mode

58.3.10.2 MCAN Configuration

The MCAN_1 controller is configured to operate at a baud rate equal to crystal frequency divided by 40, using the standard 11 bit identifier format detailed in CAN 2.0A specification. See [Table 1326](#) for Baud rates.

The Bit timing is configured as shown in [Figure 1426 \(CAN Bit Timing\)](#)

Figure 1426. CAN Bit Timing

58.3.10.3 LinflexD_0 and MCAN_1 pin configuration

[Table 1325](#) shows the device pin configurations for LINFlexD_0 and MCAN_1 modules.

Table 1325. MCAN_1 and LinFlexD_0 pin configuration

Pads	Reset Function	Initial Serial Boot Mode		Serial Boot Mode after a valid CAN message received	Serial Boot Mode after a valid LINFlex message received
		Function	Pad Configuration	Function	Function
PA[10]	GPIO Input buffer off Output buffer off	MCAN_1 Tx	Output:— Push/Pull medium drive no pullup/pulldown	MCAN_1 Tx	LINFlexD_0 Tx
PA[11]	GPIO Input buffer off Output buffer off	LINFlexD_0 Rx and MCAN_1 Rx	Input:— pull-up hysteresis TTL voltage level	MCAN_1 Rx	LINFlexD_0 Rx

58.3.10.4 Baud rates

The LINFlexD baud rate is set by frequency of external crystal oscillator/833.333.

[Table 1326](#) shows some possible baud rates.

The MCAN baud rate is set by the frequency of the external crystal/40.

Table 1326. LinFlex_0 and MCAN_1 baud rates

Crystal frequency	LINFlex baud rate	MCAN baud rate
8 MHz	9,600 baud	200 kbaud
12 MHz	14,400 baud	300 kbaud
16 MHz	19,200 baud	400 kbaud
20 MHz	24,000 baud	500 kbaud
40 MHz	48,000 baud	1000 kbaud

58.3.10.5 Protocol summary

[Table 1327](#) summarizes the protocol and BAF action during this boot mode.

Table 1327. UART serial boot mode download protocol

Protocol steps	Host message sent	BAM response message	Action
1	64-bit password (MSB first)	64-bit password (MSB first)	Password checked for validity and compared with stored password.
2	32-bit store address	32-bit store address	Load address is stored for future use.
3	VLE bit + 31 bit number of bytes (MSB first)	VLE bit + 31 bit number of bytes (MSB first)	Size of download is stored for future use. Verify VLE bit.
4	8 bits of raw binary data	8 bits of raw binary data	8 x 8 bits of data are packed into 64-bit double-words. These double-words are stored in SRAM starting from the Load address. The Load address increments until the number of data received and stored matches the size as specified in the previous steps.
5	none	none	Branch to downloaded code

58.4 Resources

- **Clocks**
Several clock configurations are made depending on the boot mode of the BAF. All settings are restored before execution of the application code (in flash memory or received via serial download).
- **LINFlexD**
The LINFlexD module is only used if normal boot header search fails and a serial download boot is attempted. All settings are restored before the application code in system RAM is executed.
- **CRC**
The CRC module is only used to validate external overlay contents if the device is an ED device and the buddy device has been initialized.
- **PFLASH**
Remapping of the external overlay memory is configured automatically under certain conditions (see [Section 58.3.4, Optionally remap calibration RAM](#))
- **Interrupts**
No external interrupts are enabled or generated by the BAF. BAF, however, handles machine check exceptions with MSR[ME] bit disabled.
- **Security watchdog (SWT3)**
When SWT2 is chosen as security watchdog, SWT3 is used for Task monitoring purpose.

59 System Status and Configuration Module (SSCM)

59.1 Introduction

59.1.1 Overview

The System Status and Configuration Module (SSCM) is pictured in [Figure 1427](#).

Figure 1427. SSCM block diagram

59.1.2 Glossary

Table 1328. Glossary

Term	Definition
0011b	Binary numbers
0Fh	Hexadecimal numbers
Pin	External physical connection.
Signal	Electronic construct whose state or change in state conveys information.
x	In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary coded X001b, the state of the first bit is a don't care.
y	y is used for a place holder of 1 hex digit for unknown values.

59.1.3 Features

The SSCM includes these distinct features:

- System Configuration and Status
 - Device Mode and System Status
 - Determine primary boot vector
 - Determine HSM boot vector

59.1.4 Modes of operation

The SSCM operates identically in all system modes.

59.2 External signal description

The SSCM has no external pins.

59.3 Memory map and register definition

This section provides a detailed description of all memory-mapped registers in the SSCM.

[Table 1329](#) shows the memory map for the SSCM. Note that all addresses are offsets; the absolute address may be calculated by adding the specified offset to the base address of the SSCM.

Table 1329. SSCM memory map

Offset from SSCM_BASE	Register	Access	Reset Value	Section/ page
0000h	SSCM System Status (STATUS)	R/W	yyy0h ⁽¹⁾	on page 2574
0002h	SSCM System Memory and ID Register (MEMCONFIG)	R	yyyyh ⁽¹⁾	on page 2575
0004h	Reserved	—	—	—
0006h	SSCM Error Configuration Register (ERROR)	R/W	0000h	on page 2575
0008h	Reserved ⁽²⁾	—	—	—
000Ah–001Ch	Reserved	—	—	—
0020h	SSCM HSM and User Option Status Register (UOPS)	R	yyyy_yyyh ⁽¹⁾	on page 2576
0024h	Reserved	—	—	—
0028h	Processor Start Address Register (PSA)	R	yyyy_yyyh ⁽¹⁾	on page 2577
002Ch	Reserved	—	—	—
0030h	SSCM HSM Start Address Register (HSA)	R	yyyy_yyyh ⁽¹⁾	on page 2578
0034h	Life Cycle Status Register (LCSTAT)	R		
0038h–0048h	Reserved	—	—	—

1. See register description for reset value details.

2. No register abort on this location.

59.3.1 Register descriptions

The following registers are available in the SSCM. Those bits that are shaded out are reserved for future use. To optimize future compatibility, these bits should be masked out during any read/write operations to avoid conflict with future revisions.

59.3.1.1 System Status Register (STATUS)

The System Status register reflects the current state of the system.

Figure 1428. System Status Register (STATUS)

Offset 0000h											Access: Read/Write					
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	CER	0	NXEN1	NXEN	1	0	0	BMODE			VLE	0	0	0	0
W		w1c														
Reset	0	0	0	_(2)	_(2)	1	0	0	_(2)			_(1)	0	0	0	0

1. Reset value depends on the associated option bits in flash memory.
2. Reset value depends on the device status after leaving reset.

Table 1330. STATUS field descriptions

Field	Description
CER 1	Configuration Error. This field indicates that the SSCM has detected a configuration error. This error may have been detected during the reset sequence. 0 No configuration problem detected by the SSCM 1 Device configuration is not correct If a non-permanent (transient) error is detected, this bit can be cleared by writing a 1. If the error is permanent, the bit will reappear immediately.
NXEN1 3	Processor 1 Nexus enable status. 0 Processor 1 Nexus disabled. 1 Processor 1 Nexus enabled
NXEN 4	Processor 0 Nexus enable status. 0 Processor 0 Nexus disabled. 1 Processor 0 Nexus enabled
BMODE 8:10	Device Boot Mode. 101 Boot from BootFlash All other values are reserved. This field is only updated during reset.

Table 1330. STATUS field descriptions (continued)

Field	Description
VLE 11	Variable Length Instruction Mode. When booting in Single Chip (SC) mode, this field indicates that the code stored in the flash memory is using the VLE instruction set. The value of this field is determined by the RCHW field of the flash memory boot sector. 0SC Boot Location contains standard PPC code 1SC Boot Location contains VLE code
MBE0 14:15	Number of multi-bit (uncorrectable) ECC errors detected during device configuration. If more than 3 errors are detected, the device will automatically reset itself and attempt configuration again.

59.3.1.2 System Memory and ID Register (MEMCONFIG)

The System Memory and ID register is a read-only register which reflects the memory configuration of the system. It also contains the JTAG ID.

Figure 1429. System memory and ID register (MEMCONFIG)

Offset 0002h												Access: Read Only				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	JPIN										1	MREV				0
W																
Reset	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	1	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0/1 ⁽¹⁾	0

1.

Reset value reflects the JTAG ID of the device.

2.

Reset value depends on boot mode and security status (see SSCM Device Configuration chapter).

Table 1331. MEMCONFIG field descriptions

Field	Description
JPIN 0:9	JTAG Part ID Number
MREV 11:14	Minor Mask Revision

59.3.1.3 Error Configuration Register (ERROR)

The Error Configuration register is a read-write register that controls the error handling of the system.

Figure 1430. Error Configuration Register (ERROR)

Offset 0006h												Access: Read/Write				
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	PAE	RAE
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1332. ERROR field descriptions

Field	Description
PAE 14	Peripheral Bus Abort Enable. This bit enables bus aborts on any access to an off-platform peripheral slot that is not used on the device. This feature is intended to aid in debugging when developing application code. 0 Illegal accesses to non-existing peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to non-existing peripherals produce a Prefetch or Data Abort exception
RAE 15	Register Bus Abort Enable. This bit enables bus aborts on illegal accesses to off-platform peripherals. Illegal accesses are defined as reads or writes to reserved addresses within the address space for a particular peripheral. This feature is intended to aid in debugging when developing application code. 0 Illegal accesses to peripherals do not produce a Prefetch or Data Abort exception 1 Illegal accesses to peripherals produce a Prefetch or Data Abort exception <i>Note: Transfers to peripheral bus resources may be aborted even before they reach the peripheral bus (in example, at the AIPS level). In this case, the PAE and RAE register bits have no effect on the abort.</i>

59.3.1.4 HSM and User Option Status Register (UOPS)

Figure 1431. HSM and User Option Status Register (UOPS)

1. Reset value reflects the Pre-Life Cycle of the device.

2. Reset value is the Life Cycle of the device.

Table 1336. LCSTAT field descriptions

Field	Description
PLC 22:23	Pre-Life Cycle - as determined by the SSCM by reading the PLC slots. The encoding is: JDP_PROD = 01 IN_FIELD = 11 FAIL_ANALYSIS = 00
LC 29:31	Life Cycle - as determined by the SSCM by reading the LC slots. The encoding is: CUST_DELIV = 011 PROD_OEM = 010 IN_FIELD = 111 FAIL_ANALYSIS = 000

59.4 Functional description

The primary purpose of the SSCM is to provide information about the current state and configuration of the system that may be useful for configuring application software and for debug of the system.

59.4.1 DCF mechanism

The SSCM maintains three DCF record areas - two in TestFlash and one in UTEST or Shadow Flash. The first TestFlash area is for differentially stored manufacturer data, the second for normally stored manufacturer data. The UTEST or Shadow area is for customer-controller data.

Which of those areas are scanned and where they are located is controlled via SSCM parameters - consult the SSCM integration guide for details.

The DCF mechanism has been developed to handle settings of device parameters via OTP flash memory.

Starting at location UTEST_OFFSET the user can store a series of DCF records - the device will process these records during the system reset sequence before the CPU leaves reset. The first record needs to be a start record followed by an application-specific number of data records as required, and finally a stop record.

Each record is 64 bits in length. [Table 1337](#) shows the DCF start record. The start record must be placed at UTEST_OFFSET to indicate to the device that the following data records should be processed.

Table 1337. DCF start record

0:31
05AA 55AFh
0:31
0000 0000h

The data records are structured similar to a CPU write instruction - 15 bits of client select, 15 bits of address, 32 bits of payload data plus a STOP bit - See [Table 1338](#). In a data record the STOP bit must always be programmed to 0. Some clients support a parity bit.

Table 1338. Format of a DCF data record

0:31			
WDATA[31:0]			
0:14	15:29	30	31
CS[14:0]	ADDR[16:2]	PRTY	STOP

The stop record indicates that processing should stop. The general format of the stop record is shown in [Table 1339](#). Only the STOP bit needs to be 1 in order to form a stop record – All other bits are ignored. An unprogrammed location in UTEST flash will be interpreted as a stop record.

Table 1339. DCF stop record

0:31	
rsvd	
0:30	31
rsvd	1

If n data records are to be stored in UTEST, the data structure must be as shown in [Table 1340](#).

Table 1340. Series of DCF records in UTEST

ADDR offset	DATA			
00h	05AA 55AFh			
04h	0000 0000h			STOP=0
08h	WDATA[31:0]			
0Ch	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
10h	WDATA[31:0]			
14h	CS[14:0]	ADDR[16:2]	PRTY	STOP=0
...	...			
$8n - 1 + 0h$	reserved			
$8n - 1 + 4h$	reserved			1
$8n + 0h$				
$8n + 4h$				

There must never be an unprogrammed record in the data structure, as that would be interpreted as a stop record, so subsequent records would be ignored. This allows programming the records in several sessions, each time appending new records at the end of the list, as shown in [Figure 1435](#)

Figure 1435. Appending DCF records

In this case a record may overwrite a client's value which was already set by a previous record. However whether such an operation is allowed depends on the rules given for the client - some clients are write-once, only allow setting bits but not clearing etc.

The parity bit (PRTY) is required for some DCF records. The parity scheme used is even parity, so the number of 1s in the WDATA and PRTY fields needs to be even. (For example, if the WDATA field has the value 0000_0001h then the PRTY field needs to be set to 1, so that the total number of 1s is even.)

59.4.2 ECC error monitoring

During DCF scanning, the SSCM will monitor the flash status signals for ECC and other unexpected access errors. If such an error occurs the SSCM will request a reset.

59.4.3 Boot mode functionality

The device supports the following boot modes for the main boot core:

- Boot Assisted by Flash (BAF) - the device will boot from TestFlash, (interface with the HSM if available) and perform device setup

If booting is not possible with the selected configuration (For example, no Boot ID is found in the selected boot location) then the device will enter serial boot mode.

If the HSM is enabled via DCF record, the HSM will boot from the location found via the HSM boot header search. [Section 59.4.5, HSM boot header search](#).

59.4.4 BAF configuration

By default the device will boot from BAF.

In BAF mode the boot core will start to execute the BAF code at the location shown in the SSCM section of the "Device Configuration" chapter. The BMODE field in the SSCM status register will be set to the value 101b. Details of the BAF operation are described in the BAF chapter.

59.4.5 HSM boot header search

The SSCM searches the code flash memory of the HSM module for a valid boot header (see the SSCM section of the “Device Configuration” chapter for address(es)) and provides the boot vector to the CPU of the HSM module.

The HSM Boot Header has the format as described in [Table 1341](#).

Table 1341. Boot header structure

00h	Boot Header ID	
08h	Reserved	Start Address
10h	Reserved for Configuration Bits	

A valid Boot Header ID has the value FFFF_0000_FFFF_0000h.

The first valid Boot Header found is the one which is passed to the HSM CPU. In order to switch from one Boot Header to a Boot Header at a higher address, the Boot Header at the lower address must be invalidated. This can be achieved by over-programming the Boot Header ID location with 0000_0000_0000_0000h. Since this value results in the same ECC encoding it will still be possible to read the location without causing an ECC error.

59.4.6 Life Cycle

The SSCM will determine the Life Cycle of the device by reading the Life Cycle slots from the UTEST flash area. The read operation is done during the reset phase with normal timings and it is protected by both operating monitors and ECC check. In addition a set of sanity checks executed over the LC read data guarantee the integrity of the final LC value.

At the end of the reset phase, the LC can have one of the following values:

- JDP Production
- Customer Delivery
- OEM Production
- In Field
- FA

The LC is written into 5 slots, 128 bits each, at fixed locations in the UTest Flash block. Each LC slot is read in one single atomic operation and it is organized into two fields:

- the valid field
- the invalid field

Depending on the possible combination of the data programmed into these fields, each LC slot can have one of the possible 4 statuses:

Table 1342. Life Cycle Slots

LC Slot		LC slot value
Valid Field (64 Bits)	Invalid Field (64 Bits)	
Erased	Erased	Erased
Marked	Erased	Active

Table 1342. Life Cycle Slots

LC Slot		LC slot value
Valid Field (64 Bits)	Invalid Field (64 Bits)	
Marked	Marked	Inactive
Any other values		Illegal

“Marked” in this case means that the value has been programmed with the bit pattern 55AA_50AF_55AA_50AFh, “Erased” is detected by the bit pattern FFFF_FFFF_FFFF_FFFFh. [Table 1343](#) shows how the slots are arranged in memory.

Table 1343. Life Cycle Slots in Memory

Offset	LC Slot word
00h	Valid[31:0]
04h	Valid[63:32]
08h	Invalid[31:0]
0Ch	Invalid[63:32]

The Life Cycle is determined as shown in [Table 1344](#) (A “*” represents a “don’t care” condition, “Erased” means the slot returns all 1’s). The priority of the entries is from top to bottom, so the first row which applies will determine the resulting Life Cycle.

Table 1344. Life Cycle Slots

PLC = JDP_PROD	LC Slot 0 JDP_PROD	LC Slot 1 CUST_DEL	LC Slot 2 OEM_PROD	LC Slot 3 IN_FIELD	LC Slot 4 FA	Resulting Life Cycle
*	Active	Erased	Erased	Erased	Erased	JDP Production
*	<i>Inactive</i>	Active	Erased	Erased	Erased	Customer Delivery
*	<i>Inactive</i>	<i>Inactive</i>	Active	Erased	Erased	OEM Production
*	<i>Inactive</i>	<i>Inactive</i>	<i>Inactive</i>	Active	Erased	In Field
*	<i>Inactive</i>	<i>Inactive</i>	<i>Inactive</i>	<i>Inactive</i>	Active	FA
No	Erased	Erased	Erased	Erased	Erased	System Reset
No	*	*	*	*	Erased	In Field
No	*	*	*	*	Not Erased ⁽¹⁾	System Reset
Yes	*	*	*	*	*	JDP Production

1. Any value but FFFF_FFFF_FFFF_FFFFh

59.5 Initialization and application information

59.5.1 Reset

The reset state of each individual bit is shown within the Register Description section (see [Section 59.3.1, Register descriptions](#)).

59.6 Additional safety measures

59.6.1 Spurious reset protection

The SSCM implements protection against spurious module resets (i.e. resets which only effect the SSCM but not other modules) by gating the state machines with the expected status of the RGM. In case of a spurious reset the SSCM will not interfere with the Flash bus or overwrite configuration registers. Status internal to the SSCM will be lost, however.

60 Power Management Controller digital interface (PMC_dig)

60.1 Introduction

The power management controller (PMC) consists of two blocks: an analog block and a digital block. This chapter describes the digital block of the PMC.

The PMC_dig block contains all of the registers and digital logic to generate all of the enable signals, trim control bits, POR reset generation, and test logic for the analog block. The PMC digital logic also contains the controls for PMC analog outputs to be sensed with the ADC module.

In addition, the PMC digital logic contains the enable signals, trim bits, and other registers for the temperature sensor.

There are also several custom interfaces to various other blocks: The Reset Generation Module (MC_RGM) block receives the LVD values during POR to use for phase transition conditions.

There is also a custom interface to flash memory via the SSCM (and DCF client blocks) that is used to load the trim values during initial POR.

The TESTPIN must never be asserted to assure that the LVD/HVDs are active in the system.

The PMC digital block generates a transfer error event to the system if the selected address is greater than the highest address in the PMC digital memory map. A transfer error is not generated if an unused address within the PMC digital memory space is accessed.

Note: It is not valid to leave any of the power domains measured by an LVD or HVD unpowered. They must always be connected in such a way as to be in a valid operating range to get the device out of POR.

60.2 Block diagram

The block diagram for the PMC is shown in [Figure 1436](#).

Figure 1436. Digital PMC block diagram

60.3 Memory Map/Register Definition

Table 1345 shows the PMC memory map. The PMC includes many registers for configuring and monitoring LVD monitors, some other control registers.

Table 1346. GR_S field descriptions

Field	Description
0–15	Reserved.
16 VD15	VD15 high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V supplies. It is asserted when any of the supplies rise above the corresponding HVD threshold, and clears when all the supplies fall below the corresponding HVD threshold. All the 6.00 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected on the high voltage 6.00 V supply.

Table 1346. GR_S field descriptions (continued)

Field	Description
17 VD14	VD14 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 4 V supplies. It is asserted when any of the supplies fall below the corresponding LVD threshold, and clears when all the supplies rise above the corresponding LVD threshold. All the 4.00 V supplies are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 4.00 V supplies.
18 VD13	VD13 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3.6 V supplies. It is asserted when any of the supplies fall below the corresponding LVD threshold, and clears when all the supplies rise above the corresponding LVD threshold. All the 3.6 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage 3.6V supply.
19 VD12	VD12 high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 3.60 V supply. It is asserted when the supply rises above the corresponding HVD threshold, and clears when the supply falls below the corresponding HVD threshold. 0 Currently no occurrence. 1 HVD occurrence detected on the high voltage 3.60 V supply.
20	Reserved.
21 VD10	VD10 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3 V supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 3.00 V supply.
22 VD9	VD9 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V supplies. It is asserted when any of the supplies fall below the corresponding LVD threshold, and clears when all the supplies rise above the corresponding LVD threshold. All of the 2.8 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage 2.8 V supplies.
23	VD8 high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 1.45 V supplies. It is asserted when any of the supplies rise above the corresponding HVD threshold, and clears when all the supplies fall below the corresponding HVD threshold. All the 1.45 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected on the low voltage 1.45 V supplies.
24 VD7	VD7 high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 1.40 V supplies. It is asserted when any of the supplies rise above the corresponding HVD threshold, and clears when all the supplies fall below the corresponding HVD threshold. All the 1.40 V HVDs are combined to form this bit. 0 Currently no occurrence. 1 HVD occurrence detected on the low voltage 1.40 V supplies.
25-26	Reserved.

Table 1346. GR_S field descriptions (continued)

Field	Description
27 VD4	VD4 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detects for the low voltage 1.14 V supply associated with the PLL, Flash, and hot point. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage 1.14 V point supply.
28 VD3	VD3 low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V supply associated with the core logic. It is asserted when any of the VD3 supplies fall below the corresponding LVD threshold, and clears when the supplies rise above the corresponding LVD threshold. All the 1.14 V LVDs are combined to form this bit. 0 Currently no occurrence. 1 LVD occurrence detected on any of the low voltage 1.14 V supplies.
29-31	Reserved.

60.3.1.2 Pending Gauge Status Register (GR_P)

This configuration register contains a mirror of the contents of the Event Pending Registers, but in a format that includes one bit for each voltage detect signal. These bits indicate the state of the voltage detect events including whether a voltage level event has occurred at any time in the past but has not been cleared (via the EPR register). These bits are read only, and they are cleared by writing a one to the corresponding EPR register.

The Pending registers are only set on an active edge of an event, so a transition must be seen before they will become set.

The raw analog block voltage detect signals are also synchronized to the bus clock before being used for the pending registers.

Table 1347. GR_P field descriptions

Field	Description
0-5	Reserved.
6 VD15_A	VD15_A high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V ADC supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD15[HVD15_A] is cleared. 0 No occurrence has happened, or EPR_VD15[HVD15_A] has been cleared. 1 HVD occurrence detected on the high voltage ADC supply.
7 VD15_C	VD15_C high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V cold point supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD15[HVD15_C] is cleared. 0 No occurrence has happened, or EPR_VD15[HVD15_C] has been cleared. 1 HVD occurrence detected on the high voltage cold point supply.
8	Reserved.
9 VD14_A	VD14_A low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 4 V ADC supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD14[LVD14_A] is cleared. 0 No occurrence has happened, or EPR_VD14[LVD14_A] has been cleared. 1 LVD occurrence detected on the high voltage ADC supply.
10 VD14_IM	VD14_IM low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 4 V I/O main supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD14[LVD14_IM] is cleared. 0 No occurrence has happened, or EPR_VD14[LVD14_IM] has been cleared. 1 LVD occurrence detected on the high voltage I/O main supply.
11-12	Reserved.
13 VD13_IM	VD13_IM low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3.6 V I/O main supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD13[LVD13_IM] is cleared. 0 No occurrence has happened, or EPR_VD13[LVD13_IM] has been cleared. 1 LVD occurrence detected on the high voltage I/O main supply.
14 VD12_F	VD12_F high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the high voltage 3.6 V flash supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD12[HVD12_F] is cleared. 0 No occurrence has happened, or EPR_VD12[HVD12_F] has been cleared. 1 HVD occurrence detected on the high voltage flash supply.
15 VD10_A	VD10_A low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3 V ADC supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD10[LVD10_A] is cleared. 0 No occurrence has happened, or EPR_VD10[LVD10_A] has been cleared. 1 LVD occurrence detected on the high voltage ADC supply.
16 VD10_F	VD10_F low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 3 V flash supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD10[LVD10_F] is cleared. 0 No occurrence has happened, or EPR_VD10[LVD10_F] has been cleared. 1 LVD occurrence detected on the high voltage flash supply.

Table 1347. GR_P field descriptions (continued)

Field	Description
17 VD9_O	VD9_O low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V OSC supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_O] is cleared. 0 No occurrence has happened, or EPR_VD9[LVD9_O] has been cleared. 1 LVD occurrence detected on the high voltage OSC supply.
18	Reserved.
19 VD9_IF	VD9_IF low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O Flexray supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_IF] is cleared. 0 No occurrence has happened, or EPR_VD9[LVD9_IF] has been cleared. 1 LVD occurrence detected on the high voltage I/O Flexray supply.
20 VD9_IJ	VD9_IJ low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O JTAG supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_IJ] is cleared. 0 No occurrence has happened, or EPR_VD9[LVD9_IJ] has been cleared. 1 LVD occurrence detected on the high voltage I/O JTAG supply.
21 VD9_IM	VD9_IM low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O main supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_IM] is cleared. 0 No occurrence has happened, or EPR_VD9[LVD9_IM] has been cleared. 1 LVD occurrence detected on the high voltage I/O main supply.
22 VD9_F	VD9_F low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V flash supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_F] is cleared. 0 No occurrence has happened, or EPR_VD9[LVD9_F] has been cleared. 1 LVD occurrence detected on the high voltage flash supply.
23	Reserved.
24 VD9_C	VD9_C low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V cold point supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD9[LVD9_C] is cleared. 0 No occurrence has happened, or EPR_VD9[LVD9_C] has been cleared. 1 LVD occurrence detected on the high voltage cold point supply.
25 VD8_C	VD8_C high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the low voltage 1.45 V cold point supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD8[HVD8_C] is cleared. 0 No occurrence has happened, or EPR_VD8[HVD8_C] has been cleared. 1 HVD occurrence detected on the low voltage cold point supply.
26 VD8_F	VD8_F high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the low voltage 1.45 V flash supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD8[HVD8_F] is cleared. 0 No occurrence has happened, or EPR_VD8[HVD8_F] has been cleared. 1 HVD occurrence detected on the low voltage flash supply.

Table 1347. GR_P field descriptions (continued)

Field	Description
27 VD7_C	VD7_C high-voltage detect flag. This read-only bit is the high-voltage status flag associated with the voltage level detect for the low voltage 1.4 V cold point supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the EPR_VD7[HVD7_C] is cleared. 0 No occurrence has happened, or EPR_VD7[HVD7_C] has been cleared. 1 HVD occurrence detected on the low voltage cold point supply.
28 VD4_C	VD4_C low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V cold point supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD4[LVD4_C] is cleared. 0 No occurrence has happened, or EPR_VD4[LVD4_C] has been cleared. 1 LVD occurrence detected on the low voltage cold point supply.
29 VD3_P	VD3_P low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V PLL supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD3[LVD3_P] is cleared. 0 No occurrence has happened, or EPR_VD3[LVD3_P] has been cleared. 1 LVD occurrence detected on the low voltage PLL supply.
30 VD3_F	VD3_F low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V flash supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD3[LVD3_F] is cleared. 0 No occurrence has happened, or EPR_VD3[LVD3_F] has been cleared. 1 LVD occurrence detected on the low voltage flash supply.
31 VD3_C	VD3_C low-voltage detect flag. This read-only bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.14 V hot point supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the EPR_VD3[LVD3_C] is cleared. 0 No occurrence has happened, or EPR_VD3[LVD3_C] has been cleared. 1 LVD occurrence detected on the low voltage hot point supply.

60.3.1.3 Interrupt Enable Pending Register (IE_P)

This configuration register contains a set of Interrupt Enable bits that correspond to each of the Event Pending Registers (EPR_XX), but in a format similar to the Pending Gauge Status register (GR_P). These bits indicate whether an interrupt occurs when the voltage event is seen. A '0' indicates that no interrupt is to be sent, and a '1' indicates that an interrupt is to occur when the voltage detect event occurs. These bits are enabled via a write of one to the MSB of this register (IE_EN). After this, these bits can be read or written at any time.

26 VD8IE_F	VD8IE_F Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
27 VD7IE_C	VD7IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
28 VD4IE_C	VD4IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
29 VD3IE_P	VD3IE_P Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
30 VD3IE_F	VD3IE_F Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.
31 VD3IE_C	VD3IE_C Interrupt Enable. This bit determines whether an interrupt is seen by the system when the voltage detect event occurs. 0 No interrupt occurs. 1 An interrupt occurs.

60.3.1.4 Event Pending Register (EPR_VD3)

This Event Pending Register indicates the present and past state of the voltage detect signals. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. To clear the flag, a one must be written to the flag bit that needs to be cleared.

Figure 1440. Event Pending Register (EPR_VD3)

Table 1349. EPR_VD3 field descriptions

Field	Description
0–23	Reserved.
24 LVD3_P	LVD3_P flag. This bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.08 V PLL supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD3IE_P bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD3[LVD3_P] is also asserted, a system reset is generated, which clears VD3IE_P and negate the interrupt request.</i> If REE_VD3[LVD3_P] is asserted and a destructive reset is selected (via RES_VD3[LVD3_P] being 0), then a destructive reset is generated. If RES_VD3[LVD3_P] is set, then a functional reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage PLL supply.
25 LVD3_F	LVD3_F flag. This bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.08 V flash supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD3IE_F bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD3[LVD3_F] is also asserted, a system reset is generated, which clears VD3IE_F and negate the interrupt request.</i> If REE_VD3[LVD3_F] is asserted and a destructive reset is selected (via RES_VD3[LVD3_F] being 0), then a destructive reset is generated. If RES_VD3[LVD3_F] is set, then a functional reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage flash supply.

Table 1349. EPR_VD3 field descriptions (continued)

Field	Description
26–30	Reserved.
31 LVD3_C	LVD3_C flag. This bit is the low-voltage status flag associated with the voltage level detect for the low voltage 1.08 V hot point supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD3IE_C bit is also asserted, a low-voltage interrupt is sent to the CPU.</i> If REE_VD3[LVD3_C] is also asserted, a system reset is generated, <i>which clears VD3IE_C and negate the interrupt request.</i> If REE_VD3[LVD3_C] is asserted and a destructive reset is selected (via RES_VD3[LVD3_C] being 0), then a destructive reset is generated. If RES_VD3[LVD3_C] is set, then a functional reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the low voltage 1.14 V hot point supply.

60.3.1.5 Reset Event Enable Register (REE_VD3)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Table 1350. REE_VD3 field descriptions

Field	Description
0–23	Reserved.
24 LVD3_P	LVD3_P reset enable. This bit defines whether an LVD assertion on the supply of the PLL generates a system reset. The RES_VD3[LVD3_P] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the PLL does not cause system reset. 1 Enabled. LVD assertion on the supply of the PLL causes system reset.

Table 1350. REE_VD3 field descriptions (continued)

Field	Description
25 LVD3_F	LVD3_F reset enable. This bit defines whether an LVD assertion on the supply of the flash generates a system reset. The RES_VD3[LVD3_F] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the flash does not cause system reset. 1 Enabled. LVD assertion on the supply of the flash causes system reset.
26–30	Reserved.
31 LVD3_C	LVD3_C reset enable. This bit defines whether an LVD assertion on the supply of the cold point generates a system reset. The RES_VD3[LVD3_C] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the cold point does not cause system reset. 1 Enabled. LVD assertion on the supply of the cold point causes system reset.

60.3.1.6 Reset Event Select Register (RES_VD3)

This Reset Event Select Register controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence.

Table 1351. RES_VD3 field descriptions

Field	Description
0–23	Reserved.
24 LVD3_P	LVD3_P reset event select. This bit defines whether an LVD assertion on the supply of the PLL generates a destructive reset or a functional reset. The REE_VD3[LVD3_P] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the PLL causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the PLL causes a functional system reset.

Table 1351. RES_VD3 field descriptions (continued)

Field	Description
25 LVD3_F	LVD3_F reset event select. This bit defines whether an LVD assertion on the supply of the flash generates a destructive reset or a functional reset. The REE_VD3[LVD3_F] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the flash causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the flash causes a functional system reset.
26–30	Reserved.
31 LVD3_C	LVD3_C reset event select. This bit defines whether an LVD assertion on the supply of the cold point generates a destructive reset or a functional reset. The REE_VD3[LVD3_C] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. LVD assertion on the supply of the cold point causes a destructive system reset. 1 Functional Reset Generated. LVD assertion on the supply of the cold point causes a functional system reset.

60.3.1.7 FCCU Event Enable Register (FEE_VD3)

This FCCU Event Enable Register controls whether the voltage detect signal event causes an event signal to be sent to the FCCU (Fault Collection and Control Unit). If the desired flag bit is enabled, the voltage detect event causes an FCCU event to be generated when the selected voltage passes the trigger event.

Field	Description
0–23	Reserved.
24 FEE3_P	FEE3_P FCCU event enable. This bit defines whether an LVD assertion on the supply of the PLL generates an FCCU event. 0 Disabled. LVD assertion on the supply of the PLL does not cause an FCCU event. 1 Enabled. LVD assertion on the supply of the PLL causes an FCCU event.
25 FEE3_F	FEE3_F FCCU event enable. This bit defines whether an LVD assertion on the supply of the flash generates an FCCU event. 0 Disabled. LVD assertion on the supply of the flash does not cause an FCCU event. 1 Enabled. LVD assertion on the supply of the flash causes an FCCU event.
26–30	Reserved.
31 FEE3_C	FEE3_C FCCU event enable. This bit defines whether an LVD assertion on the supply of the cold point generates an FCCU event. 0 Disabled. LVD assertion on the supply of the cold point does not cause an FCCU event. 1 Enabled. LVD assertion on the supply of the cold point causes an FCCU event.

60.3.1.8 Event Pending Register (EPR_VD4)

This Event Pending Register indicates the present and past state of the voltage detect signals. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Table 1364. FEE_VD8 field descriptions

Field	Description
0–24	Reserved.
25 FEE8_F	FEE8_F FCCU event enable. This bit defines whether an HVD assertion on the supply of the Flash generates an FCCU event. 0 Disabled. HVD assertion on the supply of the Flash does not cause an FCCU event. 1 Enabled. HVD assertion on the supply of the Flash causes an FCCU event.
26–30	Reserved.
31 FEE8_C	FEE8_C FCCU event enable. This bit defines whether an HVD assertion on the supply of the cold point generates an FCCU event. 0 Disabled. HVD assertion on the supply of the cold point does not cause an FCCU event. 1 Enabled. HVD assertion on the supply of the cold point causes an FCCU event.

60.3.1.20 Event Pending Register (EPR_VD9)

This Event Pending Register indicates the present and past state of the voltage detect signals. If the voltage detect event has ever passed the trigger event since the last clearing event, the flag bit is set. In order to clear the flag, a one must be written to the flag bit that needs to be cleared.

Figure 1456. Event Pending Register (EPR_VD9)

Table 1365. EPR_VD9 field descriptions

Field	Description
0–16	Reserved.
17 LVD9_O	LVD9_O flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V OSC supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD9IE_O bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVDn_O] is also asserted, a system reset is generated, which clears VD9IE_O and negate the interrupt request.</i> If REE_VD9[LVD9_O] is asserted a POR reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage OSC supply.
18–20	Reserved.
21 LVD9_IF	LVD9_IF flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O Flexray supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD9IE_IF bit is also asserted, a low-voltage interrupt is sent to the CPU. If REE_VD9[LVD9_IF] is also asserted, a system reset is generated, which clears VD9IE_IF and negate the interrupt request.</i> If REE_VD9[LVD9_IF] is asserted and a destructive reset is selected (via RES_VD9[LVD9_IF] being 0), then a destructive reset is generated. If RES_VD9[LVD9_IF] is set, then a functional reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage I/O Flexray supply.

Table 1365. EPR_VD9 field descriptions (continued)

Field	Description
22 LVD9_IJ	LVD9_IJ flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O JTAG supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD9IE_IJ bit is also asserted, a low-voltage interrupt is sent to the CPU.</i> If REE_VD9[LVD9_IJ] is also asserted, a system reset is generated, <i>which clears VD9IE_IJ and negate the interrupt request.</i> If REE_VD9[LVD9_IJ] is asserted a POR reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage I/O JTAG supply.
23 LVD9_IM	LVD9_IM flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V I/O main supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD9IE_IM bit is also asserted, a low-voltage interrupt is sent to the CPU.</i> If REE_VD9[LVD9_IM] is also asserted, a system reset is generated, <i>which clears VD9IE_IM and negate the interrupt request.</i> If REE_VD9[LVD9_A] is asserted a POR reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage I/O main supply.
24	Reserved.
25 LVD9_F	LVD9_F flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V flash supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD9IE_F bit is also asserted, a low-voltage interrupt is sent to the CPU.</i> If REE_VD9[LVD9_F] is also asserted, a system reset is generated, <i>which clears VD9IE_F and negate the interrupt request.</i> If REE_VD9[LVD9_F] is asserted a POR reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage flash supply.
26–30	Reserved.
31 LVD9_C	LVD9_C flag. This bit is the low-voltage status flag associated with the voltage level detect for the high voltage 2.8 V cold point supply. It is asserted when the supply falls below its corresponding LVD threshold, and clears when the supply rises above its corresponding LVD threshold and a one is written to this bit location. <i>If the VD9IE_C bit is also asserted, a low-voltage interrupt is sent to the CPU.</i> If REE_VD9[LVD9_C] is also asserted, a system reset is generated, <i>which clears VD9IE_C and negate the interrupt request.</i> If REE_VD9[LVD9_C] is asserted a POR reset is generated. 0 Currently no occurrence. 1 LVD occurrence detected on the high voltage cold point supply.

60.3.1.21 Reset Event Enable Register (REE_VD9)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event.

Table 1366. REE_VD9 field descriptions

Field	Description
0–16	Reserved.
17 LVD9_O	LVD9_O reset enable. This bit defines whether an LVD assertion on the supply of the OSC generates a POR reset. 0 Disabled. LVD assertion on the supply of the OSC does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the OSC causes a POR reset.
18–20	Reserved.
21 LVD9_IF	LVD9_IF reset enable. This bit defines whether an LVD assertion on the supply of the I/O segment that contains the Flexray pins generates a system reset. The RES_VD9[LVD9_IF] bit determines whether the reset is functional or destructive. 0 Disabled. LVD assertion on the supply of the I/O segment that contains the Flexray pins does not cause system reset. 1 Enabled. LVD assertion on the supply of the I/O segment that contains the Flexray pins causes a POR reset.
22 LVD9_IJ	LVD9_IJ reset enable. This bit defines whether an LVD assertion on the supply of the I/O segment that contains the JTAG pins generates a POR reset. 0 Disabled. LVD assertion on the supply of the I/O segment that contains the JTAG pins does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the I/O segment that contains the JTAG pins causes a POR reset.
23 LVD9_IM	LVD9_IM reset enable. This bit defines whether an LVD assertion on the supply of the I/O segment that contains the main pins generates a POR reset. 0 Disabled. LVD assertion on the supply of the I/O segment that contains the main pins does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the I/O segment that contains the main pins causes a POR reset.
24	Reserved.

Table 1366. REE_VD9 field descriptions (continued)

Field	Description
25 LVD9_F	LVD9_F reset enable. This bit defines whether an LVD assertion on the supply of the flash generates a POR reset. 0 Disabled. LVD assertion on the supply of the flash does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the flash causes a POR reset.
26–30	Reserved.
31 LVD9_C	LVD9_C reset enable. This bit defines whether an LVD assertion on the supply of the cold point generates a POR reset. 0 Disabled. LVD assertion on the supply of the cold point does not cause a POR reset. 1 Enabled. LVD assertion on the supply of the cold point causes a POR reset.

60.3.1.22 Reset Event Select Register (RES_VD9)

This Reset Event Select Register controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. All of the LVD9 signals are used to generate a POR except for LVD9_IF. The LVD9_IF is the only event at this voltage level that can cause a functional or destructive reset. All the others cause a POR (if enabled via the corresponding REE bit) or do not cause a reset.

Figure 1458. Reset Event Select Register (RES_VD9)

Table 1373. REE_VD12 field descriptions

Field	Description
0–24	Reserved.
25 HVD12_F	HVD12_F reset enable. This bit defines whether an HVD assertion on the supply of the flash generates a system reset. The RES_VD12[HVD12_F] bit determines whether the reset is functional or destructive. 0 Disabled. HVD assertion on the supply of the flash does not cause system reset. 1 Enabled. HVD assertion on the supply of the flash causes system reset.
26–31	Reserved.

60.3.1.29 Reset Event Select Register (RES_VD12)

This Reset Event Select Register controls whether the voltage detect signal event causes a destructive or functional reset. If the desired flag bit is enabled, the voltage detect event causes either a destructive or functional reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence.

0–15	Reserved.
16 HVD15_A	HVD15_A flag. This bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V ADC supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the supply falls below its corresponding HVD threshold and a one is written to this bit location. <i>If the VD15IE_A bit is also asserted, a high-voltage interrupt is sent to the CPU.</i> If REE_VD15[HVD15_A] is also asserted, a system reset is generated, <i>which clears VD15IE_A and negate the interrupt request.</i> If REE_VD15[HVD15_A] is asserted and a destructive reset is selected (via RES_VD15[HVD15_A] being 0), then a destructive reset is generated. If RES_VD15[HVD15_A] is set, then a functional reset is generated. 0 Currently no occurrence. 1 HVD occurrence detected on the high voltage ADC supply.
17–30	Reserved.
31 HVD15_C	HVD15_C flag. This bit is the high-voltage status flag associated with the voltage level detect for the high voltage 6 V cold point supply. It is asserted when the supply rises above its corresponding HVD threshold, and clears when the supply falls below its corresponding HVD threshold and a one is written to this bit location. <i>If the VD15IE_C bit is also asserted, a high-voltage interrupt is sent to the CPU.</i> If REE_VD15[HVD15_C] is also asserted, a system reset is generated, <i>which clears VD15IE_C and negate the interrupt request.</i> If REE_VD15[HVD15_C] is asserted and a destructive reset is selected (via RES_VD15[HVD15_C] being 0), then a destructive reset is generated. If RES_VD15[HVD15_C] is set, then a functional reset is generated. 0 Currently no occurrence. 1 HVD occurrence detected on the high voltage cold point supply.

60.3.1.40 Reset Event Enable Register (REE_VD15)

This Reset Event Enable Register controls whether the voltage detect signal event causes a reset. If the desired flag bit is enabled, the voltage detect event causes a reset to be generated when the selected voltage passes the trigger event. These bits are loaded from the flash during the boot sequence. If the flash loaded bits are programmed to be enabled (set), these bits cannot be disabled (cleared).

Field	Description
0–27	Reserved.
28 TEMP_3	TEMP_3 flag. This bit is the temperature status flag associated with the temperature for the <i>high</i> temperature sensor point (165C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a one is written to this bit location. <i>If the IETD_3 bit is also asserted, an interrupt is sent to the CPU.</i> If REE_TD[TEMP_3] is also asserted, a system reset is generated, <i>which clears IETD_3 and negate the interrupt request.</i> If REE_TD[TEMP_3] is asserted and a destructive reset is selected (via RES_TD[TEMP_3] being 0), then a destructive reset is generated. If RES_TD[TEMP_3] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.
29 TEMP_2	TEMP_2 flag. This bit is the temperature status flag associated with the temperature for the temperature sensor point (150C). It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a one is written to this bit location. <i>If the IETD_2 bit is also asserted, an interrupt is sent to the CPU.</i> If REE_TD[TEMP_2] is also asserted, a system reset is generated, <i>which clears IETD_2 and negate the interrupt request.</i> If REE_TD[TEMP_2] is asserted and a destructive reset is selected (via RES_TD[TEMP_2] being 0), then a destructive reset is generated. If RES_TD[TEMP_2] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.

Table 1389. EPR_TD field descriptions (continued)

Field	Description
30	Reserved.
31 TEMP_0	TEMP_0 flag. This bit is the temperature status flag associated with the temperature for the <i>cold</i> temperature sensor point. It is asserted when the temperature exceeds its corresponding threshold, and clears when the temperature falls below its corresponding threshold and a one is written to this bit location. <i>If the IETD_0 bit is also asserted, an interrupt is sent to the CPU.</i> If REE_TD[TEMP_0] is also asserted, a system reset is generated, <i>which clears IETD_0 and negate the interrupt request.</i> If REE_TD[TEMP_0] is asserted and a destructive reset is selected (via RES_TD[TEMP_0] being 0), then a destructive reset is generated. If RES_TD[TEMP_0] is set, then a functional reset is generated. 0 Currently no occurrence. 1 Temperature occurrence detected.

60.3.1.45 Reset Event Enable Register (REE_TD)

This Reset Event Enable Register controls whether the temperature detect signal event causes a reset. If the desired flag bit is enabled, the temperature detect event causes a reset to be generated when the selected temperature passes the trigger event.

If the Temperature Sensor REE and RES bits are set to cause a destructive reset, then during that process the TS REE and RES bits will also get cleared by the destructive reset.

Temperature Sensor assertion causes a functional system reset.
30	Reserved.
31 TEMP_0	TEMP_0 reset event select. This bit defines whether an temperature detect assertion generates a destructive reset or a functional reset. The REE_TD[TEMP_0] bit determines whether the reset event is enabled. 0 Destructive Reset Generated. Temperature Sensor assertion causes a destructive system reset. 1 Functional Reset Generated. Temperature Sensor assertion causes a functional system reset.

60.3.1.47 Temperature Sensor Configuration Register (CTL_TD)

The Temperature Sensor Registers (CTL_TD) contains two enables that must both be enabled in order for the Temperature Sensor to be operable. It also includes two four bit signed trim adjustment register bits that are used to modify both TS trim values (one bus for over temp and one bus for under temp). Finally, this register includes Interrupt Enables (IE) for each of the Temp Sensor EPR bits.

The use case for the TRIM_ADJ_OVER and _UNDER bits would be to introduce additional hysteresis into the Temp Sensor events.

For instance, the TRIM_ADJ_OVER bits could be written to 1111 (-7) and the Temp Sensor event set to be an interrupt. When this interrupt occurs, the TRIM_ADJ_OVER bits could be updated to 0111 (+7), the interrupt cleared, and the Temp Sensor event set to be a reset.

In this way, a “warning” event (like an interrupt) could be detected as well as a “shutdown” event (at a higher temperature).

Care must be taken to include a timeout during the clearing of the interrupt described in the example above. The Temp Sensor has hysteresis and a timeout may be necessary to indicate if the interrupt flag has not cleared in a reasonable amount of time. If this is the case, then an error should be indicated.

Field	Description
0–25	Reserved.
26–31 ADC_CS	ADC_CS Channel Select. These bits are used to control the analog PMC's test mux going to the ADC.

60.3.1.51 Voltage Regulator 1.2V Control Register (VREG1P2_CTRL)

This register is used to disable the Auxiliary Regulator (also known as Spike or VREG1P2 Regulator) during an intentional power down event. The LSB of this register is a bit that is OR'd with the DCF control for the PMC_VREG1P2_ENB. If either the DCF loaded bit or the LSB of VREG1P2_CTRL is a 1, then the Auxiliary Regulator is disabled.

This bit should be written high before any expected power down events.

Figure 1487. Voltage Regulator 1.2V Control Register (VREG1P2_CTRL)

Table 1396. VREG1P2_CTRL field descriptions

Field	Description
0–25	Reserved.
31 VREG1P2_ENB	VREG1P2_ENB. This bit controls if the AUX Regulator (Vreg1p2) is disabled or not. During Power Down, this bit should be written to a 1 so that the AUX regulator is disabled. By default, the DCF loaded value (PMC_VREG1P2_ENB) is used to control the AUX regulator. 0 The enable of the VREG1P2 follows the DCF loaded bit. 1 The VREG1P2 is disabled.

60.3.1.52 Module Control Register (MCR)

This register contains several status and control bits. First, it the bit that is used to detect the status and to clear the Brown Out Detection logic for the Standby RAM module. This register also contains the enables that are used to enable and disable the PMC analog block

busses. One of the enables is used for the ADC_CH_SEL bus and the other is an enable for the User Self Test bus.

The proper procedure to enable these busses would be to write the value to the register containing the bus, then write this enable high, evaluate the test associated with this bus, and then write this bus enable bit low. After that, any further tests can be continued.

Figure 1488. Module Control Register (MCR)

Table 1397. MCR field descriptions

Field	Description
0–15	Reserved.
16 ADC_CHSEL_EN	ADC_CHSEL_EN. This bit allows the ADC_CS bits in the ADC_CH register to be enabled. This bit should be set after the ADC_CS bus has been updated, and cleared after the test has completed. The ADC_CS bus should not be updated while the ADC_CHSEL_EN is enabled (high) 0 The ADC_CS bus is not enabled in the PMC analog. 1 The ADC_CS bus is enabled in the PMC analog.
17 USER_SELF_TEST_EN	USER_SELF_TEST_EN. This bit allows the VD_UTST bits in the VD_UTST register to be enabled. This bit should be set after the VD_UTST bus has been updated, and cleared after the test has completed. The VD_UTST bus should not be updated while the USER_SELF_TEST_EN is enabled (high) 0 The VD_UTST bus is not enabled in the PMC analog. 1 The VD_UTST bus is enabled in the PMC analog.

Table 1397. MCR field descriptions (continued)

Field	Description
18–23	Reserved.
24 TEST_PIN	TEST_PIN. This bit indicates the current value of the Test Pin. 0 Test Pin is not asserted. 1 Test Pin is asserted.
25–30	Reserved.
31 SBRAM_BRDET	SBRAM_BRDET. This bit is the detection status flag for the Standby RAM Brown Out Detection circuit. When a brown out event is detected in the Standby RAM logic, this signal asserts. In order to clear this flag, the brown out detection logic must no longer be detecting an event, and a one must be written to this bit location. 0 Currently no occurrence. 1 Standby RAM Brown Out occurrence detected.

60.4 Analog PMC interface

The outputs from the PMC digital to the PMC analog circuit consists of trim registers for each LVD circuit, an enable for each LVD (tied to the enabled state), and ADC channel select controls. The ADC channel select controls are described in more detail in the ADC interface section of this chapter, and in the Successive Approximation Register Analog-to-Digital Converter (SARADC) Digital Interface chapter.

The signals from the PMC analog to the PMC digital logic consists of simply POR and LVD event indication signals (both active high and active low, but only active low are used). These signals are used by the PMC digital logic to create the appropriate resets for the rest of the system.

There is a settling time for the analog voltage detect circuits specified at 5 microseconds. The PMC digital counts clock edges after the loading of new flash trim values to verify that this time has passed. This time can vary from 5 microseconds to 11.4 microseconds.

60.5 Temperature Sensor Interface Logic

The Temperature Sensor interface consists of two enables: an analog and digital enable, a set of mode registers, two 6-bit trim registers (sometimes referenced as one 12-bit trim register), and an overtemp threshold select control.

The Temperature Sensor simply outputs three signals to the PMC digital logic: over_temp1, over_temp2, and under_temp signals. These signals are used by the PMC digital logic to create the appropriate resets for the rest of the system.

There are two 4-bit signed registers (TRIM_ADJ_OVER[3:0] and TRIM_ADJ_UNDER[3:0]) that can be used by software to adjust the value of the Temp Sensor Trim values. The fourth bit of these registers indicates the sign.

TRIM_ADJ_OVER is added to TS2_TRIM and TRIM_ADJ_UNDER is added to TS0_TRIM. This addition is protected from overflow and underflow (the TRIM value will simply stay at max or min value). The test interface is discussed in the test section.

For more information regarding the Temperature Sensor function, please refer to the Temperature Sensor chapter.

60.6 Standby RAM Regulator Interface Logic

The Standby RAM Regulator interface consists of one bit that indicates that a Standby RAM Brown-out event has occurred, and a method to clear this indication (by writing a one to the flag bit).

For more information regarding the Standby RAM Regulator function, please refer to the Standby RAM Regulator Analog Chapter.

60.7 Power On Reset (MC_RGM Phase Gates)

The PMC digital logic interfaces to the Reset Generation Module in order to indicate the type and conditions of the resets from the PMC and Temperature Sensor Analog blocks.

There are two signals for each the PMC and Temp Sensor blocks; one is used to indicate a destructive reset, and one is used to indicate a functional reset.

The PMC digital logic also indicates when is ok to for the RGM to allow transition to the next POR phase.

The digital PMC also uses signals from the RGM to indicate when some of the reset signals should be masked during the POR sequence.

During the POR phase 3 exit, the PMC digital logic uses all the enabled Voltage Detects to determine if it is correct to exit from Phase 3. Once all the enabled HVD/LVDs have become deasserted and the time from the LVD/HVD circuits to adjust to new trim values has elapsed, then the signal is sent to the RGM that the correct voltage levels have been achieved to exit from Phase 3.

There are nine POR signals, POR_VDDREG, POR_VDDC, POR081_C, POR085_C, POR085_F, POR098C, POR098F, POR250_F, and POR260C.

60.8 Flash interface (DCF client usage)

The PMC digital is updated during POR from the Flash block via a DCF client. This load is used for several pieces of data, but most of the data is trim values being used for analog modules (PMC, Temperature Sensor, and ADC Bandgap).

These trim bits that are loaded from the flash are not readable via the IP bus. These trim values loaded via the DCF client are not compacted (they are written individually, and not several at a time).

The 7th bit must be written in the DCF location of the VREG1P2 flash location. This location is for the VREG1p2 enable bit to be loaded from the DCF, and without programming it, the Aux regulator may be inadvertently disabled or left enabled.

A DCF client is used to interface to the flash for these early data accesses. This client also performs triple voting to keep the data safe from stray bit flips. If there are any issues occur during any of the DCF data loads (like a second write of different data), the DCF client will indicate an error to the FCCU.

Another set of data that is loaded during the DCF single read process are updated values for the REE and RES bits. Please see section [Section 60.3.1.45, Reset Event Enable Register \(REE_TD\)](#) for more information regarding the REE/RES bits load from flash.

If the REE bit is loaded via the DCF as set (enabled), then it is not possible to clear this REE bit. The reset value of the REE DCF bits are all low (thus to allow the bits to be rewriteable), but the reset value of the REE register bits are all high (to enable the resets normally out of POR).

The REE DCF bits loaded are compacted into a single DCF write (they do not match the IPS Bus register bit locations). The REE DCF loaded bits do not have the same limitation that they can only be written once and any further writes must be to the same value. The REE DCF bits can be rewritten to a new value during a new reset event.

When the REE DCF bits are updated, the REE and RES register bits are updated at the same time to the new value.

All of the DCF clients are reset via the destructive reset signal.

For more information regarding the DCF records, please refer to the DCF chapter.

The trim data is read out of the flash's differential read space (slower access, but less issues with voltage variances). Once the differential reads are completed, the flash indicates this to the PMC digital via the SSCM module.

Once the PMC trim values have been read, the analog circuit has been given time to update to the new trim values, and the LVDs have all deasserted, a signal is asserted to the flash to indicate that the voltage is high enough for faster single access reads.

All of the LVD/HVD signals must indicate that a valid voltage has been reached before the voltage indication will be sent to the flash.

For more information regarding the Flash differential reads and voltage levels required, please refer to the Flash chapter.

60.9 Other module interfaces

The FCCU block receives several signals to indicate a fault has occurred. The first is a safety error from the DCF interface indicating that some error has happened during the load of the trim data from the flash during POR. All of the DCF client safety error signals are combined in the PMC digital logic and then sent to the FCCU.

The second set of signals indicate that an HVD, LVD, or temperature event has occurred.

The LVDs that are sent to the FCCU are LVD108_CLVD114_H, LVD108_FLVD114_F, LVD108_PLVD114_P, LVD112_CLVD114_C, LVD270_CLVD280_C, LVD270_FLVD280_F, LVD270_IFLVD280_IF, LVD270_IJLVD280_IJ, LVD270_IMLVD280_IM, LVD270_OLVD280_O, LVD295_FLVD300_F, LVD360_IM, LVD400_IM, and LVD400_A.

LVD108_CLVD108_FLVD108_PLVD112_CLVD270_CLVD270_FLVD270_IFLVD270_IJLVD270_IMLVD295_A
The HVDs that are sent to the FCCU are HVD140_C, HVD145_F, HVD145_C, HVD360_F, HVD600_C, and HVD600_A.

The Temp Sensor outputs tmpsns3, tmpsns2, and tmpsns0 are all combined and sent to the FCCU.

For more information regarding the FCCU block and these signals, please refer to the FCCU chapter.

The HSM module receives four signals from the PMC digital. There are two signals that are sent to the HSM that includes both over_temp1 and over_temp2 values. The under_temp signal is also sent to the HSM as well. The last signal indicates that the PMC has detected a voltage higher than 1.4V on the internal cold detection point.

For more information regarding the HSM block and these signals, please refer to the HSM chapter of the SPC57EM80xx Security Reference Manual.

61 Power Control Unit (MC_PCU)

61.1 Introduction

The MC_PCU module plays a different role in SPC57EM80xx microcontrollers than it does in other microcontrollers. Instead of directly providing an interface to configure and control power distribution to various segments ("power domains") of the chip, the MC_PCU as an integration module.

The SPC57EM80xx microcontroller has a single power domain, Power Domain 0, which is managed by an analog Power Management Controller (PMC) and a PMC digital interface (PMC_dig). The MC_PCU address space consists of a single power domain status register and the PMC_dig registers used to configure and control the analog PMC.

Note: The PMC_dig module also includes a temperature sensor.

[Figure 1489](#) depicts the MC_PCU block diagram.

Figure 1489. MC_PCU block diagram

61.2 Memory map and register definition

61.2.1 Memory map

Table 1398. MC_PCU registers

Offset	Name	Description	Size	Access			Location
				User	Supervisor	Test

0x0040	PCU_PSTAT	Power Domain Status Register	word	read	read	read	<i>on page 2655</i>
0x0044 – 0x0396	Reserved						
0x0400 – 0x076C	PMC_dig registers						
0x0800 – 0x3FFF	Reserved						

Note: Any access to unused registers as well as write accesses to read-only registers will:

- not change register content
- cause a transfer error

61.2.2 Register descriptions

All registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the PD0 field of the PCU_PSTAT register may be accessed as a word at offset 0x0040, as a half-word at offset 0x0042, or as a byte at offset 0x0043.

61.2.2.1 Power Domain Status Register (PCU_PSTAT)

Figure 1490. Power Domain Status Register (PCU_PSTAT)

61.3 Functional description

Please see the PMC_dig chapter for specific details on the PMC control registers.

62 Mode Entry Module (MC_ME)

62.1 Introduction

62.1.1 Overview

The MC_ME controls the chip mode and mode transition sequences in all functional states. It also contains configuration, control and status registers accessible for the application.

[Figure 1491](#) shows the MC_ME block diagram.

Figure 1491. MC_ME block diagram

62.1.2 Features

The MC_ME includes the following features:

- control of the available modes by the ME_ME register
- definition of various chip mode configurations by the ME_<mode>_MC registers
- control of the actual chip mode by the ME_MCTL register
- capture of the current mode and various resource status within the contents of the ME_GS register
- optional generation of various mode transition interrupts
- status bits for each cause of invalid mode transitions
- peripheral clock gating control based on the ME_RUN_PC0...7, ME_LP_PC0...7, and ME_PCTLn registers
- additional core clock gating and boot address control based on the ME_CCTLn and ME_CADDRn registers
- capture of current peripheral and additional core clock gated/enabled status
- progressive system clock switching when transitioning from a lower power consumption mode to a higher power consumption mode, and vice versa

62.1.3 Modes of operation

The MC_ME is based on several chip modes corresponding to different usage models of the chip. Each mode is configurable and can define a policy for energy and processing power management to fit particular system requirements. An application can easily switch from one mode to another depending on the current needs of the system. The operating modes controlled by the MC_ME are divided into system and user modes. The system modes are modes such as RESET, DRUN, SAFE, and TEST. These modes aim to ease the configuration and monitoring of the system. The user modes are modes such as RUN0...3, HALT0, and STOP0 which can be configured to meet the application requirements in terms of energy management and available processing power. The modes DRUN, SAFE, TEST, and RUN0...3 are the chip software running modes.

[Table 1400](#) describes the MC_ME modes.

Table 1400. MC_ME mode descriptions

Name	Description	Entry	Exit
RESET	This is a chip-wide virtual mode during which the application is not active. The system remains in this mode until all resources are available for the embedded software to take control of the chip. It manages hardware initialization of chip configuration, voltage regulators, clock sources, and flash modules.	system reset assertion from MC_RGM	system reset deassertion from MC_RGM
DRUN	This is the entry mode for the embedded software. It provides full accessibility to the system and enables the configuration of the system at startup. It provides the unique gate to enter user modes. BAF, when present, is executed in DRUN mode.	system reset deassertion from MC_RGM, software request from SAFE, TEST and RUN0...3	system reset assertion, RUN0...3, TEST via software, SAFE via software or hardware failure.

Table 1400. MC_ME mode descriptions (continued)

Name	Description	Entry	Exit
SAFE	This is a chip-wide service mode which may be entered on the detection of a recoverable error. It forces the system into a pre-defined safe configuration from which the system may try to recover.	hardware failure, software request from DRUN, TEST, and RUN0...3	system reset assertion, DRUN via software
TEST	This is a chip-wide service mode which is intended to provide a control environment for chip software testing.	software request from DRUN	system reset assertion, DRUN via software
RUN0...3	These are software running modes where most processing activity is done. These various run modes allow to enable different clock & power configurations of the system with respect to each other.	software request from DRUN or other RUN0...3, interrupt event from HALT0, interrupt or wakeup event from STOP0	system reset assertion, SAFE via software or hardware failure, other RUN0...3 modes, HALT0, STOP0 via software
HALT0	This is a reduced-activity low-power mode during which the clock to the core is disabled. It can be configured to switch off analog peripherals like clock sources, flash, main regulator, etc. for efficient power management at the cost of higher wakeup latency.	software request from RUN0...3	system reset assertion, SAFE on hardware failure, RUN0...3 on interrupt event
STOP0	This is an advanced low-power mode during which the clock to the core is disabled. It may be configured to switch off most of the peripherals including clock sources for efficient power management at the cost of higher wakeup latency.	software request from RUN0...3	system reset assertion, SAFE on hardware failure, RUN0...3 on interrupt event or wakeup event

62.2 External signal description

The MC_ME has no connections to any external pins.

62.3 Memory map and register definition

The MC_ME contains registers for:

- mode selection and status reporting
- mode configuration
- mode transition interrupts status and mask control
- scalable number of peripheral sub-mode selection and status reporting
- scalable number of additional core enabling and disabling control and status reporting

62.3.1 Memory map

1. There is space in the register map for 256 peripherals. Please see [Table 1401](#) for the ME_PCTLn locations actually occupied. The unoccupied locations contain a read-only byte value of 0x00.

62.3.2 Register description

Unless otherwise noted, all registers may be accessed as 32-bit words, 16-bit half-words, or 8-bit bytes. The bytes are ordered according to big endian. For example, the ME_RUN_PC0 register may be accessed as a word at address 0x080, as a half-word at address 0x082, or as a byte at address 0x083.

Some fields may be read-only, and their reset value of '1' or '0' and the corresponding behavior cannot be changed.

62.3.2.1 Global Status Register (ME_GS)

This register contains global mode status.

Figure 1492. Global Status Register (ME_GS)

Address 0x000				Access: User read, Supervisor read, Test read

Table 1403. Global Status Register (ME_GS) Field Descriptions

Field	Description
S_CURRENT_MODE	Current chip mode status 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 reserved
S_MTRANS	Mode transition status 0 Mode transition process is not active 1 Mode transition is ongoing
S_PDO	Output power-down status — This bit specifies output power-down status of I/Os. This bit is asserted whenever outputs of pads are forced to high impedance state or the pads power sequence driver is switched off. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In STOP0 mode, the slew rate control mechanism of the output pads is disabled to reduce power consumption, but the state of the output remains functional.
S_MVR	Main voltage regulator status 0 Main voltage regulator is not ready 1 Main voltage regulator is ready for use
S_FLA	Flash availability status 00 Flash is not available 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode and available for use
S_PLL1	secondary PLL status 0 secondary PLL is not stable 1 secondary PLL is providing a stable clock
S_PLL0	primary PLL status 0 primary PLL is not stable 1 primary PLL is providing a stable clock
S_XOSC	external crystal oscillator status 0 external crystal oscillator is not stable 1 external crystal oscillator is providing a stable clock

Table 1403. Global Status Register (ME_GS) Field Descriptions (continued)

Field	Description
S_IRC	16 MHz internal RC oscillator status 0 16 MHz internal RC oscillator is not stable 1 16 MHz internal RC oscillator is providing a stable clock
S_SYSClk	System clock switch status — These bits specify the system clock currently used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled

62.3.2.2 Mode Control Register (ME_MCTL)

This register is used to trigger software-controlled mode changes. Depending on the modes as enabled by ME_ME register bits, configurations corresponding to unavailable modes are reserved and access to ME_<mode>_MC registers must respect this for successful mode requests.

Note: *Byte and half-word write accesses are not allowed for this register as a predefined key is required to change its value.*

Figure 1493. Mode Control Register (ME_MCTL)

Address 0x004

Access: User read, Supervisor read/write, Test read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W	KEY															
Reset	1	0	1	0	0	1	0	1	0	0	0	0	1	1	1	1

Table 1404. Mode Control Register (ME_MCTL) Field Descriptions

Field	Description
TARGET MODE	Target chip mode — These bits provide the target chip mode to be entered by software programming. The mechanism to enter into any mode by software requires the write operation twice: first time with key, and second time with inverted key. These bits are automatically updated by hardware while entering SAFE on hardware request. Also, while exiting from the HALT0 and STOP0 modes on hardware exit events, these are updated with the appropriate RUN0...3 mode value. 0000 RESET (triggers a 'functional' reset event) 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 RESET (triggers a 'destructive' reset event)
KEY	Control key — These bits enable write access to this register. Any write access to the register with a value different from the keys is ignored. Read access will always return inverted key. KEY: 0101101011110000 (0x5AF0) INVERTED KEY: 1010010100001111 (0xA50F)

62.3.2.3 Mode Enable Register (ME_ME)

This register allows a way to disable the chip modes which are not required for a given chip. RESET, SAFE, DRUN, and RUN0 modes are always enabled.

Figure 1494. Mode Enable Register (ME_ME)

Address 0x008

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1406. Interrupt Status Register (ME_IS) Field Descriptions

Field	Description
I_ICONF_CC	Invalid mode configuration interrupt (core configuration) — This bit is set if a write access to one of the ME_CCTLn registers is attempted while a mode transition is in progress. 0 No write to an ME_CADDRn register was attempted during an ongoing mode transition 1 A write to an ME_CADDRn register was attempted during an ongoing mode transition
I_ICONF_CU	Invalid mode configuration interrupt (Clock Usage) — This bit is set during a mode transition if a clock which is required to be on by an enabled peripheral is configured to be turned off. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration (clock usage) interrupt occurred 1 Invalid mode configuration (clock usage) interrupt is pending
I_ICONF	Invalid mode configuration interrupt — This bit is set whenever a write operation to ME_<mode>_MC registers with invalid mode configuration is attempted. It is cleared by writing a '1' to this bit. 0 No invalid mode configuration interrupt occurred 1 Invalid mode configuration interrupt is pending

Table 1406. Interrupt Status Register (ME_IS) Field Descriptions (continued)

Field	Description
I_IMODE	Invalid mode interrupt — This bit is set whenever an invalid mode transition is requested. It is cleared by writing a '1' to this bit. 0 No invalid mode interrupt occurred 1 Invalid mode interrupt is pending
I_SAFE	SAFE mode interrupt — This bit is set whenever the chip enters SAFE mode on hardware requests generated in the system. It is cleared by writing a '1' to this bit. 0 No SAFE mode interrupt occurred 1 SAFE mode interrupt is pending
I_MTC	Mode transition complete interrupt — This bit is set whenever the mode transition process completes (S_MTRANS transits from 1 to 0). It is cleared by writing a '1' to this bit. This mode transition interrupt bit will not be set while entering low-power modes HALT0, or STOP0. 0 No mode transition complete interrupt occurred 1 Mode transition complete interrupt is pending

62.3.2.5 Interrupt Mask Register (ME_IM)

This register controls whether an event generates an interrupt or not.

Figure 1496. Interrupt Mask Register (ME_IM)

Address 0x010

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Table 1408. Invalid Mode Transition Status Register (ME_IMTS) Field Descriptions

Field	Description
S_MRIG	Mode Request Ignored status — This bit is set whenever a new mode is requested while a transition to the SAFE mode is in progress, a transition to STOP0 mode is requested while a wakeup or interrupt request is active, or a transition to HALT0 mode is requested while an interrupt request is active. It is cleared by writing a '1' to this bit. 0 Mode transition requested is not ignored 1 Mode transition requested is ignored
S_MTI	Mode Transition Illegal status — This bit is set whenever a new mode is requested while some other mode transition process is active (S_MTRANS is '1'). Please see Section 62.4.5, Mode Transition Interrupts , for the exceptions to this behavior. It is cleared by writing a '1' to this bit. 0 Mode transition requested is not illegal 1 Mode transition requested is illegal
S_MRI	Mode Request Illegal status — This bit is set whenever the target mode requested is not a valid mode with respect to current mode. It is cleared by writing a '1' to this bit. 0 Target mode requested is not illegal with respect to current mode 1 Target mode requested is illegal with respect to current mode
S_DMA	Disabled Mode Access status — This bit is set whenever the target mode requested is one of those disabled modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is not a disabled mode 1 Target mode requested is a disabled mode
S_NMA	Non-existing Mode Access status — This bit is set whenever the target mode requested is one of those non existing modes determined by ME_ME register. It is cleared by writing a '1' to this bit. 0 Target mode requested is an existing mode 1 Target mode requested is a non-existing mode
S_SEA	SAFE Event Active status — This bit is set whenever the chip is in SAFE mode, SAFE event bit is pending and a new mode requested other than RESET/SAFE modes. It is cleared by writing a '1' to this bit. 0 No new mode requested other than RESET/SAFE while SAFE event is pending 1 New mode requested other than RESET/SAFE while SAFE event is pending

62.3.2.7 Debug Mode Transition Status Register (ME_DMTS)

This register provides the status of different factors which influence mode transitions. It is used to give an indication of why a mode transition indicated by ME_GS.S_MTRANS may be taking longer than expected.

Note: The ME_DMTS register does not indicate whether a mode transition is ongoing. Therefore, some ME_DMTS bits may still be asserted after the mode transition has completed.

Table 1409. Debug Mode Transition Status Register (ME_DMTS) Field Descriptions

Field	Description
PREVIOUS_MODE	Previous chip mode — These bits show the mode in which the chip was prior to the latest change to the current mode. 0000 RESET 0001 TEST 0010 SAFE 0011 DRUN 0100 RUN0 0101 RUN1 0110 RUN2 0111 RUN3 1000 HALT0 1001 reserved 1010 STOP0 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 reserved
MPH_BUSY	MC_ME/MC_PCU Handshake Busy indicator — This bit is set if the MC_ME has requested a mode change from the MC_PCU and the MC_PCU has not yet completed its power-up/down sequencing. It is cleared when the MC_PCU has responded. 0 Handshake is not busy 1 Handshake is busy

Table 1409. Debug Mode Transition Status Register (ME_DMTS) Field Descriptions (continued)

Field	Description
PMC_PROG	MC_PCU Mode Change in Progress indicator — This bit is set if the MC_PCU is in the process of powering up or down power domains. It is cleared when all power-up/down processes have completed. 0 Power-up/down transition is not in progress 1 Power-up/down transition is in progress
DBG_MODE	Debug mode indicator — This bit is set while the chip is in debug mode. 0 The chip is not in debug mode 1 The chip is in debug mode
CCKL_PROG	Core Clock Enable/Disable in Progress — This bit is set while any core's clock is in the process of being enabled or disabled. 0 No core clock is being enabled or disabled 1 A core clock is being enabled or disabled
PCS_PROG	Progressive System Clock Switching in Progress — This bit is set while the progressive system clock switching process is in progress. 0 PCS is not in progress 1 PCS is in progress
SMR	SAFE mode request from MC_RGM is active indicator — This bit is set if a hardware SAFE mode request has been triggered. It is cleared when the hardware SAFE mode request has been cleared. 0 A SAFE mode request is not active 1 A SAFE mode request is active
CDP_PRPH_0_255	Clock Disable Process Pending status for Peripherals 0...255 ⁽¹⁾ — This bit is set when any peripheral appearing has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
VREG_CSRC_SC	Main VREG dependent Clock Source State Change during mode transition indicator — This bit is set when a clock source which depends on the main voltage regulator to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
CSRC_CSRC_SC	(Other) Clock Source dependent Clock Source State Change during mode transition indicator — This bit is set when a clock source which depends on another clock source to be powered-up is requested to change its power up/down state. It is cleared when the clock source has completed its state change. 0 No state change is taking place 1 A state change is taking place
IRC_SC	IRC State Change during mode transition indicator — This bit is set when the 16 MHz internal RC oscillator is requested to change its power up/down state. It is cleared when the 16 MHz internal RC oscillator has completed its state change. 0 No state change is taking place 1 A state change is taking place

Table 1409. Debug Mode Transition Status Register (ME_DMTS) Field Descriptions (continued)

Field	Description
SCSRC_SC	Secondary Clock Sources State Change during mode transition indicator — This bit is set when a secondary clock source is requested to change its power up/down state. It is cleared when all secondary system clock sources have completed their state changes. (A secondary clock source is a clock source other than IRC.) 0 No state change is taking place 1 A state change is taking place
SYSCLK_SW	System Clock Switching pending status — 0 No system clock source switching is pending 1 A system clock source switching is pending
FLASH_SC	FLASH State Change during mode transition indicator — This bit is set when the FLASH is requested to change its power up/down state. It is cleared when the DFLASH has completed its state change. 0 No state change is taking place 1 A state change is taking place
CDP_PRPH_224_255	Clock Disable Process Pending status for Peripherals 224...255 ⁽¹⁾ — This bit is set when any peripheral has been requested to have its clock disabled. It is cleared when all the peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_192_223	Clock Disable Process Pending status for Peripherals 192...223 ² — This bit is set when any peripheral appearing in ME_PS6 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_160_191	Clock Disable Process Pending status for Peripherals 160...191 ² — This bit is set when any peripheral appearing in ME_PS5 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_128_159	Clock Disable Process Pending status for Peripherals 128...159 ² — This bit is set when any peripheral appearing in ME_PS4 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_96_127	Clock Disable Process Pending status for Peripherals 96...127 ² — This bit is set when any peripheral appearing in ME_PS3 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

Table 1409. Debug Mode Transition Status Register (ME_DMTS) Field Descriptions (continued)

Field	Description
CDP_PRPH_64_95	Clock Disable Process Pending status for Peripherals 64...95 ² — This bit is set when any peripheral appearing in ME_PS2 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_32_63	Clock Disable Process Pending status for Peripherals 32...63 ² — This bit is set when any peripheral appearing in ME_PS1 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral
CDP_PRPH_0_31	Clock Disable Process Pending status for Peripherals 0...31 ² — This bit is set when any peripheral appearing in ME_PS0 has been requested to have its clock disabled. It is cleared when all these peripherals which have been requested to have their clocks disabled have entered the state in which their clocks may be disabled. 0 No peripheral clock disabling is pending 1 Clock disabling is pending for at least one peripheral

1. Peripheral n corresponds to the **ME_PCTLn** register. Please refer to [Table 1401](#) for the **ME_PCTLn** locations actually occupied, which in turn indicates which peripherals are reported in the **ME_DMTS** register.

62.3.2.8 RESET Mode Configuration Register (ME_RESET_MC)

This register configures system behavior during RESET mode. See [Table 1410](#) for details.

Note: The following configuration values are set according to the chip configuration:

- XOSCON

Figure 1499. RESET Mode Configuration Register (ME_RESET_MC)

Address 0x020

Table 1410. Mode Configuration Registers (ME_<mode>_MC) Field Descriptions

Field	Description
PWRLVL	Power level — These bits indicate the relative power consumption level of this mode with respect to that of other modes. When switching between two modes with differing power levels, system clock progressive switching is enabled.
PDO	I/O output power-down control — This bit controls the output power-down of I/Os. 0 No automatic safe gating of I/Os used and pads power sequence driver is enabled 1 In SAFE/TEST modes, outputs of pads are forced to high impedance state and pads power sequence driver is disabled. The inputs are level unchanged. In STOP0 mode, only the pad power sequence driver is disabled, but the state of the output remains functional.
MVRON	Main voltage regulator control — This bit specifies whether main voltage regulator is switched off or not while entering this mode. 1 Main voltage regulator is switched on
FLAON	Flash power-down control — This bit specifies the operating mode of the code flash after entering this mode. 00 reserved 01 Flash is in power-down mode 10 Flash is in low-power mode 11 Flash is in normal mode
PLL1ON	secondary PLL control 0 secondary PLL is switched off 1 secondary PLL is switched on
PLL0ON	primary PLL control 0 primary PLL is switched off 1 primary PLL is switched on
XOSCON	external crystal oscillator control ⁽¹⁾ 0 external crystal oscillator is switched off 1 external crystal oscillator is switched on
IRCON	16 MHz internal RC oscillator control 0 16 MHz internal RC oscillator is switched off 1 16 MHz internal RC oscillator is switched on
SYSCLK	System clock switch control — These bits specify the system clock to be used by the system. 0000 16 MHz int. RC osc. 0001 external crystal osc. 0010 primary PLL (PHI) 0011 reserved 0100 secondary PLL 0101 reserved 0110 reserved 0111 reserved 1000 reserved 1001 reserved 1010 reserved 1011 reserved 1100 reserved 1101 reserved 1110 reserved 1111 system clock is disabled in TEST mode, reserved in all other modes

- For a loss of oscillator clock, there is a dedicated monitor (CMU0) on the device. If a S/W programmable minimum frequency threshold is violated, an interrupt to the FCCU is generated and the device is safe-stated (switch to backup clock - internal RCOSC). At that point, S/W can re-enter normal mode through the MC_ME, and the oscillator is restarted. No full power down of the device is required to restart the oscillator.

62.3.2.15 Peripheral Status Register 0 (ME_PS0)

This register provides the status of the peripherals. See [Table 1411](#) for details.

HALT0	Peripheral control during HALT0 0 Peripheral is frozen with clock gated 1 Peripheral is active

62.3.2.25 Peripheral Control Registers (ME_PCTLn)

These registers select the configurations during run and non-run modes for each peripheral. Please see [Table 1401](#) for information on which ME_PCTLn locations are actually occupied. The unoccupied locations contain a read-only byte value of 0x00.

Note: After modifying any of the ME_RUN_PC0...7, ME_LP_PC0...7, and ME_PCTLn registers, software must request a mode change and wait for the mode change to be completed before entering debug mode in order to have consistent behavior between the peripheral clock control process and the clock status reporting in the ME_PSn registers.

Figure 1516. Peripheral Control Registers (ME_PCTLn)

Address 0x0C0 - 0x1BF								Access: User read, Supervisor read/write, Test read/write

SAFE	Core control during SAFE 0 the HSM is frozen with clock gated 1 the HSM is running
TEST	Core control during TEST 0 the HSM is frozen with clock gated 1 the HSM is running
RESET	Core control during RESET — the HSM is always disabled during RESET.

62.3.2.32 Core Address Register 0 (ME_CADDR0)

This register gives the boot address for peripheral core_2 and a bit for controlling whether peripheral core_2 is to be reset on the next mode change that has peripheral core_2 configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while $ME_GS[S_MTRANS] = 1$). A write access to this register during this time will result in the $ME_IS[ICONF_CC]$ flag being asserted.

Note: The reset value of the $ME_CADDR0[ADDR]$ field is determined by the chip configuration and boot mode.

Figure 1523. Core Address Register 0 (ME_CADDR0)

Table 1421. ME_CADDR0 field descriptions

Field	Description
ADDR	Core Address — This field is used by peripheral core_2 as the boot address (32-bit word aligned) when peripheral core_2 next exits reset.
RMC	Reset on Mode Change — peripheral core_2 will be reset on the next mode change that has peripheral core_2 configured to be running in the target mode. 0 peripheral core_2 will not be reset on the next mode change 1 peripheral core_2 will be reset on the next mode change that has peripheral core_2 configured to be running in the target mode

62.3.2.33 Core Address Register 1 (ME_CADDR1)

This register gives the boot address for main core_0 and a bit for controlling whether main core_0 is to be reset on the next mode change that has main core_0 configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while $ME_GS[S_MTRANS] = 1$). A write access to this register during this time will result in the $ME_IS[ICONF_CC]$ flag being asserted.

Figure 1524. Core Address Register 1 (ME_CADDR1)**Table 1422. ME_CADDR1 field descriptions**

Field	Description
ADDR	Core Address — This field is used by main core_0 as the boot address (32-bit word aligned) when main core_0 next exits reset.
RMC	Reset on Mode Change — main core_0 will be reset on the next mode change that has main core_0 configured to be running in the target mode. 0 main core_0 will not be reset on the next mode change 1 main core_0 will be reset on the next mode change that has main core_0 configured to be running in the target mode

62.3.2.34 Core Address Register 3 (ME_CADDR3)

This register gives the boot address for main core_1 and a bit for controlling whether main core_1 is to be reset on the next mode change that has main core_1 configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while ME_GS[S_MTRANS] = 1). A write access to this register during this time will result in the ME_IS[ICONF_CC] flag being asserted.

Field	Description
ADDR	Core Address — This field is used by main core_1 as the boot address (32-bit word aligned) when main core_1 next exits reset.
RMC	Reset on Mode Change — main core_1 will be reset on the next mode change that has main core_1 configured to be running in the target mode. 0 main core_1 will not be reset on the next mode change 1 main core_1 will be reset on the next mode change that has main core_1 configured to be running in the target mode

62.3.2.35 Core Address Register 4 (ME_CADDR4)

This register gives the boot address for the HSM and a bit for controlling whether the HSM is to be reset on the next mode change that has the HSM configured to be running in the target mode.

This register can be written only as a word and cannot be written after a mode change request has been made until the mode transition has completed (i.e., while ME_GS[S_MTRANS] = 1). A write access to this register during this time will result in the ME_IS[ICONF_CC] flag being asserted.

Note: The reset value of the ADDR field of the ME_CADDR4 is determined by the chip configuration.

62.4 Functional description

62.4.1 Mode transition request

The transition from one mode to another mode is normally handled by software by accessing the mode control register ME_MCTL. But the in case of special events, the mode transition can be automatically managed by hardware. In order to switch from one mode to another, the application should access the ME_MCTL register twice by writing

- the first time with the value of the key (0x5AF0) into the KEY bit field and the required target mode into the TARGET_MODE bit field,
- and the second time with the inverted value of the key (0xA50F) into the KEY bit field and the required target mode into the TARGET_MODE bit field.

Once a valid mode transition request is detected, the target mode configuration information is loaded from the corresponding ME_<mode>_MC register. The mode transition request may require a number of cycles depending on the programmed configuration, and software should check the S_CURRENT_MODE bit field and the S_MTRANS bit of the global status register ME_GS to verify when the mode has been correctly entered and the transition process has completed. For a description of valid mode requests, please see [Section 62.4.5, Mode Transition Interrupts](#).

Any modification of the mode configuration register of the currently selected mode will not be taken into account immediately but on the next request to enter this mode. This means

that transition requests such as RUN0...3 → RUN0...3, DRUN → DRUN, SAFE → SAFE, and TEST → TEST are considered valid mode transition requests. As soon as the mode request is accepted as valid, the S_MTRANS bit is set till the status in the ME_GS register matches the configuration programmed in the respective ME_<mode>_MC register.

Note: It is recommended that software polls the S_MTRANS bit in the ME_GS register after requesting a transition to HALT0 or STOP0 modes.

Figure 1527. MC_ME Mode Diagram

62.4.2 Modes details

62.4.2.1 RESET mode

The chip enters this mode on the following events:

- from SAFE, DRUN, RUN0...3, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with either "0000" for a 'functional' reset or "1111" for a 'destructive' reset
- from any mode due to a system reset by the MC_RGM because of some non-recoverable hardware failure in the system (see the MC_RGM chapter for details)

Transition to this mode is instantaneous, and the system remains in this mode until the reset sequence is finished. The mode configuration information for this mode is provided by the ME_RESET_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

62.4.2.2 DRUN mode

The chip enters this mode on the following events:

- automatically from RESET mode after completion of the reset sequence
- from RUN0...3, SAFE, or TEST mode when the TARGET_MODE bit field of the ME_MCTL register is written with "0011"

As soon as any of the above events has occurred, a DRUN mode transition request is generated. The mode configuration information for this mode is provided by the ME_DRUN_MC register. In this mode, the flash, all clock sources, and the system clock configuration can be controlled by software as required. After system reset, the software execution starts with the default configuration selecting the 16 MHz int. RC osc. as the system clock. The clock source configuration except system clock source 0 can be chosen by preloaded information in flash memory. This information is loaded into the ME_DRUN_MC register during PHASE3 of the reset sequence.

This mode is intended to be used by software

- to initialize all registers as per the system needs

Note: .Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

62.4.2.3 SAFE mode

The chip enters this mode on the following events:

- from any mode except RESET when the TARGET_MODE bit field of the ME_MCTL register is written with "0010"
- from any mode except RESET due to a SAFE mode request generated by the MC_RGM because of some potentially recoverable hardware failure in the system (see [Chapter 57: Reset Generation Module \(MC_RGM\)](#), for details)

Note: If a hardware SAFE mode request occurs during RESET, depending on the timing of the SAFE mode request, SAFE mode may be entered immediately after the normal completion of the reset sequence or several system clock cycles after DRUN entry. The SAFE mode request does not have any influence on the execution of the reset sequence itself.

As soon as any of the above events has occurred, a SAFE mode transition request is generated. The mode configuration information for this mode is provided by the ME_SAFE_MC register. This mode has a pre-defined configuration, and the 16 MHz int. RC osc. is selected as the system clock.

If the SAFE mode is requested by hardware, a SAFE mode interrupt is generated. See [Section 62.4.5.3, SAFE Mode Transition Interrupt](#) for details.

If the SAFE mode is requested by software while some other mode transition process is ongoing, the new target mode becomes the SAFE mode regardless of other pending requests or new requests during the mode transition. No new mode request made during a transition to the SAFE mode will cause an invalid mode interrupt.

Note: If software requests to change to the SAFE mode and then requests to change back to the parent mode before the mode transition is completed, the chip's final mode after mode transition will be the SAFE mode, and an invalid mode transition interrupt will be generated.

As long as a SAFE event is active, the system remains in the SAFE mode, and any software mode request during this time is ignored and lost.

This mode is intended to be used by software

- to assess the severity of the cause of failure and then to either
 - re-initialize the chip via the DRUN mode, or
 - completely reset the chip via the RESET mode.

If the outputs of the system I/Os need to be forced to a high impedance state upon entering this mode, the PDO bit of the ME_SAFE_MC register should be set. The input levels remain unchanged.

62.4.2.4 TEST mode

The chip enters this mode on the following events:

- from the DRUN mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0001”

As soon as any of the above events has occurred, a TEST mode transition request is generated. The mode configuration information for this mode is provided by the ME_TEST_MC register. Except for the main voltage regulator, all resources of the system are configurable in this mode. The system clock to the whole system can be stopped by programming the SYSCLK bit field to “1111”, and in this case, the only way to exit this mode is via a chip reset.

This mode is intended to be used by software

- to execute software test routines

Note: .Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

62.4.2.5 RUN0...3 modes

The chip enters one of these modes on the following events:

- from the DRUN, SAFE, or another RUN0...3 mode when the TARGET_MODE bit field of the ME_MCTL register is written with “0100...0111”
- from the HALT0 mode due to an interrupt event
- from the STOP0 mode due to an interrupt or wakeup event

As soon as any of the above events has occurred, a RUN0...3 mode transition request is generated. The mode configuration information for these modes is provided by the ME_RUN0...3_MC registers. In these modes, the flash, all clock sources, and the system clock configuration can be controlled by software as required.

These modes are intended to be used by software

- to execute application routines

Note: .Software must ensure that the code executes from RAM before changing to this mode if the flash is configured to be in the low-power or power-down state in this mode.

62.4.2.6 HALT0 mode

The chip enters this mode on the following events:

- from one of the RUN0...3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with “1000”.

As soon as any of the above events has occurred, a HALT0 mode transition request is generated. The mode configuration information for this mode is provided by

ME_HALT0_MC register. This mode is quite configurable, and the ME_HALT0_MC register should be programmed according to the system needs. The flash can be put in low-power or power-down mode as needed. If there is a HALT0 mode request while an interrupt request is active, the transition to HALT0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This mode is intended as a first-level low-power mode with

- the core clocks frozen the additional core clocks frozen
- only a few peripherals running

and to be used by software

- to wait until it is required to do something and then to react quickly (i.e., within a few system clock cycles of an interrupt event)

The normal exit of the HALT0 mode is from an interrupt event. Wakeup events will not cause HALT0 mode exit.

Note: It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on HALT0 mode exit to ensure that the previous RUN0...3 mode configuration has been fully restored before executing critical code.

62.4.2.7 STOP0 mode

The chip enters this mode on the following events:

- from one of the RUN0...3 modes when the TARGET_MODE bit field of the ME_MCTL register is written with "1010".

As soon as any of the above events has occurred, a STOP0 mode transition request is generated. The mode configuration information for this mode is provided by the ME_STOP0_MC register. This mode is fully configurable, and the ME_STOP0_MC register should be programmed according to the system needs. The following clock sources are switched off in this mode:

- the primary PLL
- the secondary PLL

The flash can be put in power-down mode as needed. If there is a STOP0 mode request while any interrupt or wakeup event is active, the transition to STOP0 is aborted with the resultant mode being the current mode, SAFE (on SAFE mode request), or DRUN (on reset), and an invalid mode interrupt is not generated.

This can be used as an advanced low-power mode with the core clock frozen and almost all peripherals stopped.

This mode is intended as an advanced low-power mode with

- the core clock frozen
- the additional core clocks frozen
- almost all peripherals stopped

and to be used by software

- to wait until it is required to do something with no need to react quickly (e.g., allow for system clock source to be re-started)

The normal exit from the STOP0 mode is by an interrupt or a wakeup event.

This mode can be used to stop all clock sources and thus preserve the chip status. When exiting the STOP0 mode, the 16 MHz internal RC oscillator clock is selected as the system clock until the target clock is available.

Note: .It is good practice for software to ensure that the S_MTRANS bit in the ME_GS register has been cleared on STOP0 mode exit to ensure that the previous RUN0...3 mode configuration has been fully restored before executing critical code.

62.4.3 Mode transition process

The process of mode transition follows the following steps in a pre-defined manner depending on the current chip mode and the requested target mode. In many cases of mode transition, not all steps need to be executed based on the mode control information, and some steps may not be applicable according to the mode definition itself.

Since the MC_ME ensures that all resources are in the proper state during the mode transition process, the following, for example, do not need to be checked by software.

- When the XOSC is enabled in a mode configuration register, a mode transition to that mode will not complete until the End Of Count timeout occurs for the oscillator. Software does not need to interrogate the End Of Count timeout status bit.
- When a PLL is enabled in a mode configuration register, a mode transition to that mode will not complete until the PLL is locked. Software does not need to interrogate the PLL's lock status bit.

62.4.3.1 Target mode request

The target mode is requested by accessing the ME_MCTL register with the required keys. This mode transition request by software must be a valid request satisfying a set of pre-defined rules to initiate the process. If the request fails to satisfy these rules, it is ignored, and the TARGET_MODE bit field is not updated. An optional interrupt can be generated for invalid mode requests. See [Section 62.4.5, Mode Transition Interrupts](#), for details.

In the case of mode transitions occurring because of hardware events such as a reset, a SAFE mode request, or interrupt requests and wakeup events to exit from low-power modes, the TARGET_MODE bit field of the ME_MCTL register is automatically updated with the appropriate target mode. The mode change process start is indicated by the setting of the mode transition status bit S_MTRANS of the ME_GS register.

A RESET mode requested via the ME_MCTL register is passed to the MC_RGM, which generates a global system reset and initiates the reset sequence. The RESET mode request has the highest priority, and the MC_ME is kept in the RESET mode during the entire reset sequence.

The SAFE mode request has the next highest priority after reset. It can be generated either by software via the ME_MCTL register from all software running modes or by the MC_RGM after the detection of system hardware failures, which may occur in any mode.

62.4.3.2 Target mode configuration loading

On completion of the [Target mode request](#) step, the target mode configuration from the ME_<target mode>_MC register is loaded to start the resources (voltage sources, clock sources, flash, pads, etc.) control process.

An overview of resource control possibilities for each mode is shown in [Table 1425](#). A '✓' indicates that a given resource is configurable for a given mode.

Table 1425. MC_ME resource control overview

Resource	Mode						
	RESET	TEST	SAFE	DRUN	RUN0...3	HALT0	STOP0
IRC	on	√ on	on	on	on	on	on
XOSC	off	√ off	off	√ off	√ off	√ off	√ off
PLL0	off	√ off	off	√ off	√ off	√ off	off
PLL1	off	√ off	off	√ off	√ off	√ off	√ off
FLASH	normal	√ normal	normal	√ normal	√ normal	√ low-power	√ power-down
MVREG	on	on	on	on	on	on	on
PDO	off	√ off	√ on	off	off	off	√ off

62.4.3.3 Peripheral clocks disable

On completion of the [Target mode request](#) step and the system clock frequency ramp-down of the [System clock switching](#) step, the MC_ME requests each peripheral to enter its stop mode when:

- the peripheral is configured to be disabled via the target mode, the peripheral configuration registers ME_RUN_PC0...7 and ME_LP_PC0...7, and the peripheral control registers ME_PCTLn

Note: *The MC_ME automatically requests peripherals to enter their stop modes if the power domains in which they are residing are to be turned off due to a mode change. However, it is good practice for software to ensure that those peripherals that are to be powered down are configured in the MC_ME to be frozen.*

Each peripheral acknowledges its stop mode request after closing its internal activity. The MC_ME then disables the corresponding clock(s) to this peripheral.

In the case of a SAFE mode transition request, the MC_ME does not wait for the peripherals to acknowledge the stop requests. The SAFE mode clock gating configuration is applied immediately regardless of the status of the peripherals' stop acknowledges.

Please see [Section 62.4.6, Peripheral Clock Gating](#), for more details.

Each peripheral that may block or disrupt a communication bus to which it is connected ensures that these outputs are forced to a safe or recessive state when the chip enters the SAFE mode.

62.4.3.4 Processor low-power mode entry

If, on completion of the [Peripheral clocks disable](#) step, the mode transition is to the HALT0 mode, the MC_ME requests the processor to enter its halted state. The processor acknowledges its halt state request after completing all outstanding bus transactions.

If, on completion of the [Peripheral clocks disable](#) step, the mode transition is to the STOP0 mode, the MC_ME requests the processor to enter its stopped state. The processor acknowledges its stop state request after completing all outstanding bus transactions.

62.4.3.5 Processor clocks disable

If, on completion of the [Processor low-power mode entry](#) step, and all processors which are configured in the ME_CCTLn registers to be disabled are in their appropriate stopped state, the MC_ME disables the applicable processor clocks bits to achieve further power saving.

The clocks to processors which are configured to be running in both the current and target modes or disabled in both the current and target modes are unaffected while transitioning between non-low-power modes.

Caution: Clocks to the whole chip including the processor and system memory can be disabled in TEST mode.

62.4.3.6 System clock disable

If, on completion of the [Processor clocks disable](#) step, all processor clocks have been disabled, the system clock used for non-processor system functions and memory is disabled.

62.4.3.7 Clock sources switch-on

On completion of the [Processor low-power mode entry](#) step, the MC_ME switches on all clock sources based on the <clock source>ON bits of the ME_<current mode>_MC and ME_<target mode>_MC registers. The following clock sources are switched on at this step:

- the 16 MHz internal RC oscillator
- the external crystal oscillator
- the primary PLL
- the secondary PLL

The clock sources that are required by the target mode are switched on. The duration required for the output clocks to be stable depends on the type of source, and all further steps of mode transition depending on one or more of these clocks waits for the stable status of the respective clocks. The availability status of these clocks is updated in the S_<clock source> bits of ME_GS register.

The clock sources which need to be switched off are unaffected during this process in order to not disturb the system clock which might require one of these clocks before switching to a different target clock.

62.4.3.8 Flash memory module switch-on

On completion of the step, if the flash memory needs to be switched to normal mode from its low-power or power-down mode based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, the MC_ME requests the flash memory to exit from its low-power/power-down mode. When the flash memory is

available for access, the S_FLA bit field of the ME_GS register is updated to “11” by hardware.

Caution: It is illegal to switch the FLASH or the DFLASH from low-power mode to power-down mode and from power-down mode to low-power mode. The MC_ME, however, does not prevent this nor does it flag it.

62.4.3.9 Pad outputs-on

On completion of the step, if the PDO bit of the ME_<target mode>_MC register is cleared, then

- all pad outputs are enabled to return to their previous state
- slew rate control mechanism is switched on

62.4.3.10 Peripheral clocks enable

Based on the current and target chip modes, the peripheral configuration registers ME_RUN_PC0...7, ME_LP_PC0...7, and the peripheral control registers ME_PCTLn, the MC_ME enables the clocks for selected modules as required. If the value of the PWRLVL field of the ME_<target mode>_MC register is less than that of the ME_<current mode>_MC register's, this step is executed only after the [System clock switching](#) process is completed.

62.4.3.11 System and processor clocks enable

On completion of the [Flash memory module switch-on](#) step, the MC_ME enables the non-processor system clock and the clocks of all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode.

The MC_ME initiates the resetting of all processors which are configured in the ME_CCTLn registers to be running in the target mode and which have their RMC bits in the ME_CADDRn registers set to '1'. The core_rst_b outputs remain asserted until the end of the mode transition as indicated by the S_MTRANS bit of the MW_GS register at which time they are deasserted.

If the value of the PWRLVL field of the ME_<target mode>_MC register is different from that of the ME_<current mode>_MC register's, the mode change handshake will not be initiated until after the system clock frequency ramp-down step of the [System clock switching](#) process is completed.

62.4.3.12 Processor low-power mode exit

On completion of the [System and processor clocks enable](#) step, the MC_ME requests all processors which are configured in the ME_CCTLn registers to be disabled in the current mode and to be running in the target mode by deasserting the corresponding core_stop bits.

62.4.3.13 System clock switching

Based on the SYSCLK bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the target and current system clock configurations differ, the following method is implemented for clock switching.

- The target clock configuration for the 16 MHz int. RC osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (i.e., the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the external crystal osc. takes effect only after the S_IRC bit of the ME_GS register is set by hardware (i.e., the 16 MHz internal RC oscillator has stabilized).
- The target clock configuration for the primary PLL (PHI) takes effect only after the S_XOSC bit of the ME_GS register is set by hardware (i.e., the external crystal oscillator has stabilized).
- The target clock configuration for the secondary PLL takes effect only after the S_PLL0 bit of the ME_GS register is set by hardware (i.e., the primary PLL has stabilized).
- If the clock is to be disabled, the SYSCLK bit field should be programmed with "1111". This is possible only in the TEST mode.

If the value of the PWRLVL field of the ME_<target mode>_MC register not equal to that of the ME_<current mode>_MC register's, a progressive clock switching is performed in the

The current system clock configuration can be observed by reading the S_SYSCLK bit field of the ME_GS register, which is updated after every system clock switching. Until the target clock is available, the system uses the previous clock configuration.

System clock switching starts only after

- the *Clock sources switch-on* process has completed if the target system clock source is one of the following:
 - the 16 MHz internal RC oscillator
 - the external crystal oscillator
 - the primary PLL
- the *Peripheral clocks disable* process has completed in order not to change the system clock frequency before peripherals close their internal activities
- the *Peripheral clocks enable* process has completed

An overview of system clock source selection possibilities for each mode is shown in [Table 1426](#). A '✓' indicates that a given clock source is selectable for a given mode.

Table 1426. MC_ME System Clock Selection Overview

System Clock Source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0...3	HALT0	STOP0
16 MHz int. RC osc.	✓ (default)	✓ (default)	✓ (default)	✓ (default)	✓ (default)	✓ (default)	✓ (default)
external crystal osc.		✓		✓	✓	✓	✓

Table 1426. MC_ME System Clock Selection Overview (continued)

System Clock Source	Mode						
	RESET	TEST	SAFE	DRUN	RUN0...3	HALT0	STOP0
primary PLL (PHI)		√		√	√	√	√
secondary PLL		√		√	√	√	
system clock is disabled		√ ⁽¹⁾					

1. disabling the system clock during TEST mode will require a reset in order to exit TEST mode

62.4.3.14 Pad switch-off

If the PDO bit of the ME_<target mode>_MC register is '1' then

- the outputs of the pads are forced to the high impedance state if the target mode is SAFE or TEST

This step is executed only after the [Peripheral clocks disable](#) process has completed.

62.4.3.15 Clock sources switch-off

Based on the chip mode and the <clock source>ON bits of the ME_<mode>_MC registers, if a given clock source is to be switched off, the MC_ME requests the clock source to power down and updates its availability status bit S_<clock source> of the ME_GS register to '0'. The following clock sources switched off at this step:

- the 16 MHz internal RC oscillator
- the external crystal oscillator
- the primary PLL
- the secondary PLL

For the clock sources related to the system clock, this step is executed only after the [System clock switching](#) process has completed.

62.4.3.16 Flash memory switch-off

Based on the FLAON bit field of the ME_<current mode>_MC and ME_<target mode>_MC registers, if the flash is to be put in its low-power or power-down mode, the MC_ME requests the flash to enter the corresponding power mode and waits for the flash to acknowledge. The exact power mode status of the flash is updated in the S_FLA bit field of the ME_GS register. This step is executed only when the [Processor clocks disable](#) and [System clock disable](#) processes have completed.

62.4.3.17 Current mode update

The current mode status bit field S_CURRENT_MODE of the ME_GS register is updated with the target mode bit field TARGET_MODE of the ME_MCTL register when :

- all the updated status bits in the ME_GS register match the configuration specified in the ME_<target mode>_MC register
- power sequences are done
- clock disable/enable process is finished
- processor low-power mode (stop) entry and exit processes are finished

Note: *SAFE mode entry does not wait for the clock disable/enable process to finish. It only waits for the ME_GS.S_RC bit to be set. This is to ensure that the SAFE mode is entered as quickly as possible.*

Software can monitor the mode transition status by reading the S_MTRANS bit of the ME_GS register. The mode transition latency can differ from one mode to another depending on the resources' availability before the new mode request and the target mode's requirements.

If a mode transition is taking longer to complete than is expected, the ME_DMTS register can indicate which process is still in progress.

Figure 1528. MC_ME Transition Diagram

62.4.4 Protection of Mode Configuration Registers

While programming the mode configuration registers ME_<mode>_MC, the following rules must be respected. Otherwise, the write operation is ignored and an invalid mode configuration interrupt may be generated.

- If the 16 MHz int. RC osc. is selected as the system clock, IRC must be on.
- If the external crystal osc. clock is selected as the system clock, XOSC must be on.
- If the primary PLL (PHI) clock is selected as the system clock, PLL0 must be on.
- If the secondary PLL clock is selected as the system clock, PLL1 must be on.

Note: .Software must ensure that clock sources with dependencies other than those mentioned above are switched on as needed. There is no automatic protection mechanism to check this in the MC_ME.

- Configuration “00” for the FLAON bit field is reserved.
- Configuration “00” for the DFLAON bit field is reserved.
- System clock configurations marked as ‘reserved’ may not be selected.
- Configuration “1111” for the SYSCLK bit field is allowed only for the TEST mode, and only in this case may all system clock sources be turned off.

Caution: If the system clock is stopped during *TEST* mode, the chip can exit only via a system reset.

62.4.5 Mode Transition Interrupts

The MC_ME provides interrupts for incorrectly configuring a mode, requesting an invalid mode transition, indicating a SAFE mode transition not due to a software request, and indicating when a mode transition has completed.

62.4.5.1 Invalid Mode Configuration Interrupt

Whenever a write operation is attempted to the ME_<mode>_MC registers violating the protection rules mentioned in the [Section 62.4.4, Protection of Mode Configuration Registers](#), the interrupt pending bit I_ICONF of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF of the ME_IM register is ‘1’.

In addition, during a mode transition, if a clock source has been configured in the ME_<target mode>_MC register to be off and a peripheral requiring this clock source to be on has been enabled via the ME_RUN_PC0...7/ME_LP_PC0...7 and ME_PCTLn registers, the interrupt pending bit I_ICONF_CU of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CU of the ME_IM register is ‘1’.

If an attempt to write to one of the ME_CADDRn registers is made after a mode change request has been made via the second write to the ME_CTL register and before the completion of that mode transition as indicated by the S_MTRANS bit in the ME_GS register deasserting, the interrupt pending bit I_ICONF_CC of the ME_IS register is set and an interrupt request is generated if the mask bit M_ICONF_CC of the ME_IM register is ‘1’.

62.4.5.2 Invalid Mode Transition Interrupt

The mode transition request is considered invalid under the following conditions:

- If the system is in the SAFE mode and the SAFE mode request from MC_RGM is active, and if the target mode requested is other than RESET or SAFE, then this new

mode request is considered to be invalid, and the S_SEA bit of the ME_IMTS register is set.

- If the TARGET_MODE bit field of the ME_MCTL register is written with a value different from the specified mode values (i.e., a non-existing mode), an invalid mode transition event is generated. When such a non existing mode is requested, the S_NMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If some of the chip modes are disabled as programmed in the ME_ME register, their respective configurations are considered reserved, and any access to the ME_MCTL register with those values results in an invalid mode transition request. When such a disabled mode is requested, the S_DMA bit of the ME_IMTS register is set. This condition is detected regardless of whether the proper key mechanism is followed while writing the ME_MCTL register.
- If the target mode is not a valid mode with respect to the current mode, the mode request illegal status bit S_MRI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If further new mode requests occur while a mode transition to a mode other than SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is '1'), the mode transition illegal status bit S_MTI of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a new mode request occurs while a mode transition to the SAFE mode is in progress (the S_MTRANS bit of the ME_GS register is '1'), the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a HALT0 mode request occurs while an interrupt request is active, the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.
- If a STOP0 mode request occurs while a wakeup or interrupt request is active, the mode request ignored status bit S_MRIG of the ME_IMTS register is set. This condition is detected only when the proper key mechanism is followed while writing the ME_MCTL register. Otherwise, the write operation is ignored.

Note: As the causes of invalid mode transitions may overlap at the same time, the priority implemented for invalid mode transition status bits of the ME_IMTS register in the order from highest to lowest is S_SEA, S_NMA, S_DMA, S_MRI, and S_MTI.

As an exception, the mode transition request is not considered as invalid under the following conditions:

- A new request is allowed to enter the RESET or SAFE mode irrespective of the mode transition status.
- As the exit of HALT0 and STOP0 modes depends on the interrupts of the system which can occur at any instant, these requests to return to RUN0...3 modes are always valid.
- In order to avoid any unwanted lockup of the chip modes, software can abort a mode transition by requesting the parent mode if, for example, the mode transition has not completed after a software determined 'reasonable' amount of time for whatever reason. The parent mode is the chip mode before a valid mode request was made.

Warning: Depending on the cause of the mode transition not completing, aborting via a request back to the parent mode may not be able to recover. In this case, software should request a change to either SAFE or RESET mode, since the cause of the hang-up is most likely due to a hardware fault.

- Self-transition requests (e.g., RUN0 → RUN0) are not considered as invalid even when the mode transition process is active (i.e., S_MTRANS is '1'). During the low-power mode exit process, if the system is not able to enter the respective RUN0...3 mode properly (i.e., all status bits of the ME_GS register match with configuration bits in the ME_<mode>_MC register), then software can only request the SAFE or RESET mode. It is not possible to request any other mode or to go back to the low-power mode again.

Whenever an invalid mode request is detected, the interrupt pending bit I_IMODE of the ME_IS register is set, and an interrupt request is generated if the mask bit M_IMODE of the ME_IM register is '1'.

62.4.5.3 SAFE Mode Transition Interrupt

Whenever the system enters the SAFE mode as a result of a SAFE mode request from the MC_RGM due to a hardware failure, the interrupt pending bit I_SAFE of the ME_IS register is set, and an interrupt is generated if the mask bit M_SAFE of ME_IM register is '1'.

The SAFE mode interrupt pending bit can be cleared only when the SAFE mode request is deasserted by the MC_RGM (see the MC_RGM chapter for details on how to clear a SAFE mode request). If the system is already in SAFE mode, any new SAFE mode request by the MC_RGM also sets the interrupt pending bit I_SAFE. However, the SAFE mode interrupt pending bit is not set when the SAFE mode is entered by a software request (i.e., programming of ME_MCTL register).

62.4.5.4 Mode Transition Complete interrupt

Whenever the system fully completes a mode transition (i.e., the S_MTRANS bit of ME_GS register transits from '1' to '0'), the interrupt pending bit I_MTC of the ME_IS register is set, and an interrupt request is generated if the mask bit M_MTC of the ME_IM register is '1'. The interrupt bit I_MTC is not set when entering low-power modes HALT0 and STOP0 in order to avoid the same event requesting the immediate exit of these low-power modes.

62.4.6 Peripheral Clock Gating

During all chip modes, each peripheral can be associated with a particular clock gating policy determined by two groups of peripheral configuration registers.

The run peripheral configuration registers ME_RUN_PC0...7 are chosen only during the software running modes DRUN, TEST, SAFE, and RUN0...3. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit which determines whether or not a peripheral clock is to be gated. Run configuration selection for each peripheral is done by the RUN_CFG bit field of the ME_PCTLn registers.

The low-power peripheral configuration registers ME_LP_PC0...7 are chosen only during the low-power modes HALT0 and STOP0. All configurations are programmable by software according to the needs of the application. Each configuration register contains a mode bit

which determines whether or not a peripheral clock is to be gated. Low-power configuration selection for each peripheral is done by the LP_CFG bit field of the ME_PCTLn registers.

Any modifications to the ME_RUN_PC0...7, ME_LP_PC0...7, and ME_PCTLn registers do not affect the clock gating behavior until a new mode transition request is generated.

Whenever the processor enters a debug session during any mode, the following occurs for each peripheral:

- The clock is gated if the DBG_F bit of the associated ME_PCTLn register is set. Otherwise, the peripheral clock gating status depends on the RUN_CFG and LP_CFG bits. Any further modifications of the ME_RUN_PC0...7, ME_LP_PC0...7, and ME_PCTLn registers during a debug session will take affect immediately without requiring any new mode request.

62.4.7 Application Example

[Figure 1529](#) shows an example application flow for requesting a mode change and then waiting until the mode transition has completed.

Figure 1529. MC_ME Application Example Flow Diagram

63 e200z420n3 Core Debug Support

This chapter describes the debug features of the e200z420n3 core.

63.1 Overview

Internal debug support in the e200z420n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware-based debugger, which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z420n3 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z420n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

63.1.1 Software debug facilities

e200z420n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors that are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 (DBCR0_{IDM}). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When DBCR0_{IDM} is cleared (and EDBCR0_{EDM} is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when DBCR0_{IDM} is cleared (or is overridden by EDBCR0_{EDM} being set and EDBRAC0 indicating no resource is “owned” by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

63.1.1.1 <asisitalic>PowerISA 2.06 compatibility

The e200z420n3 core implements a subset of the <asisitalic>PowerISA 2.06 internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

63.1.2 Additional debug facilities

In addition to the debug functionality defined in <asisitalic>PowerISA 2.06, e200z420n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See [Section 63.1.4, Sharing debug resources by software/hardware](#).) A data trace port is also provided.

63.1.2.1 Data trace port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z420n3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the “Data Trace Control Register (DTC)” section in the Core (e200z420n3) Nexus 3 Module chapter. The data trace port will report aligned accesses and misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0.

63.1.3 Hardware debug facilities

The e200z420n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z420n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug mode enable bit in External Debug Control register 0 (EDBCR0_{EDM}), which is also aliased to DBCR0_{EDM}. Setting EDBCR0_{EDM} overrides the Internal Debug mode enable bit DBCR0_{IDM} unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the “hardware-owned” debug facilities. In addition, since resources are “owned” by the hardware debugger, inconsistent values may be present if software attempts to read “hardware-owned” debug-related resources.

When hardware debug is enabled by setting EDBCR0_{EDM}=1, the control registers and resources described in [Section 63.3, Debug registers](#) are reserved for use by the external debugger. The same events described in [Section 63.2, Software debug events and exceptions](#) are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no

debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. EDBCR0_{EDM}, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

63.1.4 Sharing debug resources by software/hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When EDBCR0_{EDM} is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources that set DBSR bits when EBCR0_{IDM}=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources that set EDBSR0 bits when EDBCR0_{EDM}=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, (EDBCR0_{EDM}=1 and EDBRAC0_{IDM}=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

63.1.4.1 Simultaneous hardware and software debug event handling

Since it is possible that a “hardware-owned” resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented that guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSR0/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

[Figure 1530](#) shows the e200z420n3 debug resources.

Figure 1530. e200z420n3 debug resources

63.2 Software debug events and exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}=1$) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in $EDBRAC0$). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers ($DBCR0-8$). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource that is “owned” by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE} , a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when $MSR_{DE}=0$ and $DBCRO_{IDM}=1$. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE} . A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while $MSR_{DE}=0$, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction that enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** that causes both MSR_{DE} and $DBCRO_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z420n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2, which are described in [Section 63.2.11, External debug event](#).
- The Performance Monitor Interrupt event PMI, which is described in [Section 63.2.13, Performance Monitor Interrupt debug event](#).

The e200z420n3 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

63.2.1 Instruction Address Compare event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

63.2.2 Data Address Compare event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction or a cache maintenance instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. Four address compare values (DAC1–4) are provided.

The effective address of the load, store, or cache control operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the DBSR_{DAC{R,W}} bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the DBSR_{DAC{R,W}} bits are set.

Note: In contrast to the *PowerISA 2.06* definition, Data Address Compare events on e200z420n3 do not prevent the load or store class instruction from completing. If a load or store class instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting DBSR_{IDE}) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the DBSR_{DAC_OFST} field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the DBSR_{IDE} bit will be set. In addition to occurring when DBCR0_{IDM}=1, this circumstance can also occur when EDBCR0_{EDM}=1 and the event is hardware-owned, in which case EDBSR0_{IDE} will be set.

Note: DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note: DAC events will occur for cache control instructions without performing data compares, regardless of the settings of the DBCRx registers and DVC registers for data value comparison qualifications, i.e. no data comparisons are performed since these instructions do not have associated data values.

Note: DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note: DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.

Note: DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note: Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

63.2.2.1 Data Address Compare event status updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the DBSR_{DAC_OFST} field when the DVC DAC status is recorded.

[Table 1427](#) outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in [Table 1427](#), the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 1427. DAC events and resultant updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.

Table 1427. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
DVC DACx	DVC DACy, Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
DVC DACx	DVC DACy, Normal Ldst	Ldst instruction, no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
DVC DACx	DVC DACy, Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i> <i>Note: in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
DVC DACx	DVC DACy, Normal Ldst	DACy, or DVC DACy, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1427. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DVC DACy, Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
DVC DACx	Any instruction (no exception)	DSI, with or without DAC, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. <i>Note: in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
DVC DACx	Any instruction (no exception)	DACy, or DVC DACy Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1428 through Table 1431 show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 1428. DAC events and resultant updates, dual-issue case 1

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)

Table 1428. DAC events and resultant updates, dual-issue case 1 (continued)

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.</i> <i>Note: in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. No ESR update. DSRR0 points to instruction (6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.</i>

Table 1429. DAC events and resultant updates, dual-issue case 2

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction after instruction (6). No ESR update.
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction (7). No ESR update. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1429. DAC events and resultant updates, dual-issue case 2 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	Event(s)	Result
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instruction (4). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i> <i>Note: in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b101. No ESR update. DSRR0 points to instruction (7). No debug event updates for instruction (7). <i>Note: In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1430. DAC events and resultant updates, dual-issue case 3

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.

Table 1430. DAC events and resultant updates, dual-issue case 3 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6).
	Instruction (1): DVC DACx Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (5): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No debug event updates for instruction (6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
	Instruction (1): DVC DACx Instruction (5): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6) <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.

Table 1431. DAC events and resultant updates, dual-issue case 4 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). <i>Note: in this case if $x=y$, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). <i>Note: in this case if $x=y$, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

63.2.3 Linked Instruction Address Compare and Data Address Compare events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note: Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.

63.2.4 Trap debug event

A Trap debug event (TRAP) occurs if Trap debug events are enabled (DBCR0_{TRAP}=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the DBSR_{TRAP} bit is set to 1 to record the debug exception.

63.2.5 Branch Taken debug event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled (DBCR0_{BRT}=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus DBSR_{ID}E can not be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the DBSR_{BRT} bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

63.2.6 Instruction Complete debug event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled (DBCR0_{ICMP}=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The **se_sc** instruction does not fall into the category of an instruction whose execution is suppressed, since the

instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in $DSRR0$.

Instruction Complete debug events are not recognized if $MSR_{DE}=0$ at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed ($SRR0$ points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with $SRR0$ pointing to the instruction following the instruction that generated the EFPU Round exception, and $DSRR0$ will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}=1$, this circumstance can also occur when $EDBCR0_{EDM}=1$ and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}=1$, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while $MSR_{DE}=1$.

63.2.7 Interrupt Taken debug event

An Interrupt Taken debug event ($IRPT$) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}=1$) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using $SRR0/1$) cause an Interrupt Taken debug event. This event can occur and be recorded in $DBSR$ regardless of the setting of MSR_{DE} . When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in $DSRR0$ will be the address of the non-critical interrupt handler.

63.2.8 Critical Interrupt Taken debug event

A Critical Interrupt Taken debug event ($CIRPT$) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}=1$) and a critical interrupt occurs. Only critical class interrupts (an interrupt using $CSRR0/1$) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in $DBSR$ regardless of the setting of MSR_{DE} . When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in $DSRR0$ will be the address of the critical interrupt handler.

63.2.9 Return debug event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}=1$) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in $DBSR$ regardless of the setting of MSR_{DE} . When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If $MSR_{DE}=0$ at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE}=1$ at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

63.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}=1$) and an attempt is made to execute an **se_rfc**i instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If $MSR_{DE}=0$ at the time of the execution of the **se_rfc**i (i.e. before the MSR is updated by the **se_rfc**i), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE}=1$ at the time of the execution of the **se_rfc**i, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfc**i instruction.

63.2.11 External debug event

An External debug event ($DEVT1$, $DEVT2$) occurs if External debug events are enabled ($DBCR0_{DEVT1}=1$ or $DBCR0_{DEVT2}=1$), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

63.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in $DBCR0$. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

63.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}=1$), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

63.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register $EDBRAC0$, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in $EDBRAC0$ corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause

modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not “owned” by software is not guaranteed to be consistent if accessed (read) by software with a **mfsprr** instruction, other than the DBCR0_{EDM} bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

63.3.1 Debug Address and Value registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in [Figure 1531](#)) corresponds to the byte data value transferred to/from memory byte offset 0, 8, ..., and the least significant byte of the register (labeled B7 in [Figure 1531](#)) corresponds to byte offset 7, F, When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison; they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z420n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspr** and **mfsprr** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

SPR 601 (DVC1U), 318 (DVC1), 602 (DVC2U) 319 (DVC2); Read/Write; Reset: Unaffected

63.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z420n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

63.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z420n3 adds some implementation specific bits to this register, as seen in [Figure 1532](#).

Figure 1532. Debug Control Register 0 (DBCR0) register

EDM	IDM	RST		ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1		DAC2		RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	0		CIRPT	CRET	0					
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31	

SPR - 308; Read/Write; Reset⁽¹⁾ - 0x0

1. DBCR0_{EDM} is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if DBCR0_{EDM}=0, as well as unconditionally by **m_por**. If DBCR0_{EDM}=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the DBCR0_{RST} field will be reset by **p_reset_b**. The DBCR0_{RST} field will always be reset by **p_reset_b** regardless of the value of DBCR0_{EDM}.

[Table 1432](#) provides bit definitions for Debug Control Register 0.

Table 1432. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRO–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If $MSR_{DE}=1$, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 p_dbrstc[1] pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 p_dbrstc[0] pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled

Table 1434. DBCR2 field descriptions (continued)

Bit	Name	Description
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies <i>Exact Address Compare</i> since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR.

Table 1434. DBCR2 field descriptions (continued)

Bit	Name	Description
12:13	DVC1M	Data Value Compare 1 Mode When DBCR4_{DVC1C}=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. <i>Note: Inactive byte lanes of the memory access are automatically masked.</i> When DBCR4_{DVC1C}=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved <i>Note: Inactive byte lanes of the memory access are automatically masked.</i>
14:15	DVC2M	Data Value Compare 2 Mode When DBCR4_{DVC2C}=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. <i>Note: Inactive byte lanes of the memory access are automatically masked.</i> When DBCR4_{DVC2C}=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved <i>Note: Inactive byte lanes of the memory access are automatically masked.</i>

Table 1434. DBCR2 field descriptions (continued)

Bit	Name	Description
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

63.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in [Figure 1535](#).

Figure 1535. DBCR4 register

0	DVC1C	0	DVC2C	0								0	DAC1XMH	0	DAC2XMH	DAC1XM				DAC2XM				DAC1CFG				DAC2CFG			
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 563; Read/Write; Reset⁽¹⁾ - 0x0

1. DBCR4 is reset by processor reset **p_reset_b** if EDBCR0_{EDM}=0, as well as unconditionally by **m_por**. If EDBCR0_{EDM}=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

[Table 1435](#) provides bit definitions for Debug Control Register 4.

Table 1435. DBCR4 field descriptions

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.

Table 1435. DBCR4 field descriptions (continued)

Bit	Name	Description
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}=00$ 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}=00$ 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}=00$ 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). <i>Note: Unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}=0$; when $DBCR0_{DAC1} \neq 0$, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.</i>
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}=00$ 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}=00$ 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}=00$ 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. <i>Note: Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}=00$. When $DBCR0_{DAC2} \neq 0$, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.</i>

63.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in [Figure 1536](#)

Figure 1536. DBCR5 register

14	—	Reserved
15	DAC4XMH	Data Address Compare 4 Extended Mask Control High. DAC4XMH extends the range of the DAC4XM field. 0 DAC4XM masks 0–15 low-order address bits 1 DAC4XM masks 16–31 low-order address bits

Table 1438. DBCR7 field descriptions (continued)

Bit	Name	Description
16:19	DAC3XM	Data Address Compare 3 Extended Mask Control. DAC3XM allows for binary power of 2 address range compares for DAC3 without requiring the use of DAC4. Value of DAC3XMH DAC3XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC3 when comparing the storage address with the value in DAC3 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC4XM	Data Address Compare 4 Extended Mask Control. DAC4XM allows for binary power of 2 address range compares for DAC4 without requiring the use of DAC3. Value of DAC4XMH DAC4XM: 00000 No additional masking when DBCR8[DAC34M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC4 when comparing the storage address with the value in DAC4 for exact address compare (DBCR8[DAC34M] = 00). Address ranges of 2 bytes to 2GB are supported.
24:27	DAC3CFG	Data Address Compare 3 Configuration. DAC3CFG controls whether DAC3 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). 0000 DAC3 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC3 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC3 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC3 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC3 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC3 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1000 DAC3 address comparisons are used for stack limit checking. DAC3 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC3. When a qualified match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC3 watchpoints is generated. 1001–1111 Reserved
28:31	DAC4CFG	Data Address Compare 4 Configuration. DAC4CFG controls whether DAC4 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. 0000 DAC4 debug watchpoints are enabled for load-type or store-type data storage accesses 0001 DAC4 debug watchpoints are enabled only for store-type data storage accesses 0010 DAC4 debug watchpoints are enabled only for load-type data storage accesses 0011 Reserved 0100 Reserved 0101 DAC4 debug events and watchpoints are enabled only for store-type data storage accesses 0110 DAC4 debug events and watchpoints are enabled only for load-type data storage accesses 0111 DAC4 debug events and watchpoints are enabled for load-type or store-type data storage accesses 1xxx Reserved

Table 1439. DBCR8 field descriptions (continued)

Bit	Name	Description
8:9	DAC34M	Data Address Compare 3/4 Mode 00 Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 No effect 1 DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 No effect 1 DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

63.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr DBSR,RS**. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug mode is enabled ($DBCR0_{IDM}=1$). When debug interrupts are enabled ($MSR_{DE}=1$, $DBCR0_{IDM}=1$ and $EDBCR0_{EDM}=0$, or $MSR_{DE}=1$, $DBCR0_{IDM}=1$, $EDBCR0_{EDM}=1$ and software is allocated resource(s) via $EDBRAC0$), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}=1$ and $EDBRAC0_{IDM}=1$), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in [Figure 1540](#).

Figure 1540. Debug Status Register (DBSR)

IDE	UDE	MRR	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0								
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 304; Read/Clear; Reset - 0x1000 0000

Table 1440 provides bit definitions for the Debug Status Register.

Table 1440. DBSR field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $MSR_{DE}=0$ and $DBCRO_{IDM}=1$ and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store that is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 No reset occurred since these bits were last cleared by software 01 A hard reset occurred since these bits were last cleared by software 10 Reserved 11 Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred

Table 1440. DBSR field descriptions (continued)

Bit	Name	Description
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UD}[1]=1$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

63.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load, store, or cache control operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in [Figure 1541](#).

Figure 1541. Debug Data Effective Address Register (DDEAR)

Data Effective Address																															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 600; Read/Write; Reset - unaffected

63.3.3 External Debug Resource Allocation Control (EDBRAC0) register

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}=1$. EDBRAC0 settings are ignored when $EDBCR0_{EDM}=0$.

Hardware-owned resources that generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources that generate debug events if $DBCR0_{IDM}=1$ update DBSR, causing debug interrupts to occur if $MSR_{DE}=1$. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug mode is enabled. When debug interrupts are enabled ($MSR_{DE}=1$, $DBCR0_{IDM}=1$ and $EDBCR0_{EDM}=0$, or $MSR_{DE}=1$, $DBCR0_{IDM}=1$ and $EDBCR0_{EDM}=1$ and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event that is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug mode is enabled ($EDBCR0_{EDM}=1$). When $EDBCR0_{EDM}=1$, a set bit in EDBSR0 by an event that is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}=1$, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in $DBCR0-8$ or $MPU0CSR0$ are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in [Figure 1542](#).

Figure 1542. External Debug Resource Allocation Control (EDBRAC0) register

18	IAC6	Instruction Address Compare 6 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC6 control and status fields. 1 Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC7 control and status fields. 1 Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC8 control and status fields. 1 Event owned by software debug. IAC8 control are software readable/writable.

Table 1441. EDBRAC0 field descriptions (continued)

Bit	Name	Description
21	DEVT1	External Debug Event Input 1 Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{DEVT1} field. 1 Event owned by software debug. DBCR0 _{DEVT1} is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{DEVT2} field. 1 Event owned by software debug. DBCR0 _{DEVT2} is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 Event owned by hardware debug. No mtpmr access by software to the PMRs. Performance monitor interrupts set EDBSR0 _{PMI} regardless of the setting of PMGC0 _{UDI} . 1 Event owned by software debug. PMRs are software readable/writable. <i>Note: This bit is reset to '1'.</i>
24	MPU	Memory Protection Unit Debug Event 0 Event owned by hardware debug. No mpuwe access by software to region descriptors that have the DEBUG control bit set to '1' or to the MPU0CSR0 _{DRDEN,DWDEN,IDEN} control bits, unless the CPU is in a debug session (jd_debug_b is asserted). MPU debug events set EDBSR0 _{MPU} , and if not masked by EDBSRMSK0 _{MPU} , one of EDBSR0 _{IAC} , EDBSR0 _{DACR} , or EDBSR0 _{DACW} . MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (jd_debug_b is asserted). 1 Event owned by software debug. All region descriptors and the MPU0CSR0 _{DRDEN,DWDEN,IDEN} control bits are software readable/writable. <i>Note: This bit is reset to '1'.</i>
25	CIRPT	Critical Interrupt Taken Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{CIRPT} field. 1 Event owned by software debug. DBCR0 _{CIRPT} is software readable/writable.
26	CRET	Critical Return Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{CRET} field. 1 Event owned by software debug. DBCR0 _{CRET} is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 DNI resource owned by hardware debug. Execution of an e_dni or se_dni instruction results in entry into debug mode. 1 DNI resource owned by software debug. Execution of an e_dni or se_dni instruction results in either a debug interrupt (DBCR0 _{IDM} =1 and MSR _{DE} =1) or a nop (DBCR0 _{IDM} =0 or MSR _{DE} =0). <i>Note: DNI events are not blocked during a debug session</i>
28	DQM	Data Acquisition Messaging Registers 0 DEVENT _{DQTAG} and DDAM register are exclusively owned by hardware debug. No mtspr access by software to DEVENT _{DQTAG} field or DDAM register. Attempted access by software is ignored. 1 DEVENT _{DQTAG} and DDAM register are owned by software. Software has read/write access to DEVENT _{DQTAG} field and DDAM register.
29:31	—	Reserved

Table 1442 shows which resources are controlled by EDBRAC0 settings.

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when $EDBCR0_{EDM}=1$. Only software-owned bits or fields as shown in [Table 1442](#) are affected in this case, except that $DBCR0_{RST}$ and $DBSR_{MRR}$ are updated by assertion of **p_reset_b** regardless of the value of $EDBCR0_{EDM}$ or EDBRAC0.

63.3.4 Debug Event Select register (DEVENT) register

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering.

The $DEVENT_{DEVNT}$ register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the “Data Acquisition ID Tag Field” section in the Core (e200z420n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in [Figure 1543](#).

Figure 1543. Debug Event Select register (DEVENT) register

DQTAG	0	DEVNT
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31		
SPR 975; Reset ⁽¹⁾ : 0x0		

- Reset by processor reset **p_reset_b** if $EDBCR0_{EDM}=0$, as well as unconditionally by **m_por**. If $EDBCR0_{EDM}=1$, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

[Table 1443](#) provides bit definitions for the Debug Event Register.

Table 1443. DEVENT field descriptions

Bit	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 No signal is asserted xxxxxxx1 p_devnt_out[0] and jd_watchpt[12] are asserted for one clock xxxxxx1x p_devnt_out[1] and jd_watchpt[13] are asserted for one clock xxxxx1xx p_devnt_out[2] and jd_watchpt[20] are asserted for one clock xxxx1xxx p_devnt_out[3] and jd_watchpt[21] are asserted for one clock xxx1xxxx p_devnt_out[4] is asserted for one clock xx1xxxxx p_devnt_out[5] is asserted for one clock x1xxxxxx p_devnt_out[6] is asserted for one clock 1xxxxxxx p_devnt_out[7] is asserted for one clock

63.3.5 Debug Data Acquisition Message (DDAM) register

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this register. See the “Data Acquisition Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter for details.

The DDAM register is shown in [Figure 1544](#).

Figure 1544. Debug Data Acquisition Message (DDAM) register

DDAM																															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
SPR 576; Reset ⁽¹⁾ : 0x0																															

- Reset by processor reset **p_reset_b** if EDBCR0_{EDM}=0, as well as unconditionally by **m_por**. If EDBCR0_{EDM}=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

[Table 1444](#) provides bit definitions for the Debug Data Acquisition Message Register.

Table 1444. DDAM field descriptions

Bit	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

63.4 Using debug resources for stack limit checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DAC resources configured to

perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0 pointing to the address of the load or store access that generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in [Table 1435](#). Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the DBCR4_{DAC1CFG} field to '1000' or the DBCR8_{DAC3CFG} field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the DBCR4_{DAC1CFG} field is set to '1000' with DBCR2_{DAC1US} set to '00' or '10', or the DBCR7_{DAC3CFG} field is set to '1000' with DBCR8_{DAC3US} set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the DBCR4_{DAC1CFG} field is set to '1000' with DBCR2_{DAC1US} set to '00' or '01', or the DBCR7_{DAC3CFG} field is set to '1000' with DBCR8_{DAC3US} set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the EDBSR0_{ID} status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow, and for user mode accesses,

a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in [Table 1435](#) and [Table 1438](#) in [Section 63.3.2, Debug Control and Status registers](#). Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

63.5 External debug support

External debug support is supplied through the OnCE controller serial interface, which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the EDBCR0_{EDM}/DBCR0_{EDM} bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When EDBCR0_{EDM} is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of [Section 63.2, Software debug events and exceptions](#) refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note: On the initial setting of EDBCR0_{EDM} to '1', other bits in DBCR0 will remain unchanged. After EDBCR0_{EDM} has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information that could cause unintended operation.

Note: It is intended for the CPU to remain in external debug mode (EDBCR0_{EDM}=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.

Note: *EDBCR0_{EDM} operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if EDBCR0_{EDM} was previously set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all hardware debug events are blocked. Watchpoints are not blocked.*

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the EDBCR0_{EDM} bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

63.5.1 External debug registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug mode.

63.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software. However, the state of EDBCR0_{EDM} is reflected as a read-only bit in DBCR0_{EDM} to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in [Figure 1545](#).

Figure 1545. External Debug Control Register 0 (EDBCR0)

EDM	DNH_EN	0					DNI_CTL	0																							
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset⁽¹⁾: 0x0

- EDBCR0 is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**.

Table 1445 provides bit definitions for External Debug Control Register 0.

Table 1445. EDBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b . This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0.
1	DNH_EN	dnh Instruction Enable 0 Execution of e_dnh and se_dnh instructions cause illegal instruction exceptions to occur. 1 Execution of e_dnh and se_dnh instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	—	Reserved
7	DNI_CTL	dni Instruction Control 0 When the dni resource is owned by hardware, the MSR _{DE} bit is cared, and when MSR _{DE} =0, execution of e_dni and se_dni instructions are nop'ed and no entry into debug mode occurs. 1 When the dni resource is owned by hardware, the MSR _{DE} bit is don't-cared, and execution of e_dni and se_dni instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR _{DE} . <i>Note: This control bit is only used when the dni resource is owned by hardware via control in EDBRAC0_{DNI}, and thus also only when EDM=1.</i>
8:31	—	Reserved

63.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in Figure 1546.

Figure 1546. External Debug Status Register 0 (EDBSR0)

IDE	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0							
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Read/Write; Reset⁽¹⁾ - 0x0000 0000

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logics_Reset state or while EDBCR0_{EDM}=0.

Table 1446 provides bit definitions for External Debug Status Register 0.

Table 1446. EDBSR0 field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if EDBCR0 _{EDM} =1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store that is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events that are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with EDBRAC0 _{PMI} =0 regardless of the setting of PMGC0 _{UDI}

Table 1446. EDBSR0 field descriptions (continued)

Bit	Name	Description
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if EDBSRMSK0 _{MPU} is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If EDBSRMSK0 _{MPU} is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by EDBCR0 _{DNH_EN} . Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and EDBSR0 _{IDE} is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

63.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events that are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in [Figure 1547](#).

Figure 1547. External Debug Status Register Mask 0 (EDBSRMSK0)

0	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	0									
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Read/Write; Reset⁽¹⁾ - 0x0000 0000

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while EDBCR0_{EDM}=0.

[Table 1447](#) provides bit definitions for External Debug Status Register Mask 0.

Table 1447. EDBSRMSK0 field descriptions

Bit	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{UDE}
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by EDBSR0 _{DNH}
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{ICMP}
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{BRT}

22:31	—	Reserved

63.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load, store, or cache control operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of EDBSR0_{DAC{R,W}} bits that are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the EDBSR0_{DAC{R,W}} bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in [Figure 1548](#).

Figure 1548. External Debug Data Effective Address Register (EDDEAR)

Data Effective Address																															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

63.5.2 OnCE introduction

The e200z420n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z420n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated

product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

Figure 1549. OnCE TAP controller and registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Figure 1550. OnCE controller implementation

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core, which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), [Section 63.5.6.1, OnCE](#)

[Status register](#)) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will indicate the CPU is in the debug state. Instructions may be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See [Section 63.5.6.2, OnCE Command \(OCMD\) register](#)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

63.5.3 JTAG/OnCE pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

[Table 1448](#) details the primary JTAG/OnCE interface signals.

Table 1448. JTAG/OnCE primary interface signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en ⁽¹⁾	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z420n3) Core Complex Overview.

63.5.4 OnCE internal interface signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

63.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

63.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

63.5.4.3 CPU address and attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

63.5.4.4 CPU data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

63.5.5 OnCE interface signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks that may need information pertaining to debug operation.

63.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regssel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

63.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z420n3 interface) provides a fast means of entering the Debug mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug mode. Once Debug mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems that do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

63.5.5.3 OnCE Debug output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control that are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either “No Register Selected” or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See [Section 63.5.6.2, OnCE Command \(OCMD\) register](#) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

63.5.5.4 CPU Clock On input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z420n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

63.5.5.5 Watchpoint events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/DTSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to [Table 1455](#) for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

63.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates “no register selected”. This signal will assert regardless of whether the CPU is currently in debug mode. It may be

monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with “no register selected”, and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs that are not in debug mode will ignore the command.

63.5.6 OnCE controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. [Figure 1551](#) is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR, and Update-DR states.

Figure 1551. OnCE Controller and Serial Interface

63.5.6.1 OnCE Status register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

Figure 1552. OnCE Status register

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

[Table 1449](#) provides bit definitions for the OnCE Status register.

Table 1449. OnCE Status register field descriptions

Bit	Name	Description
0	MCLK	MCLK m_clk Status Bit 0 Inactive state 1 Active state This status bit reflects the logic level on the jd_mclk_on input signal after capture by j_tclk .
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
2	—	Reserved, set to zero
3	RESET	RESET Mode This bit reflects the <u>inverted</u> logic level on the CPU p_reset_b input after capture by j_tclk .
4	HALT	HALT Mode This bit reflects the logic level on the CPU p_halted output after capture by j_tclk .
5	STOP	STOP Mode This bit reflects the logic level on the CPU p_stopped output after capture by j_tclk .
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU p_waiting output after capture by j_tclk .
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

63.5.6.2 OnCE Command (OCMD) register

The OnCE Command (OCMD) register is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in [Figure 1553](#). The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Figure 1553. OnCE Command (OCMD) register

R/W	GO	EX	RS[0:6]						
0	1	2	3	4	5	6	7	8	9

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por**, or while in the Test Logic Reset state

[Table 1450](#) provides bit definitions for the OCMD.

Table 1450. OCMD field descriptions

Bit	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. <i>Note: The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on j_tdo during the first 32 clocks of Shift-DR.</i> 0 Write the data associated with the command into the register specified by RS[0:6] 1 Read the data contained in the register specified by RS[0:6]
1	GO	Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction that resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. <i>Note: Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Section 63.5.9.6, Exiting Debug mode and interrupt blocking.</i> 0 Inactive (no action taken) 1 Execute instruction in IR

Table 1450. OCMD field descriptions (continued)

Bit	Name	Description
2	EX	Exit Command Bit 0 Remain in debug mode 1 Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. <i>Note: If the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and EDBCR0_{EDM}=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode without execution of an instruction, even though the EX bit was set.</i> <i>Note: Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Section 63.5.9.6, Exiting Debug mode and interrupt blocking.</i>
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. Table 1451 indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

[Table 1451](#) indicates the OnCE register addresses.

1. Causes assertion of the `j_en_once_regsel` output.

The OnCE Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single-stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The `OSR_ERR` bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the `EDBCR0_EDM` bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of `EDBCR0_EDM`. DBSR may still be modified during a debug session via a single-stepped `mtspr` instruction, or via OnCE access.

If the CPU is not currently in debug mode, `go+exit` and `go+noexit` commands are ignored, although for a `go+exit` command with "No Register Selected", the `j_ocmd_go_exit` output will be asserted.

63.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z420n3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see [Section 63.7, MPU operation during debug](#)). The control bits are read/write. These bits are only effective while OnCE is enabled (`jd_en_once` asserted). The OCR is shown in [Figure 1554](#).

Figure 1554. OnCE Control Register (OCR)

0								I_DMDIS	0	I_DVLE	I_DI	0	D_DMDIS	0	D_DI	0	D_DG	0									WKUP	FDB	DR

Table 1452 provides bit definitions for the OnCE Control Register.

Table 1452. OCR field descriptions

Bit	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to '1' to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug 'VLE' Attribute Bit This bit is used to provide the 'VLE' attribute bit to be used during a debug session. <i>Note: This bit is ignored, since VLE is always enabled.</i>
12	I_DI	Instruction Side Debug 'I' Attribute Bit This bit is used to provide the 'I' attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to '1' to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
17:19	—	Reserved
20	D_DI	Data Side Debug 'I' Attribute Bit This bit is used to provide the 'I' attribute bit to be used for Data accesses during a debug session.
21	—	Reserved

Table 1452. OCR field descriptions (continued)

Bit	Name	Description
22	D_DG	Data Side Debug 'G' Attribute Bit This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit This control bit may be used to force the p_wakeup output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the m_clk input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the ' bkpt ' pseudo-instruction will cause the processor to enter debug mode, as if the jd_de_b input had been asserted. This bit is qualified with EDBCR0_EDM , which must be set for FDB to take effect. <i>Note: This bit has no effect on e_dnh or se_dnh instruction operation.</i>
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter Debug mode. The CPU will indicate that Debug mode has been entered via the data scanned out in the shift-IR state. 0 No Debug mode request 1 Unconditional Debug mode request When the DR bit is set, the processor will enter Debug mode at the next instruction boundary.

63.5.7 Access to debug resources

Resources contained in the OnCE Module that do not require the processor core to be halted for access may be accessed while the e200z420n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z420n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z420n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the **OCR_WKUP** control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

[Table 1453](#) provides a list of access requirements for OnCE registers.

Table 1453. OnCE register access requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
Enable_OnCE	N	N	N	N	—

PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

63.5.8 Methods of entering Debug mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See [Section 63.5.5.1, OnCE Enable \(jd_en_once\)](#).

63.5.8.1 External debug request during RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b**, and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z420n3 core to enter Debug mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z420n3 core does not execute an instruction before entering Debug mode, although the first instruction to be executed will be fetched prior to entering Debug mode in order to properly initialize the CPUSCR.

63.5.8.2 Debug request during RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

63.5.8.3 Debug request during normal activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

63.5.8.4 Debug request during Waiting, Halted, or Stopped state

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting**, **p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** output during the Shift_IR TAP controller state. This status may be

used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

63.5.8.5 Software request during normal activity

Upon executing a **'bkpt'** pseudo-instruction (for e200z420n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and EDBCR0_{EDM}=1, the CPU enters the debug mode after the instruction following the **'bkpt'** pseudo-instruction has entered the instruction register.

63.5.8.6 Debug notify halt instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by EDBCR0_{DNH_EN}, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is **not** conditioned on EDBCR0_{EDM}, allowing for debug of software debug handlers as well as other software. For e200z420n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

63.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. [Figure 1555](#) shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

Figure 1555. CPU Scan Chain Register (CPUSCR)

63.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

63.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the

operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

Figure 1556. Control State Register (CTL)

*										IRSTAT14	IRSTAT13	IRSTAT12	IRSTAT11	IRSTAT10	WAITING	PCOFST				PCINV	FFRA	IRSTAT0	IRSTAT1	IRSTAT2	IRSTAT3	IRSTAT4	IRSTAT5	IRSTAT6	IRSTAT7	IRSTAT8	IRSTAT9
										10	11	12	13	14	15					16	17	18	19	20	21	22	23	24	25	26	27

Table 1454. CTL field descriptions

Bit	Name	Description
0:9	*	Internal State Bits These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See Section 63.5.5.3, OnCE Debug output (jd_debug_b) , which is not part of the normal program execution flow, these bits should be set to a 0.
10	IRSTAT14	IR Status Bit 14 This control bit indicates an MPU Instruction Address Compare event status for the IR. 0 No MPU Instruction Address Compare event occurred on the fetch of this instruction. 1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.
11	IRSTAT13	IR Status Bit 13 This control bit indicates an Instruction Address Compare 8 event status for the IR. 0 No Instruction Address Compare 8 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.
12	IRSTAT12	IR Status Bit 12 This control bit indicates an Instruction Address Compare 7 event status for the IR. 0 No Instruction Address Compare 7 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.
13	IRSTAT11	IR Status Bit 11 This control bit indicates an Instruction Address Compare 6 event status for the IR. 0 No Instruction Address Compare 6 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.
14	IRSTAT10	IR Status Bit 10 This control bit indicates an Instruction Address Compare 5 event status for the IR. 0 No Instruction Address Compare 5 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.

Table 1454. CTL field descriptions (continued)

Bit	Name	Description
15	WAITING	WAITING State Status This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit. 0 CPU was not in the waiting state when debug mode was entered 1 CPU was in the waiting state when debug mode was entered
16:19	PCOFST	PC Offset Field This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV, which overrides this field). 0000 No correction required. 0001 Subtract 0x04 from PC. 0010 Subtract 0x08 from PC. 0011 Subtract 0x0C from PC. 0100 Subtract 0x10 from PC. 0101 Subtract 0x14 from PC. All other encodings are reserved
20	PCINV	PC and IR Invalid Status Bit This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered. 0 No error condition exists. 1 Error condition exists. PC and IR are corrupted.
21	FFRA	Feed Forward RA Operand Bit This control bit causes the content of the WBBR_{lo} to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR. For most LSP instructions using rA rB as a 64-bit source operand, WBBR_{hi}, lo is used to supply the 64-bit source value. This allows the debug firmware to update processor registers — initialize the WBBR_{lo} with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register. Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent. 0 No action. 1 Content of WBBR_{lo} used as operand value.

Table 1454. CTL field descriptions (continued)

Bit	Name	Description
22	IRSTAT0	IR Status Bit 0 This control bit indicates a TEA status for the IR. 0 No TEA occurred on the fetch of this instruction. 1 TEA occurred on the fetch of this instruction.
23	IRSTAT1	IR Status Bit 1 This control bit is reserved.
24	IRSTAT2	IR Status Bit 2 This control bit indicates an Instruction Address Compare 1 event status for the IR. 0 No Instruction Address Compare event 1 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.
25	IRSTAT3	IR Status Bit 3 This control bit indicates an Instruction Address Compare 2 event status for the IR. 0 No Instruction Address Compare 2 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.
26	IRSTAT4	IR Status Bit 4 This control bit indicates an Instruction Address Compare 3 event status for the IR. 0 No Instruction Address Compare event 3 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.
27	IRSTAT5	IR Status Bit 5 This control bit indicates an Instruction Address Compare 4 event status for the IR. 0 No Instruction Address Compare 4 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.
28	IRSTAT6	IR Status Bit 6 This control bit indicates a Parity Error status for the IR. 0 No Parity Error occurred on the fetch of this instruction. 1 Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.
29	IRSTAT7	IR Status Bit 7 This control bit indicates a Precise External Termination Error status for the IR. 0 No Precise External Termination Error occurred on the fetch of this instruction. 1 A Precise External Termination Error occurred on the fetch of this instruction.
30	IRSTAT8	IR Status Bit 8 This control bit indicates the PowerISA VLE status for the IR. 0 IR contains a BookE instruction. (unused encoding) 1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit. <i>Note: This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).</i>
31	IRSTAT9	IR Status Bit 9 This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the

desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit that was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC + 4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events that may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be reentered prior to any further instruction execution.

63.5.9.3 Program Counter (PC) register

The PC is a 32-bit register that stores the value of the program counter that was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

63.5.9.4 Write-Back Bus Register (WBBR_{low}, WBBR_{high})

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. WBBR_{low} holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. WBBR_{high} holds the updated effective address calculated by a load with update instruction. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into WBBR_{low}. The contents of WBBR_{low} can then be delivered serially to the external command controller. To update a processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed, which uses this value as a substitute data value. The Control State

register FFRA bit forces the value of the WBBR_{low} to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to [Section 63.5.9.2, Control State Register \(CTL\)](#) for more detail on the CTL_{FFRA} bit.)

WBBR_{low} and WBBR_{high} are generally undefined on instructions that do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

63.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used. This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

63.5.9.6 Exiting Debug mode and interrupt blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will reenter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

63.5.10 Reserved registers (Reserved)

The reserved registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

63.6 Watchpoint support

e200z420n3 supports the generation and signalling of watchpoints when operating in internal debug mode (DBCR0_{IDM}=1) or in external debug mode (EDBCR0_{EDM}=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with EDBCR0_{EDM} or DBCR0_{IDM}.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVENT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31]**) for various development control purposes. (See the “Watchpoint Trace Messaging” section in the Core (e200z420n3) Nexus 3 Module chapter.)

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

[Table 1455](#) shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 1455. Watchpoint output signal assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on DBCR4 _{DAC1CFG} settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on DBCR4 _{DAC2CFG} settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on DBCR7 _{DAC3CFG} settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on DBCR7 _{DAC4CFG} settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status

Table 1455. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever p_pm_event transitions from a '0' to a '1' while m_clk is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on PMLCa0 _{PMP}
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on PMLCa1 _{PMP}
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on PMLCa2 _{PMP}

Table 1455. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on PMLCa3 _{PMP}
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

63.7 MPU operation during debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR ([Section 63.5.6.3, OnCE Control Register \(OCR\)](#) for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR ([Section 63.5.6.3, OnCE Control Register \(OCR\)](#) for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

63.8 Cache array access during debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

63.9 Basic steps for enabling, using, and exiting External Debug mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug mode and initializing debug registers:

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR} , OCR_{WKUP} are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set.

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Section 63.5.9.2, Control State Register \(CTL\)](#)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with “no-register selected”, Go cleared, and determines that the PCU has reentered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Section 63.5.9.2, Control State Register \(CTL\)](#)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the EDBCR0_{EDM} bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should rewrite the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Section 63.5.9.2, Control State Register \(CTL\)](#)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note: These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

64 e200z425n3 Core Debug Support

This chapter describes the debug features of the e200z425n3 core.

64.1 Overview

Internal debug support in the e200z425n3 core allows for software and hardware debug by providing debug functions, such as instruction and data breakpoints and program trace modes. For software based debugging, debug facilities consisting of a set of software accessible debug registers and interrupt mechanisms are provided. These facilities are also available to a hardware-based debugger, which communicates using a modified IEEE 1149.1 Test Access Port (TAP) controller and pin interface. When hardware debug is enabled, the debug facilities controlled by hardware are protected from software modification.

Software debug facilities are defined as part of *PowerISA 2.06*. e200z425n3 supports a subset of these defined facilities. In addition to the facilities defined in *PowerISA 2.06*, e200z425n3 provides additional flexibility and functionality in the form of additional instruction breakpoints, linked instruction and data breakpoints, and extended range and value masking. These features are also available to a hardware-based debugger.

When not being used for debugging purposes, a portion of the debug facilities may be configured to provide a stack limit checking mechanism.

64.1.1 Software debug facilities

e200z425n3 provides debug facilities to enable hardware and software debug functions, such as instruction and data breakpoints and program single stepping. The debug facilities consist of a set of debug control registers (DBCR0–2,4–8, EDBRAC0), a set of address compare registers (IAC1–8, DAC1–4), a set of 64-bit data value compare registers (DVC1, DVC2), a Debug Status Register (DBSR) for enabling and recording various kinds of debug events, a Debug Data Effective Address Register (DDEAR), and a special Debug interrupt type built into the interrupt mechanism.

The debug facilities also provide a mechanism for software-controlled processor reset, and debug mode entry. In addition, the Performance Monitor may be configured to utilize the debug interrupt type. Also, the Memory Protection Unit (MPU) may be configured to generate debug events using region descriptors that are not utilized for performing a protection function.

Software debug facilities are enabled by setting the internal debug mode bit in Debug Control register 0 (DBCR0_{IDM}). When internal debug mode is enabled, debug events can occur, and can be enabled to record exceptions in the Debug Status register (DBSR). If enabled by MSR_{DE}, these recorded exceptions cause Debug interrupts to occur. When DBCR0_{IDM} is cleared (and EDBCR0_{EDM} is cleared as well), no debug events occur, and no status flags are set in DBSR unless already set. In addition, when DBCR0_{IDM} is cleared (or is overridden by EDBCR0_{EDM} being set and EDBRAC0 indicating no resource is “owned” by software) no Debug interrupts will occur, regardless of the contents of DBSR. A software Debug interrupt handler may access all system resources and perform necessary functions appropriate for system debug.

64.1.1.1 *PowerISA 2.06* compatibility

The e200z425n3 core implements a subset of the *PowerISA 2.06* internal debug features. The following restrictions on functionality are present:

- Instruction address compares do not support compare on physical (real) addresses.
- Data address compares do not support compare on physical (real) addresses.

64.1.2 Additional debug facilities

In addition to the debug functionality defined in *PowerISA 2.06*, e200z425n3 provides capability to link instruction and data breakpoints, provides additional instruction and data breakpoints, extended range and value masking, multiple watchpoint outputs, provides capability for the Performance Monitor to generate debug events, and allows for sharing of debug resources between software and a hardware debugger. (See [Section 64.1.4, *Sharing debug resources by software/hardware*](#).) A data trace port is also provided.

64.1.2.1 Data trace port

The data trace port interface is provided to assist in implementing extended debug watchpoint/breakpoint/trace capture capability with logic external to the e200z425n3 core. This port provides information corresponding to each read or write access completed without error by the CPU. In order to report data accesses, the Nexus 3 DTC register DI control bit must be set to trace data accesses, not instruction accesses (i.e. the normal setting. See the “Data Trace Control Register (DTC)” section in the Core (e200z425n3) Nexus 3 Module chapter. The data trace port will report aligned accesses, and most misaligned accesses as one access, unless the two portions of a misaligned access are non-contiguous, such as when the second portion of the misaligned access is to address 0. Also, for accesses generated by a LSP load/store instruction using circular addressing mode that crosses a buffer boundary, the two portions of the misaligned access will be reported separately, since otherwise it is not possible to correctly correlate the data with the initial access address.

64.1.3 Hardware debug facilities

The e200z425n3 core contains facilities that allow for external test and debugging. A modified IEEE 1149.1 control interface is used to communicate with the core resources. This interface is implemented through a standard 1149.1 TAP (test access port) controller.

By using public instructions, the external debugger can freeze or halt the e200z425n3 core, read and write internal state and debug facilities, single-step instructions, and resume normal execution.

Hardware Debug is enabled by setting the External Debug mode enable bit in External Debug Control register 0 (EDBCR0_{EDM}), which is also aliased to DBCR0_{EDM}. Setting EDBCR0_{EDM} overrides the Internal Debug mode enable bit DBCR0_{IDM} unless resources are provided back to software via the settings in EDBRAC0. When the Hardware Debug facility is enabled, software is blocked from modifying the “hardware-owned” debug facilities. In addition, since resources are “owned” by the hardware debugger, inconsistent values may be present if software attempts to read “hardware-owned” debug-related resources.

When hardware debug is enabled by setting EDBCR0_{EDM}=1, the control registers and resources described in [Section 64.3, *Debug registers*](#) are reserved for use by the external debugger. The same events described in [Section 64.2, *Software debug events and*](#)

exceptions are also used for external debugging, but exceptions are not generated to running software. Hardware-owned debug events enabled in the respective DBCR0–8 registers are recorded in the EDBSR0 register (not the DBSR) regardless of MSR_{DE}, and no debug interrupts are generated unless a) the resource is granted back to software via EDBRAC0 settings, and b) debug mode entry is not masked by the corresponding event bit in EDBSRMSK0. Instead, the CPU will enter debug mode when an enabled event causes a EDBSR0 bit to become set. EDBCRO_{EDM}, EDBSR0, EDBSRMSK0, EDDEAR, and EDBRAC0 may only be written through the OnCE port.

Access to most debug resources (registers) requires that the CPU clock (**m_clk**) be running in order to perform write accesses from the external hardware debugger.

64.1.4 Sharing debug resources by software/hardware

Debug resources may be shared by a hardware debugger and software debug based on the settings of debug control register EDBRAC0. When EDBCRO_{EDM} is set, EDBRAC0 settings determine which debug resources are allocated to software and which resources remain under exclusive hardware control. Software-owned resources that set DBSR bits when DBCRO_{IDM}=1 will cause a debug interrupt to occur when enabled with MSR_{DE}. Hardware-owned resources that set EDBSR0 bits when EDBCRO_{EDM}=1 will cause an entry into debug mode if the event is not masked in EDBSRMSK0. EDBRAC0 is read-only by software. When resource sharing is enabled, (EDBCRO_{EDM}=1 and EDBRAC0_{IDM}=1), only software-owned resources may be modified by software. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Hardware-owned resources will set status bits in the EDBSR0 register instead of in DBSR, and will report the effective address of data breakpoints in EDDEAR instead of DDEAR. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers are performed.

64.1.4.1 Simultaneous hardware and software debug event handling

Since it is possible that a “hardware-owned” resource can produce a debug event in conjunction with a software-owned resource producing a different debug event simultaneously, a priority ordering mechanism is implemented that guarantees that the hardware event is handled as soon as possible, while preserving the recognition of the software event. The CPU will give highest priority to the software event initially in order to reach a recoverable boundary, and then will give highest priority to the hardware event in order to enter debug mode as near the point of event occurrence as possible. This is implemented by allowing software exception handing to begin internal to the CPU and to reach the point where the current program counter and MSR values have been saved into DSRRO/1, and the new PC pointing to the debug interrupt handler, along with the new MSR updates. At this point, hardware priority takes over, and the CPU enters debug mode.

Figure 1557 shows the e200z425n3 debug resources.

Figure 1557. e200z425n3 debug resources

64.2 Software debug events and exceptions

Software debug events and exceptions are available when internal debug mode is enabled ($DBCR0_{IDM}=1$) and not overridden by external debug mode ($EDBCR0_{EDM}$ must either be cleared or corresponding resources must be allocated to software debug by the settings in $EDBRAC0$). When enabled, debug events cause debug exceptions to be recorded in the Debug Status Register. Specific event types are enabled by the Debug Control Registers ($DBCR0-8$). The Unconditional Debug Event (UDE) is an exception to this rule; it is always enabled. Once a Debug Status Register (DBSR) bit is set by a debug resource that is “owned” by software (other than MRR, DAC_OFST, or VLES), if Debug interrupts are enabled by MSR_{DE} , a Debug interrupt will be generated. The debug interrupt handler is responsible for ensuring that multiple repeated debug interrupts do not occur by clearing the DBSR as appropriate.

Certain debug events are not allowed to occur when $MSR_{DE}=0$ and $DBCR0_{IDM}=1$. In such situations, no debug exception occurs and thus no DBSR bit is set. Other debug events may cause debug exceptions and set DBSR bits regardless of the state of MSR_{DE} . A Debug interrupt will be delayed until MSR_{DE} is later set to '1'.

When a Debug Status Register bit is set while $MSR_{DE}=0$, an Imprecise Debug Event flag ($DBSR_{IDE}$) will also be set to indicate that an exception bit in the Debug Status Register was set while Debug interrupts were disabled. Debug interrupt handler software can use this bit to determine whether the address recorded in Debug Save/Restore Register 0 is an address associated with the instruction causing the debug exception, or the address of the instruction that enabled a delayed Debug interrupt by setting the MSR_{DE} bit. A **mtmsr** or **mtdbcr0** that causes both MSR_{DE} and $DBCR0_{IDM}$ to become set, enabling precise debug mode, may cause an Imprecise (Delayed) Debug exception to be generated due to an earlier recorded event in the Debug Status register.

There are eight types of debug events defined by *PowerISA 2.06*:

1. Instruction Address Compare debug events
2. Data Address Compare debug events
3. Trap debug events
4. Branch Taken debug events
5. Instruction Complete debug events
6. Interrupt/Critical Interrupt Taken debug events
7. Return/Critical Return debug events
8. Unconditional debug events

In addition, e200z425n3 defines additional debug events:

- The External debug events DEVT1 and DEVT2, which are described in [Section 64.2.11, External debug event](#).
- The Performance Monitor Interrupt event PMI, which is described in [Section 64.2.13, Performance Monitor Interrupt debug event](#).

The e200z425n3 debug configuration supports most of these event types. Unsupported *PowerISA 2.06* defined functionality is as follows:

- Instruction Address Compare and Data Address Compare *Real address* mode is not supported

A brief description of each of the event types follows.

64.2.1 Instruction Address Compare event

Instruction Address Compare debug events occur when enabled and execution is attempted of an instruction at an address that meets the criteria specified in the DBCR0, DBCR1, DBCR5, DBCR6, and IAC1–8 Registers. Instruction Address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . IAC events will not occur when an instruction would not have normally begun execution due to a higher priority exception at an instruction boundary.

IAC compares perform a 31-bit compare for VLE instruction storage accesses. Each halfword fetched by the instruction fetch unit will be marked with a set of bits indicating whether an Instruction Address Compare occurred on that halfword. Debug exceptions will occur if enabled and a 16-bit instruction, or the first halfword of a 32-bit instruction, is tagged with an IAC hit.

64.2.2 Data Address Compare event

Data Address Compare debug events occur when enabled and execution of a load or store class instruction results in a data access that meets the criteria specified in the DBCR0, DBCR2, DBCR4, DBCR7–8, DAC1–4, DVC1, and DVC2 Registers. Data address compares may specify user/supervisor mode, along with an effective address, masked effective address, or range of effective addresses for comparison. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . Four address compare values (DAC1–4) are provided.

The effective address of the load or store operation is recorded in the DDEAR register when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set.

Note: In contrast to the PowerISA 2.06 definition, Data Address Compare events on e200z425n3 do not prevent the load or store class instruction from completing. If a load or store class instruction completes successfully without a Data Storage interrupt, Data Address Compare exceptions are reported at the completion of the instruction. If the exception results in a precise Debug interrupt, the address value saved in DSRR0 is the address of the instruction following the load or store class instruction. For DVC DAC events, the exception can be imprecisely reported even further past the load or store class instruction generating the event (without necessarily affecting $DBSR_{IDE}$) and the saved address value can point to a subsequent instruction past the next instruction. This occurrence is indicated in the $DBSR_{DAC_OFST}$ field.

If a load or store class instruction does not complete successfully due to a Data Storage exception or a machine check condition for the load or store, and a Data Address Compare debug exception also occurs, the result is an imprecise Debug interrupt, the address value saved in DSRR0 is the address of the load or store class instruction, and the $DBSR_{IDE}$ bit will be set. In addition to occurring when $DBCR0_{IDM}=1$, this circumstance can also occur when $EDBCR0_{EDM}=1$ and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: DAC events will not be recorded if a load multiple word or store multiple word instruction is interrupted prior to completion by a critical input or external input interrupt.

Note: .DAC events are not signaled on the second portion of a misaligned load or store that is broken up into two separate accesses.

Note: DAC events are not signaled on the **mpure** or **mpuwe** MPU instructions.

Note: DAC[1,2] events are not signaled if DVC[1,2]M is non-zero and a DSI exception occurs on the load or store, since the load or store access is not performed. For a **lmw** or **stmw** transfer however, if a DVC successfully occurs on a transfer and a later transfer encounters a DSI exception, the DAC event will be reported, since a successful data value compare took place.

Note: Due to internal pipeline status, for a reported DAC event on a **lmw** or **stmw** transfer, the value stored in the DDEAR/EDDEAR will be the effective address of the first transfer of the sequence, and not necessarily the precise transfer that caused the DAC event.

64.2.2.1 Data Address Compare event status updates

Data Address Compare debug events with Data Value compares can be reported ambiguously in several circumstances involving issuing a sequence of load or store class

instructions. Due to the CPU pipeline and the delay in performing the data value compare following completion of the access, if the first load or store class instruction generates a DVC DAC, a second and possibly third load or store class instruction may also generate a DAC or DVC DAC event, or may generate a DSI exception with or without a simultaneous DAC event.

Also, since non-load/store instructions may be dual-issued in combination with a load/store instruction, the actual number of additional instructions that are completed following a recognized DVC DAC on a load/store instruction may vary from 0 to 5. This value will be reported in the $DBSR_{DAC_OFST}$ field when the DVC DAC status is recorded.

[Table 1456](#) outlines the settings of the DBSR, DSRR0 saved value, and potential updating of the ESR register for various exception cases on sequences of load/store class instructions. Not all exception combinations are covered in the table, such as IAC, ISI, or Alignment exceptions on subsequent instructions. In general these exceptions will cause further instruction issue to be halted, execution of the excepting instruction to be aborted, and reporting of these exceptions will be masked. The saved DSRR0 value will point to this excepting instruction, and the exception(s) may be regenerated after returning from the debug interrupt handler and attempting to re-execute the instruction pointed to by DSRR0. In addition, in the examples in [Table 1456](#), the DAC_OFST and DSRR0 values assume no dual issue occurs. If dual-issue occurs with the first, second, or third column, then the DAC_OFST and DSRR0 values will point beyond the values shown.

Table 1456. DAC events and resultant updates

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DSI, no DAC	—	—	Take DSI exception, no DBSR update. Update ESR.
DSI, with DACx	—	—	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST not set. DSRR0 points to 1st load/store class instruction. No ESR update.
DACx	—	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update.
DVC DACx	No exceptions, any instruction	No exceptions, Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. No ESR update.
DVC DACx	No exceptions	No exceptions, Ldst instruction	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b010. DSRR0 points to instruction after 3rd instruction. No ESR update.
DVC DACx	DSI, no DAC	—	Take Debug exception, DBSR update setting DACx, DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. <i>Note: in this case the 2nd Ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>

Table 1456. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	DSI, with DACy	—	Take Debug exception, DBSR update setting DACx. DAC_OFST not set. DSRR0 points to 2nd load/store class instruction. No ESR update. <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
DVC DACx	DACy	—	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to 3rd instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
DVC DACx	DVC DACy, Normal Ldst	Non-Ldst instruction	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
DVC DACx	DVC DACy, Normal Ldst	Ldst instruction, no exception	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
DVC DACx	DVC DACy, Normal Ldst	DSI Error, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. No ESR update. DSRR0 points to 3rd instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i> <i>Note: in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
DVC DACx	DVC DACy, Normal Ldst	DACy, or DVC DACy, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd load/store class instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
DVC DACx	DVC DACy, Ldst multiple (lmw, stmw)	Any instruction including ld/st	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1456. DAC events and resultant updates (continued)

1st load/store class instruction	2nd instruction (load/store class unless otherwise specified)	3rd instruction (load/store class unless otherwise specified)	Result
DVC DACx	Any instruction (no exception)	DSI, with or without DAC, Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx. DAC_OFST set to 3'b001. DSRR0 points to the 3rd instruction. No ESR update. <i>Note: in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
DVC DACx	Any instruction (no exception)	DACy, or DVC DACy Normal Ldst or multiple word Ldst	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction after the 3rd class instruction. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1457 through Table 1460 show some example updates for specific code sequences of dual issuing of load/store class instructions with non-load/store class instructions and the results of DAC and DVC events on selected ones of the load/store instructions.

Table 1457. DAC events and resultant updates, dual-issue case 1

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6)

Table 1457. DAC events and resultant updates, dual-issue case 1 (continued)

Instruction sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.</i> <i>Note: in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (5): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. No ESR update. DSRR0 points to instruction (6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the “no DACy” case.</i>

Table 1458. DAC events and resultant updates, dual-issue case 2

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction after instruction (6). No ESR update.
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b101. DSRR0 points to instruction (7). No ESR update. <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1458. DAC events and resultant updates, dual-issue case 2 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) load/store	Event(s)	Result
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. No ESR update. DSRR0 points to instruction (4). No debug event updates for instruction (4). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i> <i>Note: in this case the 3rd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy Instruction (6): DACy or DVC DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b101. No ESR update. DSRR0 points to instruction (7). No debug event updates for instruction (7). <i>Note: In this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1459. DAC events and resultant updates, dual-issue case 3

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.

Table 1459. DAC events and resultant updates, dual-issue case 3 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) alu (4) alu (5) load/store (6) alu	Event(s)	Result
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6).
	Instruction (1): DVC DACx Instruction (5): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (5): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No debug event updates for instruction (6). <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
	Instruction (1): DVC DACx Instruction (5): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b100. DSRR0 points to instruction (6). No ESR update. No debug event updates for instruction (6) <i>Note: in this case if x==y, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

Table 1460. DAC events and resultant updates, dual-issue case 4

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DSI, no DAC	Take DSI exception, no DBSR update, Update ESR.
	Instruction (1): DSI, with DACx	Take Debug exception, DBSR update setting DACx and IDE, DAC_OFST set to 3'b000. DSRR0 points to instruction (1). No ESR update.
	Instruction (1): DACx	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b000. DSRR0 points to instruction (2). No ESR update.

Table 1460. DAC events and resultant updates, dual-issue case 4 (continued)

Instruction Sequence: The following pairs dual-issue: (1) load/store (2) alu (3) load/store (4) alu (5) alu (6) alu	Event(s)	Result
	Instruction (1): DVC DACx No other exceptions	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6)
	Instruction (1): DVC DACx Instruction (3): DSI, with or without DAC	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b001. DSRR0 points to instruction (3). No ESR update. No debug event updates for instructions (3)–(6). <i>Note: in this case the 2nd ld/st exception is masked. This behavior is implementation dependent and may differ on other CPUs.</i>
	Instruction (1): DVC DACx Instruction (3): DACy	Take Debug exception, DBSR update setting DACx, DACy. DAC_OFST set to 3'b010. DSRR0 points to instruction (4). No debug event updates for instructions (4)–(6). <i>Note: in this case if $x=y$, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>
	Instruction (1): DVC DACx Instruction (3): DVC DACy	Take Debug exception, DBSR update setting DACx, DAC_OFST set to 3'b011. DSRR0 points to instruction (5). No ESR update. No debug event updates for instructions (5)–(6). <i>Note: in this case if $x=y$, then the resultant state of DBSR and DSRR0 may be indistinguishable from the "no DACy" case.</i>

64.2.3 Linked Instruction Address Compare and Data Address Compare events

Data Address Compare 1, 2, 3, and 4 debug events may be 'linked' with an Instruction Address Compare event by setting the DAC[1–4]LNK control bits in DBCR2 and DBCR8 to further refine when a Data Address Compare debug event is generated. DAC1 may be linked with IAC1, DAC2 (when not used as a mask or range bounds register) may be linked with IAC3. DAC3 may be linked with IAC5, DAC4 (when not used as a mask or range bounds register) may be linked with IAC7. When linked, a DAC debug event occurs when the same instruction that generates the DAC 'hit' also generates a corresponding linked IAC 'hit'. When linked, the IAC event is not recorded in the Debug Status register, regardless of whether a corresponding linked DAC event occurs, or whether the IAC event enable is set.

When enabled and execution of a load or store class instruction results in a data access with an address that meets the criteria specified in the DBCRx, DACx, and DVCx Registers, and the instruction also meets the criteria for generating an Instruction Address Compare event, a Linked Data Address Compare debug event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. The normal DAC1 status bit in the DBSR is used for recording these events. The IAC status bit is not set if the corresponding Instruction Address Compare register is linked.

Linking is enabled using control bits in DBCR2 and DBCR8. Note that linking is only available in EDM or IDM. Attempts to use linking otherwise are ignored.

Note: *Linked DAC events will not be recorded if a load multiple word or store multiple word type instruction is interrupted prior to completion by a critical input or external input interrupt.*

64.2.4 Trap debug event

A Trap debug event (TRAP) occurs if Trap debug events are enabled (DBCR0_{TRAP}=1), a Trap instruction (**tw**) is executed, and the conditions specified by the instruction for the trap are met. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE}. When a Trap debug event occurs, the DBSR_{TRAP} bit is set to 1 to record the debug exception.

64.2.5 Branch Taken debug event

A Branch Taken debug event (BRT) occurs if Branch Taken debug events are enabled (DBCR0_{BRT}=1) and execution is attempted of a branch instruction that will be taken (either an unconditional branch, or a conditional branch whose branch condition is true), and MSR_{DE}=1. Branch Taken debug events are not recognized if MSR_{DE}=0 at the time of execution of the branch instruction and thus DBSR_{ID}E can not be set by a Branch Taken debug event. When a Branch Taken debug event is recognized, the DBSR_{BRT} bit is set to 1 to record the debug exception, and the address of the branch instruction will be recorded in DSRR0.

64.2.6 Instruction Complete debug event

An Instruction Complete debug event (ICMP) occurs if Instruction Complete debug events are enabled (DBCR0_{ICMP}=1), execution of any instruction is completed, and MSR_{DE}=1. If execution of an instruction is suppressed due to the instruction causing some other exception that is enabled to generate an interrupt, then the attempted execution of that instruction does not cause an Instruction Complete debug event. The **se_sc** instruction does not fall into the category of an instruction whose execution is suppressed, since the

instruction actually executes and then generates a System Call interrupt. In this case, the Instruction Complete debug exception will also be set. When an Instruction Complete debug event is recognized, $DBSR_{ICMP}$ is set to 1 to record the debug exception and the address of the next instruction to be executed will be recorded in $DSRR0$.

Instruction Complete debug events are not recognized if $MSR_{DE}=0$ at the time of execution of the instruction, thus $DBSR_{IDE}$ is not generally set by an ICMP debug event.

One circumstance may cause the $DBSR_{ICMP}$ and $DBSR_{IDE}$ bits to be set. This occurs when a EFPU Round exception occurs. Since the instruction is by definition completed ($SRR0$ points to the following instruction), this interrupt takes higher priority than the Debug interrupt so as not to be lost, and $DBSR_{IDE}$ is set to indicate the imprecise recognition of a Debug interrupt. In this case, the Debug interrupt will be taken with $SRR0$ pointing to the instruction following the instruction that generated the EFPU Round exception, and $DSRR0$ will point to the Round exception handler. In addition to occurring when $DBCR0_{IDM}=1$, this circumstance can also occur when $EDBCR0_{EDM}=1$ and the event is hardware-owned, in which case $EDBSR0_{IDE}$ will be set.

Note: Instruction complete debug events are not generated by the execution of an instruction that sets MSR_{DE} to '1' while $DBCR0_{ICMP}=1$, nor by the execution of an instruction that sets $DBCR0_{ICMP}$ to '1' while $MSR_{DE}=1$.

64.2.7 Interrupt Taken debug event

An Interrupt Taken debug event ($IRPT$) occurs if Interrupt Taken debug events are enabled ($DBCR0_{IRPT}=1$) and a base-class interrupt occurs. Only base-class interrupts (an interrupt using $SRR0/1$) cause an Interrupt Taken debug event. This event can occur and be recorded in $DBSR$ regardless of the setting of MSR_{DE} . When an Interrupt Taken debug event occurs, the $DBSR_{IRPT}$ bit is set to 1 to record the debug exception. The value saved in $DSRR0$ will be the address of the non-critical interrupt handler.

64.2.8 Critical Interrupt Taken debug event

A Critical Interrupt Taken debug event ($CIRPT$) occurs if Critical Interrupt Taken debug events are enabled ($DBCR0_{CIRPT}=1$) and a critical interrupt occurs. Only critical class interrupts (an interrupt using $CSRR0/1$) cause a Critical Interrupt Taken debug event. This event can occur and be recorded in $DBSR$ regardless of the setting of MSR_{DE} . When a Critical Interrupt Taken debug event occurs, the $DBSR_{CIRPT}$ bit is set to 1 to record the debug exception. The value saved in $DSRR0$ will be the address of the critical interrupt handler.

64.2.9 Return debug event

A Return debug event (RET) occurs if Return debug events are enabled ($DBCR0_{RET}=1$) and an attempt is made to execute an **se_rfi** instruction. This event can occur and be recorded in $DBSR$ regardless of the setting of MSR_{DE} . When a Return debug event occurs, the $DBSR_{RET}$ bit is set to 1 to record the debug exception.

If $MSR_{DE}=0$ at the time of the execution of the **se_rfi** (i.e. before the MSR is updated by the **se_rfi**), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE}=1$ at the time of the execution of the **se_rfi**, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfi** instruction.

64.2.10 Critical Return Debug Event

A Critical Return debug event (CRET) occurs if Critical Return debug events are enabled ($DBCR0_{CRET}=1$) and an attempt is made to execute an **se_rfc**i instruction. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . When a Critical Return debug event occurs, the $DBSR_{CRET}$ bit is set to 1 to record the debug exception.

If $MSR_{DE}=0$ at the time of the execution of the **se_rfc**i (i.e. before the MSR is updated by the **se_rfc**i), then $DBSR_{IDE}$ is also set to 1 to record the imprecise debug event.

If $MSR_{DE}=1$ at the time of the execution of the **se_rfc**i, a Debug interrupt will occur provided there exists no higher priority exception that is enabled to cause an interrupt. Debug Save/Restore Register 0 will be set to the address of the **se_rfc**i instruction.

64.2.11 External debug event

An External debug event (DEVT1, DEVT2) occurs if External debug events are enabled ($DBCR0_{DEVT1}=1$ or $DBCR0_{DEVT2}=1$), and the respective **p_devt1** or **p_devt2** input signal transitions to the asserted state while the CPU is not in the Stopped state. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . When an External debug event occurs, $DBSR_{DEVT\{1,2\}}$ is set to '1' to record the debug exception. This debug event is an asynchronous event, but is only sampled when the CPU **m_clk** is active.

64.2.12 Unconditional debug event

An Unconditional debug event (UDE) occurs when the Unconditional Debug Event (**p_ude**) input transitions to the asserted state. The Unconditional debug event is the only debug event that does not have a corresponding enable bit for the event in DBCR0. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . When an Unconditional debug event occurs, the $DBSR_{UDE}$ bit is set to '1' to record the debug exception. This debug event is an asynchronous event.

64.2.13 Performance Monitor Interrupt debug event

A Performance Monitor Interrupt debug event (PMI) occurs if Performance Monitor Interrupt debug events are enabled ($PMGC0_{UDI}=1$), and a performance monitor interrupt event occurs. This event can occur and be recorded in DBSR regardless of the setting of MSR_{DE} . When a Performance Monitor Interrupt debug event occurs, $DBSR_{PMI}$ is set to '1' to record the debug exception. This debug event is an asynchronous event.

64.3 Debug registers

This section describes debug-related registers that are software accessible. These registers are intended for use by special debug tools and debug software, not by general application code.

Access to these registers (other than DBSR) by software is conditioned by the External Debug mode control bit ($EDBCR0_{EDM}$) and the settings of debug control register $EDBRAC0$, which can be set by the hardware debug port. If $EDBCR0_{EDM}$ is set and if the bit in $EDBRAC0$ corresponding to the resource is cleared, software is prevented from modifying debug register values other than in DBSR, since the resource is not "owned" by software. Software always has ownership of DBSR. Execution of a **mtspr** instruction targeting a debug register or register field not "owned" by software will not cause

modifications to occur, and no exception will be signaled. In addition, since the external debugger hardware may be manipulating debug register values, the state of these registers or register fields not “owned” by software is not guaranteed to be consistent if accessed (read) by software with a **mfspir** instruction, other than the DBCR0_{EDM} bit itself and the EDBRAC0 register. Hardware always has full access to all registers and all register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control registers as appropriate when hardware modifications to the debug registers is performed.

64.3.1 Debug Address and Value registers

Instruction Address Compare registers IAC1–8 are used to hold instruction addresses for address comparison purposes. In addition, IAC2 and IAC4 may hold mask information for IAC1 and IAC3 respectively and IAC6 and IAC8 may hold mask information for IAC5 and IAC7 respectively, when *Address Bit Match* compare modes are selected. Note that when performing instruction address compares, the low order bit of the instruction address and the corresponding IAC register is ignored for VLE instructions.

Data Address Compare registers DAC1–4 are used to hold data access addresses for address comparison purposes. In addition, DAC2 and DAC4 may hold mask information for DAC1 and DAC3 respectively when *Address Bit Match* compare modes are selected.

Data Value Compare registers DVC1 and DVC2 are used to hold data values for data comparison purposes. DVC1 and DVC2 are 64-bit registers. Data value comparisons are used to qualify Data Address compare 1 and 2 debug events. Data value comparisons are not available for Data address compare 3–4 events. DVC1 is associated with DAC1, and DVC2 is associated with DAC2. The most significant byte of the DVC1(2) register (labeled B0 in [Figure 1558](#)) corresponds to the byte data value transferred to/from memory byte offset 0, 8, ..., and the least significant byte of the register (labeled B7 in [Figure 1558](#)) corresponds to byte offset 7, F, When enabled for performing data value comparisons, each enabled byte in DVC1(2) is compared with the memory value transferred on the corresponding active byte lane of the data memory interface to determine if a match occurs. Inactive byte lanes do not participate in the comparison; they are implicitly masked. The Byte Strobe Assertion for Transfers table in the Core (e200z425n3) Core Complex Overview chapter shows active byte lanes for data transfers. Software must also program the DVC1(2) register byte positions based on the alignment of the access. Misaligned accesses are not fully supported, since the data address and data value comparisons are only performed on the initial access in the case of a misaligned access; thus, accesses that cross a 64-bit boundary cannot be fully matched. For address and size combinations that involve two transfers, only the initial transfer is used for data address and value matching.

DVC1 and DVC2 may be read or written using **mtspir** and **mfspir** instructions. The DVC1U and DVC2U SPR numbers (601,602) are used for accessing the upper 32-bit portion of the DVC register. The DVC1 and DVC2 SPR numbers (318,319) are used for accessing the lower 32-bit portion of the DVC register.

64.3.2 Debug Control and Status registers

Debug Control Registers (DBCR0–8 and EDBRAC0) are used to enable debug events, reset the processor, and set the debug mode of the processor. The Debug Status register (DBSR) records debug exceptions while Internal Debug mode is enabled. The Debug Data Effective Address register (DDEAR) records the effective address of a Data Address Compare event while Internal Debug mode is enabled.

e200z425n3 requires that a context synchronizing instruction follow a **mtspr** DBCR0–8 or DBSR to ensure that any alterations enabling/disabling debug events are effective. The context synchronizing instruction may or may not be affected by the alteration. Typically, an **se_isync** instruction is used to create a synchronization boundary beyond which it can be guaranteed that the newly written control values are in effect.

For watchpoint generation, configuration settings contained in DBCR1–8 are used, even though the corresponding event(s) may be disabled (via DBCR0) from setting DBSR flags.

64.3.2.1 Debug Control Register 0 (DBCR0)

Debug Control Register 0 is used to enable debug modes and controls which debug events are allowed to set DBSR or EDBSR0 flags. e200z425n3 adds some implementation specific bits to this register, as seen in [Figure 1559](#).

Figure 1559. Debug Control Register 0 (DBCR0) register

EDM	IDM	RST		ICMP	BRT	IRPT	TRAP	IAC1	IAC2	IAC3	IAC4	DAC1	DAC2		RET	IAC5	IAC6	IAC7	IAC8	DEVT1	DEVT2	0		CIRPT	CRET	0					
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 308; Read/Write; Reset⁽¹⁾ - 0x0

1. DBCR0_{EDM} is affected by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**. All other bits are reset by processor reset **p_reset_b** if DBCR0_{EDM}=0, as well as unconditionally by **m_por**. If DBCR0_{EDM}=1, EDBRAC0 masks off hardware-owned resources (other than RST) from reset by **p_reset_b**, and only software-owned resources indicated by EDBRAC0 and the DBCR0_{RST} field will be reset by **p_reset_b**. The DBCR0_{RST} field will always be reset by **p_reset_b** regardless of the value of DBCR0_{EDM}.

[Table 1461](#) provides bit definitions for Debug Control Register 0.

Table 1461. DBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug mode. This bit is read-only by software. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b. This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned debug events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRO–8, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0. Hardware-owned events will set status bits in EDBSR0. Programming Notes: It is recommended that debug status bits in the Debug Status Registers be cleared before disabling external debug mode to avoid any internal imprecise debug interrupts. Software may use this bit to determine if external debug has control over the debug registers. The hardware debugger must set the EDM bit to '1' before other bits in this register (and other debug registers) may be altered. On the initial setting of this bit to '1', all other bits are unchanged. This bit is only writable through the OnCE port.
1	IDM	Internal Debug mode 0 Debug exceptions are disabled. Debug events do not affect DBSR. 1 Debug exceptions are enabled. Enabled debug events owned by software will update the DBSR. If $MSR_{DE}=1$, the occurrence of a debug event, or the recording of an earlier debug event in the Debug Status Register when MSR_{DE} was cleared, will cause a Debug interrupt.
2:3	RST	Reset Control 00 No function 01 p_dbrstc[1] pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset 10 p_dbrstc[0] pin asserted by Debug Reset Control. Allows external device to initiate processor or system reset. 11 Reserved
4	ICMP	Instruction Complete Debug Event Enable 0 ICMP debug events are disabled 1 ICMP debug events are enabled
5	BRT	Branch Taken Debug Event Enable 0 BRT debug events are disabled 1 BRT debug events are enabled
6	IRPT	Interrupt Taken Debug Event Enable 0 IRPT debug events are disabled 1 IRPT debug events are enabled
7	TRAP	Trap Taken Debug Event Enable 0 TRAP debug events are disabled 1 TRAP debug events are enabled
8	IAC1	Instruction Address Compare 1 Debug Event Enable 0 IAC1 debug events are disabled 1 IAC1 debug events are enabled
9	IAC2	Instruction Address Compare 2 Debug Event Enable 0 IAC2 debug events are disabled 1 IAC2 debug events are enabled

Table 1463. DBCR2 field descriptions (continued)

Bit	Name	Description
8:9	DAC12M	Data Address Compare 1/2 Mode 00 Exact address compare. DAC1 debug events can only occur if the address of the data access is equal to the value specified in DAC1. DAC2 debug events can only occur if the address of the data access is equal to the value specified in DAC2. 01 Address bit match. DAC1 debug events can occur only if the address of the data access ANDed with the contents of DAC2, are equal to the contents of DAC1 also ANDed with the contents of DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 10 Inclusive address range compare. DAC1 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC1 and less than the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used. 11 Exclusive address range compare. DAC1 debug events can occur only if the address of the data access is less than the value specified in DAC1 or is greater than or equal to the value specified in DAC2. DAC2 debug events do not occur. DAC1US and DAC1ER settings are used.
10	DAC1LNK	Data Address Compare 1 Linked. When linked to IAC1, DAC1 debug events are conditioned based on whether the instruction also generated an IAC1 debug event. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC1 debug events are linked to IAC1 debug events. IAC1 debug events do not affect DBSR
11	DAC2LNK	Data Address Compare 2 Linked. When linked to IAC3, DAC2 debug events are conditioned based on whether the instruction also generated an IAC3 debug event. DAC2 can only be linked if DAC12M specifies <i>Exact Address Compare</i> since DAC2 debug events are not generated in the other compare modes. Note that linking is only available in EDM or IDM. 0 No effect 1 DAC 2 debug events are linked to IAC3 debug events. IAC3 debug events do not affect DBSR.

Table 1463. DBCR2 field descriptions (continued)

Bit	Name	Description
12:13	DVC1M	Data Value Compare 1 Mode When DBCR4_{DVC1C}=0: 00 DAC1 debug events not affected by data value compares. 01 DAC1 debug events can only occur when all bytes specified in the DVC1BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC1 debug events can only occur when any byte specified in the DVC1BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC1 debug events can only occur when all bytes specified in the DVC1BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC1 value. <i>Note: Inactive byte lanes of the memory access are automatically masked.</i> When DBCR4_{DVC1C}=1: 00 Reserved 01 DAC1 debug events can only occur when any byte specified in the DVC1BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC1 debug events can only occur when all bytes specified in the DVC1BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved <i>Note: Inactive byte lanes of the memory access are automatically masked.</i>
14:15	DVC2M	Data Value Compare 2 Mode When DBCR4_{DVC2C}=0: 00 DAC2 debug events not affected by data value compares. 01 DAC2 debug events can only occur when all bytes specified in the DVC2BE field match the corresponding data byte values for active byte lanes of the memory access. 10 DAC2 debug events can only occur when any byte specified in the DVC2BE field matches the corresponding data byte value for active byte lanes of the memory access. 11 DAC2 debug events can only occur when all bytes specified in the DVC2BE field within at least one of the halfwords of the data value of the memory access matches the corresponding DVC2 value. <i>Note: Inactive byte lanes of the memory access are automatically masked.</i> When DBCR4_{DVC2C}=1: 00 Reserved 01 DAC2 debug events can only occur when any byte specified in the DVC2BE field does not match the corresponding data byte value for active byte lanes of the memory access. If all active bytes match, then no event will be generated. 10 DAC2 debug events can only occur when all bytes specified in the DVC2BE field do not match the corresponding data byte values for active byte lanes of the memory access. If any active byte match occurs, no event will be generated. 11 Reserved <i>Note: Inactive byte lanes of the memory access are automatically masked.</i>

Table 1463. DBCR2 field descriptions (continued)

Bit	Name	Description
16:23	DVC1BE	Data Value Compare 1 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC1. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC1. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC1. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC1. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC1. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC1. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC1. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC1. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC1.
24:31	DVC2BE	Data Value Compare2 Byte Enables Specifies which bytes in the aligned doubleword value associated with the memory access are compared to the corresponding bytes in DVC2. Inactive byte lanes of a memory access smaller than 64 bits are automatically masked by hardware. If all bits in the DVC1BE field are clear, then a match will occur regardless of the data. Misaligned accesses that cross a doubleword boundary are not fully supported. 1xxxxxxx Byte lane 0 is enabled for comparison with the value in bits 0:7 of DVC2. x1xxxxxx Byte lane 1 is enabled for comparison with the value in bits 8:15 of DVC2. xx1xxxxx Byte lane 2 is enabled for comparison with the value in bits 16:23 of DVC2. xxx1xxxx Byte lane 3 is enabled for comparison with the value in bits 24:31 of DVC2. xxxx1xxx Byte lane 4 is enabled for comparison with the value in bits 32:39 of DVC2. xxxxx1xx Byte lane 5 is enabled for comparison with the value in bits 40:47 of DVC2. xxxxxx1x Byte lane 6 is enabled for comparison with the value in bits 48:55 of DVC2. xxxxxxx1 Byte lane 7 is enabled for comparison with the value in bits 56:63 of DVC2.

64.3.2.4 Debug Control Register 4 (DBCR4)

Debug Control Register 4 is used to extend data address and value compare matching functionality. DBCR4 is shown in [Figure 1562](#).

Figure 1562. DBCR4 register

0				0								0	DAC1XMH	0	DAC2XMH	DAC1XM				DAC2XM				DAC1CFG				DAC2CFG			
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR - 563; Read/Write; Reset⁽¹⁾ - 0x0

1. DBCR4 is reset by processor reset **p_reset_b** if EDBCR0_{EDM}=0, as well as unconditionally by **m_por**. If EDBCR0_{EDM}=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

[Table 1464](#) provides bit definitions for Debug Control Register 4.

Table 1464. DBCR4 field descriptions

Bit	Name	Description
0	—	Reserved
1	DVC1C	Data Value Compare 1 Control. DVC1C controls whether DVC1 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC1 operation. 1 Inverted polarity DVC1 operation
2	—	Reserved
3	DVC2C	Data Value Compare 2 Control. DVC2C controls whether DVC2 data value comparisons utilize the normal compare operation, or an alternate “inverted compare” operation. In inverted polarity mode, data value compares perform a not-equal comparison. See details in the DBCR2 register definition. 0 Normal DVC2 operation. 1 Inverted polarity DVC2 operation
4:12	—	Reserved
13	DAC1XMH	Data Address Compare 1 Extended Mask Control High. DAC1XMH extends the range of the DAC1XM field 0 DAC1XM masks 0–15 low-order address bits 1 DAC1XM masks 16–31 low-order address bits
14	—	Reserved
15	DAC2XMH	Data Address Compare 2 Extended Mask Control High. DAC2XMH extends the range of the DAC2XM field. 0 DAC2XM masks 0–15 low-order address bits 1 DAC2XM masks 16–31 low-order address bits
16:19	DAC1XM	Data Address Compare 1 Extended Mask Control. DAC1XM allows for binary power of 2 address range compares for DAC1 without requiring the use of DAC2. Value of DAC1XMH DAC1XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC1 when comparing the storage address with the value in DAC1 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported.
20:23	DAC2XM	Data Address Compare 2 Extended Mask Control Value of DAC2XMH DAC2XM: 00000 No additional masking when DBCR2[DAC12M] = 00 00001–11111 Exact Match Bit Mask. One to 31 low-order bits are masked in DAC2 when comparing the storage address with the value in DAC2 for exact address compare (DBCR2[DAC12M] = 00). Address ranges of 2 bytes to 2GB are supported. DAC2XM allows for binary power of 2 address range compares for DAC2.

Table 1464. DBCR4 field descriptions (continued)

Bit	Name	Description
24:27	DAC1CFG	Data Address Compare 1 Configuration 0000 DAC1 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC1}=00$ 0001 DAC1 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC1}=00$ 0010 DAC1 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC1}=00$ 0011 Reserved 01xx Reserved 1000 DAC1 address comparisons are used for stack limit checking. DAC1 address comparisons are qualified with use of GPR R1 in <EA> calculation for most load or store instructions. No debug events occur for DAC1. When a qualified DAC1 match occurs, a machine check exception is generated for supervisor-mode accesses or a DSI is generated for user-mode accesses, and a DAC1 watchpoint is generated. $DBCR0_{DAC1}$ and $DBCR2_{DVC1M}$ settings are ignored. 1001 – 1111 Reserved DAC1CFG controls whether DAC1 data address comparisons utilize the normal PowerISA operation for generating both debug events and watchpoints, a watchpoint-only function, or a stack limit checking function (with watchpoint). <i>Note: Unlike the DAC3–4CFG fields, debug event enabling for DAC1 is controlled by the DAC1 field in DBCR0. The DAC1CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC1}=0$; when $DBCR0_{DAC1} \neq 0$, DAC1 watchpoints will fire whenever a DAC1 debug event occurs.</i>
28:31	DAC2CFG	Data Address Compare 2 Configuration 0000 DAC2 debug watchpoints are enabled for load-type or store-type data storage accesses when $DBCR0_{DAC2}=00$ 0001 DAC2 debug watchpoints are enabled only for store-type data storage accesses when $DBCR0_{DAC2}=00$ 0010 DAC2 debug watchpoints are enabled only for load-type data storage accesses when $DBCR0_{DAC2}=00$ 0011 Reserved 01xx Reserved 1xxx Reserved DAC2CFG controls whether DAC2 data address comparisons utilize the normal compare operation for generating both debug events and watchpoints, or a watchpoint-only function. <i>Note: Unlike the DAC3–4CFG fields, debug event enabling for DAC2 is controlled by the DAC2 field in DBCR0. The DAC2CFG encodings 0000–0010 are used to control watchpoint generation when $DBCR0_{DAC2}=00$. When $DBCR0_{DAC2} \neq 0$, DAC2 watchpoints will fire whenever a DAC2 debug event occurs.</i>

64.3.2.5 Debug Control Register 5 (DBCR5)

Debug Control Register 5 is used to configure Instruction Address Compare operation for IAC5–8. The DBCR5 register is shown in [Figure 1563](#)

Table 1468. DBCR8 field descriptions (continued)

Bit	Name	Description
8:9	DAC34M	Data Address Compare 3/4 Mode 00 Exact address compare. DAC3 debug events can only occur if the address of the data access is equal to the value specified in DAC3. DAC4 debug events can only occur if the address of the data access is equal to the value specified in DAC4. 01 Address bit match. DAC3 debug events can occur only if the address of the data access ANDed with the contents of DAC4, are equal to the contents of DAC3 also ANDed with the contents of DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 10 Inclusive address range compare. DAC3 debug events can occur only if the address of the data access is greater than or equal to the value specified in DAC3 and less than the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used. 11 Exclusive address range compare. DAC3 debug events can occur only if the address of the data access is less than the value specified in DAC3 or is greater than or equal to the value specified in DAC4. DAC4 debug events do not occur. DAC3US and DAC3ER settings are used.
10	DAC3LNK	Data Address Compare 3 Linked 0 No effect 1 DAC3 debug events are linked to IAC5 debug events. IAC5 debug events do not affect DBSR When linked to IAC5, DAC3 debug events are conditioned based on whether the instruction also generated an IAC5 debug event. Note that linking is only available in EDM or IDM.
11	DAC4LNK	Data Address Compare 4 Linked 0 No effect 1 DAC4 debug events are linked to IAC7 debug events. IAC7 debug events do not affect DBSR When linked to IAC7, DAC4 debug events are conditioned based on whether the instruction also generated an IAC7 debug event. Note that linking is only available in EDM or IDM.
12:31	—	Reserved

64.3.2.9 Debug Status Register (DBSR)

The Debug Status Register (DBSR) contains status on debug events and the most recent processor reset. The Debug Status Register is set via hardware, and read and cleared via software. Bits in the Debug Status Register can be cleared using **mtspr DBSR,RS**. Clearing is done by writing to the Debug Status Register with a 1 in any bit position that is to be cleared and 0 in all other bit positions. The write data to the Debug Status Register is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. Debug Status bits are set by Debug events only while Internal Debug mode is enabled ($DBCR0_{IDM}=1$). When debug interrupts are enabled ($MSR_{DE}=1$ $DBCR0_{IDM}=1$ and $EDBCR0_{EDM}=0$, or $MSR_{DE}=1$, $DBCR0_{IDM}=1$, $EDBCR0_{EDM}=1$ and software is allocated resource(s) via $EDBRAC0$), a set bit in DBSR other than MRR, DAC_OFST, or VLES will cause a debug interrupt to be generated. The debug interrupt handler is responsible for clearing DBSR bits prior to returning to normal execution. When resource sharing is enabled, ($EDBCR0_{EDM}=1$ and $EDBRAC0_{IDM}=1$), only software-owned resources may be modified by software, and status bits associated with hardware-owned resources will not be set by hardware in DBSR. The DBSR register is shown in [Figure 1567](#).

Figure 1567. Debug Status Register (DBSR)

Table 1469 provides bit definitions for the Debug Status Register.

Table 1469. DBSR field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if $MSR_{DE}=0$ and $DBCR0_{IDM}=1$ and a debug event causes its respective Debug Status Register bit to be set to 1. It may also be set to '1' if an imprecise debug event occurs due to a DAC event on a load or store that is terminated with error, or if an ICMP event occurs in conjunction with a EFPU FP round exception.
1	UDE	Unconditional Debug Event Set to 1 if an Unconditional debug event occurred.
2:3	MRR	Most Recent Reset. 00 No reset occurred since these bits were last cleared by software 01 A hard reset occurred since these bits were last cleared by software 10 Reserved 11 Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if an Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if an Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if an Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a Trap Taken debug event occurred.
8	IAC	Instruction Address Compare Debug Event Set to 1 if an IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a write-type DAC debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a DNI debug event occurred

Table 1469. DBSR field descriptions (continued)

Bit	Name	Description
16	RET	Return Debug Event Set to 1 if a Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with $PMGC0_{UD}[1]=1$
24	MPU	Memory Protection Unit Debug Event Set to 1 if a MPU debug event occurred. For MPU debug events, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. Note that software MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if an ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and $DBSR_{IDE}$ is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

64.3.2.10 Debug Data Effective Address Register (DDEAR)

The Debug Data Effective Address Register (DDEAR) contains address information for data address compare debug events (DAC or MPU DAC). DDEAR is update by hardware with the effective address of the load or store operation when a data address compare event is recorded in DBSR if the previous values of the $DBSR_{DAC\{R,W\}}$ bits are zero. Once a DDEAR update is performed, these bits must be cleared by software prior to another DDEAR hardware update occurring. A subsequent DAC or MPU DAC event will not update the DDEAR register if either of the $DBSR_{DAC\{R,W\}}$ bits are set, in order to capture the first event address.

The DDEAR register is shown in [Figure 1568](#).

Figure 1568. Debug Data Effective Address Register (DDEAR)

Data Effective Address

SPR - 600; Read/Write; Reset - unaffected

64.3.3 External Debug Resource Allocation Control (EDBRAC0) register

The External Debug Resource Allocation Control Register (EDBRAC0) controls resource allocation when $EDBCR0_{EDM}$ is set to '1'. EDBRAC0 provides a mechanism for the hardware debugger to share certain debug resources with software. Individual resources are allocated based on the settings of EDBRAC0 when $EDBCR0_{EDM}=1$. EDBRAC0 settings are ignored when $EDBCR0_{EDM}=0$.

Hardware-owned resources that generate debug events update EDBSR0 instead of DBSR and cause entry into debug mode if the event is not masked in EDBSRMSK0, while software-owned resources that generate debug events if $DBCR0_{IDM}=1$ update DBSR, causing debug interrupts to occur if $MSR_{DE}=1$. EDBRAC0 is controlled via the OnCE port hardware, and is read-only to software.

The DBSR status register is always owned by software. Debug status bits in DBSR are set by software-owned debug events only while Internal Debug mode is enabled. When debug interrupts are enabled ($MSR_{DE}=1$, $DBCR0_{IDM}=1$ and $EDBCR0_{EDM}=0$, or $MSR_{DE}=1$, $DBCR0_{IDM}=1$ and $EDBCR0_{EDM}=1$ and software is allocated resource(s) via EDBRAC0), a set bit in DBSR by an event that is software-owned (other than MRR, DAC_OFST, or VLES) will cause a debug interrupt to be generated.

Debug status bits in EDBSR0 are set by hardware-owned debug events only while External Debug mode is enabled ($EDBCR0_{EDM}=1$). When $EDBCR0_{EDM}=1$, a set bit in EDBSR0 by an event that is hardware-owned (other than IDE, DAC_OFST, or VLES) will cause entry into debug mode unless entry is masked via EDBSRMSK0.

If $EDBCR0_{EDM}=1$, DBSR status bits corresponding to hardware-owned debug events are masked from being set by hardware.

Software-owned resources may be modified by software, but only the corresponding control bits in $DBCR0-8$ or $MPU0CSR0$ are affected by execution of a **mtspr**, thus only a portion of these registers may be affected, depending on the allocation settings in EDBRAC0. The debug interrupt handler is still responsible for clearing DBSR bits for software-owned resources prior to returning to normal execution. Hardware always has full access to all registers and register fields through the OnCE register access mechanism, and it is up to the debug firmware to properly implement modifications to these registers with read-modify-write operations to implement any control sharing with software. Settings in EDBRAC0 should be considered by the debug firmware in order to preserve software settings of control and status registers as appropriate when hardware modifications to the debug registers is performed.

The EDBRAC0 register is shown in [Figure 1569](#).

[Table 1469](#) provides bit definitions for the Debug External Resource Control Register. Note that EDBRAC0 controls are disabled when EDBCR0EDM=0.

Table 1470. EDBRAC0 field descriptions

Bit	Name	Description
0	—	Reserved
1	IDM	Internal Debug Mode control. When EDBRAC0 _{IDM} =1, software writes to hardware-owned bits in DBCR0–8 via mtspr are ignored. 0 Internal Debug mode may not be enabled by software. DBCR0 _{IDM} is owned exclusively by hardware. mtspr DBCR0–8 and other debug registers is always ignored. No resource sharing occurs, regardless of the settings of other fields in EDBRAC0. Hardware exclusively owns all resources. 1 Internal Debug mode may be enabled by software. DBCR0 _{IDM} is owned by software. DBCR0 _{IDM} is software readable/writable.
2	RST	Reset Field Control 0 DBCR0 _{RST} owned exclusively by hardware debug. No mtspr access by software to DBCR0 _{RST} field. 1 DBCR0 _{RST} accessible by software debug. DBCR0 _{RST} is software readable/writable.
3	UDE	Unconditional Debug Event 0 Event owned by hardware debug. 1 Event owned by software debug.
4	ICMP	Instruction Complete Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{ICMP} field. 1 Event owned by software debug. DBCR0 _{ICMP} is software readable/writable.
5	BRT	Branch Taken Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{BRT} field. 1 Event owned by software debug. DBCR0 _{BRT} is software readable/writable.
6	IRPT	Interrupt Taken Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{IRPT} field. 1 Event owned by software debug. DBCR0 _{IRPT} is software readable/writable.
7	TRAP	Trap Taken Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{TRAP} field. 1 Event owned by software debug. DBCR0 _{TRAP} is software readable/writable.
8	IAC1	Instruction Address Compare 1 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC1 control and status fields. 1 Event owned by software debug. IAC1 control fields are software readable/writable.

Table 1470. EDBRAC0 field descriptions (continued)

Bit	Name	Description
9	IAC2	Instruction Address Compare 2 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC2 control and status fields. 1 Event owned by software debug. IAC2 control fields are software readable/writable.
10	IAC3	Instruction Address Compare 3 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC3 control and status fields. 1 Event owned by software debug. IAC3 control fields are software readable/writable.
11	IAC4	Instruction Address Compare 4 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC4 control and status fields. 1 Event owned by software debug. IAC4 control fields are software readable/writable.
12	DAC1	Data Address Compare 1 Debug Event 0 Event owned by hardware debug. No mtspr access by software to DAC1 control and status fields. 1 Event owned by software debug. DAC1 control fields are software readable/writable.
13	DAC34	Data Address Compare 3 and 4 Debug Events 0 Events owned by hardware debug. No mtspr access by software to DAC3 and DAC4 control and status fields. 1 Event owned by software debug. DAC3 and DAC4 control fields are software readable/writable.
14	DAC2	Data Address Compare 2 Debug Event 0 Event owned by hardware debug. No mtspr access by software to DAC2 control and status fields. 1 Event owned by software debug. DAC2 control fields are software readable/writable.
15	—	Reserved
16	RET	Return Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{RET} field. 1 Event owned by software debug. DBCR0 _{RET} is software readable/writable.
17	IAC5	Instruction Address Compare 5 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC5 control and status fields. 1 Event owned by software debug. IAC5 control fields are software readable/writable.
18	IAC6	Instruction Address Compare 6 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC6 control and status fields. 1 Event owned by software debug. IAC6 control fields are software readable/writable.
19	IAC7	Instruction Address Compare 7 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC7 control and status fields. 1 Event owned by software debug. IAC7 control fields are software readable/writable.
20	IAC8	Instruction Address Compare 8 Debug Event 0 Event owned by hardware debug. No mtspr access by software to IAC8 control and status fields. 1 Event owned by software debug. IAC8 control are software readable/writable.

Table 1470. EDBRAC0 field descriptions (continued)

Bit	Name	Description
21	DEVT1	External Debug Event Input 1 Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{DEVT1} field. 1 Event owned by software debug. DBCR0 _{DEVT1} is software readable/writable.
22	DEVT2	External Debug Event Input 2 Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{DEVT2} field. 1 Event owned by software debug. DBCR0 _{DEVT2} is software readable/writable.
23	PMI	Performance Monitor Interrupt Debug Event 0 Event owned by hardware debug. No mtpmr access by software to the PMRs. Performance monitor interrupts set EDBSR0 _{PMI} regardless of the setting of PMGC0 _{UDI} . 1 Event owned by software debug. PMRs are software readable/writable. <i>Note: This bit is reset to '1'.</i>
24	MPU	Memory Protection Unit Debug Event 0 Event owned by hardware debug. No mpuwe access by software to region descriptors that have the DEBUG control bit set to '1' or to the MPU0CSR0 _{DRDEN,DWDEN,IDEN} control bits, unless the CPU is in a debug session (jd_debug_b is asserted). MPU debug events set EDBSR0 _{MPU} , and if not masked by EDBSRMSK0 _{MPU} , one of EDBSR0 _{IAC} , EDBSR0 _{DACR} , or EDBSR0 _{DACW} . MPU flash invalidates do not affect DEBUG=1 entries unless the CPU is in a debug session (jd_debug_b is asserted). 1 Event owned by software debug. All region descriptors and the MPU0CSR0 _{DRDEN,DWDEN,IDEN} control bits are software readable/writable. <i>Note: This bit is reset to '1'.</i>
25	CIRPT	Critical Interrupt Taken Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{CIRPT} field. 1 Event owned by software debug. DBCR0 _{CIRPT} is software readable/writable.
26	CRET	Critical Return Debug Event 0 Event owned by hardware debug. No mtspr access by software to DBCR0 _{CRET} field. 1 Event owned by software debug. DBCR0 _{CRET} is software readable/writable.
27	DNI	DNI Instruction Debug Control 0 DNI resource owned by hardware debug. Execution of an e_dni or se_dni instruction results in entry into debug mode. 1 DNI resource owned by software debug. Execution of an e_dni or se_dni instruction results in either a debug interrupt (DBCR0 _{IDM} =1 and MSR _{DE} =1) or a nop (DBCR0 _{IDM} =0 or MSR _{DE} =0). <i>Note: DNI events are not blocked during a debug session</i>
28	DQM	Data Acquisition Messaging Registers 0 DEVENT _{DQTAG} and DDAM register are exclusively owned by hardware debug. No mtspr access by software to DEVENT _{DQTAG} field or DDAM register. Attempted access by software is ignored. 1 DEVENT _{DQTAG} and DDAM register are owned by software. Software has read/write access to DEVENT _{DQTAG} field and DDAM register.
29:31	—	Reserved

Table 1471 shows which resources are controlled by EDBRAC0 settings.

1. Note: IDM not required to be set to enable software access.

EDBRAC0 also controls which bits or fields in DBCR0–8, MPU0CSR0, and the PMRs are reset by assertion of **p_reset_b** when EDBCR0_{EDM}=1. Only software-owned bits or fields as shown in [Table 1471](#) are affected in this case, except that DBCR0_{RST} and DBCR0_{MRR} are updated by assertion of **p_reset_b** regardless of the value of EDBCR0_{EDM} or EDBRAC0.

64.3.4 Debug Event Select register (DEVENT) register

The Debug Event Select Register allows instrumented software to internally generate signals when a **mtspr** instruction is executed and this register is accessed. The values written to this register determine which of the **p_devnt_out[0:7]** processor output signals are asserted upon access. Writing a '1' to any of these bit positions will cause a one clock pulse to be generated on the corresponding output. For **p_devnt_out[0:3]**, a corresponding **jd_watchpt[x]** output is asserted as well to indicate a watchpoint has occurred. These signals may be used for internal core debug resources as well as for SoC level cross-triggering.

The DEVENT_{DEVNT} register field value is undefined on a read; it may or may not remain set to the last value written. Since it is unconditionally shared by hardware debug and software, software should not rely on any value remaining.

The upper 8 bits of the DEVENT register also provide the DQTAG used to identify channels within Data Acquisition Messages. See the "Data Acquisition ID Tag Field" section in the Core (e200z425n3) Nexus 3 Module chapter for more detail on the DQTAG.

The DEVENT register is shown in [Figure 1570](#).

Figure 1570. Debug Event Select register (DEVENT) register

DQTAG	0	DEVNT
0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31		

SPR 975; Reset⁽¹⁾: 0x0

- Reset by processor reset **p_reset_b** if EDBCR0_{EDM}=0, as well as unconditionally by **m_por**. If EDBCR0_{EDM}=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**. Note that DEVNT field is shared by hardware and software but is always reset by **p_reset_b**.

[Table 1472](#) provides bit definitions for the Debug Event Register.

Table 1472. DEVENT field descriptions

Bit	Name	Description
0:7	DQTAG	Data Acquisition Message IDTAG channel identifier (supplied to Nexus 3)
8:23	—	Reserved, should be cleared.
24:31	DEVNT	Debug Event Signals 00000000 No signal is asserted xxxxxx1x p_devnt_out[0] and jd_watchpt[12] are asserted for one clock xxxxxx1x p_devnt_out[1] and jd_watchpt[13] are asserted for one clock xxxxx1xx p_devnt_out[2] and jd_watchpt[20] are asserted for one clock xxxx1xxx p_devnt_out[3] and jd_watchpt[21] are asserted for one clock xxx1xxxx p_devnt_out[4] is asserted for one clock xx1xxxxx p_devnt_out[5] is asserted for one clock x1xxxxxx p_devnt_out[6] is asserted for one clock 1xxxxxxx p_devnt_out[7] is asserted for one clock

64.3.5 Debug Data Acquisition Message (DDAM) register

The Debug Data Acquisition Message Register allows instrumented software to generate real-time Data Acquisition Messages (as defined by Nexus 3) via a **mtspr** instruction to this

register. See the “Data Acquisition Messaging” section in the Core (e200z425n3) Nexus 3 Module chapter for details.

The DDAM register is shown in [Figure 1571](#).

Figure 1571. Debug Data Acquisition Message (DDAM) register

- 1. Reset by processor reset **p_reset_b** if EDBCR0_{EDM}=0, as well as unconditionally by **m_por**. If EDBCR0_{EDM}=1, EDBRAC0 masks off hardware-owned resources from reset by **p_reset_b** and only software-owned resources indicated by EDBRAC0 will be reset by **p_reset_b**.

[Table 1473](#) provides bit definitions for the Debug Data Acquisition Message Register.

Table 1473. DDAM field descriptions

Bit	Name	Description
0:31	DDAM	Value to be transmitted in a Data Acquisition Message (DQM) (supplied to Nexus 3 with strobe)

64.4 Using debug resources for stack limit checking

The DAC1,2 and DAC3,4 resources can be used for stack overflow/underflow detection when not being used as a hardware or software debug resource. Stack limit checking is available regardless of EDM or IDM mode, and when resources used for stack limit checking are owned by software, will utilize a DSI or machine check exception. Software-owned stack limit checking does not require IDM to be set. Hardware owned stack limit checking requires EDM to be set.

When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by software, DAC events are not generated for resources configured to perform stack limit checking, and no DBSR DAC status flag will be set due to a detected stack limit violation. Instead, depending on the processor mode, a data storage interrupt or a machine check exception is signaled. When stack limit checking is enabled, and DAC resources used for stack limit checking are owned by hardware, DAC events will be generated for resources configured to perform stack limit checking, and the EDBSR0 DAC status flag will be set due to a detected stack limit violation, causing entry into debug halted mode in the same way as a DAC exception normally does. The only difference is that qualification of the access address is performed as discussed in the next paragraph.

Stack limit checking is implemented in the same way as range compares using DAC1,2 or 3,4, or extended masking using DAC1 or DAC3, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DAC resources configured to perform stack limit checking are not owned by hardware, if a stack limit violation occurs when performing the load or store, the access is aborted, and an error report machine check is generated, with MCSRR0

pointing to the address of the load or store access that generated the stack overflow/underflow. If DAC resources configured to perform stack limit checking are owned by hardware, then a normal DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event.

Enabling of this functionality is described in more detail in [Table 1464](#). Note that IDM is not required to be set for software-owned stack limit checking.

In contrast to the normal case of DAC address matching resulting in a debug event, the stack limit check address compare logic operates differently for stack limit checking. When using resources for stack limit checking, a DACn hit to a resource enabled for performing stack limit checking on a stack access indicates a stack limit violation.

When stack limit checking is enabled by the setting of the DBCR4_{DAC1CFG} field to '1000' or the DBCR8_{DAC3CFG} field to '1000' (or both), and the corresponding DACn resources are owned by software, DACn events are not generated and the DBSR DAC status flag will not be set due to a detected stack limit hit. Instead, if stack limit checking is enabled for supervisor mode stack accesses in DAC1 or DAC3, and a compare hit occurs for a supervisor mode stack access (A load or store using GPR R1 in the <EA> calculation), a machine check exception is signaled. If stack limit checking is enabled for user mode accesses, a DSI exception is signaled when a stack limit checking enabled DAC1 or DAC3 compare hit occurs for a user mode access. A watchpoint for DAC1 or DAC3 will be generated when the stack limit violation is detected, even though the instruction does not complete. Stack limit checking for supervisor mode stack accesses is considered enabled when either the DBCR4_{DAC1CFG} field is set to '1000' with DBCR2_{DAC1US} set to '00' or '10', or the DBCR7_{DAC3CFG} field is set to '1000' with DBCR8_{DAC3US} set to '00' or '10', or both. Stack limit checking for user mode stack accesses is considered enabled when either the DBCR4_{DAC1CFG} field is set to '1000' with DBCR2_{DAC1US} set to '00' or '01', or the DBCR7_{DAC3CFG} field is set to '1000' with DBCR8_{DAC3US} set to '00' or '01', or both. Note that unlike regular debug DAC events, both halves of a misaligned access are checked for limit violations.

When stack limit checking is enabled for a stack access, and DACn resources are owned by hardware, the EDBSR0 DAC status flag will be set due to a detected stack limit violation, to cause entry into debug halted mode or to generate a watchpoint, or both, in the same way as a DAC event normally does, i.e. after the access has completed. The only difference is that qualification of the access address is performed as discussed in the next paragraph. If the access is aborted due to a DSI or other exception such as machine check condition, the EDBSR0_{IDE} status bit will also be set to indicate that the data access instruction was not completed.

Stack limit checking is implemented in the same way as address compares using DACn, but qualify a load or store access address with the use of GPR R1 as the base or index register used to compute an effective address when a load or store instruction is executed. No stack limit checking is performed for other instructions that may calculate an EA using GPR R1 such as cache, MMU/MPU management instructions, or instructions that indicate GPR R1 is used to hold a decoration value (for decorated load/store type instructions) or a modify specifier (for LSP load/store instructions w/modify). When DACn resources are not owned by hardware, if a stack limit violation occurs (a hit to a stack limit enabled DAC is detected) when performing the load or store, the access request is aborted and the access is not performed. Instead, for supervisor mode accesses, an error report machine check exception is generated, with MCSRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow, and for user mode accesses, a DSI exception is generated, with SRR0 pointing to the address of the load or store instruction that generated the stack overflow/underflow. If all stack limit check enabled DACn resources are owned by

hardware, then a DAC event is generated (but qualified with use of GPR R1), and debug mode entry will occur in the same manner as for a non-stack limit DAC event. In this case, the instruction and access will normally have completed, in the same manner as a normal DAC event.

Independent limit checks for supervisor and user accesses may be implemented by allocating independent DACn resources to each, or a single limit may be applied using a single DACn resource. Typically, a DAC1,2 pair operating in exclusive address range mode is utilized for stack limit checking for a single shared limit. For separate limits, DAC3,4 may also be utilized. If more than one DACn resource is utilized, a DAC hit on any resource utilized for stack limit checking will cause the corresponding stack limit exception action to occur. If both a hardware-owned and a software-owned resource generate a stack limit exception for a given load or store, the software resource will have priority, since it is detected prior to completion of the access, and the access is aborted, thus the hardware event will not occur.

Enabling of this functionality is described in more detail in the description of the DACnCFG fields in [Table 1464](#) and [Table 1467](#) in [Section 64.3.2, Debug Control and Status registers](#). Note that for DAC1 and DAC2, access type (read, write) control is part of DBCR0.

64.5 External debug support

External debug support is supplied through the OnCE controller serial interface, which allows access to internal CPU registers and other system state while the CPU is halted in debug mode. All debug resources including DBCR0–8, DBSR, IAC1–8, DAC1–4, and DVC1–2 are accessible through the serial OnCE interface in external debug mode. Setting the EDBCR0_{EDM}/DBCR0_{EDM} bit to '1' through the OnCE interface enables external debug mode, and unless otherwise permitted by the settings in EDBRAC0, disables software updates to the debug control registers. When EDBCR0_{EDM} is set, debug events enabled to set respective status bits will also cause the CPU to enter Debug mode if the event is not masked in EDBSRMSK0, as opposed to generating Debug Interrupts, unless the specific events are allocated to software via the settings in EDBRAC0. In Debug mode, the CPU is halted at a recoverable boundary, and an external Debug Control Module may control CPU operation through the On-Chip Emulation logic (OnCE).

Note that the descriptions of events in the subsections of [Section 64.2, Software debug events and exceptions](#) refer to setting DBSR status bits, however, when resources are owned by hardware, the events for those resources set the respective status bits in EDBSR0 instead of DBSR.

Note: *On the initial setting of EDBCR0_{EDM} to '1', other bits in DBCR0 will remain unchanged. After EDBCR0_{EDM} has been set, all debug register resources may be subsequently controlled through the OnCE interface. The CPU should be placed into debug mode via the OCR_{DR} control bit prior to writing EDM to '1'. This gives the debugger the opportunity to cleanly write to the DBCRx registers and the DBSR to clear out any residual state / control information that could cause unintended operation.*

Note: *It is intended for the CPU to remain in external debug mode (EDBCR0_{EDM}=1) in order to single step or perform other debug mode entry/ reentry via the OCR_{DR}, by performing go+noexit commands, or by assertion of the **jd_de_b** signal.*

Note: *EDBCR0_{EDM} operation will be blocked if OnCE operation is disabled (**jd_en_once** negated) regardless of whether it is set or cleared. This means that if EDBCR0_{EDM} was previously*

set, and then **jd_en_once** is negated (this should not occur), entry into debug mode will be blocked, and all hardware debug events are blocked. Watchpoints are not blocked.

Due to clock domain design, the CPU clock (**m_clk**) must be active in order to perform writes to debug registers other than the OnCE Command register (OCMD), the OnCE Control register (OCR), External Debug Control Register 0 (EDBCR0), External Debug Status register 0 (EDBSR0), External Debug Status Register Mask 0 (EDBSRMSK0), or the EDBCR0_{EDM} bit. Register read data is synchronized back to the **j_tclk** clock domain. The OnCE Control register provides the capability of signaling the system level clock controller that the CPU clock should be activated if not already active.

Updates to the DBCRx, DBSR, and most other debug registers via the OnCE interface should be performed with the CPU in debug mode to guarantee proper operation. Due to the various points in the CPU pipeline where control is sampled and event handshaking is performed, it is possible that modifications to these registers while the CPU is running may result in early or late entry into debug mode, and may have incorrect status posted in the DBSR register.

If resource sharing is enabled via EDBRAC0, updates to the EDBRAC0, DBCRx, and DBSR registers must be performed with the CPU in debug mode, since simultaneous updates of register portions could otherwise be attempted, and such updates are not guaranteed to properly occur. The results of such an attempt are undefined.

64.5.1 External debug registers

The external debug registers are used for controlling several debug aspects of the core and reporting status while in External Debug mode.

64.5.1.1 External Debug Control Register 0 (EDBCR0)

EDBCR0 is a control register accessible to an external debugger through the OnCE/Jtag port. An external development tool can write to this register in order to enable external debug mode or to enable Debugger Notify Halt instructions (**e_dnh**, **se_dnh**), as well as to control aspects of Debugger Notify Interrupt instructions (**e_dni**, **se_dni**).

EDBCR0 is not accessible by software. However, the state of EDBCR0_{EDM} is reflected as a read-only bit in DBCR0_{EDM} to software. There is only one physical EDM bit implemented; it is reflected in both the DBCR0 and EDBCR0 registers, and may be written and read using either register by the hardware debugger. For future compatibility, EDBCR0 updates are preferred.

EDBCR0 is shown in [Figure 1572](#).

Figure 1572. External Debug Control Register 0 (EDBCR0)

EDM		DNH_EN		0				DNI_CTL		0																					
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset⁽¹⁾: 0x0

- EDBCR0 is affected (reset) by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state, but is not affected by **p_reset_b**.

[Table 1474](#) provides bit definitions for External Debug Control Register 0.

Table 1474. EDBCR0 field descriptions

Bit	Name	Description
0	EDM	External Debug Mode. This bit is also reflected in DBCR0. When external debug mode is enabled, hardware-owned resources in debug registers are not affected by processor reset p_reset_b . This allows the debugger to set up hardware debug events that remain active across a processor reset. 0 External debug mode disabled. Internal debug events not mapped into external debug events. 1 External debug mode enabled. Hardware-owned events will not cause the CPU to vector to interrupt code. Software is not permitted to write to debug registers {DBCRx, IAC1–8, DAC1–4, DVC1–2[U]} unless permitted by settings in EDBRAC0.
1	DNH_EN	dnh Instruction Enable 0 Execution of e_dnh and se_dnh instructions cause illegal instruction exceptions to occur. 1 Execution of e_dnh and se_dnh instructions cause entry into debug mode and a debug halt occurs, regardless of the value of EDM.
2:6	—	Reserved
7	DNI_CTL	dni Instruction Control 0 When the dni resource is owned by hardware, the MSR _{DE} bit is cared, and when MSR _{DE} =0, execution of e_dni and se_dni instructions are nop'ed and no entry into debug mode occurs. 1 When the dni resource is owned by hardware, the MSR _{DE} bit is don't-cared, and execution of e_dni and se_dni instructions cause entry into debug mode and a debug halt occurs, regardless of the value of MSR _{DE} . <i>Note: This control bit is only used when the dni resource is owned by hardware via control in EDBRAC0_{DNI}, and thus also only when EDM=1.</i>
8:31	—	Reserved

64.5.1.2 External Debug Status Register 0 (EDBSR0)

The External Debug Status Register 0 (EDBSR0) contains status on debug events owned by hardware. The External Debug Status Register 0 is set via hardware, and read and cleared via OnCE access by the debugger. Clearing is done by writing to the External Debug Status Register via the OnCE port, with a '1' in any bit position that is to be cleared and '0' in all other bit positions. The write data to EDBSR0 is not direct data, but a mask. A '1' causes the bit to be cleared, and a '0' has no effect. The EDBSR0 register is shown in [Figure 1573](#).

Figure 1573. External Debug Status Register 0 (EDBSR0)

IDE	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	VLES	DAC_OFST	0							
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Read/Write; Reset⁽¹⁾ - 0x0000 0000

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logics_Reset state or while EDBCR0_{EDM}=0.

[Table 1475](#) provides bit definitions for External Debug Status Register 0.

Table 1475. EDBSR0 field descriptions

Bit	Name	Description
0	IDE	Imprecise Debug Event Set to 1 if EDBCR0 _{EDM} =1 and an imprecise debug event occurs for a hardware-owned DAC event due to a load or store that is terminated with error, or if a hardware-owned ICMP event occurs in conjunction with a EFPU round exception. This bit will not be set for imprecise debug events that are masked via settings in EDBSRMSK0.
1	UDE	Unconditional Debug Event Set to 1 if a hardware-owned Unconditional debug event occurred.
2	DNH	Debugger Notify Halt Event Set to 1 if a debugger notify halt instruction was executed and caused a debug halt.
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 if a hardware-owned Instruction Complete debug event occurred.
5	BRT	Branch Taken Debug Event Set to 1 if a hardware-owned Branch Taken debug event occurred.
6	IRPT	Interrupt Taken Debug Event Set to 1 if a hardware-owned Interrupt Taken debug event occurred.
7	TRAP	Trap Taken Debug Event Set to 1 if a hardware-owned Trap Taken debug event occurred.
8	IAC	Instruction Address Compare 1 Debug Event Set to 1 if a hardware-owned IAC debug event occurred.
9:11	—	Reserved
12	DACR	Data Address Compare Read Debug Event Set to 1 if a hardware-owned read-type DAC debug event occurred
13	DACW	Data Address Compare Write Debug Event Set to 1 if a hardware-owned write-type DAC1 debug event occurred
14	—	Reserved
15	DNI	DNI Debug Event Set to 1 if a hardware-owned DNI debug event occurred
16	RET	Return Debug Event Set to 1 if a hardware-owned Return debug event occurred
17:20	—	Reserved
21	DEVT1	External Debug Event 1 Debug Event Set to 1 if a hardware-owned DEVT1 debug event occurred
22	DEVT2	External Debug Event 2 Debug Event Set to 1 if a hardware-owned DEVT2 debug event occurred
23	PMI	Performance Monitor Interrupt Debug Event Set to 1 if a Performance Monitor Interrupt event occurred with EDBRAC0 _{PMI} =0 regardless of the setting of PMGC0 _{UDI}

Table 1475. EDBSR0 field descriptions (continued)

Bit	Name	Description
24	MPU	Memory Protection Unit Debug Event Set to 1 if a hardware-owned MPU debug event occurred. For MPU debug events, if EDBSRMSK0 _{MPU} is cleared, the IAC, DACR, or DACW status bit will also be set, depending on the type of access that matched a region descriptor enabled to generate debug events, in order to further define the type of MPU debug event. If EDBSRMSK0 _{MPU} is set at the time a MPU debug event occurs, the IAC, DACR, and DACW status bits will not be set by MPU debug events, in order to properly mask the MPU debug event. Note that hardware MPU debug events on data accesses normally occur after the data access is performed and the instruction completes, thus act like a normal DAC debug event. The instruction may not complete if a DSI occurs. In this case, IDE will be set to indicate this occurrence.
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 if a hardware-owned Critical Interrupt Taken debug event occurred.
26	CRET	Critical Return Debug Event Set to 1 if a hardware-owned Critical Return debug event occurred
27	VLES	VLE Status Set to 1 if a hardware-owned ICMP, BRT, TRAP, RET, CRET, IAC, or DAC debug event occurred on a PowerISA VLE Instruction. Also set for execution of an e_dnh or se_dnh instruction when enabled by EDBCR0 _{DNH_EN} . Undefined for IRPT, CIRPT, DEVT[1,2], and UDE events
28:30	DAC_OFST	Data Address Compare Offset Indicates offset-1 of saved DSRR0 value from the address of the load or store instruction that took a hardware-owned DAC Debug exception, unless a simultaneous DSI error occurs, in which case this field is set to 3'b000 and EDBSR0 _{IDE} is set to 1. Normally set to 3'b000 by a non-DVC DAC. A DVC DAC may set this field to any value.
31	—	Reserved

64.5.1.3 External Debug Status Register Mask 0 (EDBSRMSK0)

The External Debug Status Register Mask 0 (EDBSRMSK0) is used to mask debug events set in EDBSR0 from causing entry into debug halted mode. A '1' stored in any mask bit prevents debug mode entry caused by the corresponding bit being set in EDBSR0. The mask has no effect on DBSR actions or on the setting of EDBSR0 status bits by hardware-owned events, except that the IDE bit will not be set by imprecise hardware-owned debug events that are masked. EDBSRMSK0 may be used to allow debug events owned by hardware to be configured for watchpoint generation purposes without causing debug mode entry when the watchpoint occurs. EDBSRMSK0 is read and written via OnCE access by the debugger. No software access is provided. The EDBSRMSK0 register is shown in [Figure 1574](#).

Figure 1574. External Debug Status Register Mask 0 (EDBSRMSK0)

0	UDE	DNH	0	ICMP	BRT	IRPT	TRAP	IAC	0	DACR	DACW	0	DNI	RET	0	DEVT1	DEVT2	PMI	MPU	CIRPT	CRET	0									
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Read/Write; Reset⁽¹⁾ - 0x0000 0000

1. Reset by **j_trst_b** or **m_por** assertion, and remains reset while in the Test_Logic_Reset state or while EDBCR0_{EDM}=0.

[Table 1476](#) provides bit definitions for External Debug Status Register Mask 0.

Table 1476. EDBSRMSK0 field descriptions

Bit	Name	Description
0	—	Reserved
1	UDE	Unconditional Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{UDE}
2	DNH	Debugger Notify Halt Event Set to 1 to mask debug mode entry by EDBSR0 _{DNH}
3	—	Reserved
4	ICMP	Instruction Complete Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{ICMP}
5	BRT	Branch Taken Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{BRT}
6	IRPT	Interrupt Taken Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{IRPT}
7	TRAP	Trap Taken Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{TRAP}
8	IAC	Instruction Address Compare Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{IAC}

Table 1476. EDBSRMSK0 field descriptions (continued)

Bit	Name	Description
25	CIRPT	Critical Interrupt Taken Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{CIRPT}
26	CRET	Critical Return Debug Event Set to 1 to mask debug mode entry by EDBSR0 _{CRET}
22:31	—	Reserved

64.5.1.4 External Debug Data Effective Address Register (EDDEAR)

The External Debug Data Effective Address Register (EDDEAR) contains address information for hardware-owned data address compare debug events, including MPU DAC events. EDDEAR is update by hardware with the effective address of the load or store operation when an unmasked data address compare event is recorded in EDBSR0 if the previous values of EDBSR0_{DAC{R,W}} bits that are unmasked in EDBSRMSK0 are zero. Once an EDDEAR update is performed, these unmasked bits must be cleared by the hardware debugger prior to another EDDEAR hardware update occurring. A subsequent hardware-owned unmasked DAC event will not update the EDDEAR register if either of the EDBSR0_{DAC{R,W}} bits are set and are not masked by EDBSRMSK0, in order to capture the first unmasked event address. EDDEAR is read and written via OnCE access by the debugger. No software access is provided.

The EDDEAR register is shown in [Figure 1575](#).

Figure 1575. External Debug Data Effective Address Register (EDDEAR)

64.5.2 OnCE introduction

The e200z425n3 on-chip emulation circuitry (OnCE™/Nexus Class 1 interface) provides a means of interacting with the e200z425n3 core and integrated system so that a user may examine registers, memory, or on-chip peripherals facilitating hardware/software development. OnCE operation is controlled via an industry standard IEEE 1149.1 TAP controller. By using public instructions, the external hardware debugger can freeze or halt the CPU, read and write internal state, and resume normal execution. The core does not contain IEEE 1149.1 standard boundary cells on its interface, as it is a building block for further integration. It does not support the JTAG related boundary scan instruction functionality, although JTAG public instructions may be decoded and signaled to external logic.

The OnCE logic provides for Nexus Class 1 static debug capability (utilizing the same set of resources available to software while in internal debug mode).

In order to enable full OnCE operation, the **jd_enable_once** input signal must be asserted. In some system integrations, this is automatic, since the input will be tied asserted. Other integrations may require the execution of the Enable OnCE command via the TAP and appropriate entry of serial data. Exact requirements will be documented by the integrated

product specification. The **jd_enable_once** input signal should not change state during a debug session, or undefined activity may occur.

The following figures show the TAP controller state model and the TAP registers implemented by the OnCE logic.

Figure 1576. OnCE TAP controller and registers

The OnCE controller is implemented as a 16-state FSM, with a one-to-one correspondence to the states defined for the JTAG TAP controller.

Figure 1577. OnCE controller implementation

Access to processor registers and the contents of memory locations are performed by enabling external debug mode (setting $EDBCR0_{EDM}$ to '1'), placing the processor into debug mode, followed by scanning instructions and data into and out of the CPU Scan Chain (CPUSCR); execution of scanned instructions by the CPU is used as the method to access required data. Memory locations may be read by scanning a load instruction into the CPU core, which will reference the desired memory location, executing the load instruction, and then scanning out the result of the load. Other resources are accessed in a similar manner.

The initial entry by the CPU into the debug state (or mode) from normal, Waiting, Stopped, or Halted states (all indicated via the OnCE Status Register (OSR), [Section 64.5.6.1, OnCE](#)

Status register) by assertion of one or more debug requests, begins a *debug session*. The **jd_debug_b** output signal indicates that a debug session is in progress, and the OSR will indicate the CPU is in the debug state. Instructions may be single-stepped by scanning new values into the CPUSCR, and performing a OnCE go+noexit command (See [Section 64.5.6.2, OnCE Command \(OCMD\) register](#)). The CPU will then temporarily exit the debug state (but not the debug session) to execute the instruction, and will then return to the debug state (again indicated via the OnCE Status Register (OSR)). The debug session remains in force until the final OnCE go+exit command is executed, at which time the CPU will return to the previous state it was in (unless a new debug request is pending). A scan into the CPUSCR is required prior to executing each go+exit or go+noexit OnCE command.

64.5.3 JTAG/OnCE pins

The JTAG/OnCE pin interface is used to transfer OnCE instructions and data to the OnCE control block. Depending on the particular resource being accessed, the CPU may need to be placed in the Debug mode. For resources outside of the CPU block and contained in the OnCE block, the processor is not disturbed, and may continue execution. If a processor resource is required, an internal debug request (**dbg_dbgrq**) may be asserted to the CPU by the OnCE controller, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for further commands. Asserting **dbg_dbgrq** will cause the chip to temporarily exit the Waiting, Stopped or Halted power management states.

[Table 1477](#) details the primary JTAG/OnCE interface signals.

Table 1477. JTAG/OnCE primary interface signals

Signal name	Type	Description
j_trst_b	I	JTAG test reset
j_tclk	I	JTAG test clock
j_tms	I	JTAG test mode select
j_tdi	I	JTAG test data input
j_tdo	O	Test data out to master controller or pad
j_tdo_en ⁽¹⁾	O	Enables TDO output buffer

1. j_tdo_en is asserted when the TAP controller is in the shift_DR or shift_IR state.

A full description of JTAG pins is provided in the JTAG Support Signals section of the Core (e200z425n3) Core Complex Overview.

64.5.4 OnCE internal interface signals

The following paragraphs describe the OnCE interface signals to other internal blocks associated with the OnCE controller.

64.5.4.1 CPU Debug Request (dbg_dbgrq)

The **dbg_dbgrq** signal is asserted by the OnCE control logic to request the CPU to enter the debug state. It may be asserted for a number of different conditions, and causes the CPU to finish the current instruction being executed, save the instruction pipeline information, enter the debug mode, and wait for further commands.

64.5.4.2 CPU Debug Acknowledge (cpu_dbgack)

The **cpu_dbgack** signal is asserted by the CPU upon entering the debug state. This signal is used as part of the handshake mechanism between the OnCE control logic and the rest of the CPU. The CPU core may enter debug mode either through a software or hardware event.

64.5.4.3 CPU address and attributes

The CPU address and attribute information are used by the Nexus3 unit with information for real-time address trace information.

64.5.4.4 CPU data

The CPU data buses are used to supply the Nexus3 debug unit with information for real-time data trace capability.

64.5.5 OnCE interface signals

The following paragraphs describe additional OnCE interface signals to other external blocks such as a Nexus controller and external blocks that may need information pertaining to debug operation.

64.5.5.1 OnCE Enable (jd_en_once)

The OnCE enable signal **jd_en_once** is used to enable the OnCE controller to allow certain instructions and operations to be executed. Assertion of this signal will enable the full OnCE command set, as well as operation of control signals and OnCE Control register functions. When this signal is disabled, only the Bypass, ID and Enable_OnCE commands are executed by the OnCE unit, and all other commands default to a "Bypass" command. The OnCE Status register (OSR) is not visible when OnCE operation is disabled. In addition, OnCE Control register (OCR) functions are disabled, as is the operation of the **jd_de_b** input. Secure systems may choose to leave the **jd_en_once** signal negated until a security check has been performed. Other systems should tie this signal asserted to enable full OnCE operation. The **j_en_once_regssel** output signal is provided to assist external logic performing security checks.

The **jd_en_once** input must only change state during the Test-Logic-Reset, Run-Test/Idle, or Update_DR TAP states. A new value will take affect after one additional **j_tclk** cycle of synchronization. In addition, **jd_enable_once** input signal must not change state during a debug session, or undefined activity may occur.

64.5.5.2 OnCE Debug Request/Event (jd_de_b, jd_de_en)

If implemented at the SoC level, a system level bidirectional open drain debug event pin **DE_b** (not part of the e200z425n3 interface) provides a fast means of entering the Debug mode of operation from an external command controller (when input) as well as a fast means of acknowledging the entering of the Debug mode of operation to an external command controller (when output). The assertion of this pin by a command controller causes the CPU core to finish the current instruction being executed, save the instruction pipeline information, enter Debug mode, and wait for commands to be entered. If **DE_b** was used to enter the Debug mode then **DE_b** must be negated after the OnCE controller responds with an acknowledge and before sending the first OnCE command. The assertion of this pin by the CPU Core acknowledges that it has entered the Debug mode and is waiting for commands to be entered.

To support operation of this system pin, the OnCE logic supplies the **jd_de_en** output and samples the **jd_de_b** input when OnCE is enabled (**jd_en_once** asserted). Assertion of **jd_de_b** will cause the OnCE logic to place the CPU into Debug mode. Once Debug mode has been entered, the **jd_de_en** output will be asserted for three **j_tclk** periods to signal an acknowledge. **jd_de_en** can be used to enable the open-drain pulldown of the system level **DE_b** pin.

For systems that do not implement a system level bidirectional open drain debug event pin **DE_b**, the **jd_de_en** and **jd_de_b** signals may still be used to handshake debug entry.

64.5.5.3 OnCE Debug output (jd_debug_b)

The OnCE Debug output **jd_debug_b** is used to indicate to on-chip resources that a debug session is in progress. Peripherals and other units may use this signal to modify normal operation for the duration of a debug session, which may involve the CPU executing a sequence of instructions solely for the purpose of visibility/system control that are not part of the normal instruction stream the CPU would have executed had it not been placed in debug mode. This signal is asserted the first time the CPU enters the debug state, and remains asserted until the CPU is released by a write to the OnCE Command Register with the GO and EX bits set, and a register specified as either “No Register Selected” or the CPUSCR. This signal will remain asserted even though the CPU may enter and exit the debug state for each instruction executed under control of the OnCE controller. See [Section 64.5.6.2, OnCE Command \(OCMD\) register](#) for more information on the function of the GO and EX bits. This signal is not normally used by the CPU.

64.5.5.4 CPU Clock On input (jd_mclk_on)

The CPU Clock On input **jd_mclk_on** is used to indicate that the CPU's **m_clk** input is active. This input signal is expected to be driven by system logic external to the e200z425n3 core, is synchronized to the **j_tclk** (scan clock) clock domain, and is presented as a status flag on the **j_tdo** output during the Shift_IR state. External firmware may use this signal to ensure proper scan sequences will occur to access debug resources in the **m_clk** clock domain.

64.5.5.5 Watchpoint events (jd_watchpt[0:31])

The **jd_watchpt[0:31]** signals may be asserted by the OnCE control logic to signal that a watchpoint condition has occurred. Watchpoints do not directly cause the CPU to be affected. They are provided to allow external visibility only or for triggering purposes. Watchpoint events are conditioned by the settings in the DBCRxx registers, as well as by the DEVENT register, the DTC/D TSA/DTEA registers, the Performance Monitor control register settings, and generation of MPU debug events. Refer to [Table 1484](#) for details of the signal assignments. Note that assertion of most watchpoint outputs is conditioned on being in EDM or IDM. The Performance monitor, DEVENT, and DTC watchpoints are not conditioned however, and may assert regardless of the state of EDM or IDM. In addition, DAC1 or DAC3 watchpoints may be generated for stack limit violation occurrences when those resources are configured to perform stack limit checking, regardless of the state of EDM or IDM.

64.5.5.6 Update DR w/go+exit (j_ocmd_go_exit)

This signal indicates the TAP controller is in the Update_DR state and that the go and exit bits in the OnCE Command register are high, and RS indicates “no register selected”. This signal will assert regardless of whether the CPU is currently in debug mode. It may be

monitored by external logic to cause a synchronous exit from debug mode of other modules (but not other CPUs) in the system. A debugger can place all of the CPU tap controllers in parallel, scan in a go+exit command with “no register selected”, and sequence through the Update_DR state to cause any CPU currently in debug mode to exit. CPUs that are not in debug mode will ignore the command.

64.5.6 OnCE controller and serial interface

The OnCE Controller contains the OnCE command register, the OnCE decoder, and the status/control register. [Figure 1578](#) is a block diagram of the OnCE controller. In operation, the OnCE Command register acts as the IR for the TAP controller, and all other OnCE resources are treated as data registers (DR) by the TAP controller. The Command register is loaded by serially shifting in commands during the TAP controller Shift-IR state, and is loaded during the Update-IR state. The Command register selects a resource to be accessed as a data register (DR) during the TAP controller Capture-DR, Shift-DR, and Update-DR states.

Figure 1578. OnCE Controller and Serial Interface

64.5.6.1 OnCE Status register

Status information regarding the state of the CPU is latched into the OnCE Status register when the OnCE controller state machine enters the Capture-IR state. When OnCE operation is enabled, this information is provided on the **j_tdo** output in serial fashion when the Shift_IR state is entered following a Capture-IR. Information is shifted out least significant bit first.

Figure 1579. OnCE Status register

MCLK	ERR	0	RESET	HALT	STOP	DEBUG	WAIT	0	1
0	1	2	3	4	5	6	7	8	9

[Table 1478](#) provides bit definitions for the OnCE Status register.

Table 1478. OnCE Status register field descriptions

Bit	Name	Description
0	MCLK	MCLK m_clk Status Bit 0 Inactive state 1 Active state This status bit reflects the logic level on the jd_mclk_on input signal after capture by j_tclk.
1	ERR	ERROR This bit is used to indicate that an error condition occurred during attempted execution of the last single-stepped instruction (GO+NoExit with CPUSCR or No Register Selected in OCMD), and that the instruction may not have been properly executed. This could occur if an Interrupt (all classes including External, Critical, machine check, Storage, Alignment, Program, etc.) occurred while attempting to perform the instruction single step. In this case, the CPUSCR will contain information related to the first instruction of the Interrupt handler, and no portion of the handler will have been executed.
2	—	Reserved, set to zero
3	RESET	RESET Mode This bit reflects the <u>inverted</u> logic level on the CPU p_reset_b input after capture by j_tclk.
4	HALT	HALT Mode This bit reflects the logic level on the CPU p_halted output after capture by j_tclk.
5	STOP	STOP Mode This bit reflects the logic level on the CPU p_stopped output after capture by j_tclk.
6	DEBUG	Debug Mode This bit is asserted once the CPU is in debug mode. It is negated once the CPU exits debug mode (even during a debug session)
7	WAIT	Waiting Mode This bit reflects the logic level on the CPU p_waiting output after capture by j_tclk.
8	0	Reserved, set to 0 for 1149.1 compliance
9	1	Reserved, set to 1 for 1149.1 compliance

64.5.6.2 OnCE Command (OCMD) register

The OnCE Command (OCMD) register is a 10-bit shift register that receives its serial data from the TDI pin and serves as the instruction register (IR). It holds the 10-bit commands to be used as input for the OnCE Decoder. The Command Register is shown in [Figure 1580](#). The OCMD is updated when the TAP controller enters the Update-IR state. It contains fields for controlling access to a resource, as well as controlling single-step operation and exit from OnCE mode.

Although the OCMD is updated during the Update-IR TAP controller state, the corresponding resource is accessed in the DR scan sequence of the TAP controller, and as such, the Update-DR state must be transitioned through in order for an access to occur. In addition, the Update-DR state must also be transitioned through in order for the single-step and/or exit functionality to be performed, even though the command appears to have no data resource requirement associated with it.

Figure 1580. OnCE Command (OCMD) register

R/W	GO	EX	RS[0:6]						
0	1	2	3	4	5	6	7	8	9

Reset - 10'b1000000010 on assertion of **j_trst_b** or **m_por**, or while in the Test_Logic_Reset state

[Table 1479](#) provides bit definitions for the OCMD.

Table 1479. OCMD field descriptions

Bit	Name	Description
0	R/W	Read/Write Command Bit The R/W bit specifies the direction of data transfer. The table below describes the options defined by the R/W bit. <i>Note: The R/W bit generally ignored for read-only or write-only registers, although the PC FIFO pointer is only guaranteed to be update when R/W=1. In addition, it is ignored for all bypass operations. When performing writes, most registers are sampled in the Capture-DR state into a 32-bit shift register, and subsequently shifted out on j_tdo during the first 32 clocks of Shift-DR.</i> 0 Write the data associated with the command into the register specified by RS[0:6] 1 Read the data contained in the register specified by RS[0:6]
1	GO	Go Command Bit If the GO bit is set, and the CPU is currently in debug mode, the CPU will execute the instruction that resides in the IR register in the CPUSCR. To execute the instruction, the processor leaves the debug mode, executes the instruction, and if the EX bit is cleared, returns to the debug mode immediately after executing the instruction. The processor goes on to normal operation if the EX bit is set, and no other debug request source is asserted. The GO command is executed only if the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the GO bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. On a GO+NoExit operation, returning to debug mode is treated as a debug event, thus exceptions such as machine checks and interrupts may take priority and prevent execution of the intended instruction. Debug firmware should mask these exceptions as appropriate. The OSR_{ERR} bit indicates such an occurrence. If the CPU is not currently in debug mode, then the GO command will be ignored. <i>Note: Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Section 64.5.9.6, Exiting Debug mode and interrupt blocking.</i> 0 Inactive (no action taken) 1 Execute instruction in IR

Table 1479. OCMD field descriptions (continued)

Bit	Name	Description
2	EX	Exit Command Bit 0 Remain in debug mode 1 Leave debug mode If the EX bit is set, the processor will leave the debug mode and resume normal operation until another debug request is generated. The Exit command is executed only if the Go command is issued, and the operation is a read/write to CPUSCR or a read/write to "No Register Selected". Otherwise the EX bit is ignored. The processor will leave the debug mode after the TAP controller Update-DR state is entered. <i>Note: If the DR bit in the OnCE control register is set or remains set, or if a bit in EDBSR0 is set and EDBCR0_{EDM}=1 (external debug mode is enabled), or if another debug request source is asserted, then the processor may return to the debug mode without execution of an instruction, even though the EX bit was set.</i> <i>Note: Asynchronous interrupts are blocked on a GO+Exit operation until the first instruction to be executed begins execution. See Section 64.5.9.6, Exiting Debug mode and interrupt blocking.</i>
3:9	RS	Register Select The Register Select bits define which register is source (destination) for the read (write) operation. Table 1480 indicates the OnCE register addresses. Attempted writes to read-only registers are ignored.

[Table 1480](#) indicates the OnCE register addresses.

111 1101	LSRL Select (see Test Specification)
111 1110	Enable_OnCE ⁽¹⁾
111 1111	Bypass

1. Causes assertion of the j_en_once_regssel output.

The OnCE Decoder receives as input the 10-bit command from the OCMD, and status signals from the processor, and generates all the strobes required for reading and writing the selected OnCE registers.

Single-stepping of instructions is performed by placing the CPU in debug mode, scanning in appropriate information into the CPUSCR, and setting the Go bit (with the EX bit cleared) with the RS field indicating either the CPUSCR or No Register Selected. After executing a single instruction, the CPU will re-enter debug mode and await further commands. During single-stepping, exception conditions may occur if not properly masked by debug firmware (interrupts, machine checks, bus error conditions, etc.) and may prevent the desired instruction from being successfully executed. The OSR_{ERR} bit is set to indicate this condition. In these cases, values in the CPUSCR will correspond to the first instruction of the exception handler.

Additionally, the EDBCR0_{EDM} bit is forced to '1' internally while single-stepping to prevent Debug events from generating Debug interrupts. Also, during a debug session, the DBSR register is frozen from updates due to debug events other than execution of a DNI-type instruction, regardless of EDBCR0_{EDM}. DBSR may still be modified during a debug session via a single-stepped **mtspr** instruction, or via OnCE access.

If the CPU is not currently in debug mode, go+exit and go+noexit commands are ignored, although for a go+exit command with "No Register Selected", the j_ocmd_go_exit output will be asserted.

64.5.6.3 OnCE Control Register (OCR)

The OnCE Control Register is a 32-bit register used to force the e200z425n3 core into debug mode and to enable / disable sections of the OnCE control logic. It also provides control over the MPU during a debug session (see [Section 64.7, MPU operation during debug](#)). The control bits are read/write. These bits are only effective while OnCE is enabled (j_d_en_once asserted). The OCR is shown in [Figure 1581](#).

Figure 1581. OnCE Control Register (OCR)

0								I_DMDIS	0	I_DVLE	I_DI	0	D_DMDIS	0	D_DI	0	D_DG	0	0								WKUP	FDB	DR		
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

Reset - 0xo000_0000 on **m_por**, **j_trst_b**, or entering Test logic Reset state

Table 1481 provides bit definitions for the OnCE Control Register.

Table 1481. OCR field descriptions

Bit	Name	Description
0:7	—	Reserved
8	I_DMDIS	Instruction Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Instruction Accesses. When enabled, the MPU functions normally. When disabled, for Instruction Accesses, the I bit is taken from the OCR bit I_DI. The SX and UX access permission control bits are set to '1' to allow full access. When disabled, no MPU exceptions are generated for Instruction accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
9:10	—	Reserved
11	I_DVLE	Instruction Side Debug 'VLE' Attribute Bit This bit is used to provide the 'VLE' attribute bit to be used during a debug session. <i>Note: This bit is ignored, since VLE is always enabled.</i>
12	I_DI	Instruction Side Debug 'I' Attribute Bit This bit is used to provide the 'I' attribute bit to be used for Instruction accesses for Instruction accesses during a debug session.
13:15	—	Reserved
16	D_DMDIS	Data Side Debug MPU Disable Control Bit This bit may be used to control whether the MPU is enabled normally, or whether the MPU is disabled during a debug session for Data Accesses. When enabled, the MPU functions normally. When disabled, for Data Accesses, the MPU I and G bits are taken from the OCR bits D_DI and D_DG. The SR, SW, UR, and UW access permission control bits are set to '1' to allow full access. When disabled, no MPU exceptions are generated for Data accesses. External access errors can still occur. MPU entries with DEBUG=1 are not affected by this control bit. 0 MPU not disabled for debug sessions 1 MPU disabled for debug sessions
17:19	—	Reserved
20	D_DI	Data Side Debug 'I' Attribute Bit This bit is used to provide the 'I' attribute bit to be used for Data accesses during a debug session.
21	—	Reserved

Table 1481. OCR field descriptions (continued)

Bit	Name	Description
22	D_DG	Data Side Debug 'G' Attribute Bit This bit is used to provide the 'G' attribute bit to be used for Data accesses during a debug session.
23:28	—	Reserved
29	WKUP	Wakeup Request Bit This control bit may be used to force the p_wakeup output signal to be asserted. This control function may be used by debug firmware to request that the chip-level clock controller restore the m_clk input to normal operation regardless of whether the CPU is in a low power state to ensure that debug resources may be properly accessed by external hardware through scan sequences.
30	FDB	Force Breakpoint Debug Mode Bit This control bit is used to determine whether the processor is operating in breakpoint debug enable mode or not. The processor may be placed in breakpoint debug enable mode by setting this bit. In breakpoint debug enable mode, execution of the ' bkpt ' pseudo-instruction will cause the processor to enter debug mode, as if the jd_de_b input had been asserted. This bit is qualified with EDBCR0_EDM , which must be set for FDB to take effect. <i>Note: This bit has no effect on e_dnh or se_dnh instruction operation.</i>
31	DR	CPU Debug Request Control Bit This control bit is used to unconditionally request the CPU to enter Debug mode. The CPU will indicate that Debug mode has been entered via the data scanned out in the shift-IR state. 0 No Debug mode request 1 Unconditional Debug mode request When the DR bit is set, the processor will enter Debug mode at the next instruction boundary.

64.5.7 Access to debug resources

Resources contained in the OnCE Module that do not require the processor core to be halted for access may be accessed while the e200z425n3 core is running, and will not interfere with processor execution. Accesses to other resources such as the CPUSCR require the e200z425n3 core to be placed in debug mode to avoid synchronization hazards. Debug firmware may ensure that it is safe to access these resources by determining the state of the e200z425n3 core prior to access. Note that a scan operation to update the CPUSCR is required prior to exiting debug mode if debug mode has been entered.

Some cases of write accesses other than accesses to the OnCE Command and Control registers, or the EDM bit of DBCR0 require **m_clk** to be running for proper operation. The OnCE control register provides a means of signaling this need to a system level clock control module via the **OCR_WKUP** control bit.

In addition, since the CPU may cause multiple bits of certain registers to change state, reads of certain registers while the CPU is running (DBSR, etc.) may not have consistent bit settings unless read twice with the same value indicated. In order to guarantee that the contents are consistent, the CPU should be placed into debug mode, or multiple reads should be performed until consistent values have been obtained on consecutive reads.

[Table 1482](#) provides a list of access requirements for OnCE registers.

Table 1482. OnCE register access requirements

Register name	Access requirements					Notes
	Requires jd_en_once to be asserted	Requires EDBCR0 EDM = 1 for write access	Requires m_clk active for write access	Requires CPU to be halted for read access	Requires CPU to be halted for write access	
Enable_OnCE	N	N	N	N	—	
Bypass	N	N	N	N	N	
CPUSCR	Y	Y	Y	Y	Y	
DAC1–4	Y	Y	Y	N	*(1)	
DBCR0	Y	Y	Y	N	*(1)	*EDBCR0 _{EDM} access only requires jd_en_once asserted
DBCR1–8	Y	Y	Y	N	*(1)	
DEVENT	Y	Y	Y	N	*(1)	
EDBRAC0 (DBERC0)	Y	N	Y	N	*(1)	
DBSR	Y	Y	Y	N ⁽²⁾	*(1)	
EDBCR0	Y	N	N	N	N	
EDBSR0	Y	N	Y	N	N	
EDBSRMSK0	Y	N	N	N	N	
IAC1–8	Y	Y	Y	N	*(1)	
JTAG ID	N	N	—	N	—	Read-only
MPU0CSR0	Y	N	Y	N	N	
OCR	Y	N	N	N	N	
OSR	Y	N	—	N	—	Read-only, accessed by scanning out IR while jd_en_once is asserted
Cache Debug Access Control (CDACNTL)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Cache Debug Access Data (CDADATA)	Y	N	Y	N	N	CPU gives lowest priority to a Cache access request when it is not debug halted
Nexus3-Access	Y	N	N	N	N	
PMR-Access	Y	N	N	N	N	
PMR Registers	Y	Y	Y	N	N	
External GPRs	Y	N	N	N	N	
LSRL Select	Y	N	?	?	?	System Test logic implementation determines LSRL functionality

1. Writes to these registers while the CPU is running may have unpredictable results due to the pipelined nature of operation, and the fact that updates are not synchronized to a particular clock, instruction, or bus cycle boundary, therefore it is strongly recommended to ensure the processor is first placed into debug mode before updates to these registers are performed.
2. Reads of these registers while the CPU is running may not give data that is self-consistent due to synchronization across clock domains.

64.5.8 Methods of entering Debug mode

The OnCE Status Register indicates that the CPU has entered the debug mode via the DEBUG status bit. The following sections describe how Debug mode is entered assuming the OnCE circuitry has been enabled. OnCE operation is enabled by the assertion of the **jd_en_once** input See [Section 64.5.5.1, OnCE Enable \(jd_en_once\)](#).

64.5.8.1 External debug request during RESET

Holding the **jd_de_b** signal asserted during the assertion of **p_reset_b**, and continuing to hold it asserted following the negation of **p_reset_b** causes the e200z425n3 core to enter Debug mode. After receiving an acknowledge via the OnCE Status Register DEBUG bit, the external command controller should negate the **jd_de_b** signal before sending the first command. Note that in this case the e200z425n3 core does not execute an instruction before entering Debug mode, although the first instruction to be executed will be fetched prior to entering Debug mode in order to properly initialize the CPUSCR.

64.5.8.2 Debug request during RESET

Asserting a debug request by setting the DR bit in the OCR during the assertion of **p_reset_b** and then negating **p_reset_b** causes the chip to enter debug mode. In this case the CPU will fetch the first instruction of the reset exception handler in order to properly initialize the CPUSCR, but does not execute an instruction before entering debug mode.

64.5.8.3 Debug request during normal activity

Asserting a debug request by setting the DR bit in the OCR during normal chip activity causes the chip to finish the execution of the current instruction and then enter the debug mode. Note that in this case the chip completes the execution of the current instruction and stops after the newly fetched instruction enters the CPU instruction register. This process is the same for any newly fetched instruction including instructions fetched by the interrupt processing, or those that will be aborted by the interrupt processing.

64.5.8.4 Debug request during Waiting, Halted, or Stopped state

Asserting a debug request by setting the DR bit in the OCR when the chip is in the Waiting state (**p_waiting** asserted), Halted state (**p_halted** asserted) or Stopped state (**p_stopped** asserted) causes the CPU to exit the state and enter the debug mode once the CPU clock **m_clk** has been restored. Note that in this case, the CPU will negate the **p_waiting**, **p_halted** and **p_stopped** outputs. Once the debug session has ended, the CPU will return to the state it was in prior to entering debug mode.

To signal the chip-level clock generator to re-enable **m_clk**, the **p_wakeup** output will be asserted whenever the debug block is asserting a debug request to the CPU due to OCR_{DR} being set, or **jd_de_b** assertion, and will remain set from then until the debug session ends (**jd_debug_b** goes from asserted to negated). In addition, the status of the **jd_mclk_on** input (after synchronization to the **j_tclk** clock domain) may be sampled along with other status bits from the **j_tdo** output during the Shift_IR TAP controller state. This status may be

used if necessary by external debug firmware to ensure proper scan sequences occur to registers in the **m_clk** clock domain.

64.5.8.5 Software request during normal activity

Upon executing a '**bkpt**' pseudo-instruction (for e200z425n3, defined to be an all 0's instruction opcode) when the OCR register's (FDB) bit is set (debug mode enable control bit is true), and EDBCR0_{EDM}=1, the CPU enters the debug mode after the instruction following the '**bkpt**' pseudo-instruction has entered the instruction register.

64.5.8.6 Debug notify halt instructions

The **e_dnh** and **se_dnh** instructions allow software to transition the core from a running state to a debug halted state if enabled by EDBCR0_{DNH_EN}, and provide the external debugger with bits reserved in the instruction itself to pass additional information. Entry into debug mode is **not** conditioned on EDBCR0_{EDM}, allowing for debug of software debug handlers as well as other software. For e200z425n3, when the CPU enters a debug halted state due to a **e_dnh** or **se_dnh** instruction, the instruction will be stored in the CPUSCR[IR] portion, and the CPUSCR[PC] value will point to the instruction. The external debugger should update the CPUSCR prior to exiting the debug halted state to point past the **e_dnh** or **se_dnh** instruction.

64.5.9 CPU Status and Control Scan Chain Register (CPUSCR)

A number of on-chip registers store the CPU pipeline status and are configured in a single scan chain for access by the OnCE controller. The CPUSCR register contains these processor resources, which are used to restore the pipeline and resume normal chip activity upon return from the debug mode, as well as a mechanism for the emulator software to access processor and memory contents. [Figure 1582](#) shows the block diagram of the pipeline information registers contained in the CPUSCR. Once debug mode has been entered, it is required to scan in and update this register prior to exiting debug mode.

Figure 1582. CPU Scan Chain Register (CPUSCR)

64.5.9.1 Instruction Register (IR)

The Instruction Register (IR) provides a mechanism for controlling the debug session by serving as a means for forcing in selected instructions, and then causing them to be executed in a controlled manner by the debug control block. The opcode of the next instruction to be executed when entering debug mode is contained in this register when the scan-out of this chain begins. This value should be saved for later restoration if continuation of the normal instruction stream is desired.

On scan-in, in preparation for exiting debug mode, this register is filled with an instruction opcode selected by debug control software. By selecting appropriate instructions and controlling the execution of those instructions, the results of execution may be used to examine or change memory locations and processor registers. The debug control module external to the processor core will control execution by providing a single-step capability. Once the debug session is complete and normal processing is to be resumed, this register may be loaded with the value originally scanned out.

64.5.9.2 Control State Register (CTL)

The Control State Register (CTL) is a 32-bit register that stores the value of certain internal CPU state variables before the debug mode is entered. This register is affected by the

operations performed during the debug session and should normally be restored by the external command controller when returning to normal mode. In addition to saved internal state variables, two of the bits are used by emulation firmware to control the debug process. In certain circumstances, emulation firmware must modify the content of this register as well as the PC and IR values in the CPUSCR before exiting debug mode. These cases are described below.

Figure 1583. Control State Register (CTL)

*										IRSTAT14	IRSTAT13	IRSTAT12	IRSTAT11	IRSTAT10	WAITING	PCOFST				PCINV	FFRA	IRSTAT0	IRSTAT1	IRSTAT2	IRSTAT3	IRSTAT4	IRSTAT5	IRSTAT6	IRSTAT7	IRSTAT8	IRSTAT9
										10	11	12	13	14	15					16	17	18	19	20	21	22	23	24	25	26	27

Table 1483. CTL field descriptions

Bit	Name	Description
0:9	*	Internal State Bits These control bits represent internal processor state and should be restored to their original value after a debug session is completed, i.e when a OnCE command is issued with the GO and EX bits set and not ignored. When performing instruction execution during a debug session. See Section 64.5.5.3, OnCE Debug output (jd_debug_b) , which is not part of the normal program execution flow, these bits should be set to a 0.
10	IRSTAT14	IR Status Bit 14 This control bit indicates an MPU Instruction Address Compare event status for the IR. 0 No MPU Instruction Address Compare event occurred on the fetch of this instruction. 1 An MPU Instruction Address Compare event occurred on the fetch of this instruction.
11	IRSTAT13	IR Status Bit 13 This control bit indicates an Instruction Address Compare 8 event status for the IR. 0 No Instruction Address Compare 8 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 8 event occurred on the fetch of this instruction.
12	IRSTAT12	IR Status Bit 12 This control bit indicates an Instruction Address Compare 7 event status for the IR. 0 No Instruction Address Compare 7 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 7 event occurred on the fetch of this instruction.
13	IRSTAT11	IR Status Bit 11 This control bit indicates an Instruction Address Compare 6 event status for the IR. 0 No Instruction Address Compare 6 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 6 event occurred on the fetch of this instruction.
14	IRSTAT10	IR Status Bit 10 This control bit indicates an Instruction Address Compare 5 event status for the IR. 0 No Instruction Address Compare 5 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 5 event occurred on the fetch of this instruction.

Table 1483. CTL field descriptions (continued)

Bit	Name	Description
15	WAITING	WAITING State Status This bit indicates whether the CPU was in the waiting state prior to entering debug mode. If set, the CPU was in the waiting state. Upon exiting a debug session, the value of this bit in the restored CPUSCR will determine whether the CPU re-enters the waiting state on a go+exit. 0 CPU was not in the waiting state when debug mode was entered 1 CPU was in the waiting state when debug mode was entered
16:19	PCOFST	PC Offset Field This field indicates whether the value in the PC portion of the CPUSCR must be adjusted prior to exiting debug mode. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored into the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction instead of the original IR value, other wise the original value of IR should be restored. (But see PCINV, which overrides this field). 0000 No correction required. 0001 Subtract 0x04 from PC. 0010 Subtract 0x08 from PC. 0011 Subtract 0x0C from PC. 0100 Subtract 0x10 from PC. 0101 Subtract 0x14 from PC. All other encodings are reserved
20	PCINV	PC and IR Invalid Status Bit This status bit indicates that the values in the IR and PC portions of the CPUSCR are invalid. Exiting debug mode with the saved values in the PC and IR will have unpredictable results. Debug firmware should initialize the PC and IR values in the CPUSCR with desired values prior to exiting debug mode if this bit was set when debug mode was initially entered. 0 No error condition exists. 1 Error condition exists. PC and IR are corrupted.
21	FFRA	Feed Forward RA Operand Bit This control bit causes the content of the WBBR_{lo} to be used as the RA operand value (RS for logical, mtspr, mtdcr, cntlzw, and shift operations, RX for VLE se_ instructions, RT for e_{logical_op}2i type instructions, RB for evaddiw, evsubifw, and the value to use as the PC for calculating the LR update value for branch with link type instructions) of the first instruction to be executed following an update of the CPUSCR. For most LSP instructions using rA rB as a 64-bit source operand, WBBR_{hi, lo} is used to supply the 64-bit source value. This allows the debug firmware to update processor registers — initialize the WBBR_{lo} with the desired value, set the FFRA bit, and execute a ori Rx,Rx,0 instruction to the desired register. Note: not all instructions support using the FFRA control. FFRA is mainly intended for use with the ori instruction to allow the debugger to write to a GPR. Support for other instructions is implementation-dependent. 0 No action. 1 Content of WBBR_{lo} or WBBR_{hi,lo} used as operand value.

Table 1483. CTL field descriptions (continued)

Bit	Name	Description
22	IRSTAT0	IR Status Bit 0 This control bit indicates a TEA status for the IR. 0 No TEA occurred on the fetch of this instruction. 1 TEA occurred on the fetch of this instruction.
23	IRSTAT1	IR Status Bit 1 This control bit is reserved.
24	IRSTAT2	IR Status Bit 2 This control bit indicates an Instruction Address Compare 1 event status for the IR. 0 No Instruction Address Compare event 1 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 1 occurred on the fetch of this instruction.
25	IRSTAT3	IR Status Bit 3 This control bit indicates an Instruction Address Compare 2 event status for the IR. 0 No Instruction Address Compare 2 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 2 event occurred on the fetch of this instruction.
26	IRSTAT4	IR Status Bit 4 This control bit indicates an Instruction Address Compare 3 event status for the IR. 0 No Instruction Address Compare event 3 occurred on the fetch of this instruction. 1 An Instruction Address Compare event 3 occurred on the fetch of this instruction.
27	IRSTAT5	IR Status Bit 5 This control bit indicates an Instruction Address Compare 4 event status for the IR. 0 No Instruction Address Compare 4 event occurred on the fetch of this instruction. 1 An Instruction Address Compare 4 event occurred on the fetch of this instruction.
28	IRSTAT6	IR Status Bit 6 This control bit indicates a Parity Error status for the IR. 0 No Parity Error occurred on the fetch of this instruction. 1 Parity Error occurred on the fetch of this instruction from the I-Cache or the IMEM.
29	IRSTAT7	IR Status Bit 7 This control bit indicates a Precise External Termination Error status for the IR. 0 No Precise External Termination Error occurred on the fetch of this instruction. 1 A Precise External Termination Error occurred on the fetch of this instruction.
30	IRSTAT8	IR Status Bit 8 This control bit indicates the PowerISA VLE status for the IR. 0 IR contains a BookE instruction. (unused encoding) 1 IR contains a PowerISA VLE instruction, aligned in the Most Significant Portion of IR if 16-bit. <i>Note: This bit should not be modified by the debugger, otherwise the resulting operation is boundedly undefined. It should always indicate VLE (=1).</i>
31	IRSTAT9	IR Status Bit 9 This control bit is reserved.

Emulation firmware should modify the content of the CTL, PC, and IR values in the CPUSCR during execution of debug related instructions as well as just prior to exiting debug with a go+exit command. During the debug session, the CTL register should be written with the FFRA bit set as appropriate, and all other bit set to '0', and the IR set to the value of the

desired instruction to be executed. IRStat8 will be used to determine the type of instruction present in the IR.

Just prior to exiting debug mode with a go+exit, the PCINV status bit that was originally present when debug mode was first entered should be tested, and if set, the PC and IR initialized for performing whatever recovery sequence is appropriate for a faulted exception vector fetch. If the PCINV bit is cleared, then the PCOFST bits should be examined to determine whether the PC value must be adjusted. Due to the pipelined nature of the CPU, the PC value must be backed up by emulation software in certain circumstances. The PCOFST field specifies the value to be subtracted from the original value of the PC. This adjusted PC value should be restored in to the PC portion of the CPUSCR just prior to exiting debug mode with a go+exit. In the event the PCOFST is non-zero, the IR should be loaded with a nop instruction (such as **ori r0,r0,0**) instead of the original IR value, otherwise the original value of IR should be restored. Note that when a correction is made to the PC value, it will generally point to the last completed instruction, although that instruction will not be re-executed. The nop instruction is executed instead, and instruction fetch and execution will resume at location PC + 4. IRStat8 will be used to determine the type of instruction present in the IR, thus should be cleared in this case. Note that debug events that may occur on the nop (ICMP) will be generated if enabled.

For the CTL register, the internal state bits should be restored to their original value. The IRStatus bits should be set to '0's if the PC was adjusted. If no PC adjustment was performed, emulation firmware should determine whether other IRStat flags should be set to '0' to avoid re-entry into debug mode for an instruction breakpoint request. Upon exiting debug mode with go+exit, if one of these bits is set, debug mode will be reentered prior to any further instruction execution.

64.5.9.3 Program Counter (PC) register

The PC is a 32-bit register that stores the value of the program counter that was present when the chip entered the debug mode. It is affected by the operations performed during the debug mode and must be restored by the external command controller when the CPU returns to normal mode. PC normally points to the instruction contained in the IR portion of CPUSCR. If debug firmware wishes to redirect program flow to an arbitrary location, the PC and IR should be initialized to correspond to the first instruction to be executed upon resumption of normal processing. Alternatively, the IR may be set to a nop and the PC set to point to the location prior to the location at which it is desired to redirect flow to. On exiting debug mode, the nop will be executed, and instruction fetch and execution will resume at PC+4.

64.5.9.4 Write-Back Bus Register (WBBR_{low}, WBBR_{high})

WBBR is used as a means of passing operand information between the CPU and the external command controller. Whenever the external command controller needs to read the contents of a register or memory location, it will force the chip to execute an instruction that brings that information to WBBR. WBBR_{low} holds the 32-bit result of most instructions including load data returned for a load or load with update instruction. For LSP instructions that generate 64-bit results, WBBR_{low} holds the low-order 32 bits of the result. WBBR_{high} holds the updated effective address calculated by a load with update instruction. For LSP instructions that generate 64-bit results, WBBR_{high} holds the high-order 32 bits of the result. It is undefined for other instructions.

As an example, to read the 32 bits of processor register **r1**, an **ori r1,r1,0** instruction is executed, and the result value of the instruction will be latched into WBBR_{low}. The contents of WBBR_{low} can then be delivered serially to the external command controller. To update a

processor resource, this register is initialized with a data value to be written, and an **ori** instruction is executed, which uses this value as a substitute data value. The Control State register FFRA bit forces the value of the WBBR_{low} to be substituted for the normal RS source value of the **ori** instruction, thus allowing updates to processor registers to be performed. (Refer to [Section 64.5.9.2, Control State Register \(CTL\)](#) for more detail on the CTL_{FFRA} bit.)

WBBR_{low} and WBBR_{high} are generally undefined on instructions that do not writeback a result, and due to control issues are not defined on **lmw** or branch instructions as well.

64.5.9.5 Machine State Register (MSR)

The MSR is a 32-bit register used to read/write the Machine State Register. Whenever the external command controller needs to save or modify the contents of the Machine State Register, this register is used. This register is affected by the operations performed during the debug mode and must be restored by the external command controller when returning to normal mode.

64.5.9.6 Exiting Debug mode and interrupt blocking

When exiting debug mode with a Go+Exit, “asynchronous” interrupts are blocked until the first instruction to be executed begins execution. This includes External and Critical input, NMI, and machine check interrupts. Asynchronous debug interrupts are not blocked however, and the CPU will reenter debug mode without executing an instruction following Go+Exit, although it may fetch an instruction and discard it. Exceptions due to an illegal instruction or error flags set within the CPUSCR CTL register are not blocked, since they apply to the instruction in the CPUSCR IR.

64.5.10 Reserved registers (Reserved)

The reserved registers are used to control various test control logic. These registers are not intended for customer use. To preclude device and/or system damage, these registers should not be accessed.

64.6 Watchpoint support

e200z425n3 supports the generation and signalling of watchpoints when operating in internal debug mode (DBCR0_{IDM}=1) or in external debug mode (EDBCR0_{EDM}=1). Watchpoints are indicated with a dedicated set of interface signals. The **jd_watchpt[0:31]** output signals are used to indicate that a watchpoint has occurred. Certain watchpoints however (DEVENT-based, DTC-based, and Performance Monitor watchpoints) are not qualified with EDBCR0_{EDM} or DBCR0_{IDM}.

Each debug address compare function (IAC1–8, DAC1–4), as well as other event types are capable of triggering a watchpoint output. The DBCRx control fields are used to configure watchpoints, regardless of whether events are enabled in DBCR0. Watchpoints may occur whenever an associated event would have been posted in the Debug Status Register if enabled. No explicit enable bits are provided for watchpoints; they are always enabled by definition, although the data address compare watchpoints may be controlled for read and write accesses via configuration fields in DBCR4, 7, and 9. During a debug session, debug events (other than PMI, DEVT1 and DEVT2) with a corresponding DBSR bit are blocked from asserting a watchpoint. The Performance Monitor, DEVENT-based and DTC-based watchpoints are not blocked during a debug session. If not desired, for address-based

events the base address values for these events may be programmed to an unused system address. MSR_{DE} has no effect on watchpoint generation.

External logic may monitor the assertion of these signals for debugging or triggering purposes. Watchpoints are signaled in the clock cycle following the occurrence of the actual event. The Nexus3 module also monitors assertion of a portion of these output signals (**jd_watchpt[0:31]**) for various development control purposes. (See the “Watchpoint Trace Messaging” section in the Core (e200z425n3) Nexus 3 Module chapter.)

Note that these signals are **m_clk** domain signals, not **j_tclk** domain signals.

[Table 1484](#) shows the **jd_watchpt[0:31]** output signal assignments to various debug events.

Table 1484. Watchpoint output signal assignments

Signal Name	Type	Description
jd_watchpt[0]	IAC1	Instruction Address Compare 1 watchpoint Asserted whenever an IAC1 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[1]	IAC2	Instruction Address Compare 2 watchpoint Asserted whenever an IAC2 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[2]	IAC3	Instruction Address Compare 3 watchpoint Asserted whenever an IAC3 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[3]	IAC4	Instruction Address Compare 4 watchpoint Asserted whenever an IAC4 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[4]	DAC1	Data Address Compare 1 watchpoint Asserted whenever a DAC1 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC1CFG}$ settings
jd_watchpt[5]	DAC2	Data Address Compare 2 watchpoint Asserted whenever a DAC2 compare occurs regardless of being enabled to set DBSR status, based on $DBCR4_{DAC2CFG}$ settings
jd_watchpt[6]	DAC3	Data Address Compare 3 watchpoint Asserted whenever a DAC3 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC3CFG}$ settings
jd_watchpt[7]	DAC4	Data Address Compare 4 watchpoint Asserted whenever a DAC4 compare occurs regardless of being enabled to set DBSR status, based on $DBCR7_{DAC4CFG}$ settings
jd_watchpt[8]	IAC5	Instruction Address Compare 5 watchpoint Asserted whenever an IAC5 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[9]	IAC6	Instruction Address Compare 6 watchpoint Asserted whenever an IAC6 compare occurs regardless of being enabled to set DBSR status

Table 1484. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[10]	DEVT1	Debug Event Input 1 watchpoint Asserted whenever a DEVT1 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[11]	DEVT2	Debug Event Input 2 watchpoint Asserted whenever a DEVT2 debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[12]	DEVNT0	Debug Event Output 0 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[12]
jd_watchpt[13]	DEVNT1	Debug Event Output 1 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[13]
jd_watchpt[14]	IAC7	Instruction Address Compare 7 watchpoint Asserted whenever an IAC7 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[15]	IAC8	Instruction Address Compare 8 watchpoint Asserted whenever an IAC8 compare occurs regardless of being enabled to set DBSR status
jd_watchpt[16]	IRPT	Interrupt watchpoint Asserted whenever an IRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[17]	RET	Return watchpoint Asserted whenever a RET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[18]	CIRPT	Critical Interrupt watchpoint Asserted whenever a CIRPT debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[19]	CRET	Critical Return watchpoint Asserted whenever a CRET debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[20]	DEVNT2	Debug Event Output 2 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[20]
jd_watchpt[21]	DEVNT3	Debug Event Output 3 watchpoint Asserted whenever a '1' is written to the bit of the DEVNT field of the DEVENT debug register corresponding to jd_watchpt[21]
jd_watchpt[22]	PMEVENT	Performance Monitor Event input watchpoint Asserted whenever p_pm_event transitions from a '0' to a '1' while m_clk is running
jd_watchpt[23]	PMC0	Performance Monitor Counter 0 watchpoint Asserted whenever PMC0 triggers an event based on PMLCa0 _{PMP}
jd_watchpt[24]	PMC1	Performance Monitor Counter 1 watchpoint Asserted whenever PMC1 triggers an event based on PMLCa1 _{PMP}

Table 1484. Watchpoint output signal assignments (continued)

Signal Name	Type	Description
jd_watchpt[25]	PMC2	Performance Monitor Counter 2 watchpoint Asserted whenever PMC2 triggers an event based on PMLCa2 _{PMP}
jd_watchpt[26]	PMC3	Performance Monitor Counter 3 watchpoint Asserted whenever PMC3 triggers an event based on PMLCa3 _{PMP}
jd_watchpt[27]	MPU	Memory Protection Unit watchpoint Asserted whenever a the MPU generates a debug event based on region descriptor matches with DEBUG control enabled.
jd_watchpt[28]	TRAP	TRAP watchpoint Asserted whenever an TRAP debug event occurs regardless of being enabled to set DBSR status
jd_watchpt[29]	DTC1	Data Trace Control Range 1 watchpoint Asserted whenever an access meets the conditions for DTC Range 1
jd_watchpt[30]	DTC2	Data Trace Control Range 2 watchpoint Asserted whenever an access meets the conditions for DTC Range 2
jd_watchpt[31]	DTC3	Data Trace Control Range 3 watchpoint Asserted whenever an access meets the conditions for DTC Range 3

64.7 MPU operation during debug

A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may substitute default values obtained from the OnCE Control Register for Access Attribute (I, G) bits. Refer to the bit definitions in the OCR ([Section 64.5.6.3, OnCE Control Register \(OCR\)](#)) for more detail.

Normal operation of the MPU may be modified during a 'debug session' via the OnCE Control Register (OCR). A debug session begins when the CPU initially enters debug mode, and ends when a OnCE command with GO+EXIT is executed, releasing the CPU for normal operation. If desired during a debug session, the debug firmware may disable the MPU protection mechanism and may substitute default values for the Access Protection (UX, UR, UW, SX, SR, SW) bits, and values obtained from the OnCE Control Register for Memory Attributes (I, G) bits normally provided by a matching MPU entry.

When disabled during a debug session, no MPU-related storage interrupt conditions will occur. If the debugger desires to use the normal protection mechanism, the MPU may be left enabled in the OnCE OCR, and normal protections provided by the MPU (including the possibility of a storage interrupt) will remain in effect.

The OCR control bits are used when debug mode is entered. Refer to the bit definitions in the OCR ([Section 64.5.6.3, OnCE Control Register \(OCR\)](#)) for more detail. When the MPU is disabled for instruction accesses (OCR_{I_DMDIS}) or for data accesses (OCR_{D_DMDIS}), substituted access attribute bits will control operation on respective accesses initiated during debug.

64.8 Cache array access during debug

The cache arrays may be read and written during debug mode via the CDACNTL and CDADATA debug registers.

64.9 Basic steps for enabling, using, and exiting External Debug mode

The following steps show one possible scenario for a debugger wishing to use the external debug facilities. *This simplified flow is intended to illustrate basic operations, but does not cover all potential methods in depth.*

Enabling External Debug mode and initializing debug registers:

- The debugger should ensure that the **jd_en_once** control signal is asserted in order to enable OnCE operation.
- Select the OCR and write a value to it in which OCR_{DR} , OCR_{WKUP} are set to '1'. The tap controller must step through the proper states as outlined earlier. This step will place the CPU in a debug state in which it is halted and awaiting single-step commands or a release to normal mode
- Scan out the value of the OSR to determine that the CPU clock is running and the CPU has entered the Debug state. This can be done in conjunction with a Read of the CPUSCR. The OSR is shifted out during the Shift_IR state. The CPUSCR will be shifted out during the Shift_DR state. The debugger should save the scanned-out value of CPUSCR for later restoration.
- Select the DBCR0 register and update it with the $EDBCR0_{EDM}$ bit set.
- Clear the DBSR status bits.
- Write appropriate values to the DBCR0–8, IAC, and DAC registers. Note that the initial write to DBCR0 will only affect the EDM bit, so the remaining portion of the register must now be initialized, keeping the EDM bit set.

At this point the system is ready to commence debug operations. Depending on the desired operation, different steps must occur.

- Optionally, ensure that the values entered into the MSR portion of the CPUSCR during the following steps cause interrupt to be disabled (clearing MSR_{EE} and MSR_{CE}). This will ensure that external interrupt sources do not cause single-step errors.

To single-step the CPU:

- debugger scans in either a new or a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Section 64.5.9.2, Control State Register \(CTL\)](#)), with a Go+Noexit OnCE Command value.
- The debugger scans out the OSR with “no-register selected”, Go cleared, and determines that the PCU has reentered the Debug state and that no ERR condition occurred.

To return the CPU to normal operation (without disabling external debug mode)

- The OCR_{DR} control bit should be cleared, leaving the OCR_{WKUP} bit set.
- The debugger restores the CPUSCR with a previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Section 64.5.9.2, Control State Register \(CTL\)](#)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

To exit External Debug mode

- The debugger should place the CPU in the debug state via the OCR_{DR} with OCR_{WKUP} asserted, scanning out and saving the CPUSCR.
- The debugger should write the DBCR0–8 registers as needed, likely clearing every enable except the EDBCR0_{EDM} bit.
- The debugger should write the DBSR to a cleared state.
- The debugger should rewrite the DBCR0 with all bits including EDM cleared.
- The debugger should clear the OCR_{DR} bit.
- The debugger restores the CPUSCR with the previously saved value of the CPUSCR (with appropriate modification of the PC and IR as described in [Section 64.5.9.2, Control State Register \(CTL\)](#)), with a Go+Exit OnCE Command value.
- The OCR_{WKUP} bit may then be cleared.

Note: These steps are meant by way of examples, and are not meant to be an exact template for debugger operation.

65 Debug and Calibration Interface (DCI)

65.1 Introduction

The Debug and Calibration Interface (DCI) module provides debug and calibration features for the MCU. It includes a standard 1149.1/1149.7 compatible JTAG interface which is used to connect with an external JTAG tool using a low frequency clock interface.

To provide high-speed calibration capability, the DCI also provides a mechanism to use 5-pin LFAST debug tool which shares its pins with the standard JTAG interface.

It also features a software based debug mode which can be controlled by the MCU without using an external tool. Additionally, the DCI provides features for debug control using break-points and synchronous restart of the cores. This chapter describes the DCI features for the Production device (PD) only (information about the Buddy device (BD) is not included).

65.1.1 Features

The DCI features are the following:

- Debug mode enable control for connected tool or software
- Port sharing logic to allow the 5-pin debug port to be shared between the JTAG and the LFAST
- 1149.1 and 1149.7 controllers
- Debug break and cross-triggering control
- Synchronous restart control for all CPUs when exiting debug mode
- Tool hot plug capability
- Security access control
- Debug reset control

65.1.2 Overview

The DCI can take the following different inputs for its JTAG signals:

- P.JTAG—JTAG signals coming from the Production device JTAG pads. This is the standard 5-pin JTAG interface and is the default operating mode.
- M.JTAG—JTAG signals generated by JTAGM module using LFAST or software debug mode.
 - When using LFAST with a connected calibration/debug tool, JTAG packets are received from the tool via LFAST and output JTAG packets are transmitted back to the tool. The LFAST's 5-pin interface consists of an LVDS pair for transmit signals, an LVDS pair of receive signals and a reference clock output signal.
 - In software debug mode, there is no tool, and debug software running on the MCU generates the JTAG packets and writes them to JTAGM using special debug registers in the JTAGM module.

By default the DCI operates in standard 5-pin JTAG mode (IEEE 1149.1). It can be configured in 3-pin reduced pin JTAG mode (IEEE 1149.7) after starting from standard 5-pin JTAG mode. The LFAST-based debug interface shares its five pins with the standard JTAG pins.

When reduced pin JTAG mode (IEEE 1149.7) is configured TMSC pin is configured in bidirectional mode during operation.

As the LFAST-based debug interface shares its five pins with JTAG pins, the DCI provides a safe switching logic to switch to LFAST-based debug mode.

The DCI also provides a centralized break control for system IPs and cores, which can be controlled by an external tool as well as the internal debug peripherals such as GTM/SPU, etc. The DCI also provides the Event Out (EVTO) signals to the debug tool in case of the occurrence of any internal debug event.

Figure 1584 shows the DCI block diagram.

Figure 1584. DCI block diagram

Figure 1585 shows the DCI configuration for the standard production package.

Figure 1585. DCI in a standard configuration

65.1.3 Operating modes

Selection between various JTAG sources is done using a JTAG register bit, DCI_CR[EN_LFAST], and a JTAGM register bit, JTAGM_MCR[DTM]. The JTAG bit, DCI_CR[EN_LFAST], can only be programmed using JTAG instructions and is used to select standard JTAG or LFAST debug tool. The JTAGM bit, JTAGM_MCR[DTM], is programmable via memory-mapped registers. JTAGM is selected as a JTAG source when either DCI_CR[EN_LFAST] or JTAGM_MCR[DTM] is set.

[Table 1485](#) shows a summary of the configuration options.

Table 1485. DCI JTAG source selection

DCI_CR[EN_LFAST]	JTAGM_MCR[DTM]	DCI Source	JCOMP
0	0	P.JTAG (Standard JTAG)	Asserted
1	x	M.JTAG (LFAST)	Asserted
x	1	M.JTAG (Software)	Negated

The reset signal to the DCI block consists of the following:

- Power-on reset, Low/High voltage detection on IO/Core supplies
- JCOMP reset

The DCI puts the JTAGC TAP in reset when either power-on/low-voltage-detect reset is asserted or JCOMP is negated.

The M.JTAG provides an alternate interface to the debug logic.

When enabled, it allows high speed debug through the LFAST and JTAGM modules. The high speed link uses LFAST commands that are translated to JTAG commands in the

JTAGM module. The selection between LFAST based debug or software based debug is managed in the JTAGM. However, it is important to note that the dynamic switching between tool-based debug and software debug is not allowed. Software based debug is done only in those cases when an external tool is not present.

An LFAST based tool starts in JTAG mode and then switches to LFAST mode. This switching is managed through a control set of operations which is described in [Section 65.1.3.1, Port sharing between JTAG and LFAST modes](#). During the switch from JTAG to LFAST and back, the DCI uses a latched value of JCOMP to prevent all debug configuration reset.

The LFAST uses LVDS ports for LFAST communication and the JTAG ports uses CMOS level GPIOs. These signals are double-bonded to share the same pins at the tool interface. [Table 1486](#) shows the port mapping.

When no debug tool is connected, device power-on reset puts the DCI in standard 5-pin JTAG mode. This configures the TDO pin in output mode with the reset value (1'b0). There is no change in port values if no debug tool is connected.

Table 1486. DCI LFAST/JTAG port sharing

JTAG pad	Type in JTAG mode	LFAST pad	Type in LFAST mode
TDI	Input	LVDS TxN	Output
TMS	Input	LVDS TxP	Output
TDO	Output	LVDS RxP	Input
JCOMP	Input	LVDS RxN	Input
TCK	Input	DRCLK	Output

[Figure 1586](#) shows the DCI mode switching operation.

Figure 1586. DCI operating modes state diagram

Note: `.JTAGM_MCR[jtagm_JCOMP]` should not be asserted in LFAST mode to avoid any undesired behavior.

[Table 1487](#) contains the operating mode descriptions.

Table 1487. DCI operating modes

Mode	Description
DCI_JTAG	JTAG mode. This is the default state after power-on reset. In this mode the DCI is in JTAG mode (controlled with P.JTAG) and is controlled by an external JTAG tool.
DCI_SW_DBG	Software Debug State. This state is achieved when no tool is present and software sets the JTAGM_MCR[DTM] bit. The DCI is then controlled using M.JTAG signals.
DCI_JTAG_SAFE	SAFE_JTAG state. When an external tool sets the DCI_CR[EN_LFAST] bit, this indicates that the external tool is going to switch to the LFAST mode. The external tool puts the DCI in Run-Test-Idle state to start the switching operation. To enable safe switching operation, the DCI enters the JTAG_SAFE state where it performs the following operations: – JCOMP is latched inside to control until switching gets completed – The DCI releases control of the JTAG ports and uses high on TMS inside, thus keeping the DCI in the Run-Test-Idle state – An internal counter starts to count to a tool specified value as programmed in DCI_CR[SWITCH_CNTR1].
DCI_LFAST_SWITCH	LFAST port switching state. In this state, the DCI asserts the enable signal to indicate to the LFAST that it is now ready for LFAST port switching. In this mode, the LFAST Rx pads are enabled. The switch counter starts another count operation to count to the DCI_CR[SWITCH_CNTR2] value.
DCI_LFAST	LFAST mode with escape mode enabled. This mode indicates that the switching is now completed and the debug tool is operating in the LFAST mode. However, there is another feature called Escape Mode, which enables the LFAST pads to detect any disconnection fault on its Rx pads. When these pads are working in Escape Mode, a sensing logic is enabled in the pad which detects and flags any out of common mode voltage range for the Rx pads. If this flag is asserted, it is used to force the DCI to go to LFAST_SAFE mode to ensure safe switching to the JTAG state.
DCI_LFAST_SAFE	LFAST_SAFE mode. While the tool is switching from LFAST mode to JTAG mode, it resets the DCI_CR[EN_LFAST] bit. The external tool puts the DCI in the Run-Test-Idle state to start the switching operation. To account for the switching time for the pads, the DCI enters in a safe LFAST state. It then restarts a counter to count to a tool specified value in DCI_CR[SWITCH_CNTR1], and disables both the LFAST function on the pads and the LFAST module.

Figure 1587 shows a block diagram of the JTAG/LFAST connections.

Figure 1587. DCI JTAG/LFAST switch integration

65.1.3.1 Port sharing between JTAG and LFAST modes

By default the DCI is configured in JTAG mode using the standard JTAG port (P.JTAG). Therefore, the initial configuration is done using low speed JTAG signals. In order to switch from JTAG mode to LFAST mode, the tool accesses the following fields in the DCI control register (DCI_CR):

- EN_LFAST—Bit to indicate enable/disable LFAST mode
- SWITCH_CNTR1 and SWITCH_CNTR2—Bit fields to program a count value that corresponds to the delay for switching the pin functions when changing modes.

As the JTAG to LFAST mode switching reflects change in port input/output behavior, it is done through a controlled procedure. The DCI_CR is only accessible through JTAG sequences. While switching from JTAG to LFAST mode, the tool programs this register via P.JTAG to enable switching to LFAST mode. As the pins are shared between JTAG and LFAST functions, a programmable delay based on switch counters is required which allows a safe switching for the MCU as well as for the tool to change its mode. In LFAST mode, the tool can write this register to switch back from high speed debug to low speed debug. Again, the similar switching delay mechanism is used. The switching schematic is shown in [Figure 1588](#).

A programmable switching delay and tri-stating port pins during switching allow a connected tool to safely tune the device turn-around of pin functions from JTAG mode to LFAST mode and vice versa. These delays are programmed according to the time required by the tool to change its operation from JTAG mode to LFAST and vice versa. This reduces the possibility of device damage during switching.

The programmable counter uses the LFAST system clock as the clock source.

Figure 1588. DCI switching between JTAG and LFAST modes

65.1.3.1.1 Switching from JTAG mode to LFAST mode

The steps to switch operation from JTAG to LFAST mode are as follows:

1. System starts in port JTAG mode after power-on-reset.
2. External tool programs the following bits in the DCI_CR:
 - EN_LFAST
 - SWITCH_CNTR1
 - SWITCH_CNTR2
3. Tool puts JTAG TAP in the Run-Test-Idle mode.
4. An internal finite state machine (FSM) starts the switching operation using the LFAST reference clock. The switching process takes four LFAST reference clocks to start, and an external tool should not change the JTAG signals during this period. The DCI forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. The DCI also triggers a switching counter to allow for some time for the tool to change its mode from JTAG to LFAST.
5. After the counter counts to the DCI_CR[SWITCH_CNTR1] value, the LFAST IP and LFAST pads are enabled. Then the counter is reset. Also, internally JTAGM is selected as the JTAG source for the DCI.
6. Counter counts to the DCI_CR[SWITCH_CNTR2] value to enable the Escape mode feature for the LFAST Rx pads. This time allows the tool to settle down in LFAST mode.
7. Tool starts LFAST transmission when it detects pulses on the DRCLK pin. Tool now can use the LFAST to program the JTAGM to generate JTAG sequences.

Figure 1589 shows the timing sequence.

Figure 1589. DCI JTAG to LFAST switching diagram

65.1.3.1.2 Switching from LFAST mode to JTAG mode

The steps to switch operation from LFAST to JTAG mode are as follows:

1. External tool programs the DCI_CR to reset the EN_LFAST bit and SWITCH_CNTR1 for the switching delay.
2. Tool puts JTAG TAP in the Run-Test-Idle mode.
3. An internal FSM starts switching operation. It forces TMS to 0 and JCOMP to 1 internally so as not to change JTAG TAP status during switching. It also triggers a switching counter to count to DCI_CR[SWITCH_CNTR1] to allow for the tool to change its mode from LFAST to JTAG.
4. After the counter overflows, the JTAG pads are enabled and JTAGM releases its control for the DCI JTAG source.

[Table 1491](#) and [Table 1493](#) summarize the MCU and tool behaviors. [Figure 1590](#) shows the timing sequence.

Figure 1590. DCI LFAST to JTAG switching diagram

65.1.3.2 VSS detection

When the LFAST pads are operating in Escape mode, a sensing logic is enabled in the pad which detects and flags any disconnection of the LFAST Rx pads. This flag, if asserted, is used to force the DCI to go to JTAG mode to ensure safe operation. This flag, when asserted, also resets the JTAG TAP to restart in JTAG mode and the EN_LFAST bit is reset accordingly. This flag resets only JTAG TAPs and does not affect any Nexus blocks.

This feature is enabled only when DCI_CR[EN_ESC_MODE] is set. By default this feature is not enabled. To tune the tool behavior it is possible to emulate the pad fault using the DCI_CR[FLVDS_PAD_FLT] bit.

65.1.3.3 Software enabled debug and calibration mode

Apart from the JTAG sources, such as a JTAG-based tool or LFAST-based tool, it is possible to generate JTAG sequences through software programming using JTAGM IP. The JTAGM, which generates JTAG sequences using LFAST protocol, is also used to generate JTAG sequences using software programming.

To support a software debug session via a CAN or SPI link, the software can enable debug and calibration mode via an memory-mapped register. It is done first by setting a control bit in the JTAGM (JTAGM_MCR[DTM]). For more details, refer to the JTAGM documentation. When enabled, the DCI is configured to receive M.JTAG signals which are driven by JTAGM registers accessible through software. Software can control all DCI features like any other JTAG source.

After a system reset, the JTAGM_MCR[DTM] bit is reset and the JCOMP pad is pulled-low, thus keeping the DCI in the reset state. Therefore, software is required to first change to a non-secured mode. Then it can program the JTAGM_MCR[DTM] bit, to select M.JTAG as the source inside the DCI, and then set the JTAGM_MCR[jtagm_JCOMP] bit present in the JTAGM, which takes all debug modules out of reset.

There is a software programmable bit, MCR[jtagm_JCOMP], present in JTAGM block which, when programmed to 0, asserts reset for the JTAGC block, thus putting the debug and calibration logic in reset state. This bit is used during software based debug to initialize the debug and calibration logic.

Software based debug is not possible when a tool is connected. The presence of the tool is determined using the rising edge of the JCOMP pad to set an internal flag which, when set, disables the selection of JTAGM as a JTAG source.

Note: .It is recommended to utilize either hardware based debug (JTAG or LFAST) or software based debug. If only one of the debug method is used, all three connection methods (connect and reset target, connect and break application, connect and keep application running) are supported.

If both debug methods are used simultaneously, then an external tool may arbitrarily connect when the SoC has already been halted using the software debug mode. In this case, two consecutive assertions of external JCOMP are necessary to allow the external tool to take control of debug session.

65.1.3.4 Nexus reset control

The JCOMP input that is used as the primary reset signal for the DCI is also used by the DCI to generate a single-bit reset signal for other Nexus blocks. It is used to reset all debug functions without affecting any system level functions. The DCI provides the reset signal for all Nexus blocks. This reset is controlled using the following signals:

- Power-on reset/Low voltage detect
- JCOMP
- SoC Debug_Enable signal
- System PLL is out of lock state and not bypassed

Asserting power-on reset, negating JCOMP, or negating the Debug_Enable signal, results in asynchronous entry into reset state. Following negation of power-on reset, the Nexus reset signal remains asserted until the system clock achieves lock or in bypass mode, as indicated by the system clock lock status signal, and Debug_Enable is asserted and JCOMP is asserted. Any subsequent loss of PLL lock does not generate a Nexus reset.

This reset signal is unaffected by other sources of reset. If Debug_Enable is de-asserted by the SoC security modules (HSM or PASS), then the DCI holds the debug and trace logic in reset. The Debug_Enable signal is generated by security logic after functional or destructive reset based on the device censored mode, the PASS_LOCK3[DBL] control, and the device life cycle. If the Debug_Enable signal is asserted by the security logic, it is possible to trace through functional resets

The following table shows how the Nexus reset is asserted/negated based on various signals.

Table 1488. Nexus reset truth table

POR	JCOMP	Debug_Enable	PLL lock	Nexus reset
Assert	X	X	X	Assert
X	Negate	X	X	Assert
X	X	Disable	X	Assert
X	X	X	Unlocked	Assert
Negate	Assert	Enable	Locked	Negate

65.1.3.5 System watchdog control

The DCI is also used to enable or disable the Software Watchdog Timer (SWT). The DCI provides a single bit SWT enable signal which is used to control all SWTs in the MCU. For this, the EVTI[0] pin is used. If the EVTI[0] pin remains high when the tool asserts JCOMP, then the SWT is enabled. But if the tool drives the EVTI[0] pin low before asserting JCOMP pin, then the SWT is disabled. By default the SWT is enabled and a tool has an option to enable/disable the SWT using the EVTI[0] pin.

65.1.3.6 Break control

The DCI provides central break control among the CPUs and non-CPU debug modules such as GTM, DMA, Watchdog and other peripherals.

There are various different input sources that provide debug requests:

- [BLG_DCI_0016][Covers: ADD23.025][Covers: ADD23.029][Covers: ADD23.134]EVTI[1:0] signals from EVTI pads[end]
- EVTI[1:0] signals from JTAGM
- EVTI[1:0] signals from the Sequence Processing Unit (SPU)

The DCI generates following debug request signals:

- Debug Request signal to be used for all non-CPU peripherals
- External Debug Request to be used to request external debug event to processor cores
- OnCE Debug Request to be used to request OnCE debug event to processor coresAll break control requests are issued simultaneously to CPUs and peripherals, then synchronized to each clock domain

Figure 1591. DCI debug control mechanism

The various sources of $\overline{\text{EVTI}}[1:0]$ inputs are synchronized and logically ANDed in the DCI to generate two debug requests $\text{DCI_EVTI}[1:0]$ for the processor cores and non-CPU peripherals. Of these two inputs, $\text{EVTI}[0]$ is used to generate debug requests for non-CPU peripherals and for processor cores through the external debug request signal. The other input, $\text{EVTI}[1]$, is also used to generate debug requests for non-CPU peripherals and it generates debug requests to processor cores through the OnCE debug request signal.

The external debug request to processor core is asserted as a single cycle pulse and is synchronized on the respective core clock. The OnCE debug request is negated when the acknowledge signal from the Cores is asserted. The CPU(s) remain in the debug state until GO+EX command is executed for that CPU. Exiting a CPU out of debug state by executing GO+EX command does not take other CPUs out of debug state. The peripheral debug request is negated when the processor core(s) execute GO+EXIT command. The $\text{EVTI}[1:0]$ signals coming from the pads are enabled for debug control using $\text{DCI_CR}[5:4]$ bits.

In order to selectively enable/disable debug requests to system peripherals, the respective debug enable bit inside the peripheral should be used.

[Figure 1592](#) shows the timing sequence.

Figure 1592. DCI debug signal generation

65.1.3.7 Cross-triggering control

Many of the blocks in the device, including the Nexus trace blocks and more sophisticated peripherals, have debug features that allow them to request device-wide breaks to enter debug mode. Many blocks can be programmed to halt operation upon debug mode entry or ignore it and continue normal operation. All debug mode entry requests are input to the DCI, ORed together and the result is used to produce the debug requests to the CPUs and non-CPU peripherals.

The cross-triggering feature is implemented through selectively enabling debug control bits in the respective modules. Processor cores (enabled using DBCR0[DEVT1] bit) and non-core peripherals can be programmed to halt operation through their respective control bits. Cross-triggering provides a selective feature to put modules in debug mode upon receiving halt request signals from Nexus modules.

65.1.3.8 Synchronous restart control

The DCI implements a synchronous restart control feature to synchronously restart all debug peripherals (CPU and non-CPU peripherals which are put in debug state). This is accomplished with the following steps:

1. The tool sequentially scans into CPUSCR for each processor core to restore the proper processor state.
2. The tool scans into the Production device tap controller the AUX_PARALLEL instruction, which then selects all processor core tap controllers in parallel.
3. To synchronously exit any combination of processor cores from debug mode, the tool simultaneously scans into all processor core tap instruction registers (OCMD) the 10-bit sequence 0x180 (i.e. set GO and EX, clear RS[0:6]).
4. If a processor core is out of debug mode, it sets a flag OnCE GO+EXIT.
5. When the OR of the processor core OnCE GO+EXIT signals is asserted, then all other selected non-processor cores and peripherals in debug would also be synchronously exited from debug mode. It is done by negating peripheral debug request signal.

65.1.3.9 EVTO management

The EVTO management block diagram is presented in [Figure 1593](#).

Figure 1593. DCI EVTO management

The DCI module controls sharing of the EVTO outputs between all Nexus Clients including the cores that produce $\overline{\text{EVTO}}[1:0]$ signals. The DCI uses a high frequency clock to sample EVTO signals coming from all modules which might generate EVTO outputs at their own clock frequency. After receiving a single clock period of asserted $\overline{\text{EVTO}}[1:0]$ signals from any Nexus client, the DCI immediately asserts $\overline{\text{EVTO}}[1:0]$ outputs and stretches it for a minimum of one output clock period for the output to the tool ([Figure 1594](#)). The DCI also generates EVTO outputs in other device clock domains so that other Nexus clients can receive EVTO inputs without the need of any synchronization. EVTO function is active as long as the DCI is not in reset.

The DCI also allows the GTM to take control of the EVTO outputs by controlling the EOS0/EOS1 fields of the GTMDI_DC register. If these fields are programmed to HALT/TIM/TOM/ATOMEVTO value, the GTM EVTO outputs are directly available on the ports bypassing the stretch logic.

Figure 1594. DCI EVTO timing diagram

65.1.3.10 Reset control

The DCI includes control bits to allow a connected tool to force a reset of the connected device. The description is as follows:

- [BLG_DCI_0038][Covers: ADD23.026][Covers: ADD23.032]Force functional reset—This reset is generated by programming the DCI_CR[FPD_FUNC] bit. When set, it forces functional reset. This bit has to be reset by the tool to negate the reset signal.[end]
- [BLG_DCI_0043][Covers: ADD23.026][Covers: ADD23.032]Force POR or destructive reset—This reset is generated by programming DCI_CR[FPD_DEST] bit. When set it forces destructive reset. This bit has to be reset by the tool to negate the reset signal.[end]

These reset signals are directly connected to the respective DCI_CR bits. The DCI does not reset the DCI_CR bits after generation of the respective reset signals. The tool must specifically reset the appropriate DCI_CR bits to remove the reset signals. These reset control bits can be set/reset through JTAG programming, and only reset through JCOMP assertion or Power-on-reset.

65.1.3.11 Security

The SoC security logic provides a Debug_Enable signal to the DCI. The DCI uses the Debug_Enable signal as a control input to generate debug module reset. When debug disable is requested, the DCI keeps all debug blocks in the reset state. This is a protection mode used to disable debug accesses to the peripheral when the device is in a secured state.

65.2 External signal description

The JTAGC module used inside DCI module defines the interface with external signals. It consists of five signals (TMS/TDI/TDO/TCK/JCOMP) that connect to off chip development tools and allow access to test support functions. For more details for JTAG signals, refer to JTAGC documentation.

65.3 Register description

The PD DCI module contains two registers, DCI_CR and DCI_PINCR, which are present inside the JTAGC module. These registers are only controlled using the JTAGC TAP and no memory-mapped registers are present.

65.3.1 DCI control register (DCI_CR)

The DCI_CR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. [Figure 1595](#) shows the format of the DCI_CR.

Figure 1595. DCI control register (DCI_CR)

15:11 SWITCH_CNTR1	Width of Switch_CNTR1. Decides the first timeout value while switching from JTAG to LFAST mode, and the timeout value while switching from LFAST mode to JTAG mode. The maximum timeout duration = $32 \times T_{lfast_sysclk}$

Table 1489. DCI_CR field descriptions (continued)

Field	Description
10 FLVDS_PAD_FLT	Force LVDS Pad Fault. Forces the pad fault condition to tune the tool without actually having the pad fault on LFAST Rx pads. This bit is effective only when DCI_CR[EN_ESC_MODE] is set. 0 Do not force Rx LVDS Pad Fault 1 Force Rx LVDS Pad Fault if DCI_CR[EN_ESC_MODE] is set
9 FPD_FUNC	Force Functional reset 0 Do not force functional reset 1 Force functional reset
8 FPD_DEST	Force Destructive reset 0 Do not force destructive reset 1 Force destructive reset
6 FORCE_LFAST	Force enable for LFAST 0 LFAST not forced to enable and is controlled using DCI_CR[EN_LFAST] bit 1 LFAST forcefully enabled (without using DCI_CR[EN_LFAST] bit)
5 EVTI1_PAD_EN	$\overline{\text{EVTI}}[1]$ feature enable 0 $\overline{\text{EVTI}}[1]$ disabled (default) 1 $\overline{\text{EVTI}}[1]$ enabled
4 EVTI0_PAD_EN	$\overline{\text{EVTI}}[0]$ feature enable 0 $\overline{\text{EVTI}}[0]$ disabled (default) 1 $\overline{\text{EVTI}}[0]$ enabled
3 EVTO1_PAD_EN	Output enable for $\overline{\text{EVTO}}[1]$ pad 0 $\overline{\text{EVTO}}[1]$ pad output not enabled (default) 1 $\overline{\text{EVTO}}[1]$ pad output enabled
2 EVTO0_PAD_EN	Output enable for $\overline{\text{EVTO}}[0]$ pad 0 $\overline{\text{EVTO}}[0]$ pad output not enabled (default) 1 $\overline{\text{EVTO}}[0]$ pad output enabled
1 EN_ESC_MODE	Enable Escape Mode. Fault detect feature enable for LFAST Rx pads 0 Fault detect feature not present for LFAST Rx pads (default) 1 Fault detect feature present for LFAST Rx pads and are enabled after the successful switching to LFAST mode
0 EN_LFAST ⁽¹⁾	Enable for LFAST-based tool selection. This bit can be reset either by programming by tool, or pad fault condition in which JTAGC block is reset. 0 LFAST tool not enabled. DCI operates in JTAG mode (default) 1 LFAST tool enabled

1. DCI_CR is a JTAG data register and is not accessible for software read. However, the DCI_CR[EN_LFAST] bit is mapped to JTAGM register bit JTAGM_SR[1] to allow for software read access and a mechanism for software to be aware of an active debug tool interface.

65.3.2 DCI EVTx pin multiplexing control register (DCI_PINCR)

The DCI_PINCR is a 32-bit data register. This register is programmed using JTAG shift with the corresponding enable instruction described in the JTAGC chapter. For a description of the DCI_PINCR functionality, see the Calibration and Debug configuration chapter which describes how the modules are configured.

65.4 Functional description

65.4.1 DCI mode transition

After power-on reset, the DCI starts in JTAG mode. To enable LFAST mode, the external tool has to first operate in JTAG mode, configure DCI and then switch to LFAST mode. This requires certain careful steps so as to avoid any contention on double-bonded pads for JTAG/LFAST. [Table 1490](#) and [Table 1491](#) show the steps and expected states for the MCU and tool for JTAG to LFAST switching. [Table 1492](#) and [Table 1493](#) contains the different steps, and the MCU and tool expected states for the LFAST to JTAG switching.

Table 1490. MCU operation (JTAG to LFAST switching)

MCU pin	JCOMP low	JCOMP high (JTAG mode)	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	1st Timeout	2nd Timeout	LFAST ICLC enable command received
TDI	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxN
TMS	Logic Input	Logic Input	Logic Input	Hi-Z	Hi-Z	Hi-Z	LVDS TxP
TDO	Hi-Z	Logic Output	Logic Output	Hi-Z	LVDS Rx	LVDS Rx	LVDS RxP
JCOMP	Logic Input	Logic Input	Logic Input Latch	Hi-Z	LVDS Rx	LVDS Rx	LVDS RxN
TCK	Logic Input	Logic Input	Logic Input	Hi-Z	Logic Output	Logic Output	Logic Output
Mode Escape	Inhibit	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable
LFAST_SYSCLK_EN	Inhibit	Inhibit	Inhibit	Inhibit	Enable	Enable	Enable

Table 1491. Tool operation (JTAG to LFAST switching)

Tool	JCOMP low	JCOMP high (JTAG mode) ⁽¹⁾	DCI_CR [EN_LFAST]=1	Run-Test-Idle state	TCK detected	Internal timer elapse
TDI	Don't Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxN
TMS	Don't Care	Logic Output	Hi-Z	Hi-Z	LVDS Rx	LVDS TxP
TDO	Hi-Z	Logic Input	Hi-Z	Hi-Z	LVDS Tx	LVDS RxP
JCOMP	Hi-Z	Logic Output (High)	Hi-Z	Hi-Z	LVDS Tx	LVDS RxN
TCK	Don't Care	Logic Output	Logic Input	Logic Input	Logic Input	Logic Input

1. This state is used to set DCI_CR[EN_LFAST] bit.

Table 1492. MCU operation (LFAST to JTAG switching)

MCU pin	LFAST mode	DCI_CR[EN_LFAST]=0	First timeout
TDI	LVDS Tx	Logic Input	Logic Input
TMS	LVDS Tx	Logic Input	Logic Input
TDO	LVDS Rx	Hi-Z	Logic Output
JCOMP	LVDS Rx	Logic Input Latch	Logic Input (sample JCOMP pin)
TCK	Logic Output	Logic Input	Logic Input
Mode Escape	Enable	Inhibit	Inhibit
LFAST_SYSCLK_EN	Enable	Inhibit	Inhibit

Table 1493. Tool operation (LFAST to JTAG switching)

Tool	Send command to clear DCI_CR[EN_LFAST]	LFAST transmits idle after command sent	TCK input clock stops or LVDS Rx both low	Internal timeout: start sending JTAG messages
TDI	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TMS	LVDS Rx	LVDS Rx	Logic Output	Logic Output
TDO	LVDS Tx	Hi-Z	Logic Input	Logic Input
JCOMP	LVDS Tx	Hi-Z	Logic Output (High)	Logic Output (High)
TCK	Logic Input	Logic Input	Logic Output	Logic Output

65.4.2 LFAST LVDS pad fault

It is possible that when the tool is operating in LFAST mode, the tool may get disconnected due to external disturbances, which could put the MCU in an undetermined state. It is imperative to keep the MCU in a safe state. Thus the LFAST Rx pads have a sensing logic which detects if the Rx pad voltages are not equal to the common mode voltage when the DCI is in LFAST mode. If it is found that the LFAST Rx pads are not corresponding to the common mode voltage, the pad logic sends a signal to the DCI which then puts the DCI into JTAG mode. [Table 1494](#) and [Table 1495](#) contain the different steps and expected states for the MCU and tool for LFAST to JTAGRST switching.

Table 1494. MCU operation (LFAST to JTAGRST switching)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
TDI	LVDS TxN	Logic Input
TMS	LVDS TxP	Logic Input
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Input
TCK	Logic Output	Logic Input
Mode Escape	Enable	Inhibit

Table 1494. MCU operation (LFAST to JTAGRST switching) (continued)

MCU pin	LFAST mode	JCOMP detected low (mode escape)
LFAST_SYSCLK_EN	Enable	Inhibit
Internal TRST	Negated	Asserted

Table 1495. Tool operation (LFAST to JTAGRST switching)

Tool	LFAST mode	Tool forces JCOMP low
TDI	LVDS TxN	Don't Care
TMS	LVDS TxP	Don't Care
TDO	LVDS RxP	Hi-Z
JCOMP	LVDS RxN	Logic Output (Low)
TCK	Logic Input	Don't Care

66 JTAG Controller (JTAGC)

66.1 Introduction

The JTAGC block provides the means to test chip functionality and connectivity while remaining transparent to system logic when not in test mode. Testing is performed via a boundary scan technique, as defined in the IEEE 1149.1-2001 standard. All data input to and output from the JTAGC block is communicated in serial format.

66.1.1 Block Diagram

The following is a block diagram of the JTAG Controller (JTAGC) block.

Figure 1596. JTAG (IEEE 1149.1) block diagram

66.1.2 Features

The JTAGC block is compliant with the IEEE 1149.1-2001 standard, and supports the following features:

- IEEE 1149.1-2001 Test Access Port (TAP) interface
 - 4 pins (TDI, TMS, TCK, and TDO)
- JCOMP input that provides reset control and the ability to share the TAP.
- Instruction register that supports several IEEE 1149.1-2001 defined instructions as well as several public and private device-specific instructions. Refer to [Table 1499](#) for a list of supported instructions.
- Sharing of the TAP with other TAP controllers via ACCESS_AUX_x instructions
- JTAG_PASSWORD register
- Data registers, bypass register, boundary scan register, and device identification register.
- TAP controller state machine that controls the operation of the data registers, instruction register and associated circuitry.

66.1.3 Modes of operation

The JTAGC block uses JCOMP and a power-on reset indication as its primary reset signals. Several IEEE 1149.1-2001 defined test modes are supported, as well as a bypass mode.

66.1.3.1 Reset

The JTAGC block is placed in reset when either power-on reset is asserted, JCOMP is negated, or the TMS input is held high for enough consecutive rising edges of TCK to sequence the TAP controller state machine into the Test-Logic-Reset state. Holding TMS high for five consecutive rising edges of TCK guarantees entry into the Test-Logic-Reset state regardless of the current TAP controller state. Asserting power-on reset or setting JCOMP to a value other than the value required to enable the JTAGC block results in asynchronous entry into the reset state. While in reset, the following actions occur:

- The TAP controller is forced into the Test-Logic-Reset state, thereby disabling the test logic and allowing normal operation of the on-chip system logic to continue unhindered
- The instruction register is loaded with the IDCODE instruction

66.1.3.2 IEEE 1149.1-2001 defined test modes

The JTAGC block supports several IEEE 1149.1-2001 defined test modes. A test mode is selected by loading the appropriate instruction into the instruction register while the JTAGC is enabled. Supported test instructions include EXTEST, HIGHZ, CLAMP, SAMPLE and SAMPLE/PRELOAD. Each instruction defines the set of data register(s) that may operate and interact with the on-chip system logic while the instruction is current. Only one test data register path is enabled to shift data between TDI and TDO for each instruction.

The boundary scan register is enabled for serial access between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. The single-bit bypass register shift stage is enabled for serial access between TDI and TDO when the BYPASS, HIGHZ, CLAMP or reserved instructions are active. The functionality of each test mode is explained in more detail in [Section 66.4.4, JTAGC block instructions](#).

66.1.3.3 Bypass mode

When no test operation is required, the BYPASS instruction can be loaded to place the JTAGC block into bypass mode. While in bypass mode, the single-bit bypass shift register is used to provide a minimum-length serial path to shift data between TDI and TDO.

66.2 External signal description

The JTAGC consists of five signals that connect to off chip development tools and allow access to test support functions. The JTAGC signals are outlined in the following table and described in the following sections.

Table 1496. JTAG signal properties

Name	I/O	Function	Reset State	Pull
TCK	Input	Test Clock	—	Down
TDI	Input	Test Data In	—	Up
TDO	Output	Test Data Out	High Z ⁽¹⁾	—
TMS	Input	Test Mode Select	—	Up
JCOMP	Input	JTAG Compliancy	—	Down

1. TDO output buffer enable is negated when the JTAGC is not in the Shift-IR or Shift-DR states. A weak pull may be implemented at the TDO pad for use when JTAGC is inactive.

66.2.1 TCK—Test clock input

Test Clock Input (TCK) is an input pin used to synchronize the test logic and control register access through the TAP.

66.2.2 TDI—Test data input

Test Data Input (TDI) is an input pin that receives serial test instructions and data. TDI is sampled on the rising edge of TCK.

66.2.3 TDO—Test data output

Test Data Output (TDO) is an output pin that transmits serial output for test instructions and data. TDO is three-stateable and is actively driven only in the Shift-IR and Shift-DR states of the TAP controller state machine, which is described in [Section 66.4.3, TAP controller state machine](#).

66.2.4 TMS—Test mode select

Test Mode Select (TMS) is an input pin used to sequence the IEEE 1149.1-2001 test control state machine. TMS is sampled on the rising edge of TCK.

66.2.5 JCOMP—JTAG compliancy

The JCOMP signal provides IEEE 1149.1-2001 compatibility and provides the ability to share the TAP. The JTAGC TAP controller is enabled when JCOMP is set to the JTAGC enable encoding, otherwise the JTAGC TAP controller remains in reset.

66.3 Register description

This section provides a detailed description of the JTAGC block registers accessible through the TAP interface, including data registers and the instruction register. Individual bit-level descriptions and reset states of each register are included. These registers are not memory-mapped and can only be accessed through the TAP.

66.3.1 Instruction register

The JTAGC block uses a 6-bit instruction register as shown in the following figure. The instruction register allows instructions to be loaded into the block to select the test to be performed or the test data register to be accessed or both. Instructions are shifted in through TDI while the TAP controller is in the Shift-IR state, and latched on the falling edge of TCK in the Update-IR state. The latched instruction value can only be changed in the Update-IR and Test-Logic-Reset TAP controller states. Synchronous entry into the Test-Logic-Reset state results in the IDCODE instruction being loaded on the falling edge of TCK. Asynchronous entry into the Test-Logic-Reset state results in asynchronous loading of the IDCODE instruction. During the Capture-IR TAP controller state, the instruction shift register is loaded with the value 000001b, making this value the register's read value when the TAP controller is sequenced into the Shift-IR state.

	5	4	3	2	1	0
R	0	0	0	0	0	1
W	Instruction Code					
Reset:	0	0	0	0	0	1

Figure 1597. 6-bit instruction register

66.3.2 Bypass register

The bypass register is a single-bit shift register path selected for serial data transfer between TDI and TDO when the BYPASS, CLAMP, HIGHZ or reserve instructions are active. After entry into the Capture-DR state, the single-bit shift register is set to a logic 0. Therefore, the first bit shifted out after selecting the bypass register is always a logic 0.

66.3.3 Device identification register

The device identification (JTAG ID) register, shown in the following figure, allows the revision number, part number, manufacturer, and design center responsible for the design of the part to be determined through the TAP. The device identification register is selected for serial data transfer between TDI and TDO when the IDCODE instruction is active. Entry into the Capture-DR state while the device identification register is selected loads the IDCODE into the shift register to be shifted out on TDO in the Shift-DR state. No action occurs in the Update-DR state.

Figure 1598. Device identification register

The following table describes the device identification register functions.

Table 1497. Device identification register field descriptions

Field	Description
PRN	Part Revision Number. Contains the revision number of the part. Value is 0x0.
DC	Design Center. Indicates the design center. Value is 0x2B.
PIN	Part Identification Number. Contains the part number of the device. Value is 0x30A.
MIC	Manufacturer Identity Code. Contains the reduced Joint Electron Device Engineering Council (JEDEC) ID. Value is 0x020.
IDCODE ID	IDCODE Register ID. Identifies this register as the device identification register and not the bypass register. Always set to 1.

66.3.4 JTAG_PASSWORD register

The JTAG_PASSWORD register is a 256-bit shift register path from TDI to TDO selected when the ENABLE_JTAG_PASSWORD instruction is active. The default reset value of the JTAG_PASSWORD register is 256'b0. The JTAG_PASSWORD register transfers its value to a parallel hold register on the rising edge of TCK when the TAP controller state machine is in the Update-DR state. Once the ENABLE_JTAG_PASSWORD instruction is executed, the register value remains valid until a JTAG reset occurs. The operation of this register is described in the security documentation.

1. The reset value of JTAG_PASSWORD is 256'b0.

Figure 1599. JTAG_PASSWORD register

The following table describes the JTAG_PASSWORD register functions.

Table 1498. JTAG_PASSWORD register field descriptions

Field	Description
JTAG_PASSWORD	JTAG Password. The JTAG_PASSWORD bits are used to provide the JTAG password for security.

66.3.5 Boundary scan register

The boundary scan register is connected between TDI and TDO when the EXTEST, SAMPLE or SAMPLE/PRELOAD instructions are active. It is used to capture input pin data, force fixed values on output pins, and select a logic value and direction for bidirectional pins. Each bit of the boundary scan register represents a separate boundary scan register cell, as described in the IEEE 1149.1-2001 standard and discussed in [Section 66.4.5, Boundary scan](#). The size of the boundary scan register and bit ordering is device-dependent and can be found in the device BSDL file.

66.4 Functional description

This section explains the JTAGC functional description.

66.4.1 JTAGC reset configuration

While in reset, the TAP controller is forced into the Test-Logic-Reset state, thus disabling the test logic and allowing normal operation of the on-chip system logic. In addition, the instruction register is loaded with the IDCODE instruction.

66.4.2 IEEE 1149.1-2001 (JTAG) Test Access Port

The JTAGC block uses the IEEE 1149.1-2001 TAP for accessing registers. This port can be shared with other TAP controllers on the MCU. Ownership of the port is determined by the value of the currently loaded instruction. For more detail on TAP sharing via JTAGC instructions refer to [Section 66.4.4.8, ACCESS_AUX_x instructions](#).

Data is shifted between TDI and TDO through the selected register starting with the least significant bit, as illustrated in the following figure. This applies for the instruction register, test data registers, and the bypass register.

Figure 1600. Shifting data through a register

66.4.3 TAP controller state machine

The TAP controller is a synchronous state machine that interprets the sequence of logical values on the TMS pin. The following figure shows the machine's states. The value shown next to each state is the value of the TMS signal sampled on the rising edge of the TCK signal. As the following figure shows, holding TMS at logic 1 while clocking TCK through a sufficient number of rising edges also causes the state machine to enter the Test-Logic-Reset state.

The value shown adjacent to each state transition represents the value of TMS at the time of a rising edge of TCK.

Figure 1601. IEEE 1149.1-2001 TAP controller finite state machine

66.4.3.1 Enabling the TAP controller

The JTAGC TAP controller is enabled by setting JCOMP to a logic 1 value.

66.4.3.2 Selecting an IEEE 1149.1-2001 register

Access to the JTAGC data registers is achieved by loading the instruction register with any of the JTAGC block instructions while the JTAGC is enabled. Instructions are shifted in via the Select-IR-Scan path and loaded in the Update-IR state. At this point, all data register access is performed via the Select-DR-Scan path.

The Select-DR-Scan path is used to read or write the register data by shifting in the data (LSB first) during the Shift-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the Capture-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the Update-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

66.4.4 JTAGC block instructions

The JTAGC block implements the IEEE 1149.1-2001 defined instructions listed in the following table. This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1499. 6-bit JTAG instructions

Instruction	Code[5:0]	Instruction Summary
IDCODE	000001	Selects device identification register for shift
SAMPLE/PRELOAD	000010	Selects boundary scan register for shifting, sampling, and preloading without disturbing functional operation
SAMPLE	000011	Selects boundary scan register for shifting and sampling without disturbing functional operation
EXTEST	000100	Selects boundary scan register while applying preloaded values to output pins and asserting functional reset
Factory debug reserved	000101	Intended for factory debug only
Factory debug reserved	000110	Intended for factory debug only
ENABLE_JTAG_PASSWORD	000111	Selects JTAG_PASSWORD register
HIGHZ	001001	Selects bypass register while three-stating all output pins and asserting functional reset
Factory debug reserved	001010	Intended for factory debug only
CLAMP	001100	Selects bypass register while applying preloaded values to output pins and asserting functional reset
ENABLE_DCI_CR	001110	Enables access to DCI CR register
ENABLE_DCI_PINCR	001111	Enables access to DCI PINCR register
ACCESS_AUX_x	100000-111110	Grants one of the auxiliary TAP controllers ownership of the TAP as shown in the cells below.
Reserved	100000	Reserved
ACCESS_AUX_NR_PD	100001	Enables access to the NAR TAP controller on PD
Reserved	100010	Reserved
Reserved	100011	Reserved

Table 1499. 6-bit JTAG instructions (continued)

Instruction	Code[5:0]	Instruction Summary
Reserved	100100	Reserved
Factory test reserved	100101	Intended for factory test only
ACCESS_AUX_JDC	100110	Enables access to the JDC TAP controller, to access the HSM challenge and response registers
ACCESS_AUX_HSM	100111	Enables access to the HSM core TAP controller
ACCESS_AUX_CORE_0	101000	Enabled access to E200 Core 0
ACCESS_AUX_CORE_1	101001	Enables access to E200 Core 1
ACCESS_AUX_CORE_2	101010	Enables access to E200 Core 2
Reserved	101011	Reserved
Reserved	101100	Reserved
Reserved	101101	Reserved
Reserved	101110	Reserved
Reserved	101111	Reserved
Reserved	110000	Reserved
Reserved	110001	Reserved
Reserved	110010	Reserved
ACCESS_AUX_GTM	110011	Enables access to GTM TAP controller
ACCESS_AUX_BUS_MON_0	110100	Enables access to NXMC Client 0 TAP controller
ACCESS_AUX_BUS_MON_1	110101	Enables access to NXMC Client 1 TAP controller
Reserved	110110	Reserved
Reserved	110111	Reserved
Reserved	111000	Reserved
Reserved	111001	Reserved
ACCESS_AUX_SPU_A	111010	Enables access to SPU Client TAP controller
Reserved	111011	Reserved
ACCESS_AUX_PARALLEL ⁽¹⁾	111100	Enables access to all cores in parallel
Reserved	111101	Reserved
Reserved	111110	Reserved
BYPASS	111111	Selects bypass register for data operations
Reserved ⁽²⁾	All other opcodes	Decoded to select bypass register

1. The use of this instruction is limited to the synchronous exit of debug mode via the execution of the GO+EXIT OnCE command. The execution of other instructions or commands is not supported
2. The manufacturer reserves the right to change the decoding of reserved instruction codes in the future

66.4.4.1 IDCODE instruction

IDCODE selects the 32-bit device identification register as the shift path between TDI and TDO. This instruction allows interrogation of the MCU to determine its version number and other part identification data. IDCODE is the instruction placed into the instruction register when the JTAGC block is reset.

66.4.4.2 SAMPLE/PRELOAD instruction

The SAMPLE/PRELOAD instruction has two functions:

- First, the SAMPLE portion of the instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE/PRELOAD instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. Both the data capture and the shift operation are transparent to system operation.
- Secondly, the PRELOAD portion of the instruction initializes the boundary scan register cells before selecting the EXTEST or CLAMP instructions to perform boundary scan tests. This is achieved by shifting in initialization data to the boundary scan register during the Shift-DR state. The initialization data is transferred to the parallel outputs of the boundary scan register cells on the falling edge of TCK in the Update-DR state. The data is applied to the external output pins by the EXTEST or CLAMP instruction. System operation is not affected.

66.4.4.3 SAMPLE instruction

The SAMPLE instruction obtains a sample of the system data and control signals present at the MCU input pins and just before the boundary scan register cells at the output pins. This sampling occurs on the rising edge of TCK in the Capture-DR state when the SAMPLE instruction is active. The sampled data is viewed by shifting it through the boundary scan register to the TDO output during the Shift-DR state. There is no defined action in the Update-DR state. Both the data capture and the shift operation are transparent to system operation.

66.4.4.4 EXTEST—External test instruction

EXTEST selects the boundary scan register as the shift path between TDI and TDO. It allows testing of off-chip circuitry and board-level interconnections by driving preloaded data contained in the boundary scan register onto the system output pins. Typically, the preloaded data is loaded into the boundary scan register using the SAMPLE/PRELOAD instruction before the selection of EXTEST. EXTEST asserts the internal system reset for the MCU to force a predictable internal state while performing external boundary scan operations.

66.4.4.5 ENABLE_JTAG_PASSWORD instruction

The ENABLE_JTAG_PASSWORD instruction selects the JTAG_PASSWORD register for connection as the shift path between TDI and TDO.

66.4.4.6 HIGHZ instruction

HIGHZ selects the bypass register as the shift path between TDI and TDO. While HIGHZ is active all output drivers are placed in an inactive drive state (e.g., high impedance). HIGHZ also asserts the internal system reset for the MCU to force a predictable internal state.

66.4.4.7 CLAMP instruction

CLAMP allows the state of signals driven from MCU pins to be determined from the boundary scan register while the bypass register is selected as the serial path between TDI and TDO. CLAMP enhances test efficiency by reducing the overall shift path to a single bit (the bypass register) while conducting an EXTEST type of instruction through the boundary scan register. CLAMP also asserts the internal system reset for the MCU to force a predictable internal state.

66.4.4.8 ACCESS_AUX_x instructions

The JTAGC is configurable to allow other TAP controllers on the device to share the port with it. This is done by providing ACCESS_AUX_x instructions for each of these TAP controllers. When this instruction is loaded, control of the JTAG pins are transferred to the selected TAP controller. Any data input via TDI and TMS is passed to the selected TAP controller, and any TDO output from the selected TAP controller is sent back to the JTAGC to be output on the pins. The JTAGC regains control of the JTAG port during the UPDATE-DR state if the PAUSE-DR state was entered. Auxiliary TAP controllers are held in RUN-TEST/IDLE while they are inactive. Instructions not used to access an auxiliary TAP controller on a device are treated like the BYPASS instruction.

66.4.4.9 BYPASS instruction

BYPASS selects the bypass register, creating a single-bit shift register path between TDI and TDO. BYPASS enhances test efficiency by reducing the overall shift path when no test operation of the MCU is required. This allows more rapid movement of test data to and from other components on a board that are required to perform test functions. While the BYPASS instruction is active the system logic operates normally.

66.4.5 Boundary scan

The boundary scan technique allows signals at component boundaries to be controlled and observed through the shift-register stage associated with each pad. Each stage is part of a larger boundary scan register cell, and cells for each pad are interconnected serially to form a shift-register chain around the border of the design. The boundary scan register consists of this shift-register chain, and is connected between TDI and TDO when the EXTEST, SAMPLE, or SAMPLE/PRELOAD instructions are loaded. The shift-register chain contains a serial input and serial output, as well as clock and control signals.

66.5 Initialization/Application information

The test logic is a static logic design, and TCK can be stopped in either a high or low state without loss of data. However, the system clock is not synchronized to TCK internally. Any mixed operation using both the test logic and the system functional logic requires external synchronization.

To initialize the JTAGC block and enable access to registers, the following sequence is required:

1. Set the JCOMP signal to the JTAGC enable value, thereby enabling the JTAGC TAP controller
2. Load the appropriate instruction for the test or action to be performed

ZBS	Zero Bit Scan

67.3 Introduction

The CJTAG module implements parts of the IEEE 1149.7 standard for test and debug capabilities. IEEE 1149.7 defines enhanced test and debug capabilities which are backwards compatible with IEEE P1149.1. This standard is also known as “Compact JTAG” or “CJTAG”.

The module implements the following parts of the IEEE 1149.7 standard:

- IEEE 1149.1 compliant behavior while allowing multiple on-chip TAP controllers
- Ability to assert test reset
- Improved system scan performance with one-bit IR and DR chip bypass paths
- Physical connection of a Debug and Test System (external tool) to a running system without corrupting its operation
- Operation with both 4-pin and 2-pin scan topologies

67.3.1 Types of operation

The 1149.7 standard provides a scalable and flexible solution to meet the needs of varied component and system complexities. There are three types of operation:

- **Compliant**
 - Compliant with the IEEE 1149.1 standard
 - Four-pin operation using the “Standard Protocol” — IEEE 1149.1 signaling where TCK, TMS, TDI and TDO signals transfer control/data information
 - More than one TAPC may be associated with the TAP (once made visible by private instructions)
- **Extended**
 - Compatible with the IEEE 1149.1 standard
 - Four-pin operation using the “Standard Protocol” — IEEE 1149.1 signaling where TCK, TMS, TDI(C) and TDO(C) signals transfer control/data information
 - Additional test/debug functions
- **Advanced**
 - Two-pin operation using the “Advanced Protocol” — signaling where TCK(C) and TMS(C) signals transfer control/data information
 - The TMS(C) signal is operated in a bidirectional manner with the TMS, TDI and TDO TAP information serialized and transferred via this signal

67.3.2 Deployment by class

The TAP.7 capabilities are deployed using five capability classes (T0–T4), each matching the needs of certain scan topologies and mixes of 1149.1 TAPs and 1149.7 TAPs. The classes provide the following capability:

- **Compliant Operation** – provides behavior compliant with the IEEE 1149.1-2001 standard:
 - **Class T0** – 1149.1 compliance when multiple TAPs are used on the same chip.
- **Extended Operation** – extends the capabilities of the IEEE 1149.1-2001 standard:
 - **Class T1** – T0 + Test access port power management, functional reset, and test reset.
 - **Class T2** – T1 + Chip bypass (1-bit) for IR/DR Scans + hot-connection with no errors.
 - **Class T3** – T2 + Star operation (TAPs are paralleled) with series equivalent scans for test.
- **Advanced Operation** – adds capabilities addressing test and debug needs in complex environments:
 - **Class T4** – T3 + Scan with two pins with the Advanced Protocol. A number of protocol optimizations maximize scan performance. TDI(C)/TDO(C) pins are optional and may have programmable function when implemented.

67.3.3 1149.7 TAP signals

The TAP signals for the T0–T4 TAP.7 classes are listed in [Table 1501](#). Signal names that end in “C” are associated with expanded functionality (above that provided by the IEEE 1149.1 standard).

The notation used in the table is as follows:

- M = Mandatory signal
- MC = Mandatory signal with expanded functionality
- O = Optional signal
- OC = Optional signal with expanded functionality

The CJTAG module provides T4 capability and implements the TCKC, TMS, TDIC, TDOC, and nTRST pins.

Table 1501. TAP.7 signal list

Signal Name	Description	Class				
		T4	T3	T2	T1	T0
TCK/TCKC	Test clock	MC	M	M	M	M
TMS/TMSC	Test mode select	MC	M	M	M	M
TDI/TDIC	Test data input	OC	MC	M	M	M
TDO/TDOC	Test data output	OC	MC	M	M	M
nTRST	Test reset	O	O	O	O	O
Mandatory signal count (minimum)		2	4	4	4	4

67.3.4 TAP.7 architecture

The TAP.7 hardware architecture is shown in [Figure 1602](#). It is described with the hardware layers listed below:

- **STL – System Test Logic** – Logic with 1149.1 compliant behavior and underlying TAP hierarchy (T0 capabilities). Provides an IEEE 1149.1 interface for the T0 TAP.7. This logic is outside the CJTAG module.
- **RSU – Reset and Selection Unit** – A hardware layer that is placed between the APU, EPU, or STL and the TAP.7 signals (Added as an option to support the use of the Control Protocol) Provides reset and TAP.7 Controller selection services.
- **EPU – Extended Protocol Unit** – A hardware layer that is placed between the STL and the TAP.7 signals. (Added for T1, T2, and T3 capabilities). Provides an IEEE 1149.1 interface for the T1–T3 TAP.7s.
- **APU – Advanced Protocol Unit** – A hardware layer that is placed between the STL/EPU and the TAP.7 signals (added for T4 capabilities). Provides a T4 TAP.7 interface that is either narrow or wide, with the wide version providing an IEEE 1149.1 interface.

The CJTAG module supports T4 functionality that includes STL, RSU, EPU, and APU hardware layers.

Figure 1602. TAP.7 Controller Architecture

67.3.5 Protocols

The TAP.7 architecture utilizes the three protocols shown in [Figure 1603](#).

Figure 1603. TAP.7 Behaviors

The Standard Protocol transfers data with the TMS(C) signal value being sampled with a TCK(C) edge. The Advanced and Control Protocols use both data transferred with the TMS(C) signal value being sampled with a TCK(C) signal edge and escape sequences. The Standard Protocol may be used to switch to the use of the Advanced Protocol and vice versa. The Control Protocol can also be used to switch between the use of the Standard and the Advanced Protocol. The mandatory and optional deployment of these protocols with the TAP.7 classes is shown in [Table 1502](#).

Table 1502. Class/protocol relationship

Class	Protocol		
	Standard	Control	Advanced
T0 – T2	Mandatory	Optional	N/A
T3	Mandatory	Mandatory	N/A
T4	Mandatory	Mandatory	Mandatory

The CJTAG module implements T4 functionality and supports the Standard, Advanced, and Control Protocols.

67.3.5.1 Standard Protocol

The Standard Protocol is the signaling defined by the IEEE 1149.1 standard. This protocol is also used to implement TAP.7 commands using only the TCK(C) and TMS(C) signals in a manner that does not require either TAP.7 controller instruction or data registers. The TAP.7 controller does not add bits to the scan paths of underlying technology. The Standard Protocol can be used to manage the TAP.7 controller functionality independent of the function associated with the availability of the TDI and TDO signals. The Standard Protocol supports STL data transfers only when these signals are present and provide the 1149.1 functionality defined by the IEEE 1149.1 standard.

67.3.5.2 Advanced Protocol

The Advanced Protocol supports both STL data transfers and management of the TAP.7 controller functionality with both the 2-signal (narrow) and 4-signal (wide) configurations. The Advanced Protocol serializes the TMS, TDI, and TDO information used with the Standard Protocol using only the TCK(C) and TMS(C) signals. A number of additional scan formats provide bit sequences optimized for specific use cases. Each of these additional scan formats affects the TMS signaling sequences.

67.3.5.3 Control Protocol

The Control Protocol uses Escape sequences to reset the TAP.7 controller, place a TAP.7 controller offline or online, and indicate End of Transmission (EOT) with the Advanced Protocol. The characteristics of this protocol provide Hot-Connect-Protection by requiring a preamble of alternating ones and zeroes preceding a selection escape when a TAP controller is started up offline.

67.3.6 Operating models

[Figure 1604](#) illustrates a simplified view of the CJTAG operating model.

Figure 1604. CJTAG operating model

67.4 CJTAG implementation summary

The CJTAG module is a T4 TAP.7 controller that implements the following functions.

67.4.1 T0 Functions

- IDCODE. - implemented in chip level TAPC (JTAGC module)
- 1149.1 Compliance at start-up
- Isolating / Excluding of embedded TAPs – implemented in chip level TAPC (JTAGC module)
- Operation with other technologies and scan topologies
- Multiple embedded TAPs

67.4.2 T1 functions

- EPU Command processing
- EPU Class-Specific Registers
- Asserting a test reset to the STL (TRESET Register)

67.4.3 T2 functions

- “Super Bypass” function – JScan0, JScan1, JScan2 scan formats. Allows the STL to be coupled or decoupled.

67.4.4 T3 functions

- Generation of a TAP.7 controller reset with a Reset Escape Sequence
- JScan3 Scan Format

67.4.5 T4 functions

- TMSC sampling on rising edge or falling edge of TCKC
- MScan (For test and debug)
- OScan 0-7
- TDIC and TDOC / Alternate pin function multiplexing (wide 4 only)

67.5 Ancillary services

67.5.1 Overview

Ancillary services are pertinent to any TAP.7 controller implemented with an RSU, such as the CJTAG module.

Ancillary services include:

- Resets
- Start-up options
- Escape sequences
- TAPC state machine

67.5.2 Resets

The TAP.7 controller reset function expands the reset function provided by the IEEE 1149.1 standard to provide additional reset types. It supports six reset types, Type-0 – Type-5, listed below. It can be implemented with as few as two reset types (Type-2 and Type-4), or as many as six reset types (all types) of reset inputs: This is determined by the class and options implemented.

The CJTAG module utilizes Type-0, Type-2, Type-3, Type-4, and Type-5 resets.

- **Type-0** – Reset of the TAP.7 by power management logic (power-on reset)
- **Type-1** – Chip level generated Test Reset. (equivalent to Type-2)
- **Type-2** – Externally generated Test Reset (nTRST/nTRST_PD pin)
- **Type-3** – TAP.7 controller generated reset
- **Type-4** – *Test-Logic-Reset* state
- **Type-5** – TAP.7 Controller TReset Register reset of the CLTAPC

Figure 1605. Conceptual view of the EPU reset logic and state machines

67.5.2.1 Type 5 reset

A Type-5 reset affects only the STL via the nSYS_TRST pin. It is asserted when the TRESET Register value is a logic 1. This register is set to its inactive state by reset Types 0-4.

67.5.2.2 Type 4 reset

A Type-4 reset is created by the *Test-Logic-Reset* state. It does not affect the TAP.7 TAPC state machine state as this state is the source of this reset, nor does it cause the assertion of the nSYS_TRST signal. It does however affect the coupling and decoupling of the STL. The Type-4 reset initializes the TAP.7 registers and most controller state machines. It affects but does not initialize the control state machine managing TAP.7 controller selection. It also establishes the default operating conditions.

67.5.2.3 Type 3 reset

A Type-3 reset is created by reset requests generated by the TAP.7 controller. A Type-3 reset performs the functions associated with a Type-4 reset and creates the *Test-Logic-Reset* state.

A Type-3 reset is generated in response to reset requests generated by EPU and APU logic

- A reset escape sequence
- Reset protocol sequences (delay packet directive, check packet directive)

A Type-3 reset request is generated with a reset escape sequence. This function is similar to but not the same as the reset function generated by a test reset pin. The Advanced Protocol includes certain bit patterns that initiate Type-3 resets. These bit patterns assist in the initialization of the TAP.7 controller when the TCKC signal is sourced by the TS and the external tool/TS connection is broken. The external tool may also generate these sequences, if desired, while the external tool/TS connection remains intact. These reset requests cause a Type-3 reset that is one clock wide.

With this being the case, consideration may be given to integrating the CJTAG module without the use of the Test Reset signal (nTRST/nTRST_PD pin).

67.5.2.4 Type 2 reset

A Type-2 reset is created by chip level logic to initialize the TAP.7 controller when TAP.7 power control is not implemented. It is unimplemented otherwise. It performs all of the functions of the Type-3 reset in addition to initializing the escape sequence detection logic.

67.5.2.5 Type 1 reset

A Type-1 reset is created with either the nTRST or nTRST_PD pin. It is not created when neither of these pins is implemented. It performs all of the functions of the Type-2 reset. It initiates TAP.7 controller power down provided the TAP.7 power control mode permits power down.

67.5.2.6 Type 0 reset

A Type-0 reset is implemented when TAP.7 controller power down is implemented. It performs all of the functions of a Type-1 reset and also initializes the TAP.7 power control logic.

67.5.2.7 Reset State Machine

The Reset State Machine assists in the translation of the reset inputs to the reset outputs. It handles Type-3 reset controller reset requests. The state machine state assures Type-0, Type-1, and Type-2 resets are forwarded to the STL without modifying their duration.

This state machine allows a Type-3 reset only when its state is “T3 Reset” (two TCK(C) falling edges have occurred in the absence of a Type-0, Type-1, and Type-2 reset).

Figure 1606. Reset state machine

Table 1503. Reset state descriptions

Reset state		Description
ARA	Async. Reset Asserted	An async. reset has occurred or is occurring
ARC	Async. Reset Completed	An async. reset has occurred and has been released

Table 1503. Reset state descriptions

Reset state		Description
No Reset	No Reset	No Reset
T3 Reset	Type-3 Reset	A Type-3 reset request has been processed.

Type-0, Type-1, and Type-2 resets are fully asynchronous. These resets are passed directly to nSYS_TRST without modification. The Type-3, Type-4, and Type-5 resets are fully synchronous.

The effects of the TAP.7 controller reset types are shown in [Table 1504](#).

Table 1504. Reset effects

Reset	CLTAPC	Pin-Hi-Z	State Machines other than CSM	Control State Machine (CSM)	TAPC SM State	Escape Sequence Detection	Power Control State
Type-5	Yes	–	–	–	–	–	–
Type-4	–	Yes	Yes	–	–	–	–
Type-3	Yes	Yes	Yes	Yes	Yes	–	–
Type-2	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-1	Yes	Yes	Yes	Yes	Yes	Yes	–
Type-0	Yes	Yes	Yes	Yes	Yes	Yes	Yes

67.5.3 Start-up Options

67.5.3.1 Overview

The TAP.7 start-up options are shown in [Table 1505](#). The only startup option currently supported by the CJTAG module is 1149.1 Compliant.

Table 1505. Start-up Options

Start-up Option	Description
1149.1 Compliant	TAP.1 signal functionality, the CLTAPC is coupled
1149.1 Compatible	TAP.7 signal functionality, the CLTAPC is decoupled
1149.1 Protocol Compatible	No, or alternate TDIC/TDOC signal functionality, the CLTAPC is decoupled.
Offline-at-Start-up (Dormant)	The TAP.7 controller is offline and awaits synchronization to external tool operation so as to be placed online, the CLTAPC is decoupled after its state is moved to <i>Run-Test/Idle</i>

67.5.3.2 1149.1 Compliant start-up

Start-up behavior with the 1149.1 Compliant behavior start-up option:

- 1149.1-specific behavior / Standard protocol
- The TAPC finite state machine operated in lock step with the CLTAPC finite state machine.
- The TDIC and TDOC pins are present and provide the TDI and TDO function.
- The CLTAPC is coupled at start-up.

With this start-up option, the TAP.7 controller may be programmed and the scan topology may be interrogated. If the scan topology is known to be the Series Scan Topology at power-up, the TAP.7 can be operated as though it is a TAP.1.

Table 1506. Reset values for TAP.7 start-up options

Start-up Option	Type-0 – Type-3 Reset?	Default TAP.7 and TAP.7 controller characteristics				
		TAP.7 Controller online	CLTAPC Coupled	SGC Reg. == 1	SCNFMT	Initial TMS pin bias
1149.1 Compliant	x	Yes	Yes	Yes	JScan0	PU

67.5.4 RSU operation

The RSU uses TCKC and TMS with the control protocol for configuration control.

67.5.4.1 General Operation

From a very high level, the RSU enables the remainder of the TAP.7 functionality when the TAP.7 controller is Online and disables the remainder of the TAP.7 functionality otherwise. The RSU either consumes or discards the TMS(C) information while the TAP.7 controller is Offline. The relationship of the escape sequence detection, technology selection logic, and the underlying technology is shown in [Figure 1607](#).

Figure 1607. Conceptual view of technology selection mechanism

67.5.4.2 Common Signaling Across Technologies

With the TAP.7 architecture, the signaling conventions chosen for technology selection is multiple data transitions of the TMS(C) signal while the TCK(C) signal is a logic 1. The common signaling space is available when the external tool sources the TCK(C) signal as it is capable of creating these signaling conventions. It is unavailable when the TS sources the TCK(C) signal as the external tool cannot stop the TCKC signal at a logic 1 to create these signaling conventions.

67.5.4.3 Escape Sequence Detection

TAP.7 TAPC interprets the count of the number of TMS(C) edges while TCK(C) is a logic 1 as one of four escape sequences. Each escape sequence has a different function and TMSC edge count. These escape sequences, their edge counts, and their functions are described below:

- **Custom** (2 or 3 edges)– Ends scan and transport transfers with a TAP.7 controller, may be used for other purposes with another technology.
- **Reset** (> 7 edges)– Resets all technologies (generates a Type-3 TAP.7 TAPC reset)

The external tool creates an escape sequence by generating one or more TMS(C) edge pairs while the TCK(C) signal is a logic 1 value. Even and odd TMS(C) edge counts beginning with two are given the same meaning.

An escape sequence:

- Can be detected only when a Type-0, Type-1 or Type-2 reset is **not** asserted.
- Begins and ends while the TCK(C) is a logic 1.
- Uses TMS(C) as a clock while the TCK(C) is a logic 1.
- Overlays additional control information onto the normal information that is transferred with the TCK(C) and the TMS(C) without changing the normal information.
- Must be detected when TCK(C) is a logic 1 regardless of the TCK(C) and TMS(C) drive histories.

67.5.4.3.1 Custom escape sequence

An online technology can use the custom escape sequence in any manner it chooses. It is used as the End of Transmission (EOT) of certain data types (formats OScan4-7) with T4 and above TAP.7s.

67.5.4.3.2 Reset escape sequences

A reset event initializes all technologies sharing the TCK(C) and TMS(C) connectivity. A reset escape sequence resets the technology. It is recommended that this reset occur with the falling edge of TCKC. With a TAP.7 controller a reset escape sequence generates a Type-3 reset beginning with the falling edge of TCK(C) following the asynchronous detection of the event.

67.5.5 TAPC State Machine

T1 and above TAP.7s require knowledge of the TAPC state machine state. With T2 and above TAPs this knowledge must be developed independently of the CLTAPC. This is generally accomplished by implementing a TAPC state machine within the EPU. This TAPC state machine provides the function of the state machine within a standard 1149.1 TAPC. It is recommended that this state machine is implemented to change state on the falling edge of TCK(C) as this has numerous advantages to a TAP.7 controller. The EPU does not

contain 1149.1 Instruction or Data Registers. The APU controls the state changes of this TAPC state machine with T4 and above TAP.7s.

Figure 1608. Falling edge TAP controller state machine

67.6 EPU (Extended Protocol Unit) Operation

67.6.1 EPU Operation

The EPU adds functionality to the BYPASS and IDCODE instructions.

67.6.1.1 Zero-bit DR-Scans (ZBS)

A zero-bit DR-Scan (ZBS) is a TAPC-state sequence that begins with the *Select-DR-Scan* state and ends with an exit from the *Update-DR* state without an intervening *Shift-DR* state. The external tool controls the EPU using ZBSs.

The use of ZBSs can begin immediately following the *Test-Logic-Reset* state since this state initializes the Instruction Registers of TAPs with either the *BYPASS* or *IDCODE* instructions.

67.6.1.2 Utilizing ZBSs for TAP.7 Controller Functionality

Beginning with a ZBS count of zero, the ZBS count is incremented with each consecutive occurrence of a ZBS without encountering a *Shift-DR* state. This count cannot be incremented past seven. *Run-Test/Idle* is the only state that may occur between consecutive occurrences of ZBSs without terminating the count of consecutive ZBSs.

67.6.1.3 Locking the ZBS Count

When a DR-Scan containing a *Shift-DR* state occurs, and the ZBS count is greater than zero, the ZBS count is not incremented when the *Update-DR* state is reached. It is instead locked at its current value. ZBSs occurring after locking the ZBS count do not affect the locked ZBS count. Locking the ZBS count is the equivalent of storing the count for subsequent use.

67.6.1.4 Control levels

Locking the ZBS count activates a control level that is equal to the locked ZBS count (1-7) when ZBSs are being used for TAP.7 functionality and merely locks the ZBS count otherwise.

1. ZBSs may be used by the STL or another function
2. TAP.7 command generation
3. Reserved control level
4. Accesses to optional TAP.7 scan paths
5. Accesses to optional TAP.7 scan paths
6. Force offline operation (optional)
7. External tool uses

Control level one may be used by the STL since there is no TAP.7 controller functionality associated with this control level.

Control level two enables DR-Scans to create TAP.7 commands. A portfolio of these commands supports the deployment of TAP.7 controllers in the Series or Star Scan Topologies. These commands manage TAP.7 controller registers and perform other functions.

Control level three is reserved for use with a subsequent specification revision.

Control levels four and five provide access to custom (private) scan paths when access to these paths is permitted by a TAP.7 register bit used for this purpose. The EPU provides a 1-bit scan path otherwise. No other EPU functionality is associated with these control levels. The CJTAG module does not support the use of this control level.

Control level six may be optionally used to force offline operation with a TAP.7 controller that supports this capability. The EPU provides a 1-bit scan path for this control level. The CJTAG module does not support the use of this control level.

Control level seven is reserved for external tool use. With this control level, external tool capabilities may be managed using the same infrastructure used to manage TAP.7 controller capability. The EPU provides a 1-bit scan path for this control level.

67.6.1.5 Exiting a Control Level

A control level is exited when one of the following occurs:

- The *Select-IR-Scan* TAP.7 controller state
- The *Test-Logic-Reset* state
- Certain TAP.7 controller commands (Exit Control Level – ECL register bit)
- An event that synchronizes the operation of TAP.7 controllers

67.6.1.6 Zeroing the ZBS Count

Events causing an exit from a control level also zero the ZBS count. Scan Selection Directives (SSDs) associated with T3 and above TAP.7s zero the ZBS count when the control level has not been locked.

67.6.1.7 Utilizing ZBSs within the STL

After the *Test-Logic-Reset* state, ZBSs are used for basic EPU control. ZBSs that are intended for TAP.7 use are henceforth called “**TAP.7 ZBSs**”. ZBSs that are intended for other uses are henceforth called “**Other ZBSs**”. Two TAP.7 registers enable the STL’s use of ZBSs. Storing these registers causes a control level exit, zeroes the ZBS count, and enables the use of Other ZBSs. Storing the Suspend Register (**SUSPEND**) suspends the use of control levels. Storing the ZBS Inhibit Register (**ZBSINH**) inhibits ZBS detection.

When either of these methods is used, the *Test-Logic-Reset* state enables the use of TAP.7 ZBSs in addition to initializing the TAP.7 controller.

The operation of the TAP.7 controller changes with the use of these two paths.

When the System Path is used:

- A count of eight consecutive ZBSs is used to create a logic 0 SUSPEND Register value.
- The CLTAPC supplies the TAP.7 scan path and controls the drive of TDO(C), provided it is not bypasses.
- The EPU supplies the TAP.7 scan path (a one bit bypass) when the CLTAPC is bypassed.
- Functions supporting Boundary Scan in a Star Scan Topology are enabled.

When the EPU Path is used:

- When the control level has not been locked, the TDO(C) signal remains high-impedance.
- The command control level may be created
- When commands are used, the TDO(C) signal remains high-impedance except during *Shift-DR* states within CR-Scans, and remains high impedance at other times.
- Auxiliary scan paths may be accessed with control levels four and five.

67.6.2 EPU Registers

67.6.2.1 Global

A global register is a register whose value is stored at the same time and with the same value as registers with the same name in all TAP.7 TAPCs sharing an external tool connection. They are stored using TAP.7 TAPC commands dedicated for this purpose. These commands store a single global register. Global registers manage TAP.7 TAPC

functions that affect the synchronized operation of a TAP.7 TAPC. An example of a global register is the Scan Format (SCN_FMT) Register used to define the TAPC signal protocol.

A second means of storing all global registers is available. The selection of the TAP.7 TAPC with the technology selection function stores either the Scan Format register value (short form) or all global registers (long form). Storing all global registers provides a simple means to synchronize the values of all global registers when Technology Selection causes a non-operating TAP.7 TAPC to become operational while other TAPCs are operational.

67.6.2.2 Local

Local registers manage TAP.7 TAPC functions that do not affect the synchronized operation of TAP.7 TAPCs. Local registers are conditionally stored using TAP.7 controller commands dedicated for this purpose. These commands provide for changing the value of these registers one at a time with a unique value in a Series Scan Topology based on the TAPC's position on the scan chain. Local registers are stored with a unique value in a Star Scan Topology based on a TAPC address assigned to the TAPC.

Registers programmed with commands are described in this section. The CJTAG module implements all mandatory T4 registers as well as the optional APFC, TRESET, and RDBACK0 registers. There are 16 mandatory and 10 optional registers that can be grouped in classes as shown in Read-only – Configuration and register read back..

- **Control** – TAP.7 controller behaviors and characteristics.
- **Options** – Control of optional functions.
- **Select** – Controls the selection of a TAP.7 for Scan and execution of conditional commands.
- Read-only – Configuration and register read back.

Table 1507. TAP.7 controller register list (managed with commands)

Register type	Global/ local	Width	Register mnemonic	Name
Control	Global	1	ECL	Exit Control Level
		1	SUSPEND	Suspend
		1	ZBSINH	ZBS Detect Inhibit
		5	SCNFMT	Scan Format
		1	SSDE	SSD Enable
		2	DLYC	Delay control
		2	RDYC	Ready Control
Options	Local	1	TRESET	Test Reset
		2	APFC	Aux. Pin Func. Cntl.
Select	Local	1	CGM	Cond. Group Member
		1	SGC	Scan Group Candidate
		1	SEDGE	Sampling Edge
Read-only	Local	32	RDBACK0	Read-back 0
		32	CNFG0	Configuration Register 0
M = Mandatory register O = Optional register				

67.6.2.3 Registers

67.6.2.3.1 Exit Control Level (ECL)

Storing this register zeroes the ZBS count and unlocks the control level.

This register is set using the STMC command. It remains logic 1 only momentarily before immediately returning to logic 0.

This register is cleared by a global register load.

67.6.2.3.2 Suspend (SUSPEND)

Setting this register suspends the use of control levels. When this register is a logic 1, the "System Path" (STL) is used.

- **1** – Suspend use of control levels. Enables "System Path."
- **0** – Enable use of control levels.

SUSPEND is set with the STMC command.

This register is cleared when 8 consecutive ZBSs are detected without the locking of the ZBS count.

This register is cleared by a global register load.

67.6.2.3.3 ZBS Inhibit (ZBSINH)

Storing to ZBSINH inhibits ZBS detection.

- **1** – Inhibit ZBS detection.
- **0** – Enable ZBS detection.

ZBSINH is set with the STMC command.

This register is cleared by a global register load.

67.6.2.3.4 Scan Format (SCNFMT[4:0])

Set using Store Scan Format (STFMT) command.

Read using Scan String (SCNS) command.

Table 1508. Scan Format Register Values

TAPC.7 Class	SCNFMT	Description
T2–T4	00000	JScan0: – 1149.1 Compliant Operation. – Requests the coupling of the CLTAPC when the Run-Test/Idle state is reached.
	00001	JScan1: – 1149.1 Compatible Operation – Requests the decoupling of the CLTAPC when the Run-Test/Idle state is reached.
	00010	JScan2: – 1149.1 Compatible Operation. – Requests the coupling or decoupling of the CLTAPC when the Run-Test/Idle state is reached based on the value of the CACT register
T3–T4	00011	JScan3: – Non-compatible 1149.1 Operation – Allows the detection of a T2 TAP.7 controller that is deployed in a Star-4 topology. – Enables TDOC signal behavior that prevents drive conflicts in a Star-4 Scan Topology. – Enables the use of SSDs

Table 1508. Scan Format Register Values (continued)

TAPC.7 Class	SCNFMT	Description
T4	01000	OScan0 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01001	OScan1 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01010	OScan2 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01011	OScan3 – TAP.1 components – No TDI in non-shift states – No TDO in any state
T4	01100	OScan4 – Data rate dependent components – Single TAP.7 communication – Debug and Test applications
	01101	OScan5 – TAP.1 components – Single/Multi-TAP.7 communication – Debug and Test applications
	01110	OScan6 – TAP.1 components – No TDI or TDO in non-shift states – Debug applications
	01111	OScan7 – TAP.1 components – No TDI in non-shift states – No TDO in any state
	10000	MScan – Data rate dependent components – Multi TAP.7 communication – Directed CID assignment – Virtually any IP with compliant or non-compliant 1149.1 behavior
	10001 – 11111	Reserved

The use of a Scan Format value other than 00000b – 10000 shall not change the value of the SCNFMT Register.

67.6.2.3.5 Scan Selection Directive Enable (SSDE)

This register specifies whether the Scan Selection State may be managed using the scan selection directives.

- **0** – Scan selection directives are not enabled.
- **1** – Scan selection directives are enabled.

This register is set using the STMC command.

This register is read using SCNS (Scan String), RDBACK0.

67.6.2.3.6 Delay Control (DLYC[1:0])

The Delay Control register provides a means for the external tool to delay the completion of an SP. This delay is essentially an external tool stall. This delay may be zero, one, two, or n TCKC periods. This delay is especially useful when the TCKC is sourced by the TS and a Standard-to-Advanced Protocol adapter is added to an external tool supporting only the Standard Protocol. It allows an external tool design additional time to receive TDO, advance the external tool TAPC state, receive TMS and TDI information, and begin generation of a new SP payload. The DLYC register should be programmed before the use of the Advanced Protocol begins after the use of the Standard Protocol.

Set using the STMC command.

Read using SCNS, RDBACK0

Bits 18-17 of the “Global Register.”

67.6.2.3.7 Ready Control (RDYC[1:0])

The Ready Control register defines behavior exhibited in the SP payload output bit frames when the STL stall opportunities (RDY bits) are included as control information. This register defines the number of additional bits inserted in these bit frames. These bits provide more time for a high-performance external tool to ascertain whether the TAP.7 controller is ready to complete the SP payload. The use of these bits makes a high-performance external tool design easier as input and output buffer delays play less of a role in limiting the TAP.7 controller performance. The RDYC register should be programmed before the use of the Advanced Protocol begins.

Set using the STMC command.

Read using SCNS, RDBACK0.

Bits 18-17 of the Global register state.

67.6.2.3.8 Test Reset (TRESET)

Asserts a test reset to the STL.

- **0** – The nSYS_TRST and SYS_TMS signals presented to the STL is not influenced by this bit.
- **1** – The nSYS_TRST presented to the STL is asserted and the SYS_TMS signal is a logic 1.

Set using the STC1 command.

The effects of the TRESET Register may be modified by a private TAP.7 controller register. When this private register is unimplemented or has a value of zero, the TRESET register causes the maximum initialization of the STL with nSYS_TRST and the SYS_TMS logic 1

value. Otherwise, the value of the private register may modify the function of the TRESET Register bit.

When the TRESET Register is a logic 1, the STL scan path appears broken as the state of CLTAPC remains *Test-Logic-Reset* while the EPUTAPC state progression continues. When the operation of the EPUTAPC and CLTAPC controllers is coupled, as with a T1 TAP.7, the state of these two TAPCs may be resynchronized to the *Run-Test/Idle* state by:

- An STC1 Command that sets the TRESET Register value to a logic 0.
- A stay in the Run-Test/Idle state of two or more SYS_TCK periods immediately following the Update-DR state of this command

A failure to follow the guidelines is considered a programming error and will result in erroneous system operation. The EPUTAPC and CLTAPC states will not be synchronized as they progress through the state diagram.

67.6.2.3.9 Auxiliary Pin Function Control (APFC)

This register enables TDI and TDO alternate functions when 2-pin TAP.7 operation is selected.

- **0** – TDI and TDO have JTAG function.
- **1** – TDI and TDO have alternate function.

Set using STC2 command.

Read using SCNS, RDBACK0.

67.6.2.3.10 Conditional Group Member (CGM)

Used by STC1, STC2, STTESTM, and EXC3 – EXC0 commands as the “condition” for updating registers.

Set and cleared using MCM and SCNB commands.

Read using SCNS, RDBACK0.

67.6.2.3.11 Scan Group Candidate (SGC)

This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used.

- **0** – Decoupling action.
- **1** – Coupling action.

Set and cleared using STMC, MSC, and SCNB commands.

Read using SCNS, RDBACK0.

67.6.2.3.12 Sampling Edge (SEDGE)

The Sampling Edge register defines the TCKC edge used to sample the TMSC input.

- **0** – Sample TMSC on the TCKC falling edge.
- **1** – Sample TMSC on the TCKC rising edge.

Set and cleared using STC1 command.

Read using SCNS, RDBACK0

67.6.2.3.13 Read Back 0 (RDBACK0)

Non-transport related register information.

Read using SCNS command.

Unimplemented registers shall read back as “0”.

Table 1509. RDBACK register format

Bit	Width	Register Mnemonic	Name
4:0	5	SCNFMT	Scan Format
6:5	2	PWRMODE	Power-control Modes
7	1	FRESET	Functional Reset
8	1	TRESET	Test Reset
9	1	SGC	Scan Group Candidate

NC = No Change

DF = Default Scan Format

DM = Default Power Control Mode

DCA = Default Coupling Action

DT = Default Topology

DP = Default Pin Function

67.6.3 EPU Commands

There are two command types:

- Two Part Commands
- Three Part Commands

Any number of two-part and three part commands may be issued in any combination before the command control level is exited. If the command control level is exited before a two- or three-part command is completed, the command is aborted and becomes a NOP.

67.6.3.1 Two Part Commands

TAP.7 controller commands are 10-bit values. The 10-bit commands are created by two consecutive DR-Scans when the control level is locked at the command control level (two). The first DR-Scan provides a five-bit command opcode. The second DR-Scan provides a five-bit operand. These two scans are called the command part one (CP1) and command part two (CP2), respectively. A command created entirely with these two scans is called a two-part command.

67.6.3.2 Three Part Commands

Some commands are used to send and/or receive data values other than values embedded in the command's operand. These commands are called three-part commands. With these commands, CP1 and CP2 are followed by an additional DR-Scan to transport a data value to or from an EPU scan path. When used for this purpose, the DR-Scan is called a Control Register Scan (CR-Scan). The CR-Scan is a minimum of zero bits in length with there being no maximum length. The CR-Scan path is described in SECTION.

67.6.3.3 Command Sequence

The two 5-bit values concatenated to create the 10-bit command represent the number of *Shift-DR* states between the *Capture-DR* and *Update-DR* states of CP1 and CP2. The count within CP1 creates the MSBs of the command while the count within CP2 creates the LSBs of the command. The command is decoded when the *Update-DR* state of the second DR-Scan is reached. A determination as to whether the command is a two- or three-part command is made at this point. The command format is shown in [Figure 1609](#).

Figure 1609. DR_Scan sequence used for command creation

The 10-bit command created by CP1 and CP2 determines the command's function and whether the command is a two- or three-part command. If the command is a two part command, the function specified by the command is performed when command part 2 completes. If the command is a three-part command, the DR-Scan following CP2 performs a TAP.7 controller function designated by the 10-bit controller command. This DR-Scan is called a **Control-Register Scan** (CR-Scan) and can be any length. A CR-Scan has many of the attributes of the DR-Scan as it moves data between the external tool and TAP.7 controller and accesses various EPU scan paths. There are many two part commands, but only three three-part commands, each having a special purpose.

67.6.3.4 Commands

There are 11 mandatory and 5 optional commands that can be grouped in classes as shown in the following list:

- Store – The operand is stored in a register or causes an action.
- Select – Controls participation of Scan and conditional command execution.
- Scan – Inputs and outputs with a CR-Scan.
- Enumerate – Controller ID allocation and de-allocation.
- Private – Commands available for chip-specific definition.

The definition of the commands with their operands is shown in [Table 1512](#).

Table 1512. TAP.7 controller command list

Command class	Op-code count	Mnemonic	Name	TAP.7 class			
				1	2	3	4
Store	0x00	STMC	Store Miscellaneous Control	M	M	M	M
	0x01	STC1	Store Conditional 1-bit	M	M	M	M
	0x02	STC2	Store Conditional 2-bit	M	M	M	M
	0x03	STFMT	Store Format	-	M	M	M
	0x04	STDCST	Store Data Channel State	-	-	-	-
Select	0x06	MCM	Make Cond. Group Member	M	M	M	M
	0x07	MSC	Make Scan Group Candidate	-	M	M	M
Scan	0x08	SCNB	Scan Bit	M	M	M	M
	0x09	SCNS	Scan String	M	M	M	M
Enumerate (1)	0x0A	CIDA	Allocate Controller ID	-	-	M	M
	0x0B	CIDD	De-allocate Controller ID	-	-	M	M
Reserved	0x0C–0x1F	Reserved	Reserved	-	-	-	-

1. Enumerate commands are not currently supported by the CJTAG module.

67.6.3.4.1 Store Commands

Store commands are two-part commands that are available in both Star and Series Scan Topologies. The Store Miscellaneous Control (STMC) Command performs control functions that affect all TAP.7 controllers sharing a external tool connection. It stores values in one-bit and two-bit registers.

The Store Conditional 1 bit (STC1) and Store Conditional 2 bit (STC2) Commands store one-bit and two-bit values in registers, respectively. These commands operate two ways:

1. Unconditionally storing registers in all TAP.7 controllers or
2. Storing registers in only the TAP.7 controllers that have a logic 1 Conditional Group Member (CGM) Register value.

The Store Format (STFMT) Command unconditionally stores a five-bit Scan Format value.

The Store Data Channel State (STDCST) Command stores a five-bit value identifying the states supporting transport.

67.6.3.4.2 Select Commands

Select commands are two-part commands that are available in both Star and Series Scan Topologies. Their primary use is to select TAP.7 controllers of interest in a Star Scan Topology. These commands define the TAP.7 controller(s) participating in scans and the TAP.7 controllers that conditionally execute STC1 and STC2 Commands.

The Make Conditional Group Member (MCM) Command specifies which TAP.7 controllers execute store conditional commands as it manages the Command and Path Enable (CAPE) Register. This register also affects the execution of private commands and is utilized in EPU scan path selection.

The Make Scan Group Candidate (MSC) command manages the SGC register. This register determines whether the STL is coupled when the *Run-Test/Idle* state is reached when scan formats other than JScan0 and JScan1 are used. Select commands execute only when the CIDI Register is a logic 0, indicating the TAP.7 controller's CID is valid, and are treated as no operations otherwise.

67.6.3.4.3 Scan Commands

Scan commands are three-part commands that are available in both Star and Series Scan Topologies. The CR-Scan portion of Scan Bit (SCNB) and Scan String (SCNS) Commands is used to set and test bits (SCNB) or transfer strings of bits (SCNS). The commands may be used to access both public and private registers.

67.6.3.5 Command Definitions

67.6.3.5.1 Store Commands

67.6.3.5.1.1 Store Miscellaneous Control Command (STMC)

Table 1513. Store Miscellaneous Control

STMC		Store Miscellaneous Control				
Opcode	Operand	bbb		x	y	Description
00000	bbb x y	000	StateCtl	0	0	NOP
				0	1	ExitCmdLev(ECL)
				1	0	Exit/Suspend (SUSPEND) = 1
				1	1	ZBS Inhibit (ZBSINH) = 1
		001	ScanCtl	0	-	SGC = y
				1	-	CGM = y
		010	RdyCtl	-	-	RDYC = xy
		011	DlyCtl	-	-	DLYC = xy
		100	ScnFunc	0	-	SSDE = y
				1	0	Star-4 Topology Test
				1	1	Reserved
		101	Reserved	-	-	Reserved
		110				
		111				

67.6.3.5.1.2 Store Conditional 1-bit (STC1)

Table 1514. Store Conditional 1 bit (STC1)

STC1		Store Conditional 1 bit			
Opcode	Operand	c	bbb	CAPE	Description
00001	c bbb v	0	000	-	SREDGE = v
			001	-	Reserved
			010	-	TRESET = v
			011 – 111	-	Reserved
		1	--	0	No change
			000	1	SREDGE = v
			001	1	Reserved
			010	1	TRESET = v
			011 – 111	1	Reserved

67.6.3.5.1.3 Store Conditional 2-bit (STC2)

Table 1515. Store Conditional 2 bit (STC2)

STC2		Store Conditional 2 bit			
Opcode	Operand	c	bb	CAPE	Description
00010	c bb vv	0	00	-	Reserved
			01	-	STCKDC = vv
			10	-	APFC = vv
			11	-	Reserved
		1	—	0	No change
			00	1	Reserved
			01	1	STCKDC = vv
			10	1	APFC = vv
			11	1	Reserved

67.6.3.5.1.4 Store Scan Format (STFMT)

Table 1516. Store Scan Format (STFMT)

STFMT		Store Scan Format
Opcode	Operand	
00011	nnnnn	SCNFMT = nnnnn

67.6.3.5.2 Select Commands

67.6.3.5.2.1 Make Conditional Group Member (MCM)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controllers CID is invalid). Otherwise it sets the CGM bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The CGM Register is also stored with the STMC and SCNB commands.

Table 1517. Make Conditional Group Member (MCM)

MCM		Conditional Group Member	
Opcode	Operand	m	Description
00110	m iiii	0	CGM bit of the non-targeted controller is cleared
		1	CGM bit of the targeted controller is set. CGM bit of a non-targeted controller is unaffected.

67.6.3.5.2.2 Make Scan Group Candidate (MSC)

This command operates as a no operation when the CIDI Register is a logic 1 (The Controller's CID is invalid). Otherwise it sets the SGC bit in a TAP.7 controller that has a valid CID and the CID matches the operand CID field (iiii). The SGC Register is also stored with the STMC and SCNB commands.

Table 1518. Make Scan Group Candidate (MSC)

MCM		Conditional Group Member	
Opcode	Operand	m	Description
00111	m iiii	0	SGC bit of the non-targeted controller is cleared
		1	SGC bit of the targeted controller is set. SGC bit of a non-targeted controller is unaffected.

67.6.3.5.3 Scan Commands

67.6.3.5.3.1 Scan Bit (SCNB)

This is a 3-part command. The operand chooses the bit to be read or written by the CR-Scan.

Table 1519. Scan Bit (SCNB)

SCNB			Scan Bit		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
01000	yyyyy	-	0	Scan Group Candidate (SGC)	Write only
		-	1	Conditional Group Member (CGM)	Write only
		-	2	CNFG[0]	Read only
		-	3	CNFG[1] (not implemented)	Read only
		-	4	CNFG[2] (not implemented)	Read only
		-	5	CNFG[3] (not implemented)	Read only
		-	6	Functional reset requested (FRESETR) (not implemented)	Read only
		-	7	Series topology detect	Write only
		-	15 – 8	Reserved	Read only

67.6.3.5.3.2 Scan String (SCNS)

This is a 3-part command. The operand chooses the string to be read or written by the CR-Scan.

Table 1520. Scan String (SCNS)

SCNS			Scan String		
Opcode	Operand	CR-Scan	yyyyy	Description	R/W
01001	yyyyy	-	0	RDBACK[0] Register [31:0]	Read only
		-	1	RDBACK[1] Register [31:0] (not implemented)	Read only
		-	2	CNFG[0] Register [31:0]	Read only
		-	3	CNFG[1] Register [31:0] (not implemented)	Read only
		-	4	CNFG[2] Register [31:0] (not implemented)	Read only
		-	5	CNFG[3] Register [31:0] (not implemented)	Read only
		-	6 - 7	Reserved (read logic 0)	Read only
		-	31 - 8	Private – available for customization	

67.6.4 EPU operating states

The TAP.7 controller and STL share the use of ZBSs. The EPU has three operating states as shown in [Figure 1610](#).

Figure 1610. EPU operating states

The values of the SUSPEND and ZBSINH Registers determine the type of operation as shown in [Table 1521](#). The Test-Logic-Reset state sets the SUSPEND and ZBSINH Register values to a logic 0.

Table 1521. ZBS use state characteristics with both TAP.7 and other ZBS use

ZBSINH	SUSPEND	EPU operating state	ZBS use by:	Until
0	0	RUNNING	EPU	Command allocates to STL
0	1	SUSPENDED	STL	ZBS sequence allocates to EPU
1	0	STOPPED	STL	Test-Logic-Reset state allocates to EPU
1	1	Not possible		

67.6.5 System and EPU Paths

The System path is utilized when the external tool requires access to system (STL) resources. This path is used when either the SUSPEND Register is a logic 1 or the ZBS count is less than or equal to one. The EPU path is used otherwise.

The EPU scan path is constructed from five types of EPU scan paths:

- **Bypass** – A 1-bit scan path
- **Bit** – Supports set and test bit operations (a 1-bit shift register)
- **String** – Support 32-bit reads or 32-bit writes
- **Enumerate** – A 36-bit scan path that transports a TAPC address with T3 and above TAP.7s
- **Auxiliary** – An n-bit scan path that transports 1 – n bits using a conventional IEEE 1149.1 style DR-Scan path using Control Levels 4 and 5.

67.7 APU (Advanced Protocol Unit)

67.7.1 Overview

The Advanced Protocol Unit (APU) is placed between the EPU and the RSU to create the T4 TAP.7 controller. The APU delivers advanced capabilities with a number of operating modes (new scan formats) that utilize the Standard Protocol and the Advanced Protocol in both the narrow and wide T4 TAP.7 versions.

The APU enables scan transfers with two signals by serializing the information related to a TAPC state machine state. It provides a number of serialization formats to balance scan flexibility and scan performance. It multiplexes the use of the TMS signal for T4 TAP.7 controller functions. The serialization is bypassed to provide T3 TAP.7 capability.

With a wide TAP.7, the chip architect may choose to implement the TDIC and TDOC signal functions as fixed functionality (the T3 TDIC and TDOC functions) or as programmable between the T3 TDIC and TDOC signal functions and an alternate function using a TAP.7 controller register. In this case, the default signal function may be either of the programmable choices. Programmable TDIC and TDOC functionality provides a means to fully utilize these signals in any scan topology as the T3 TAP.7 functionality is fully supported.

The entire EPU infrastructure (i.e., ZBS detection, control-level management, and command generation) is utilized when either the Standard Protocol or the Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state machine state progression. The EPU is unaware of the APU's existence. All T4 features are managed outside of the EPU.

The TAP.7 serialization schemes are specified with scan formats that complement the JScan 0-3 Scan Formats inherited from the T3 TAP.7. The scan formats are called advanced scan formats as they support two-signal operation.

Three groups of scan formats (MScan, OScan0-7, and SScan0-3) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. The OScan and SScan Scan Formats are broken into two groups with the same function, one group has better performance but may only be used with an external tool sourced TCKC. The external tool chooses a scan format that matches the constraints imposed by the application, chip components, and possibly the external tool itself.

The MScan and OScan formats address Test and Debug use cases. The mandatory MScan and OScan0-1 formats emphasize flexibility over performance. The remaining optional Oscan2-7 formats emphasize performance over flexibility by not transmitting unneeded information such as TDI and TDO in non-shift TAPC state machine states.

The optional capabilities added with T4 and above TAP.7s change the bit sequences seen at the TAP.7 signals. A TAP.7 controller comprehends only the bit sequences generated by the use of the features it supports. It is never exposed to bit sequences it does not comprehend. A check for supporting an enabled feature is made before the feature is used (alters the bit sequences). When a T4 TAP.7 controller detects the use of an unsupported scan format, it halts its operation and places itself in a state where its operation may be resumed. This state is henceforth called "offline". A TAP.7 controller that is not offline is henceforth called "online". While offline the TAP.7 controller awaits the detection of a special signaling sequence called the Online Activation Protocol. This protocol sequence places an offline TAP.7 controller online and synchronizes the operation of all online TAP.7s.

The Advanced Protocol Unit supports the stall of a transfer by both the external tool and STL at any TAPC state.

The APU provides the following functions:

- Bypass (for operation with the Standard Protocol)
- Scan control (for SP use)
- Configuration Control (for CP use)

The Scan Control, Configuration Control, and Transport Control functions are idled when the Standard Protocol is used as the Bypass Function connects the TCKC and TMSC pins to the EPU.

Figure 1611. Conceptual block diagram of the APU functions

The APU's internal interface includes a connection to EPU registers, the EPU's TAP interface, connections to chip-level data channels (when they are implemented), and reset signaling with the EPU. The APU's TAP interface provides mutually exclusive use of the TMSC pin for:

- Bypass Function
- Scan Control Function
- Configuration Control Function

When the Standard Protocol is used, the APU's Bypass function connects the EPU directly to the TAP.7 pins. When the TDIC and TDOC pin functions are not available (narrow TAP.7 or TDIC and TDOC pin functions are an alternate function), the APU sources a logic 1 to the EPU inputs associated with these pins.

When the Advanced Protocol is used, the APU multiplexes the use of the TMSC pin between the other APU functions. Scan Control acts as a serial to parallel converter, translating the parallel information at the EPU's TAP interface into bidirectional serial transfers. Since the Scan Control is literally a protocol adaptor, the entire EPU infrastructure (ZBS detection, control-level management, and command generation) is utilized when either the Standard or Advanced Protocol is used, as these TAP.7 controller attributes are controlled entirely from the TAPC state progression.

67.7.2 Operation

The conceptual view of the APU operation is shown in [Figure 1612](#).

Figure 1612. Conceptual view of APU operation

The APU operating states managing the use of the TAP pins and the ancillary (RSU) services use of the TMS pin.

APU operating states:

- **BPA** – ByPass Active
- **CPA** – Change Packet Active
- **SPA** – Scan Packet Active

67.7.2.1 BPA

The *BPA* state allocates the use of the TMS pin to the Standard Protocol. This state is entered two ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up online.
- From the CPA state when a TAP.7 controller register write specifies the use of the Standard Protocol.

67.7.2.2 CPA

The CPA state allocates the use of the TMS pin to a CP. This state is entered in one of three ways:

- As a result of a TAP.7 controller reset when the TAP.7 controller starts up offline.
- A value specifying the use of the Advanced Protocol is written to the SCNFMT Register when using the Standard Protocol.
- A TAP.7 controller register write occurs when using the Advanced Protocol.

67.7.2.3 SPA

The SPA state allocates the use of the TMS pin to an SP. This state is entered when the SCNFMT Register specifies the use of the Advance Protocol when a CP ends.

67.7.3 Escape sequences

Escape-sequence detection provides services to the Reset Logic, Scan, Configuration Control, and Transport Control functions as outlined below:

- **Scan and Transport Control** – End of Transfer (EOT) escape sequence detected.
- **Configuration Control** – Synchronize Advanced Protocol (SAP) escape sequence.
- **Reset Logic** – Reset (RES) escape sequence detected.

An EOT escape sequence is used to increase the efficiency of OScan Scan formats.

An SAP escape sequence is used to place TAP.7 controllers online.

A RES escape sequence asynchronously causes generation of a Type-3 Reset. Following a RES escape sequence, the drive of the TMS pin is inhibited so it is not driven when TCKC becomes a logic 0 immediately following the RES escape sequence.

67.7.4 Signal behaviors

The TCKC signal:

- The test clock

The TMS signal:

- An input when the Standard Protocol is used
- Bi-directional when the Advanced Protocol is used

The TDI and TDO signals:

- Deleted with a narrow TAP.7
- One of two functions with a wide TAP.7
 - Fixed – as the TAP.7 TDIC and TDOC pin functions, or
 - Programmable – as the TAP.7 TDIC and TDOC signal functions or alternate functions with a TAP.7 controller reset establishing the default signal function.

67.7.5 APU Functions

67.7.5.1 Bypass Active (BPA) Function

When the Standard Protocol is used, the APU connects the EPU inputs and outputs directly to the TAP.7 pins. If the TDIC and TDOC pin functions are not present (e.g., a narrow TAP.7

or the TDIC and TDOC pins have an alternate function assigned to them), the APU provides a logic 1 to the EPU for unsupported pin functions and ignores the EPU's TDO output data.

67.7.5.2 Scan Packet Active (SPA) Function

The Scan Control function is encapsulated within the Scan Packet Active (SPA) state. With the Standard Protocol, the external tool and TAP.7 exchange the scan information associated with a single TAPC state machine state in one TCK period using the TMS(C), TDI(C), and TDO(C) pins. With the Advanced Protocol all or part of this information is exchanged serially within a Scan Packet (SP) as shown in . There is a one to one correspondence between SPs and TAPC state machine state changes, except when the SPA state precedes the CPA state. In this case the SP preceding a CP does not advance the TAPC state machine state.

Figure 1613. Scan Packet sequence

A comparison of the parallel transfer of TAP information with the Standard Protocol and the serialization and de-serialization of the TAP information using the TCKC and TMSC pins with the Advanced Protocol is shown in FIGURE. The IEEE 1149.1 signals between the EPU and STL are prefixed with SYS_.

The APU manages the serialization and de-serialization of the scan information. The APU converts the TDI and TMS information within a Scan Packet (SP) into the TMS and TDI information presented to the EPU. It converts the combination of the EPU TDO and EPU TDO_OE signals into the TDO information in the same SP. If the EPU indicates that the TDO pin drive is not enabled, logic 1 TDO data is created, otherwise the TDO data is the supplied by either the EPU or STL.

Information within a Scan Packet is first passed from the external tool to the TAP.7 followed by information passed from the TAP.7 to the external tool. In this example the scan format specifies the exchange of the TMS, TDI, and TDO TAPC information. Each TAPC state machine state takes three TCKC periods. Other scan formats specify the exchange of different mixes of information. Control information is added with the most flexible scan formats. Some scan formats send less information and consequently take fewer TCKC periods.

Figure 1614. Serialization and De-serialization of Scan Packet Information

In order to produce comparable TAPC state machine state rates with a TAP.1 and TAP.7 controller:

- Full-cycle timing between the external tool and TAP.7 allows operation at higher TCKC frequencies.
- The number of bits transferred to advance a TAPC state machine is minimized. (reaching as few as one for some scan formats.)

The TAP.7 controller provides both full-cycle bit timing (falling TCKC edge to falling TCKC edge) and half-cycle bit timing (falling TCKC edge to rising TCKC edge), with a TAP.7 register used to define the type of timing used. Half-cycle timing is used as the default following a TAP.7 controller reset. The TCKC frequency is reduced to accommodate half-cycle timing.

With full-cycle timing, the TMSC input and output data are both output with and sampled with the falling edge of the TCKC. This means that the entire TCKC period may be spent transferring a bit from the external tool to the TAP.7 or vice-versa. The TCKC frequency can therefore be maximized when full-cycle timing is used. With half-cycle timing, the APU samples the TMSC input data with the rising edge of the TCKC and outputs TMSC data with the falling edge of TCKC.

Minimizing the number of bits transferred per TAPC state machine state is affected by a number of factors. The information that must be transferred per TAPC state machine state varies for different test and debug applications. Also, with some test and debug applications, all TAPC state machine states do not require that the same amount of information be transferred. This is especially true with debug applications where specialized use of the TAP is more likely.

67.7.5.3 Control Process Active (CPA) Function

While using the Advanced Protocol, all TAP.7 configuration changes occur within the CPA state. All online and offline transitions also occur while in the CPA state. When entering the CPA state from the BPA or SPA state, the CPA state checks for the use of supported features affecting the Advanced Protocol. The CPA state is exited when the enabled features affecting the Advanced Protocol are supported.

Figure 1615. CPA State Entry from BPA State with Continued Online Operation

An SP preceding a CP does not advance the TAPC state machine state. This SP performs housekeeping functions that assure the contents of the SP preceding this SP have been fully utilized. This has significance when the SP contains control information that allows the STL to stall the completion of a SP.

Figure 1616. CPA State Entry from the SPA State with Continued Online Operation

When an unsupported feature is enabled, the TAP.7 controller is placed offline. This suspends the TAP.7 controller's operation at a point where its operation may later be synchronized to the remainder of the system. The APU stops advancing the EPU's and CLTAPC's TAPC state machine state while offline. It also suspends Data Channels activity while offline. The detection of the appropriate Online Activation Protocol while the TAP.7 controller is offline places the TAP.7 controller online and causes an exit from the CPA state to the SPA state. An offline to online transition initiates the use of a predefined set of mandatory features in all online TAP.7 controllers to assure they operate synchronously.

Figure 1617. CPA State Entry from the BPA State with Offline Operation

Figure 1618. CPA State Entry from the SPA State with Offline Operation

A TAP.7 controller reset places the TAP.7 controller offline when the offline at start-up option is used. From this point the TAP.7 controller awaits being placed online.

67.7.6 Configuration Change Packets (CP)

A Change Packet (CP) is comprised of three element types:

- **Preamble** – A 1-bit value that is a don't care. This bit facilitates a Standard to Advanced Protocol change with some external tool implementations.
- **Body** – Two or more bits representing one or more CP directives
 - **00** – CP_END
 - **01** – CP_NOP (extends the body by 1-bit)
 - **10** – CP_NOP (extends the body by 1-bit)
 - **11** – CP_RES (Generate a Type-3 TAP.7 controller reset coincident with the postamble bit).
- **Postamble** – A 1-bit value that is a don't care. This bit facilitates and Advanced to Standard Protocol change with some external tool implementations.

A minimum-length CP has a Preamble, a 2-bit Body, and a Postamble. This can be as simple as four logic zero values.

67.7.7 Scan Packet

A Scan Packet defines the period of TMS pin activity where control information exchanged by the external tool and TAP.7 controller affects the TAPC state, except when the SP precedes a Change Packet. The external tool should view the Scan Packet as:

- Exchanging only the necessary TAPC information (TMS, TDI, and TDO or some subset thereof)
- Causing an advance of the TAP.7 TAPC state when it is not followed by a Change Packet.
- Causing an advance of the STL TAPC state when it is not followed by a Change Packet and when the STL is coupled.

With this perspective, the external tool views Scan Packets as running a virtual TAPC state machine at the TAP.7 pins. The effects of each Scan Packet take effect when the Scan Packet completes. The real TAP.7 and STL controller state machine states may change state before or after the virtual state machine.

67.7.8 SP Format

A SP serially exchanges the TDI, TMS, and TDO or a subset thereof, between the external tool and TAP.7 controller. Control information may be added to this exchange. A SP has three parts:

- **Payload** – Data + Control information (all scan formats), the payload content is varied to trade-off performance and flexibility. RDY bit(s) within the payload are included with some scan formats to provide the STL a means to stall progression of the TAPC state.
- **Delay** – Control information (optional) providing separation of adjacent payloads in time. Delay elements support simple external tool implementations where a delay element is used to stall progression of the TAPC state while it develops a new SP following the completion of the prior payload.

The header elements, delay elements, and control information within the payload element is consumed by the TAP.7 controller. This and other control information within the SP payload is not visible to the EPU and STL TAPCs.

67.7.8.1 Payload Element Content

67.7.8.1.1 Input and Output Bit Frames

An input bit frame is sourced by the external tool and an output bit frame is sourced by the TAP.7 controller. The payload may contain an input bit frame, an output bit frame, or both. When an input bit frame arrives at the TAP.7 controller, the TDI and TMS information within it is presented in parallel to the TAP.1 controllers within the EPU and STL. The output bit frame begins when the input frame is completed. The payload is completed when the EPU and STL are ready to utilize this information and the TDO data needed to complete the output bit frame is available. This process is repeated for each SP.

With input bit frames, MScan and OScan scan formats have no control bits input bit frames.

With output bit frames:

- TDO information passed to the external tool is a logic 1 when the EPU indicates the TDO pin would be high impedance.
- RDY bits provide TAP.7 stall opportunities with MScan and some OScan formats.
- PC0 and PC1 bits are added to MScan scan formats to allow Wire-ANDed output.

67.7.8.1.2 Varying the content of input and output bit frames

The various scan formats (MScan, OScan0-7) provide a number of options for the serialization of scan information for use in a Star-2 scan topology. These scan formats vary the content of SPs to balance flexibility and performance for different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use cases. The MScan and OScan scan formats determine the factors affecting the payload content as shown in [Table 1522](#).

Table 1522. Factors determining the SP payload content

Scan format	Payload content determined by the :	
	TAPC state	Header
MScan	—	—
OScan	Yes	—

67.7.8.2 Delay Element Content

A delay element can be zero, one, two, or n bits in length. One and two bit delay elements are fixed length with neither the external tool or TAP.7 controller driving the TMSC pin. The TMSC pin is kept at the last value driven by either the external tool or TS. With an n-bit delay elements, the external tool drives the TMSC pin for the first n-1 bits and may drive the TMSC pin the nth bit. With an n-bit delay element the string of delay element bits is a series of directives virtually the same as those used by a CP (DLY_NOP, DLY_END, and DLY_RES).

67.7.8.3 Scan Formats

67.7.8.3.1 Overview

Scan formats utilizing the Advanced Protocol address different use cases. The amount of information transferred per TAPC state is based on the constraints imposed by these use

cases. In one extreme two types of control information, the first allowing the stall of the completion of the Scan Packet, and the second supporting the Wire-AND of TAP.7 controller output are added to the TMS, TDI, and TDO information within the Scan Packet. In the other extreme, the external tool may minimize the information transferred for each TAPC state using its understanding of the application and transfer only the data of interest. In some cases the transfer of only one bit of information per TAPC is required. There are a number of scan formats that operate between these two extremes. The external tool chooses a scan format that best matches the performance/functionality needs of the application.

The scan formats added to specify the use of the Advance Protocol are listed below:

- **MScan** – Maximum flexibility.
- **OScan0-7** – Optimized for test and debug applications.

These scan formats provide seven different functions. Five factors have influenced the definition of these scan formats:

- Supporting the capabilities of the IEEE1149.x and IEEE 1532 Standards.
- Providing the STL and external tool an opportunity to stall the TAPC state progression.
- Providing a minimum pin count and scalable functionality.
- Maximizing the efficiency of scan operations utilized for applications debug operations.
- Providing a rich set of capability for high end applications debug.

The performance and flexibility of MScan and OScan scan formats are shown in [Table 1523](#) and [Table 1525](#), respectively. The performance and flexibility of these scan formats are given subjective/approximate ratings in these tables. These ratings range from least to best. Use cases for these scan formats are also included in these tables.

67.7.8.3.2 MScan scan formats

The MScan scan format provides a universal scan function. It is the most flexible but lowest-performance scan format. The Scan Packets used by these scan formats are packed with data and control information and is the same for all TAPC states. This scan format accommodates the deployment of IEEE 1149.1 IP with non-compliant behavior within the STL. The STL is allowed to stall the TAPC state progression (to pace the arrival of Scan Packets with its ability to process them), and uses Wire-ANDed Output.

Table 1523. MScan scan format use case summary

Scan format	Supporting	Performance	Flexibility	TCKC source
MScan	STL Stalls	Least	Best	External tool or TS
	Test			
	Non-compliant behavior STL IP			
	Multi-chip debug communication			
	Controller ID Allocation

Figure 1619. MScan Transaction

67.7.8.3.3 OScan Scan Formats

The OScan scan formats provide optimization choices where no knowledge of the data content of the scan exchange is needed. The Scan Packet content of these scan formats is modulated by a combination of the scan format and the TAPC state for some OScan scan formats. For instance, TDI data and TDO data is not exchanged for non-shift TAPC states and included in shift TAPC states in certain OScan formats. The modulation of Scan Packet content with TAPC state varies by scan format.

Figure 1620. OScan Scan Packet content/TAPC state relationships

OScan scan formats replicate four functions in two forms:

- **OScan0 – OScan3:** Providing the best performance for a test clock source by the target system.
- **OScan 4 – OScan7:** Providing the best performance for a test clock sourced by the external tool.

The OScan4 – OScan7 scan formats are more efficient, as EOT escape sequences are used to identify an exit from the Shift-xR TAPC state. A Scan Packet associated with the Shift-xR TAPC state does not include a TMS bit. Instead, an EOT escape sequence overlaid on an nTDI bit causes an exit from shift TAPC state with no exit from this state occurring otherwise. A look at the 32-bit DR-Scan shows the impact of this optimization. A total of 96 bits are required when each Scan Packet associated with a Shift TAPC state when TMS is included in these Scan Packets while a total of 64 bits are required when TMS is not included in these Scan Packets. Assuming the EOT escape adds the equivalent of three bit periods, the number of TCK periods for this transfer is 67/96 or roughly 70% of the total without this optimization.

These scan formats may only be used with an external tool sourced TCKC as EOTs are utilized to improve its performance. The OScan0 – OScan3 Scan Formats always have a TMS bit included in the Scan Packet. The OScan scan format use case summary is shown in [Table 1525](#).

Table 1525. OScan scan format use case summary

Scan Format	Supporting	Performance	Flexibility	TCKC Source
OScan0	Stalls	↓	Best	External tool
OScan1	Test		↑	
OScan2	Debug Performance			
OScan3	Debug Downloads (input only)	Best		External tool or TS
OScan4	Stalls	↓	Best	
OScan5	Test		↑	
OScan6	Debug Performance			
OScan7	Debug Downloads (input only)	Best		

Certain OScan optimizations are applied in a hierarchical manner.

- **Optimization I:** OScan1/OScan5 – RDY bit(s) and their trailing ONE bits are deleted from all Scan Packets.
- **Optimization II:** OScan2/OScan6 – Optimization I + nTDI and TDO bits are deleted from Scan Packets associated with non-shift TAPC states.
- **Optimization III:** OScan3/OScan7 – Optimization II + TDO bits are deleted from Scan Packets.
- **Optimization IV:** OScan4 – OScan7 – TMS bits are deleted from Scan Packets associated with shift TAPC states.

Table 1526. OScan Scan Format “Payload”

Scan Format	Non-shift TAP controller states					Shift TAP controller states			
OScan0	nTDI	TMS	RDY	TDO		nTDI	TMS	RDY	TDO
OScan1	nTDI	TMS	–	TDO		nTDI	TMS	–	TDO

68 JTAG Data Communication (JDC)

68.1 Introduction

The JTAG Data Communication (JDC) module provides the capability to move register data between the IPS and JTAG domains. This facilitates communication between internal resources that access memory mapped register space and an external tool that accesses the JTAG port.

68.2 Overview

The JDC module consists of IPS accessible registers, JTAG accessible registers, and associated logic to coordinate movement of data from one register domain to another.

The JDC implements the following IPS data registers, occupying separate memory space:

- 32-bit memory mapped register that can be read or written via IPS (JOUT_IPS), and whose contents are ported out for capture into a JTAG register (JOUT) to be read via the JTAG port.
- 32-bit memory mapped register that can only be read via IPS (JIN_IPS), and whose contents are loaded from a JTAG register (JIN).

In addition to the data registers themselves, logic is implemented to indicate when new data has been shifted in via the JTAG port and is ready to be read from the JIN_IPS register, and when new data has been written to the JOUT_IPS register and is ready to be read via the JTAG port. The state of these flags is captured into a status register (MSR), and also provided to a JTAG register (JOUT) for tool visibility.

The JTAG accessible registers are provided through an instance of the existing JTAC module.

There is a single bus interface to port register data out to the JTAC, and a single bus interface to port data in from the JTAC. The architecture is shown in [Figure 1621](#).

Figure 1621. JDC block diagram

68.3 Register definition

[Table 1527](#) shows the JDC module registers. Four 32-bit registers are implemented. Only 32-bit accesses are valid. The effects of access that are not 32 bits are not defined.

Table 1527. JDC memory map

Address offset	Register	Access	Reset value	Location
0x0	Module Configuration Register (MCR)	R/W	0x0000_0000	on page 2971

The JOUT_IPS register is described in [Table 1530](#).

Table 1530. JOUT_IPS register field descriptions

Field	Description
JOUT_IPS Data	Contains JOUT_IPS data.

68.3.1.4 JTAG input IPS data register (JIN_IPS)

Data written to the JTAG input data register (JIN) via the JTAG port is held in the JIN_IPS register, where it can be read via IPS. [Figure 1625](#) shows the format of the JIN_IPS register.

Figure 1625. JIN_IPS register

The JIN_IPS register is described in [Table 1531](#).

Table 1531. JIN_IPS register field descriptions

Field	Description
JIN_IPS Data	Contains JIN_IPS data.

68.3.2 Non-Memory mapped register definition

The JDC also implements two JTAG accessible registers that are not memory mapped. One JTAG register is used to shift in data to be placed in the JIN_IPS register. The other JTAG register captures data from the JOUT_IPS register and ready status from the MSR to be shifted out via the JTAG port.

68.3.2.1 JTAG output data register (JOUT)

The JOUT register captures data from the JOUT_IPS register upon execution of the JOUT_READ JTAG instruction. It also holds the JIN_RDY and JOUT_RDY status bits. [Figure 1626](#) shows the format of the JOUT register.

1. The reset value of the JOUT register is 34'b0.

Figure 1626. JOUT JTAG register

The JOUT register is described in [Table 1532](#).

Table 1532. JOUT JTAG register field descriptions

Field	Description
JOUT_IPS Data	Data value from JOUT_IPS register
JIN_RDY	State of JIN_RDY bit from MSR
JOUT_RDY	State of JOUT_RDY bit from MSR

68.3.2.2 JTAG input data register (JIN)

Data is written to the JIN register via JTAG during execution of the JIN_WRITE JTAG instruction. The JIN data is later captured in the JIN_IPS register to be read via IPS.

[Figure 1627](#) shows the format of the JIN register.

1. The reset value of the JIN register is 32'b0.

Figure 1627. JIN JTAG Register

The JIN register is described in [Table 1533](#).

Table 1533. JIN JTAG register field descriptions

Field	Description
JIN Data	Contains data to be captured in JIN_IPS register upon exit of Update-DR state when executing WRITE_JIN JTAG instruction.

68.4 Functional description

The JDC module provides the ability to shift in data via the JTAG port and capture that data into a memory mapped register that can be accessed via IPS. It also provides the ability to capture data written to a memory mapped register into a JTAG shift register for output via the JTAG port. An overview of the module functionality is described below.

- A software write to the JOUT_IPS register sets the JOUT_RDY flag bit, indicating new data is available to be read from the JOUT register via the JTAG port. The state of the JOUT_RDY bit is reflected in the MSR and also ported out to the JOUT register. A JTAG read of the JOUT register via execution of the JOUT_READ instruction with a JOUT_RDY bit whose value is logic 1 indicates the register contains new data. The JOUT_RDY flag bit is cleared upon exit of the Capture-DR JTAG state during execution of the JOUT_READ instruction. Clearing the JOUT_RDY bit indicates to software that a new data value can be written to the JOUT_IPS register.
- A JTAG write to the JIN register via execution of the JIN_READ JTAG instruction updates the contents of the JIN_IPS register upon exit of the Update-DR state. An update of the JIN_IPS register sets the JIN_RDY flag bit, indicating new data is available to be read via IPS. The state of the JIN_RDY bit is reflected in the MSR register and also ported out to the JOUT register. The JIN_RDY flag bit is cleared upon software read of the JIN_IPS register. A JTAG read of the JOUT register with a JIN_RDY value of logic 0 indicates new data can be written to the JIN register.

68.4.1 IPS register access

IPS access is available to the registers described in [Section 68.3.1, Register descriptions](#).

68.4.2 JTAG register access

Refer to the JTAGC documentation for information on how to access the JTAG registers.

68.4.2.1 JDC block instructions

The JDC block implements the IEEE 1149.1-2001 defined instructions listed in [Table 1534](#). This section gives an overview of each instruction; refer to the IEEE 1149.1-2001 standard for more details. All undefined opcodes are reserved.

Table 1534. JTAG instructions

Instruction	Code[4:0]	Instruction Summary
Reserved	00001	Factory debug reserved
JOUT_READ	00010	Selects JOUT data register. Data from JOUT_IPS is captured into JOUT data register upon entry to Capture-DR state while JOUT_READ is active.
JIN_WRITE	01110	Selects JIN data register. Data from JIN is captured into JIN_IPS upon exit of Update-DR state while JIN_WRITE is active.
BYPASS	11111	Selects bypass register for data operations
Reserved	All other opcodes	Decoded to select bypass register

68.5 Use case example

A summary of how the JDC can be used to interact with the Hardware Security Module (HSM) to perform challenge/response password authorization is as follows:

1. After exit of reset, all registers are at their reset values. JIN_RDY bit value of 0 indicates the tool may write data to the JIN register. JOUT_RDY bit value of 0 indicates that software may write data to the JOUT_IPS register.
2. The MCR register is programmed to enable JOUT and JIN interrupts, or not.
3. Once the tool is ready to start the authorization process, it writes a value to the JIN register via execution of the JTAGC JIN_WRITE instruction.
4. Software monitors the state of the JIN_RDY bit or enables the JIN interrupt and uses the interrupt assertion as a trigger to start the authorization process.
5. Once the authorization process is started, software writes the first JOUT value to the JOUT_IPS register. This sets the JOUT_RDY bit value to 1.
6. Following the initial tool write to the JIN register, the tool polls the JOUT register to determine when software has provided a challenge word. Upon reading the JOUT register with JOUT_RDY bit set, the tool records the data value to be used to generate the appropriate response. The read of the JOUT register clears the JOUT_RDY bit.

The clearing of the JOUT_RDY bit also sets the JOUT_INT bit and asserts the JOUT interrupt if the MCR[JOUT_IEN] is set.

7. With the JOUT_RDY bit cleared, software may now provide the next challenge word.
8. Once the tool has generated a response word, it uses the value of the JIN_RDY bit from the JOUT register read to determine when it can perform a write to the JIN register to provide the response.
9. The HSM can provide additional challenge words and read back the corresponding response words as needed, repeating the process.

Simply providing a password without using the challenge/response protocol can be done in a similar way. The tool provides 32-bits of the password at a time with each write to the JIN register, and monitors the JIN_RDY bit value of the JOUT register to determine when the next JIN register value can be written. There is no need for software to write the JOUT_IPS register in this case.

69 Sequence Processing Unit (SPU)

69.1 Introduction

The Sequence Processing Unit (SPU) provides an on-device trigger functions similar to those found on a logic analyzer. In a complex SoC, performance monitor functions are available at two levels: system level and CPU level. Complex trigger and system performance monitor functions are implemented in the SPU module. System level performance monitor functions are integrated into the SPU complex trigger logic, and thus allow counting and timing of any debug trigger combinations supported by the SPU.

Various clients such as the cores, GTM, or crossbar switch, generate watchpoints and triggers when operating in their debug mode. The SPU collects these triggers (such as interrupt occurrence, address watchpoint, and so on) and uses them as conditions to sequence through states, with resultant actions (such as start/stop trace, start/stop counter, capture timebase, and so on). The SPU provides the capability to create complex debug triggers. By configuring each of the events to trigger specific actions, complex logic-analyzer-like behavior can be achieved, providing vital real-time visibility and debug ability of the activities of the system.

69.1.1 SPU block diagram

Figure 1628 shows a top-level block diagram of the SPU.

Figure 1628. SPU block diagram

69.1.2 Overview

The SPU is able to generate complex debug events, based upon input events from sources (CPUs, GTM, and system bus clients) throughout the SoC. The SPU has the ability to create a state machine to trigger a debug action. Single or multiple actions can be triggered by a state machine, which results in debug events being created. There are a selection of timers and counters available to assist comparison events.

Complex trigger support is implemented in the State Logic Unit (SLU). There are numerous inputs coming from different clients. Users can choose 63 inputs from a set of 209 inputs at the level one Mux. There are actually 64 inputs to the Muxes but one of the inputs is permanently connected to a high level, so users can only choose 63 of the inputs. Out of these 63 inputs, users can select 16 inputs for each SLU. This is shown in [Figure 1667](#).

One SLU consists of four input AND gates, the output of which are ORed together. One of the inputs of each AND gate has the option to invert it. Also, the output of each AND gate can be optionally inverted. Finally, the output of each SLU has the option of inversion. The block diagram for one SLU state is shown in [Figure 1668](#). The SPU includes eight SLUs states.

Users can utilize these states to form a configurable state machine. This allows users to join states together with the if-then-else operations to create a sequence. Each state in a sequence has the ability to move to another state based on the true condition from the state logic, and the ability to route to another state based on the a false condition from the state logic. This is shown in [Figure 1669](#) and [Figure 1670](#). At a given time, a maximum of four sequences are allowed. Each sequence can have one state or maximum of eight states. Each state can only be used in one unique sequence. The number of states in all the sequences cannot exceed eight. Each state has the ability to trigger one to four actions based on a true/false condition in the active sequence.

An example of typical complex trigger for the SPU would be: if FunctionA is entered, monitor CPU0 writes to VariableB. If CPU0 writes a value to VariableB which is 0x100, then enable trace for the GTM and halt CPU 0.

The SPU consists of the following sub-blocks:

- Input Mux Unit—receives the numerous triggers from various clients and reduces them down into a user selected set. The muxing unit selects sixteen inputs for each sequencing SLU from a set of 63 static inputs. This selection is done using two levels of muxing. At the first level of muxing, users select 63 out of 209 inputs. At the second level of muxing, out of these 63 inputs, one input can be selected for each of the four input AND gates. There are 128 64×1 Muxes to cater the needs of 128 inputs of all the eight states. This input mux selection logic is shown in [Figure 1667](#).
- State Logic Units (SLU)—responsible for performing operations on the selected input events to produce desired events. Each SLU has a control register that manages how the various inputs are combined to produce a desired event. Only one input of each four input AND gate can be independently inverted. The combined event can also be optionally inverted. These optional inversions coupled with DeMorgan's law allows for generalized signal combinations. This is shown in [Figure 1668](#).
- Action Processing Unit—takes an action request from a SLU state and converts this into one or multiple actions. The action unit can be programmed to trigger various actions in response to each processed event from the SLU unit. The user can define the actions associated with each state from each SLU.
- Counters/Timers—The SPU implements 16 32-bit timer/counter functionality. Timer or counter selection is done via a configurable register in the SPU. Each counter/timer

has its own control register. A 32-bit comparator value can optionally be compared against the timer/counter. These registers are accessible via JTAG.

69.1.3 Features

The features of the SPU are as follows:

- clients:
 - 3 CPUs
 - 1 GTM
 - 2 System Bus clients(NXMC)
- Input watchpoints/triggers selection
- Input debug triggers for instruction execution selection
- Input interrupt selection
- Sequences and states criteria
 - Up to 4 user programmable number of active/simultaneous sequences
 - Up to 8 user programmable states that can be split between all four sequences
 - Each state can only be used in one unique sequence
 - A sequence can consist of a single state or any number of states up to 8
- State logic
 - Each state logic consist of sum of products (SOP)
 - SOP consist of four 4-input AND gates, and one 4-input OR gate
 - Optional inversion on one input of each AND gate of each state logic
 - Optional inversion on output of each AND gate.
 - Optional inversion on output of OR gate of each state
 - States are joined together with if-then-else statement to create a sequence
- SLU events
 - Up to 8 user programmable derived events/actions
 - Any state can optionally trigger of 1 to 4 actions based on a true condition
 - Any state can optionally trigger of 1 to 4 actions based on a false condition
 - User selection of trigger actions generated in response to each programmed trigger

- SPU counters/timers
 - 16 32-bit counters/timers
 - Timer/counter configurability selection via a register
 - Start/increment when used as timer/counter respectively
 - Reset when used as timer/counter respectively
 - Counter value compare match
 - Counter overflow event status
 - Generation of a greater than condition against a 32-bit comparator value (no support for range condition from single counter)
 - Range support using two counters
 - Use of counter/timer registers to generate counted or timed triggers
 - Use of counter/timer registers to capture system performance statistics
 - Each timer/counter value has the ability to be inserted into the Nexus trace stream upon an SPU action
 - Access to timer/counter values via JTAG
- Prescaler for timer mode only
 - Configurable prescaler of /1, /4, /16 or /32 of the clock for timer operation inside the SPU
- Asynchronous interfaces
 - SPU to/from CPU (fastest clock)
 - SPU to/from NXMC
 - SPU to/from GTM
 - SPU to/from NAR
 - SPU to/from DCI
 - SPU to/from JTAGM
- Interfaces
 - CPU
 - GTM
 - System bus
 - NAR
 - DCI
- Configuration registers—32-bit double word aligned configuration registers (byte and halfword access not supported)
- SPU actions—SPU block triggers various actions based on the derived events, these actions are defined in [Section 69.2, SPU actions](#)

69.2 SPU actions

Sequence actions describe what is triggered. A sequence state may only have a GoTo action to determine the next sequence state. The complete set of actions are as follows:

- Start/stop trace for a source
- Start/stop/increment counter/timer counter/timer[0–15]
- Reset counter/timer[0–15]
- Capture counter/timer Values[0–15]—place the specified counter/timer value into the trace stream for counters[0–15]
- Halt1—single signal (EVTI0) that can be used to halt a pre-configured DCI group1
- Halt2—single signal (EVTI1) that can be used to halt a pre-configured DCI group2
- Generate a watchpoint trigger for a respective ID field the NXMC (global timestamp must be enabled from the NAR)
- Capture the global timebase and place it into the trace stream with a watchpoint ID field of respective watchpoints at the NXMC (send TIMESTAMPx where x is related to an watchpoint ID field of NXMC only)
- Single interrupt for INTC to interrupt a CPU—de-assert (cleared) via JTAGM]
- Generate a pulse on the EVTO pin—output pulse over EVTO1 and EVTO2
- Start or Stop Performance Counters (PMC) for a CPU source—Start/Stop CPUn
- Optional trace group 1 (Start/Stop Trace a pre-configured set of trace signals)—four (DTM,PTM,WTM,OTM) independent start/stop trace groups can be formed. One or more clients (CPUn and Nexus) can be part of a particular group.

Note: GoTo is not part of the Action list described above but it is implemented in the state logic to move from one state to another. If there is nothing defined for GoTo, it signifies the end of the sequence.

In the condition where a state (State n) updates a counter and the next state in the sequence (State n+1) evaluates the value of the same counter (for example, to compare if the counter is less-than a certain value), the update to the counter (from State n) is not applied before the counter evaluation in the next state (State n+1). This results in the old value of the counter being evaluated (in State n+1), rather than the desired updated value. This is due to hardware limitations of the SPU as the update to the counter does not complete until the clock cycle after the evaluation of the next state. This limitation is only applicable in Div1 mode and not in Div4 mode.

To workaround this hardware limitation, a delay should be inserted between the update to a counter and the evaluation of this counter. A dummy state can be used between the counter update (State n) and the counter evaluation (State n+1). A dummy state is a state with any input, that on both then/else conditions, the action proceeds to the next state (State n+1) where the counter evaluation occurs. The insertion of this dummy state provides sufficient time for the update of the counter to be applied, in time for the counter evaluation. The same outcome is also possible in a complex sequence with multiple states by scheduling states so that counter update and counter evaluation are not performed on consecutive states in a sequence.

69.3 Operation mode

69.3.1 SPU enable/disable

By default, the SPU is in disabled mode. In this state, all events/inputs are disabled such that no counting or other actions occur. All the SPU control registers are accessible in this state. All the configurations must be done before enabling the SPU by programming the SPU Enable/Disable register.

69.4 SPU module interface

The SPU is connected to many clients such as the cores, GTM, system bus, NAR and Nexus clients. The SPU also interfaces to the DCI and the JTAG modules as shown in [Figure 1629](#).

Figure 1629. SPU module interface

69.5 Register definition

The SPU contains 32-bit aligned registers (byte and half-word access are not supported). All configuration registers in the SPU are JTAG registers such that these registers are accessible via JTAG interface only. Write access to reserved locations have no impact while read access to reserved locations always return 0. These registers have Nexus reset and JTAG reset control.

Note: The SPU does not check for correctness of the programmed values in the registers and programmers must ensure that correct values are being written.

[Table 1535](#) lists the memory mapped registers which control the operation of the SPU. There are two instructions for the SPU registers:

- Instruction to enable the SLU (first set of registers with offsets 1–0x49) registers is 4'h3
- Instruction to enable the Counter Control Unit (second set of registers with offsets 1–72) is 4'h2

Table 1535. SPU register summary

Offset (hex)	Register	Access	Reset Value	Location

69.5.1 Register descriptions

69.5.1.1 Level1 input Mux configurations registers

A set of input Mux control registers is used to narrow down the large number of SPU watchpoints to a manageable set. There are sixty-four 8×1 (eight inputs and one output) multiplexers. Three bits per Mux are used to select one input out of 8 inputs. 8 Muxes are configured with each 32-bit register; in other words, 8 inputs out of 64 for each register. This provides the flexibility to the programmer to route any input trigger to any state input. The detail of this selection is shown in [Figure 1667](#).

Note: Users cannot program MUX 63 in L1SEL7 (the 64th mux). All eight inputs of the 63rd mux are tied to high and the output is always high (1'b1).

69.5.1.1.1 Level1 Mux Selection 0 (L1SEL0)

[Figure 1630](#) shows the format of the L1SEL0 register. The values for the fields of the L1SEL0 register are device dependent. For a description of these fields, see the device-specific chapter that describes how the modules are configured.

69.5.1.2 Level2 input Mux configurations registers

At level1, the set of input Mux control registers (described in [Section 69.5.1.1, Level1 input Mux configurations registers](#)) narrows down the large number of SPU watchpoints to a manageable set using sixty-four 8×1 multiplexers. At Level2, 16 inputs are selected for each SLU from the 64 level1 outputs using 16 64×1 multiplexers. Six bits per Mux select one input out of 64 (in fact 63) inputs. Each 32-bit register configures the AND gates of one state; therefore, eight registers are used to configure inputs for the 8 SLUs. All the 63 inputs are static for all the eight states. Any 16 inputs can be selected from the 63 input triggers for a state.

The detail selection is shown in the [Figure 1667](#) for State0. Similar logic is provided for States 1–7.

Figure 1646. Level2 Mux AND gates input pin routing for State0

Note: If any SLU AND gate is unused, then its output is logic low (1'b0). Thus, if all four inputs of a particular AND gate are at the default value 1'b1 (none of the inputs have been routed from the Level 2 mux to the inputs of AND gates), then the output of that AND gate is logic low. This provides protection to avoid the masking of other inputs to the OR gate.

69.5.1.2.1 Level2 Mux state n selection 0 (L2nSEL0)

[Figure 1647](#) shows the format of the L2nSEL0 register, where n, the state number, is equal to 0–7.

Figure 1647. L2nSEL0 register format

69.5.1.3 Sequence unit registers

69.5.1.3.1 Input/output Inversion control state n (IOICn)

An input control register is provided for each event generated by the SLU. This register is programmed to specify how the input signals to each SLU are combined to generate the resulting event for that particular sequence. In total, there are 16 inputs for each state and only one (the first) of the inputs can be used with or without inversion. The input can be left unused if not required for that state by selecting 000000 (No input selected option) in the L2nSEL registers. The output of each AND gate has the optional inversion control as well. The output can be routed directly or with inversion from each AND gate to the input of OR gate. [Figure 1651](#) shows the format of the IOICn register, where n, the state number, is equal to 0–7.

9:31	Reserved. Read returns 0.

69.5.1.3.2 Sequence control (SCTRL)

This configuration register is provided to enable the sequence and to select the states that are part of a particular sequence. There can be at most four active sequences. Each sequence can have one state or a maximum of eight states. However, each state can only be used in one unique sequence. In other words, if one state has been selected for a sequence, then this state cannot be used for any other defined sequence. Each sequence has a start state and end state. [Figure 1652](#) shows the format of the SCTRL register.

30:28 ST2	Sequence 4 End State. 000 State 0 is the Stop state for sequence 4 001 State 1 is the Stop state for sequence 4 010 State 2 is the Stop state for sequence 4 011 State 3 is the Stop state for sequence 4 100 State 4 is the Stop state for sequence 4 101 State 5 is the Stop state for sequence 4 110 State 6 is the Stop state for sequence 4 111 State 7 is the Stop state for sequence 4
31	Reserved. Read returns 0.

- Multiple active sequences such as Sequence 2, Sequence 3 and Sequence 4 must be programmed with Div4 option only.
- Ideally, the start state for a sequence should be the state immediately after the stop state for the previous sequence. For example, if sequence 1 starts at state 0 and ends at state3, sequence 2 should start at state4.

69.5.1.3.3 State n goto control (SnGC)

SLU states are linked to each other based on if-then-else conditions. There are two conditions: true and false. A SLU state can remain in the same state or jump to any other state. The state goto control register is programmed to specify the GoTo a particular state from current state.

[Figure 1653](#) shows the format of the SnGC register, where n, the state number, is equal to 0–7.

Figure 1653. SnGC register format

The SnGC register fields are described in [Table 1549](#).

Table 1549. SnGC register field descriptions

Field	Description
0 TE	GoTo Control of State Under True Condition. Defines the Goto control of a state under the true condition. If this bit is enabled, then the State moves to the next state based on bits[3:1]. If disabled, then this is the end of a sequence when the sequence comes to this state. Actions associated with states under true condition are executed. Disabling this bit ends the sequence under a true condition. 0 Disable Goto control 1 Enable Goto control
3:1 NT	Next State on True Condition. Defines the Goto next state in case of true condition from the present state. States may remain in the same state on a true condition if the same state is chosen as the next state. 000 Goto State 0 001 Goto State 1 010 Goto State 2 011 Goto State 3 100 Goto State 4 101 Goto State 5 110 Goto State 6 111 Goto State 7
4 FE	GOTO Control of State Under False Condition. Defines the Goto control of a state under the false condition. If this bit is enabled, then the state moves to the next state based on bits[7:5] . If disabled, then this is the is end of a sequence when the sequence comes to this state. Actions associated with states under false condition are executed. Disabling this bit end the sequence under a false condition. 0 Disable Goto control 1 Enable Goto control
7:5 NF	Next State on False Condition. Defines the Goto next state in case of false condition from the present state. States may remain in the same state on a false condition if the same state is chosen as the next state. 000 Goto State 0 001 Goto State 1 010 Goto State 2 011 Goto State 3 100 Goto State 4 101 Goto State 5 110 Goto State 6 111 Goto State 7
31:8	Reserved. Read returns 0.

69.5.1.4 SLU status (SS) register

The SLU status register indicates the states that have been hit/encountered in any of the active sequences. [Figure 1654](#) shows the format of the SS register.

Figure 1654. SS register format

The active state might be different in the previous clock and the next clock. 000 State0 is the active state 001 State1 is the active state 010 State2 is the active state 011 State3 is the active state 100 State4 is the active state 101 State5 is the active state 110 State6 is the active state 111 State7 is the active state
16:14 SAS3	Sequence 3 Active State. Two consecutive read cycles are required to know the active state. These bits capture the active state of sequence 3 at the clock when these bits are read. The active state might be different in the previous clock and the next clock. 000 State0 is the active state 001 State1 is the active state 010 State2 is the active state 011 State3 is the active state 100 State4 is the active state 101 State5 is the active state 110 State6 is the active state 111 State7 is the active state
19 :17 SAS4	Sequence 4 Active State. Two consecutive read cycles are required to know the active state. These bits capture the active state of sequence 4 at the clock when these bits are read. The active state might be different in the previous clock and the next clock. 000 State0 is the active state 001 State1 is the active state 010 State2 is the active state 011 State3 is the active state 100 State4 is the active state 101 State5 is the active state 110 State6 is the active state 111 State7 is the active state
20 EM0	Exception Match 0. This bit indicates the status of the processor exception vector match value of CPU0. 0 No match 1 Match occurred
21 EM1	Exception Match 1. This bit indicates the status of the processor exception vector match value of CPU1. 0 No match 1 Match occurred

Table 1550. SS register field descriptions (continued)

Field	Description
22 EM2	Exception Match 2. This bit indicates the status of the processor exception vector match value of CPU2. 0 No match 1 Match occurred
23 IM0	Interrupt Match 0. This bit indicates the status of the match value on interrupt priority register of CPU0. 0 No match 1 Match occurred
24 IM1	Interrupt Match 1. This bit indicates the status of the match value on interrupt priority register of CPU1. 0 No match 1 Match occurred
25 IM2	Interrupt Match 2. This bit indicates the status of the match value on interrupt priority register of CPU2. 0 No match 1 Match occurred
31:26	Reserved. Read returns 0

69.5.1.5 SPU enable (SE) register

The SPU enable/disable register is used to enable and disable the SPU. If disabled, all inputs are masked. [Figure 1655](#) shows the format of the SE register.

Figure 1655. SE register format

The SE register fields are described in [Table 1551](#).

Table 1551. SE register field descriptions

Field	Description
0 SED	SPU Enable/Disable. This bit should be set after programming all of the SPU configuration registers. 0 SPU is disabled 1 SPU is enabled
1 DIV	Div Option. Select Div4 and Div1 programmable options based on number of active sequences. 0 Use Div4 option, when multiple up to four sequences are active or only one sequence is active which does not require the highest resolution. 1 Use a Div1 option, when only one sequence (Sequence1) is active and highest resolution is required
31:2	Reserved

Note: *Div option mapping with active sequences must be correctly programmed by the user. No hardware checks are implemented.*

69.5.1.6 Sample and hold mechanism

SPU supports Div4/Div1 sample and state processing frequency (both are effectively the same). For the Div1 option, the sample and state processing frequency is the SPU clock frequency. Likewise, for the Div4 option, the sample and state processing frequency is 1/4th the SPU clock frequency.

The Div1 or Div4 is related to hold circuitry (among other circuits as well), but the sample circuitry is always Div1. Therefore, if Div4 is selected for hold circuitry, then four samples are taken and then latched into a hold circuitry (for the next four Div1 clocks, synchronized for all inputs).

This sample and hold mechanism is applicable for external signals only, but counters logic process differently. These external signals may be considered as selected conditions for any sequence, and for any of the states of any sequence. There is no difference based on state or sequence, as all inputs are treated the same regardless.

69.5.1.6.1 Functional limitations

If there are multiple true conditions in a Div4 period, only one condition is registered. Never are there any missed true conditions, except for extra true conditions in a Div4 period. Therefore, the user should select the resolution of SPU based on number of active sequences.

- If the signal changes faster than the sample and state frequency, then the SPU would probably only detect one event per the sample period (for example: If there are multiple true conditions in a Div4 period, only one condition is registered).
- If the signal changes faster than the sample and state frequency, then the SPU would only be able to process one event per state processing frequency.

69.5.1.6.2 Assumption

When using Div1, SPU counter operations are not available for state evaluation in the immediately next clock cycle. Therefore, special handling must be done in state evaluation during this delayed effect to assure that it does not create undesirable results. Refer to counter workaround description in [Section 69.2, SPU actions](#).

When using Div4, however, there are no delayed effects when using SPU counter operations. This is because subsequent state evaluations are done four clocks apart, instead of every clock for Div1 selection. Therefore, counter workaround description in [Section 69.2, SPU actions](#), becomes redundant with Div4 option.

69.5.1.7 SLU action unit registers

The action unit of the SPU is responsible for generating the action triggers supported by various actions. List of the actions is given in [Section 69.2, SPU actions](#). The action triggers are mapped to the events by programming the action registers. Each event can be programmed to trigger interrupts, watchpoints, trace signals, counter stop/reset/increment and many other general actions. [Table 1552](#) shows the bit mapping for all the possible actions. All possible actions are divided in three groups: client based, counter based, system related.

Table 1552. SPU action decoder

Group bit [11:10]		Client/counter bit [9:5]		Action bit [4:1]			Enable bit [0]

1. The valid actions for Trace group are OTM trace, PTM trace, DTM trace or WTM trace. No other actions can be selected with Trace group. The group can be defined using the Trace group configuration registers.

69.5.1.7.1 State n true action 0 (SnTA0)

The SPU can be programmed to enable up to four different actions against a True condition of every state. All the possible actions and their encoding are listed in [Table 1552](#). A total of 12 bits are needed to code every action. The first two actions for true condition are defined in SnTA0 and the next two actions are defined in SnTA1.

[Figure 1656](#) shows the format of the SnTA0 register, where n, the state number, is equal to 0–7.

Figure 1656. SnTA0 register format

The SnTA0 register fields are described in [Table 1553](#).

Table 1553. SnTA0 register field descriptions

Field	Description
0:11 ACTION1	Action 1 to be performed for State n true condition. The decoding of these bits is defined in Table 1552
12:15	Reserved
16:27 ACTION2	Action 2 to be performed for State n true condition. The decoding of these bits is defined in Table 1552
28:31	Reserved

69.5.1.7.2 State n true action 1 (SnTA1)

The SPU can be programmed to enable up to four different actions against a True condition of every state. All the possible actions and their encoding are listed in [Table 1552](#). A total of 12 bits are needed to code every action. The first two actions for true condition are defined in SnTA0 and the next two actions are defined in SnTA1. [Figure 1657](#) shows the format of the SnTA1 register, where n, the state number, is equal to 0–7.

Figure 1657. SnTA1 register format

The SnTA1 register fields are described in [Table 1554](#).

69.5.1.7.5 Trace group configuration registers (DTMGC, PTMGC, OTMGC and WTMGC)

There are four action trace groups and a configuration register for each trace group:

- DTM trace—clients are configured with the DTM trace group configuration (DTMGC) register
- PTM trace—clients are configured with the PTM trace group configuration (PTMGC) register
- OTM trace—clients are configured with the OTM trace group configuration (OTMGC) register
- WTM trace—clients are configured with the WTM trace group configuration (WTMGC) register

Each of these groups are specific to a trace. Any number of clients can be enabled for one trace using the action trace group.

[Figure 1660](#) shows the format of the trace group configuration registers.

Figure 1660. Trace group configuration register format

The trace group configuration register fields are described in [Table 1557](#).

Table 1557. Trace group configuration register field descriptions

69.5.1.8 Counters/timers control n (CTRLn) registers

There are 16 configurable counters/timers in the SPU. Configuration control of these counters is defined in the counter control registers. [Figure 1662](#) shows the format of the CTRLn registers, where n, the counter number, is equal to 0–15.

Figure 1662. CTRLn register format

69.5.1.9 Counters/timers compare n (CCMPn) registers

A 32-bit comparator value can be programmed for each of the counters. This value is compared with the corresponding counter/timer to generate an event for the SPU. [Figure 1663](#) shows the format of the CCMPn registers, where n, the counter number, is equal to 0–15.

Figure 1663. CCMPn register format

The CCMPn register fields are described in [Table 1560](#).

69.6 Functional description

69.6.1 Input Mux unit

The SPU receives numerous inputs in the form of complex triggers from various clients to create a predefined sequence. One state logic can accommodate 16 inputs at one point of time. Therefore, an input Muxing unit becomes essential for reducing the debug and performance events to a manageable set of 16 inputs for each SLU. In addition to client input signals, there are certain performance events which are fed directly to the different counters inside the SPU.

The selection of 16 inputs for each state logic is done at two level of muxing both of which are shown in [Table 1667](#).

- Level 1 Muxing—At this level, there are 209 inputs. Out of these possible inputs, 63 inputs are selected. This selection is done using an 8:1 Mux. Therefore, sixty-four 8×1 muxes are required. The set of 63 watchpoints are passed to the second level of muxing. The selection mechanism is shown in [Figure 1667](#).
- Level 2 Muxing—At this level, 16 inputs are selected out of the 63 possible inputs for each SLU. These 63 inputs consist of multiple set of 8 watchpoints from different clients, processor exception signals, interrupt from clients, and event IN/OUT signals. In addition, certain events from counters are used as feedback in the present state logic of each state.

At level two there are 16 banks of 64:1 muxes for the selection of 16 inputs for one state logic. The inputs to these Muxes are expected to be somewhat unique. In general, care should be take to choose signal assignments that allow for key use cases to be achieved without encountering concurrency restrictions. Since there are eight such states, 16×8 banks of 64:1 mux are required. The selection mechanism is shown in [Figure 1667](#).

Figure 1667. Input Mux unit block diagram

69.6.2 Processor exception vector encoding

Active-high input signals from the CPU indicate the particular exception being processed when the CPU exception enable signal is asserted. These signals can be used for debug triggering mechanisms. The SPU captures the CPU exception vector whenever the CPU exception enable signal is asserted and the SPU uses the exception vector as an input

condition as shown in [Table 1564](#). The CPU exception vector values from the CPUs must be byte swapped before they are programmed to the CPU_n field of the CnPEVP (n = 0–2) registers as shown in [Table 1564](#).

Table 1564. Processor exception processing conditions

CPU exception vector	CnPEVP register CPU _n field value	Exception condition
0x0000	0x0000	Critical Input—autovectored
0x0010	0x1000	Machine check
0x0020	0x2000	Data storage
0x0030	0x3000	Instruction storage
0x0040	0x4000	External input—autovectored
0x0050	0x5000	Alignment
0x0060	0x6000	Program trap
0x0061	0x6100	Program illegal
0x0062	0x6200	Program privileged
0x0070	0x7000	Performance monitor
0x0080	0x8000	System call
0x0090	0x9000	Debug
0x00A0	0xA000	EFPU data exception
0x00B0	0xB000	EFPU round exception
0xVVVV ₃ , low two bits = 01	0xVVVV ₃ , high two bits = 01	External input—vectored
0xVVVV ₃ , low two bits = 01	0xVVVV ₃ , high two bits = 01	Critical input—vectored

69.6.3 State logic unit (SLU)

Complex triggers and system performance monitor functions are implemented in the SLU. The SPU creates debug events based upon states in a sequence. A sequence can consist of a single state, or any number of states up to 8. Each state consists of combinational logic allowing AND/OR operations on inputs from the trigger source unit. Single or multiple (up to 8) actions can be triggered by a state machine.

A logic diagram of one SLU state is shown in [Figure 1668](#).

Figure 1668. SLU block diagram

Each state consists of AND gates, the outputs of which are ORed together.

- Each AND gate can have up to 4 inputs, selected from the trigger source unit by the user.
- The user has an option to invert one input signal into the AND gate.
- The OR gate has a user selectable option to invert the output.
- The output of the OR gate is used as the trigger to move to the next state in the sequence.

The SLUs are responsible for performing operations on the selected input events to produce derived events. Each SLU has a control register that manages how the various inputs are combined to produce a derived event.

An event is triggered from each state based on all the possible selected inputs for each state. This event is used to trigger an Action.

Note: With only one optional inversion at the input of each AND gate and optional inversion at the output of the OR gate, many combinations are not possible.

69.6.4 Sequence formation

Event sequencing can be accomplished with the if-then-else operations. The next event can be fed back as a necessary condition for the current event. For example, event5 can be designated as a necessary condition for event4 in case test condition fails in event5. Event5 can be in turn be designated as necessary for event6 in case test condition passes, and so on. In this way, events can be chained together to create a sequence.

To create complex triggers, a configurable state machine is implemented. This allows the user to join states together with if-then-else operations to create a sequence. The SPU supports up to four simultaneous sequences, however only eight states are supported regardless of the number of active sequences, and each state can only be used in one unique sequence.

For example, the following state configurations are possible:

- 1 active sequence, with 8 states
- 2 active sequences, each with 4 states
- 2 active sequences, the first with 3 states and the second with 5 states
- 4 active sequences, each with 2 states
- 4 active sequences, each with 1 state

Each sequence has the following options which are shown in [Figure 1669](#):

- The ability to optionally trigger one or more actions based on a true condition from any state in the sequence.
- The ability to optionally trigger one or more actions based on a false condition from any state in the sequence.
- Each state in a sequence has the ability to route to another state on a true condition from the state logic, and the ability to route to a different state based on a false condition from the state logic

Figure 1669. Example of a simple configurable if-then-else sequence

69.6.4.1 Complex sequence example

A user can create a complex sequence using five states as shown in the state transition diagram in [Figure 1670](#).

Figure 1670. Complex sequence example

69.6.4.2 Typical sequence example

For this example, the user would like to create a timestamp in the trace stream each time a function is entered, and upon the 12th time of entering the function, stop the trace signal. This use case can be implemented as follows:

- State 0 takes an instruction address compare as its input. On a match of the instruction address to a specific function, called function_x, the sequence moves to State 1. Upon this action, State0 is configured to insert a timestamp into the trace stream and also increment an SPU counter, say counter[0].
- The sequence is now in State 1. State 1 takes an input from counter[0]. Counter[0] has been pre-configured to create a match event when the counter value is equal to 12.
 - If the value of counter[0] is less than 12, then the sequence moves back to State0.
 - If the value of counter[0] is equal to 12, then the sequence completes and an action from State1 disables the trace signal.

69.6.4.3 Sequence status register description

A status register providing feedback on each sequence is provided to allow debug tools to identify the source of a debug event from the SPU. The status register consists of two field types:

- States—each state has a sticky bit that is set upon a true match of the state logic. This sticky bit is cleared upon a write to this register.
- Sequence status—each sequence has a field indicating the active state of the state machine. This is a read only field.

69.6.5 Performance counters/timers unit

The SPU counters are 32-bit counters that may be used to delay events, count distances, count latencies or count events as shown in [Figure 1671](#). Therefore, these counter are used as either counters or timers. The selection between counter or timer for each of the counters is done via configuration register. The basic counting operation is straightforward. Once enabled (default is disabled mode), whenever the selected input is driven to a logic 1, the counter increments using the platform clock.

Each of the counter/timer registers are accessible (via the JTAG interface) for the configuration of timer/counter, the compare registers and global SPU timer/counter status registers. These register are accessible via the JTAG interface even when the SPU is in disabled mode.

Figure 1671. Counters/timers overview

69.6.5.1 Counter events and actions

Each counter is capable of detecting one event condition, such as compare value match. The compare value match is used for triggering actions in the SPU. Each counter can be reset in response to a reset action generated from the SPU. Capture registers are available for capturing the counter state in response to a SPU trigger condition. This capture information is updated in the status register which is accessible to users via JTAG interface. These status registers are if type write 1 to clear (W1C).

There are two classes of signals, actions and events:

- **Actions**—each timer/counter has an interface from the action unit to start/increment and reset as appropriate. The start/increment signal is a single signal, with the

operation selected in the SPU configuration registers. The generation of the appropriate count/reset signal is generated in the SPU.

On an action to insert the timer/counter value into the trace stream, the value stored in the timer/counter is buffered inside the SPU and routed to the appropriate SoC block to insert the value into the trace stream one by one.

- Events—on a match event, whereby the a timer/counter value matches the value of the respective compare register, a signal is sent to the trigger source unit to indicate this.

69.6.5.2 Counter input selection at SPU level

There are two main inputs that are considered to increment the count of a counter. Each counter has the option to increment itself either from the SPU action or direct from the CPU performance measurement counters (CPU_PMC), as shown in [Figure 1672](#). These inputs include signals from the primary SPU muxes or SPU events of counters.

Figure 1672. Input selection for count increment

69.6.5.3 Counters increment assignment

When configured as a counter, the counter has an increment signal. This can optionally be routed from the SPU action unit, or directly from a CPU performance counter signal. The assignment of which signal is used to increment a counter is handled in the SPU, and is configurable by user. The assignment of increment signals to counters is shown in [Figure 1673](#).

Figure 1673. SPU counters increment assignment

69.6.5.4 CPU PMC mapping to counters

Each of the CPUs in the system has four performance measurement counters (PMC). The outputs (overflow signals) from these counters (of CPU_n) are routed to the SPU debug unit. The counters inside the SPU can be configured to count the pulses from the PMCs. There is a one-to-one mapping between the PMC inputs and the counters that they trigger. Their mapping is shown in the [Figure 1674](#).

Figure 1674. CPU PMC mapping inside the SPU unit

69.6.6 Action unit

The action unit block of the SPU is responsible for the generating the action triggers supported by various actions. A state has true and false (if-else-then) condition. Four simultaneous actions can be generated under true/false condition of a particular state. The list of the actions is given in the [Section 69.2, SPU actions](#). The actions triggers are mapped to the events by programming the set of SPU group action control for events registers. Each event can be programmed to trigger interrupts, timestamp watch points, trace signals, PMCs, start/reset/increment counters and many other general actions.

69.6.7 Optional trace group

User defined trace group can be defined through the configuration register. Configuration registers registers, defined in [Table 1557](#), are available where the user can group the different traces from same or different clients.

70 JTAG Master (JTAGM)

70.1 Introduction

The JTAG Master (JTAGM) is a module that is able to act as JTAG master inside the device. The module has a parallel interface that can exchange data with another serial communication module (such as the LFAST module) or via customer software.

The data transferred to this module is transformed to produce TCK, TMS, TDI and TRST outputs and to accept TDO inputs. The JTAGM is connected in the device to allow these five signals to connect to the JTAGC as if the JTAG data is coming from an outside tool. The JTAGM generates all required JTAG scan chains to allow software and high speed serial communication access to all JTAG mapped resources.

70.1.1 Overview

The JTAGM is the master to drive JTAG signals from within the device. It has options to receive parallel data from software through the IPS interface or from the LFAST through the parallel interface. The JTAGM has the capability to differentiate between data from software and LFAST. It then sends this data on TDI, TMS and TCK to the DCI. The JTAGM also receives serial data through TDO from the DCI and transfers this data to the LFAST through another parallel interface. The JTAGM has the following registers:

- Configuration register
- Status register
- Four data output registers
- RxCRC receive register
- Two data input registers

All these registers, described in detail in [Section 70.4, Memory map and register definition](#), are memory mapped and can be accessed by software.

The clocks for the JTAGM are derived from the system clock. The JTAGM also samples the ready signal from the Nexus, to provide a more efficient handshake to the external tool to read and write any memory mapped address location within the device.

[Figure 1675](#) shows the block diagram of the JTAGM.

Figure 1675. JTAGM block diagram

70.1.2 Feature description

The main features of the JTAGM are the following:

- Provides efficient handshake to the external tool to read any memory mapped address location within the device
- Provides software the option to write data for driving JTAG
- Receives/provides JTAG data from/to the LFAST

70.2 Functional description

70.2.1 Module architecture

The JTAGM is simple in concept. TCK is generated from the device system clock. Data is pushed to the modules via a 32-bit wide parallel interface. The data is in the form of 60 bits of TMS data and 60 bits of TDI data. This data is the logical state to be driven onto the TMS and TDI output pins on each of the 60 TCK cycles. During these 60 TCK cycles, the TDO pin is sampled and the 60 bits of sampled data is transferred to the 32-bit wide module

interface. This concept allows complete flexible generation on TMS and TDI data and capture of TDO data. The only limitation is that JTAG signals can only be generated in 60 TCK cycles packets. Extra cycles are wasted in idle cycles at the end of a scan chain.

Figure 1676 shows the flow diagram of the LFAST to DCI connection.

Figure 1676. LFAST-to-DCI flow diagram

70.2.2 JTAGM JCOMP usage in LFAST

JTAGM is used to drive JTAG sequences in software mode and in LFAST mode. The JTAGM_MCR[jtagm_JCOMP] bit is provided to reset all TAP controllers by generating a JCOMP signal to JTAGC.

The guidelines to be considered for the usage of JTAM_MCR[jtagm_JCOMP]:

- Do not clear the JTAM_MCR[jtagm_JCOMP] bit while in LFAST mode as this operation is not guaranteed
- If for some reasons during the LFAST mode there is a loss of communication, one of the following should be done (instead of clearing the jtagm_JCOMP bit):
 - Generate the escape sequence and then, once the device is back in JTAG mode, generate a test-logic-reset state via the TCK and TMS signals. This resets all TAP controllers but does not affect the client debug configuration
 - Generate the escape sequence and then, once the device is back in JTAG mode, force the JCOMP pin low. This resets all TAP controllers as well as the client debug configuration

Note: The escape sequence is generated by forcing LFAST LVDS ports RX+ and RX- to zero.

70.2.3 JTAM data error detection

To improve the integrity of the JTAG operation, data passed to and from the JTAM includes an 8-bit CRC only in LFAST mode. The data sent to the JTAM consists of 60 bits of TMS data, 60 bits of TDI and an 8-bit CRC. The JTAM recalculates the 8-bit CRC for the first 120 bits of data and compares the result with the received CRC. If the two match, the data is assumed to be valid and the JTAM converts this data into a valid JTAG frame.

If the CRCs do not match, the module sets the CRC error status bit (CRC_err) in the JTAM status register (JTAM_SR) and sends a standard 96-bit response frame to the LFAST channel B, with all 60 data bits set to 0. The CRC error status bit is automatically cleared as soon as the response frame has been sent to the LFAST.

Data sent from the JTAM to the LFAST also includes an 8-bit CRC. The data sent from the JTAM is in the form of a 96-bit frame consisting of 60 bits of TDO data + 4 bits of zero-padding + 32 bits of the status register. The 8-bit CRC value is calculated for the first 88 bits of the 96-bit frame and inserted into the least significant 8 bits of the status register; which is also the last 8 bits of the 96-bit frame. The tool is responsible for checking the CRC of the received data and taking corrective action.

70.2.4 JTAM message tagging

The JTAM, in conjunction with the LFAST, is pipelined to allow several JTAM messages to be sent from the tool before any response is received back. This allows better utilization of the LFAST bandwidth. To enable the tool to associate individual messages with the correct response, the messages are tagged. The tool sends data messages on LFAST channels E, F, G and H in sequence. The JTAM module returns responses on the same channel they were received. For example, if the tool sends a data command on channel E, JTAM returns the response on channel E; if the tool sends a data command on channel F, the JTAM returns the response on channel F; and so on. This way, the tool can ensure a response was generated by a specific command.

Configuration commands to write/read the configuration and status registers within the JTAM are sent on channel A and response data is also sent back on channel A.

70.2.5 JTAM Ready signal

The Nexus Read/Write Access (RWA) module allows an external tool to read and write any memory mapped address location within the device via JTAG commands. Read accesses to memory take a finite amount of time and a JTAG read of the data register too soon results in erroneous data being read back. There is a bit in a JTAG register to show the read data is available. In conventional JTAG mode, the status of this ready bit is also provided back to

the tool via a dedicated pin to allow the tool to know data is ready and the JTAG read register can be accessed. With the LFAST interface providing pipelined data to the JTAGM, this technique is not available. Two interlocked mechanisms are provided within the JTAGM that use this ready bit to allow optimized data reads without ready bit errors.

70.2.5.1 Status register ready bit

A bit is provided in the JTAGM status register to indicate the status of the ready signal. To provide this ready signal functionality, the ready signal is monitored. If the ready signal has toggled between the start of the previous 60 TCK shift period and start of the current 60 TCK shift period, the ready bit in the JTAGM status register is set. Otherwise the ready bit in the status register is cleared.

The entire content of the 32-bit status register is appended to the 60 bits of JTAG TDO data captured along with 4 bits of 0-padding and sent as output on the parallel output port as a 96-bit payload on channel A. This provides back to the tool, an indication that the data read in the current transaction is valid.

70.2.5.2 Inter-JTAG frame gap timer

To operate in conjunction with the status register ready bit, a configurable timer is provided to force a programmable gap between the end of one 60-bit JTAG frame and the start of the next. This timer is configured via the JTAGM configuration register from 1 to 64 TCKs in 1 TCK intervals. Furthermore, if the ready signal asserts during this inter-frame gap period, the gap timer is aborted and the next JTAG frame starts immediately.

70.2.6 $\overline{\text{EVTO}}$ and $\overline{\text{EVTI}}$ signals

The standard Nexus EVTI (Event In) and EVTO (Event Out) signals are optionally present on dedicated package pins and are used by an external tool in conjunction with the JTAG interface to pass information, events and triggers between the tool and the MCU.

The JTAGM as well as providing a higher speed alternative to the standard JTAG interface, also allows control and status of the EVTI and EVTO signals to be embedded into the serial protocol. The EVTI0 and EVTI1 signals can be asserted by writing control bits in the Module Configuration Register (JTAGM_MCR). The JTAGM can be configured by bits in the Module Configuration Register (JTAGM_MCR) to respond to a rising/falling/both edge transition of either EVTO0 or EVTO1. The response is either an unsolicited serial message to the tool when in LFAST mode (DTM = 0); or a CPU interrupt when in software mode (DTM = 1).

The unsolicited LFAST message is sent on LFAST channel B to allow the tool to distinguish the message from normal JTAG response data (channels E, F, G & H) and Config Command Responses (channel A). The CPU interrupt is gated by an Interrupt enable bit, in MCR and reported by Interrupt Status flags in the Status Register (JTAGM_SR). The status bits stay set until cleared by writing to the clear bits in the JTAG_SR.

Asserting the evti0_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. Asserting the evti1_assert bit in the JTAGM_MCR register can trigger debug mode in the DCI. The DTM bit in the JTAGM_MCR register can put the DCI in LFAST or SW mode.

70.2.7 JTAGM configuration and status monitoring

The JTAGM module requires some level of configuration and status monitoring. The JTAGM includes a 32-bit configuration register (JTAGM_MCR) and a 32-bit status register (JTAGM_SR, which includes the ready bit mentioned in [Section 70.2.5.1, Status register](#)

ready bit). The configuration register is accessed via the parallel input port by a 128-bit payload arriving on channel A. The 128-bit payload is made from the following:

- 32-bit mask of which bits within the configuration register should be written +
- 32-bit value to be written to the configuration register +
- 24-bit mask of which bits within the status register should be written +
- 8 bits of zero-padding +
- 24-bits of data to be written to the status register +
- 8-bit CRC (The least significant 8 bits of the status register cannot be written because they contain automatically generated CRC data).

The masked data is transferred to the 32-bit configuration register and 32-bit status register. The JTAGM module responds to this configuration/status write by outputting a 96-bit payload to the parallel output port to channel number A. The 96-bit payload is made up of the 32-bit value of the configuration register plus 32 bits of zero-padding plus 32-bit value of the status register (including the least significant 8 bits which are an 8-bit CRC calculated on the previous 88 bits).

While the current messages are being transmitted from the second buffering (memory mapped registers), the first buffers are continuously filled up. The status register also includes status bits provided by the LFAST module and the DCI module. The JTAGM requests data from the LFAST only when at least one internal buffer is free.

70.2.8 JTAGM to DCI serial interface

Figure 1677 shows the data transfer timings between JTAGM and DCI.

Figure 1677. JTAGM to DCI serial interface diagram

70.2.9 JTAGM data handling and CRC calculation in LFAST mode

Figure 1678 shows the bit ordering when a data frame is transmitted from LFAST to JTAGM for subsequent transmission to DCI.

bit 127 to bit 68				bit 67 to bit 8				7	6	5	4	3	2	1	0
TMS (60 bits)				TDI (60 bits)				CRC (8 bits)							
bit 0 to bit 59				bit 0 to bit 59											
Last TMS bit transmitted by JTAGM		First TMS bit transmitted by JTAGM		Last TDI bit transmitted by JTAGM		First TDI bit transmitted by JTAGM									

Figure 1678. Bit ordering for LFAST to JTAGM transfer

[Figure 1679](#) shows the bit ordering when a data frame is transmitted from JTAGM to LFAST consisting of TDO data received from DCI.

bit 95 to bit 36			bit 35 to bit 32			bit 31 to bit 8			7	6	5	4	3	2	1	0
TDO (60 bits)			0 pad (4 bits)			JTAGM_SR (24 bits)			CRC (8 bits)							
bit 0 to bit 59			bit 0 to bit 59			bit 31 to bit 8										
First TDO bit received by JTAGM		Last TDO bit received by JTAGM														

Figure 1679. Bit ordering for JTAGM to LFAST transfer

The CRC calculation is described in following example.

The data transferred from LFAST to JTAGM (in four frames) is as follows:

- D0—F7B3_D591
- D1—E6A2_C486
- D2—A2C4_80F7
- D3—B3D5_9183

These are supplied to CRC block starting from D0 to D3. The CRC calculation begins on D0 with the MSB (left bit) going first. D3 is supplied as B3D5_9100 (after masking CRC).

JTAGM extracts TMS and TDI information from the data received as follows:

- TMS = F7B3_D591_E6A2_C48
- TDI = 6A2C_480F_7B3D_591

JTAGM transmits the data to DCI starting from LSB (right bit going first). Corresponding to this TMS and TDI transmission, JTAGM receives TDO data from DCI and stores it as first bit to most significant location in TDO frame (shown in [Figure 1679](#)).

70.2.10 Software interface

It is possible for software to write the 120 bits of JTAG data to be output and to read the 60 bits of data. The JTAGM module has an IPS interface.

70.3 Modes of operation

There are no special modes of operation. The JTAGM works normally in the debug mode.

70.4 Memory map and register definition

[Table 1565](#) contains the memory map of the JTAGM registers.

The JTAGM_SR register is described in Table 1567.

Table 1567. JTAGM_SR register field descriptions

Field	Description
0 overrun	Set by hardware when the JTAGM overwrites the first Tx data with the second Tx data. Writing 1 clears this bit. This bit is set only in LFAST mode.
1	Reserved
2:7 lfast_status	Status information from the LFAST to be used by software. The composition of these bits are as follows: bit 2 Indicates either data frame or ping frame was transmitted successfully bit 3 Indicates Tx data Interface not enabled and a frame is ready to be transmitted bit 4 Indicates Rx data FIFO overflow bit 5 Indicates reception of frame with invalid frame payload size bit 6 Indicates reception of frame with invalid ICLC code bit 7 Indicates reception of illegal LCT frame
8:15 dci_status	Status information from the DCI. The composition of these bits are as follows: bit 8 Reserved to 0 bit 9 DCI LVDS port enable bit 10 DCI JTAG port enable bit 11 DCI LVDS safe mode bit 12 DCI JTAG safe mode bit 13 DCI LVDS escape mode bit 14 DCI enable LFAST bit 15 DCI tool present , set when a debug tool is connected

Table 1567. JTAGM_SR register field descriptions (continued)

Field	Description
16 evto0_edge	In LFAST mode (DTM = 0) a channel B message is sent on LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto0_clr bit 0 No activity sensed on $\overline{\text{EVTO0}}$ 1 Activity defined by evto0_sense detected on $\overline{\text{EVTO0}}$
17 evto1_edge	In LFAST mode (DTM = 0) a channel B message is sent to the LFAST and the bit is automatically cleared. In software mode (DTM = 1), the bit stays set until cleared by writing to evto1_clr bit 0 No activity sensed on $\overline{\text{EVTO1}}$ 1 Activity defined by evto1_sense detected on $\overline{\text{EVTO1}}$
18 SPU_INT_CLR	Write 1 clears the SPU_INT This is a self clearing bit. If SPU_INT is not set then SPU_INT_CLR remains set until SPU_INT is set, and both are cleared.
19 SPU_INT	This bit is set when the SPU interrupt request input rising edge is detected. Writing a 1 to SPU_INT_CLR resets this bit.
20 CRC_err	CRC error bit. Set when the calculated CRC does not match the last received CRC. This bit is cleared when the error packet is sent to the LFAST on channel B.
21 Nexus_err	Nexus error bit. It is set when there is an error, else it is 0.
22 Idle	Idle bit. Idle bit is cleared while a JTAG frame is in progress. This bit is set to 1 when a JTAG frame ends. Writing a 1 to the Idle bit clears the Idle_interrupt in SW Mode. A read always gives the JTAG frame status but does not give the write value.
23 NR	Status of Ready bit from Nexus RWA. This bit is automatically cleared when a new JTAG message is started. 0 RDY has not asserted indicating Nexus RWA is not ready 1 RDY has asserted indicating a Nexus RWA has completed bus access and is ready for the data register to be read <i>Note: In LFAST mode (when DTM = 0), this bit has no effect and acts as a "don't care". This bit should not be used by the application in the LFAST mode</i>
24:31 CRC	Calculated CRC. CRC calculated on the information received. LFAST Mode: Bit 24:31 reads the CRC. Write has no effect. SW Mode: – Bit 24:31 reads as 0x00. Writing a 0 to any bit have no effect. – Writing 1 on bit 24 clears evto0_edge – Writing 1 on bit 25 clears evto1_edge

70.4.1.3 Data out register 0 (JTAGM_DOR0)

[Figure 1683](#) shows the format of the JTAGM_DOR0.

28:31	Reserved

71 LVDS Fast Asynchronous Serial Transmission (LFAST) – High Speed Debug

71.1 Introduction

This chapter describes the specifications of the LVDS Fast Asynchronous Serial Transmission (LFAST) module. LFAST is used in slave only mode enabling high speed debug communications through the JTAG port.

71.2 Block diagram

Figure 1690 depicts LFAST interaction with other modules on the device.

Figure 1690. LFAST block diagram

71.3 External signals

LFAST is a six pin interface with the following signals after enabling high speed debug mode:

- lfast_sysclk_en
 - Interface enable signal in LFAST Slave Only mode
- lfast_sysclk
 - Reference clock of the LFAST master and slave
- txdatap/txdatan
 - Differential transmit (Tx) interface pair
- rxdatap/rxdatan
 - Differential receive (Rx) interface pair

LFAST interface is an asynchronous high speed LVDS interface with maximum data rate of 320 Mbps.

71.3.1 LFAST operating data rates

[Table 1575](#) shows the operating modes for the LFAST interface.

Table 1575. Operating modes for LFAST interface

Interface	Tx/Rx Data Rate
LFAST Transmit	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps
LFAST Receive	6.5 Mbps / 5 Mbps or 312 Mbps or 320 Mbps

The change of data rate is controlled by the LFAST master by issuing appropriate Interface Control Logical Channel (ICLC) packets to the LFAST slave. Henceforth, the data rate 6.5 Mbps/5 Mbps ($\text{lfast_sysclk} \div 4$ or $\text{lfast_sysclk} \div 2$) is referred to as low and data rates 312 Mbps and 320 Mbps is referred to as high data rates.

71.4 LFAST frame structure

LFAST frames are transmitted and received across a serial interface using a packeted asynchronous communication format.

A LFAST frame is made up of three fields:

- Sync pattern
- Header
- Payload

Sync pattern and header fields are of fixed length. A sync pattern is used to synchronize incoming data stream in LFAST module.

Header field of the frame distinguishes various types of data and control transferred and also contains information about the length of the payload. The payload field is the actual data that is transferred across the channel. See [Figure 1691](#) for details of the LFAST frame.

Figure 1691. LFAST frame structure

The same protocol is used on both transmit and receive interfaces for communications of data, control and status information. A synchronization pattern (16 bits) and header (8 bits) are present in every frame.

Figure 1692. Serial frame structure

The frame structure is shown in [Figure 1692](#) and consists of the following:

- **16-bit synchronization pattern:** Used for clock synchronization and pattern recognition. The frame synchronization code at the start of every frame is a unique reserved word that is used to identify whether the data received is the start of the frame and for synchronization (clock phase extraction) with the stream data. A synchronous sequence is used to give a high quality auto correlation. The LFAST 16-bit synchronization sequence = 1010_1000_0100_1011b = A84Bh.
- **Header - 3 MSB (b7 - b5):** Defines the payload size according to [Table](#) .

Table 1576. Header payload sizes

b7-b5 (bin)	Payload Size	Frame Size
000	8	32
001	32	56
010	64	88
011	96	120
100	128	152
101	256	280
110	288	312
111	—	—

- **Header - (b4 - b1):** Defines the logical channel types, which indicate the type of payload that the frame carries. How the payload field of a frame is used for any other logical channel type is system side module specific except in the case of the interface control logical channel type.
- **Header - (b0):** CTS on the both LFAST master and slave devices. In slave only mode the CTS field will always be 1.
- **Payload: Content dependent upon frame type.**
- **Bit after frame:** This bit determines entry into Sleep mode (1 = Sleep mode, 0 = normal mode).

71.5 Features

- Supports slave only mode.
- Supports asynchronous data transfer rates up to a maximum of 320 Mbps
- Transmits and receives data and unsolicited frames.
- Receives ICLC frames
- Supports processor controlled transfer of ICLC frame with 8-bit payload size to implement the data rate changes and test modes.
- Supports flow control using sliding window protocol.
- Provides transmit of data frame length with 96 bits of payload size and reception of data frame with 128 bits of payload size.
- Provides configurable frame length for unsolicited frame with variable payload sizes of 8, 32, 64, 96, 128, 256 or 288 bits.
- Supports PLL configuration (for example, feedback loop divider, etc.) through registers.
- Supports LVDS configuration through registers.
- Supports multiple loopback modes for checking the physical interface.
- Supports automatic ping response generation.
- Supports for detection of unsupported channel number and unsupported payload size.

71.6 Memory map and register definition

All registers are 32 bits wide.

71.6.1 Memory map

Table 1577. LFAST memory map

The conventions in [Figure 1693](#) and [Table 1578](#) serve as a key for the register summary and individual register diagrams.

Figure 1693. Key to Register Fields

[Table 1578](#) provides a key for register figures and tables and the register summary.

Table 1578. Register conventions

Convention	Description
	Depending on its placement in the read or write row, indicates that the bit is not readable or not writable.
FIELDNAME	Identifies the field. Its presence in the read or write row indicates that it can be read or written.
Register Field Types	
R	Read only. Writing this bit has no effect.
W	Write only.
R/W	Standard read/write bit. Only software can change the bits value (other than a hardware reset).
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
Self-clearing bit	Writing a one has some effect on the module, but its cleared by the H/W once the operation defined by the bit is over
Reset Values	
0	Resets to zero.
1	Resets to one.
[signal_name]	Reset value is determined by polarity of indicated signal.

71.6.2 Register descriptions

71.6.2.1 Mode Configuration Register (MCR)

Figure 1694. Mode Configuration Register (MCR)

Offset: 0000h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
R	0	0	0	0	0	0	0	IPGDBG	0	0	0	0	0	0	0	0
W																LSSEL
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

1. Set by user software and cleared by system hardware.

Table 1579. MCR field descriptions

Bits	Description
0-6	Reserved
7 IPGDBG	Control bit to enable support for IPG Debug mode. This mode is indicated by assertion of IPG debug mode signal. 0 IPG debug mode enable signal will be ignored. 1 IPG debug mode enable signal will not be ignored.
8-14	Reserved
15 LSSEL	Selects the fraction of sysclk in Low Speed Select mode. Refer to Section 71.10.2, Slow speed clock for more detailed description. 0 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/2. 1 Low Speed Mode in which where lfast_sysclk input is used to generate 4 phases of lfast_sysclk/4.
16 DRFEN	LFAST Enable. This bit enables/disables the reception and transfer of LFAST device. 0 LFAST is immediately disabled. All current/pending requests are terminated and the Tx and Rx data FIFOs are flushed. If this bit is cleared in the middle of a transmit/receive operation, then that operation is terminated immediately and nothing is transmitted/received further. All the programmable registers retain their values and status registers are cleared to their reset values. Registers read/write operations can be performed through the IPS Bus. 1 LFAST is Enabled.

Table 1579. MCR field descriptions (continued)

Bits	Description
17 RXEN	LFAST Receiver Enable. This bit controls the reception of the frames and decoding on the LFAST device. This bit also disables the Rx LVDS LR. 0 Receiver Interface is disabled. If this bit is cleared during a data transfer, the current frame is received and then the Rx block is disabled. After the Rx block is disabled, all new frames from LFAST peer device are ignored. System Side Module Rx interface is not disabled by this bit. 1 Receiver Interface is Enabled.
18 TXEN	LFAST Transmitter Enable. This bit controls the transmission of frames from the LFAST device and disables the Tx LVDS LD. This bit can also be set and cleared by LFAST slave H/W on reception of an ICLC command frame. 0 LFAST transmitter Interface is disabled. No new request is accepted but ongoing request is served. 1 Not allowed. Do not set when in slave only mode.
19-26	Reserved
27 TXARBD	Tx Arbiter Disable. This bit enables/disables the Tx block arbiter. Current frame transfer is completed, but new frame requests are ignored. 0 Enable Tx arbiter and framer. When enabled it takes all the frame request and services based on priority. 1 Disable Tx arbiter and framer. All frame requests are ignored.
28-29	Reserved
30 DRFRST	LFAST Soft Reset. This bit is automatically cleared after reset. 0 No soft reset. 1 Soft reset to LFAST is asserted. When set it causes a reset of the LFAST module; all the registers will be reset to their default values and all the FIFOs will be flushed.
31 DATAEN	DATA Frame Enable. This bit enables/disables the transmission and reception of data frames between the LFAST master and slave devices. 0 Data frame transmission and reception is disabled. Tx data frame requests are ignored by the transmitter. Frame with LCT of data frame is ignored by the receiver. 1 Data frame transmission and reception is enabled. Tx data frame requests are serviced by the transmitter. Frame with LCT of data frame is received and placed into the Rx data FIFO.

71.6.2.2 Speed Control Register (SCR)

The SCR is used to configure the Rx and Tx data rate of the LFAST.

Figure 1695. Speed Control Register (SCR)

Offset: 0004h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

1. Only writable when MCR[DRFEN] = 0.

Table 1580. SCR field descriptions

Bits	Description
0-14	Reserved
15 DRMD	Data Rate Controller mode. Defines the mode setting for LFAST slave device by S/W or LFAST master. This bit should not be modified by S/W and left as SCR[DRMD] =1.
16 - 22	Reserved
23 RDR	Receiver Data Rate. This bit defines the receiver data rate. This bit should not be modified by S/W.
24-30	Reserved
31 TDR	Transmit Data Rate. This bit defines the transmitter data rate. This bit should not be modified by S/W.

71.6.2.3 Correlator Control Register (COCR)

The COCR is used to select the sampler data path and the number of bits of correlation to be used.

Figure 1696. Correlator Control Register (COCR)

Offset: 0008h Access: User read/write

	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

1. Only writable only when MCR[RXEN] = 0.

Table 1581. COCR field descriptions

Field	Description
0-7 SMPSEL	Sampler Data Path Selector (overrides the correlator selection). Defines the sampler data path to be activated at all the times. All the bits should be 0 (00h) for Sampler Data Path to be selected by the correlator. In Low Speed mode only Sampler Data Paths 0-3 are valid. 00h Sampler Data Path selected by correlator 01h Sampler Data Path 0 selected 02h Sampler Data Path 1 selected 04h Sampler Data Path 2 selected 08h Sampler Data Path 3 selected 10h Sampler Data Path 4 selected 20h Sampler Data Path 5 selected 40h Sampler Data Path 6 selected others Sampler Data Path 7 selected
8-27	Reserved
28-30 CORRTH	Correlator threshold level. Defines the correlation threshold level. 000 9 Bits of correlation 001 10 Bits of correlation ... 110 15 Bits of correlation 111 16 Bits of correlation
31 PHSSEL	Polyphase 8 or 4 phase selection. Defines the number of phases for the polyphase generator used. This bit is ignored in low speed mode since only 4 Phases are used in low speed mode. In High Speed mode phase 0, 2, 4 and 6 are used when 4 phase mode is selected. 0 8 phases 1 4 phases

71.6.2.4 Test Mode Control Register (TMCR)

The TMCR enables and configures the LFAST clock test and loopback modes

Figure 1697. Test Mode Control Register (TMCR)

Offset: 000Ch								Access: User read/write								
	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15

1. Only writable when MCR[DRFEN] = 0.

2. Set by user software and cleared by system hardware.

Table 1586. PICR field descriptions

Bits	Description
0-14	Reserved
15 PNGREQ	Ping Response Frame Request. This bit is set to initiate the transfer of Ping response frame. Cleared after transmission of Ping response frame. 1 Ping response frame transmission request is queued 0 No pending Ping response frame transmission request
16 PNGAUTO	Ping Response Enable. Defines when ping response should be automatically sent on reception of Ping ICLC frame from LFAST master This bit should not be modified by S/W.
17-23	Reserved
24-31 PNGPYLD	Defines the LFAST slaves ping reply frame payload content.

71.6.2.9 LVDS Control Register (LCR)

Table 1587. LCR field description

Bits	Description
0-7	Reserved
8 SWWKLD	SW signal to take LVDS LD out of Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be taken out of sleep (provided no other source is trying to put it in sleep)
9 SWSLPLD	SW signal to put LVDS LD into Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LD will be put in sleep
10 SWWKLR	SW signal to take LVDS LR out of Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be taken out of sleep (provided no other source is trying to put it in sleep)
11 SWSLPLR	SW signal to put LVDS LR into Sleep mode. This bit can be changed only when DRFEN is high. 0 No effect 1 LVDS LR will be put in sleep (provided no other source is trying to wake it up)
12 SWOFFLD	SW signal to turn OFF the LVDS LD. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
13 SWONLD	SW signal to turn ON the LVDS LD. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
14 SWOFFLR	SW signal to turn OFF the LVDS LR. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.

Table 1587. LCR field description (continued)

Bits	Description
15 SWONLR	SW signal to turn ON the LVDS LR. This bit can be changed only when DRFEN is high. This bit should not be modified by S/W.
16 LVRXOFF	Indicates the value driven onto LVDS LR output when in shutdown mode
17 LVTXOE	LVDS LD output buffer enable. 0 LVDS LD output buffer enable is disabled. 1 LVDS LD output buffer enabled
18 TXCMUX	Tx and Clock Mux. The bit can be used to bring out PLL Phase 0 clock on Tx LVDS pad. 0 No effect 1 PLL Phase 0 clock will be brought out to Tx LVDS pad
19 LVRFEN	LVDS pad reference enable 0 LVDS reference pad disabled 1 LVDS reference pad enabled
20 LVLPEN	Tx LVDS internal loopback enable. The internal loopback is not intended for board level functionality, so this feature should not be implemented. 0 Tx LVDS normal mode enabled 1 Tx LVDS internal loopback mode enabled
21	Reserved
22-24 LVRXOP	LVRXOP[2] Termination resistance 0 Disable termination 1 Enable termination LVRXOP[1] Not used LVRXOP[0] Defines the LVDS LR Bias current reference
25-28	Reserved
29 LVTXOP	Control signal for LFAST and Micro-Second Bus selection. 0 Micro-Second Bus selection 1 LFAST Bus selection
30 LVCKSS	LVDS Data select. This bit is used for selecting use of clock sampled data or normal data in LVDS. 0 normal data to be used inside the LVDS 1 synchronised data to be used inside the LVDS
31 LVCKP	LVDS clock select. This bit is used for selecting use of direct pll clock or inverted pll clock in LVDS. 0 Direct pll clock to be used inside the LVDS 1 Inverted pll clock to be used inside the LVDS

Table 1597. UNSRDRn field descriptions

Bits	Description
0-31 UNRXD	Unsolicited Receive Data. This represents 9 registers for Unsolicited received data. It is read only register. The first bit received as part of the payload will be stored at UNRXD8[31], second bit at UNRXD8[30], and so on. So the last bit will be stored at UNRXD0[0] in case of 288 bit payload.

71.6.3 Register safety classification requirements

This module is classified as NoSaMo (Non-Safety relevant Module) for safety requirements^(x). All registers of the LFAST module are classified as non-safety relevant.

The MCR[IPGDBG] fulfills the safety requirements for monitoring of the debug freeze signal.

71.7 Functional description

71.7.1 Startup procedure

The LFAST requires a sequence of operations before it can be used for communication. The procedure to enable LFAST for proper operation is listed below.

71.7.1.1 LFAST slave interface startup procedure

1. After POR the RCDCCR are programmed according to the LVDS parameter in the device datasheet.
2. The PLLCR^(y) is programmed with the configuration parameters of the PLL.
3. The LCR is programmed with the configuration parameters of the LVDS.
4. MCR[DATAEN] fields is programmed to select the LFAST mode.
5. Write MCR[TXARBD] = 0 to enable Tx of frames.
6. Write MCR[DRFEN] = 1 to enable LFAST.
7. Write MCR[RXEN] = 1 to enable LFAST Rx.
8. On the assertion of the LFAST interface enable the signals LR power down and LR disable are negated.
9. When an ICLC frame with payload 31h is received H/W writes RIISR[ICTEF] = 1 and MCR[TXEN] = 1.
10. The ping frame is sent when an ICLC frame with payload 00h frame is received and H/W writes RIISR[ICPRF] = 1.

x. See the "Functional Safety" chapter for register classification details.

y. The PLLCR is shared between the LFAST – Interprocessor Communications and the LFAST – High Speed Debug modules. The programming values for the PLLCR in the LFAST – Interprocessor Communications are also used by the LFAST – High Speed Debug module.

Speed mode change:

11. The PLL starts when an ICLC frame with payload 02h is received and H/W writes RIISR[ICPONF] = 1.
12. The speed of the Tx interface is changed when an ICLC frame with payload 80h is received and H/W writes RIISR[ICTFF] = 1. This will cause SRC[TDR] = 1.
13. The speed of the Rx Interface is changed when an ICLC frame with payload 10h is received and H/W writes RIISR[ICRFF] = 1. This will cause SCR[RDR] = 1.
14. The ping frame is sent when an ICLC frame with payload 00h is received and H/W writes RIISR[ICPRF] = 1.

71.7.2 LFAST Interface enable signal (lfast_sysclk_en)

The lfast_sysclk_en signal comes from the DCI module. It is asserted by the DCI internal state machine when switching from JTAG to LFAST and vice-versa can safely be done. The detailed effects of lfast_sysclk_en on the module are:

LFAST interface enable (lfast_sysclk_en) negation:

1. If LCR[SWONLD] = 0 the LD LVDS pad is powered down.
2. If LCR[SWONLR] = 0 the LR LVDS pad is powered down.
3. The LFAST slave exits the test mode (for example, loopback mode or clock test mode). Then S/W writes MCR[CLKTST] = 0 and MCR[LPON] = 0.
4. The LFAST slave Rx and Tx interfaces are set to Low Speed mode. Then write SCR[TDR] = 0 and SCR[RDR] = 0.
5. The Tx and Rx interface controllers are disabled.
6. The status registers are cleared.

LFAST interface enable (lfast_sysclk_en) assertion:

1. The LD LVDS pad is power up, if all conditions are met:
 - LCR[SwoffLD] = 0.
 - LCR[SWONLD] = 1.
 - MCR[TXEN] = 1.
 - When frame ICR[ICLCPLD] = 31h is received.
2. LR LVDS pad is powered up if all conditions are met:
 - LCR[SwoffLR] = 0.
 - LCR[SWONLR] = 1.
 - MCR[RXEN] = 1.

71.7.3 Line Receiver (LR)**71.7.3.1 Introduction**

The LR detects the voltage swing on the differential pair and converts it to a CMOS logic level that feeds the adaptive auto correlation block. The received data is sampled using the best of the 8 (default) or 4 (alternative setting) possible sampling edges from the high speed clock or 4 phases using the low speed clock. The sampling edge is chosen by checking which of the 8/4 Correlators provide the maximum correlation. If more than one sampling edge provides the maximum then the state machine will choose the sampling edge based on a defined selection algorithm.

After the correct sampling edge is chosen, the remaining unused sampling edges are turned off. Once the header is received the length of the frame (payload size) and logical channel definition can be obtained. The logical channel definition will determine the data type of the payload and therefore will determine the destination for the payload. Decoding of the ICLC commands from the payload is required in order to extract the interface control, rate mode and PLL commands.

Figure 1713 shows the block diagram of Uplink Controller.

Figure 1713. Top Level Receive Controller

71.7.3.2 Edge-Detection & Auto correlation

The edge-detection and auto correlation are described together, as the mode setting of the auto-correlation block impacts largely on whether the edge-detection circuitry is used or not. The edge-detection will be performed first if required before auto-correlation.

71.7.3.2.1 Auto correlation modes

71.7.3.2.1.1 Hunt correlation mode

On reset the Receive Controller will always come up in Hunt Correlation mode. In this mode all the Correlators are enabled and the Receive Controller is always hunting for the

synchronization pattern. The phase enables (either 8 or 4) to the external clock control module are always high. There is no edge detection for the first bit of the synchronization pattern. Hunt Correlation mode is considered the safest mode as the Receive Controller is always checking for the synchronization pattern, but it is the mode that consumes the most power. In Hunt Correlation mode the correlation is performed over all 16 bits of the synchronization pattern.

Figure 1714. Hunt Correlation mode

71.7.3.2.2 Edge detection

The edge detector is disabled in Hunt Correlation mode.

71.7.3.2.3 Auto correlation

The data transmission between the 2 devices LD and LR is asynchronous in nature. Hence the Receive Controller does not have the knowledge about the correct clock phase to be used for extracting the data. The task of the auto correlation (or synchronization) scheme is to estimate the best clock phase (8 or 4) for extraction of data as shown in [Figure 1715](#).

Figure 1715. High Speed 8 Phase Selection

The objective of the auto correlation is to select the clock phase that occurs closest to the center of the eye diagram window. For 8 Phase clock alignment the worst case selection is when the clock edge is just after the LR output transition. The 8 clock phases will sample the correct value but the middle clock phases are the ideal selection. If one of the middle phases are selected then the minimum distance to the LR transition is 3 clock phases as shown in [Figure 1716](#).

Figure 1716. High Speed 8 Phase Clock Alignment Example

Each of the 8 high speed phases are 45 degrees separated. For 4 phases, whether high or low speed, the phases are 90 degrees separated but can have different phases enabled as shown in [Figure 1717](#) and [Figure 1718](#).

Figure 1717. High Speed 4 Phase Clock Alignment Example

Figure 1718. Low speed 4 phase clock alignment example

The auto correlation and selection of the correct clock phase starts after the edge detection finds a 0 to 1 transition. The high speed (312/320 MHz) 8 or 4 phases from the PLL and the low speed 4 phases (generated inside the Clocking Module) are muxed inside the clocking module. The LFAST interface block will determine which phases are to be enabled and disabled. The only time the interface does not choose the phases is when the Clocking Module overrides the phase enables using COCR[SMPSEL].

The input data path can be sampled by different samplers depending on the configuration:

- High Speed 8 Phases: Samplers 0,1,2,3,4,5,6,7
- High Speed 4 Phases: Samplers 0,2,4,6
- Low Speed 4 Phases: Samplers 0,1,2,3

Each sampler block samples the data path with a different clock phase from the Clocking Module, and re-samples it to a intermediate phase as shown in [Table 1598](#), [Table 1599](#), and [Table 1600](#) before re-sampling it to Phase 0. The intermediate phase is used to make static timing between the initial phase and the final phase 0. The final phase, Phase 0 is chosen so all the clock trees after the sampler are clocked by the same clock.

Table 1598. High speed 8 phase selection - sampling procedure

Samplers	Initial Sample	Intermediate Sample	Final Sample
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Phase 4	Phase 2	Phase 0
5	Phase 5	Phase 2	Phase 0

Table 1598. High speed 8 phase selection - sampling procedure (continued)

Samplers	Initial Sample	Intermediate Sample	Final Sample
6	Phase 6	Phase 4	Phase 0
7	Phase 7	Phase 4	Phase 0

Table 1599. High speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Disabled	Disabled	Disabled
2	Phase 2	Phase 0	Phase 0
3	Disabled	Disabled	Disabled
4	Phase 4	Phase 2	Phase 0
5	Disabled	Disabled	Disabled
6	Phase 6	Phase 4	Phase 0
7	Disabled	Disabled	Disabled

For High speed 4 Phase selection, See [Table 1599](#), Samplers 1, 3, 5, 7 are disabled. In the Phase Select algorithm Phase 1 is mapped to Phase0, Phase 3 is mapped to Phase 2, Phase 5 is mapped to Phase 4, Phase 7 is mapped to Phase 6 so it simplifies the algorithm and allows the algorithm to be the same independent of 4 or 8 Phases in high speed.

Table 1600. Low speed 4 phase selection - sampling procedure

Samplers	Initial Sample Phase	Intermediate Sample Phase	Final Sample Phase
0	Phase 0	Phase 0	Phase 0
1	Phase 1	Phase 0	Phase 0
2	Phase 2	Phase 0	Phase 0
3	Phase 3	Phase 0	Phase 0
4	Disabled	Disabled	Disabled
5	Disabled	Disabled	Disabled
6	Disabled	Disabled	Disabled
7	Disabled	Disabled	Disabled

For low speed 4 Phase selection, See [Table 1600](#), Samplers 4, 5, 6, 7 are disabled. The first four Samplers (0,1,2,3) of the low 4 phase speed selection algorithm are the same as the four samplers required for the high 8 phase speed. Therefore the same architecture can be used for both high speed and low speed with the other four data paths disabled for low speed.

71.7.3.2.4 Sampler block and phase enable and disable

There are 8 data sampler paths in total inside the auto correlation block, each data sampler has 3 sampling registers with the possibility of each register being clocked by a different phase (in example, Sampler 5 for high speed can have Phases 5, 2 and 0). Therefore after the correct data sampler has been selected for either high or low speed, the block can turn off all the sampler paths except for one, therefore 3 out of 24 registers will remain enabled while the others are disabled, as shown in [Figure 1719](#).

After correlation and the correct data sampler has been selected all the other data samplers whose initial phase does not match the select phase are disabled. The selected sampler will then keep the required phases needed enabled, this can be max 3 phases (e.g Sampler 5 has Phases 5, 2, 0) or min 1 phase (in example, Sampler 0 has all Phase 0 content).

The end result is that the Rx Controller can disable the required number of unused sampler registers and disable any unnecessary phases from the Clocking Module by de-asserting the respective phase enables.

Figure 1719. Samplers, each Sampler has 3 Registers

In order to achieve the sampler and phase enable requirements each Sampler block will require the logic as shown in [Figure 1720](#).

The Clock Gating Element resides inside the Clocking Module block. The interface will provide the enables to the Clocking Module and the Clocking Module will in return provide the individual clocks to the sampling registers.

Figure 1720. Sampler 5 Logic

71.7.3.3 Header and Payload Extraction

Once the Phases/Samplers are chosen after Synchronization and Correlation the next part of the flow is the header extraction. The Receive Controller will output a 16 bit word, bit shifted every Phase 0 clock as shown in [Figure 1721](#)

Figure 1721. Extracting Header and Payload from the 16-bit output from Auto correlation.

71.7.3.3.1 Line Receiver states

The LD has the following states:

- Shutdown**
 The LR enters in the shutdown state when the power down signal is high. In this state the LR regulator is supplying a V_{dd} level, however the LR is not enabled. In this state the LR holds its off value. Once power down signal is negated, a predefined settling time is required before the LR may be used for communication. During the settling time the peer LFAST device should not start its transfer.
- Sleep**
 The LR enters in the Sleep state when the sleep signal is high. In the sleep state, the LR is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In this

mode the receiver current consumption is reduced. Hysteresis in the LR ensures that it continues to present a 1 to the LFAST module.

- **Normal**
In the Normal state, the LR is primed for reception. Receiver converts differential signals to a single ended logic signal.

Table 1601. Line Receiver State

LR State	LFAST Slave Triggers (at least one of the following)
Shutdown	– LFAST interface enable assertion/negation – Programing of LCR[SwoffLR] or LCR{SWONLR} – Programing MCR[RXEN] and MCR[TXEN]
Sleep	– Programing of LCR[SWSLPLR] or LSC[SWWKLR]
Normal	Absence of above mentioned conditions

71.7.4 Transmit Controller

71.7.4.1 Introduction

The Transmit Controller uses Rx information, status information and error control data and codes them into the appropriate frame structure for transmission to the LD. This includes the synchronization and header, in preparation for the LD, which transmits the frame to peer LFAST IC at either low or high speed. The Transmit Controller creates a frame structure that is converted to a serial format for the LD.

An arbitration block will determine which message has higher priority data, unsolicited, ICLC, ping etc. The data frames are extracted from the FIFO controller, the unsolicited message from the register block, the CTS messages from the Recieve Controller and the ping response from the register block.

The Tx interface has two speed modes:

- Low Speed
- Fast Speed

The Transmit Controller consists of the following blocks as shown in [Figure 1722](#).

- Arbitrator
- Framer
- Request Clock Control

The arbitrator will grant access to the framer from the request that has the highest priority. The framer block will extract the payload data from the granted request source and build the frame (adding synchronization or header if required). The frame is fed into a PISO (Parallel In Serial Out) and eventually sent to the LD.

Figure 1722. Transmit Controller Connections

71.7.4.2 Arbitration

The arbitration block prioritizes between requests from multiple sources like:

- S/W programmable registers
- System side interface FIFO
- Rx interface controller
- LFAST Slave: LFAST interface enable (lfast_sysclk_en)

The level of priority for each request is shown in [Table 1602](#).

Table 1602. Priority Levels for the Tranmsit Controller

Request	LFAST Slave Priority	Triggering Conditions (at least one of the listed)
LFAST interface enable (lfast_sysclk_en)	1	– LFAST interface enable (lfast_sysclk_en) is asserted – LFAST interface enable (lfast_sysclk_en) is negated
Tx Interface disabled	2	– MCR[DRFEN] = 0 – MCR[TXEN] = 0 – MCR[DRFRST] = 1 – MCR[TXARBD] = 1 – LFAST Slave: ICLC frame with payload for “Disable Rx interface” received

Table 1602. Priority Levels for the Transmit Controller

Request	LFAST Slave Priority	Triggering Conditions (at least one of the listed)
Tx Interface speed mode change	3	– SCR[TDR] is modified – LFAST Slave: ICLC frame with payload for changing Rx interface speed received
Loopback frame in Loopback mode	4	– TMCR[LPON] = 1 – LFAST Slave: ICLC frame with payload for loopback mode enable received <i>Note:</i> Valid only for following TMCR[LPMOD] settings: LPMOD[2:0] = 011b LPMOD[2:0] = 100b
Ping response request	5	– LFAST Slave: ICLC frame with payload for ping request received and PICR[PNGAUTO] = 1 – LFAST Slave: PICR[PNGREQ] = 1
Unsolicited frame request	6	– Valid only if Last Frame with header b0 = 1 received from the peer LFAST – UNSTCR[USNDRQ] = 1
Data frame from Tx FIFO	7	– Tx FIFO contains one or more frames – Last Frame with header b0 = 1 received from the peer LFAST device – MCR[DATAEN] = 1
Clock mode test	8	– TMCR[CLKTST] = 0 – LFAST Slave: ICLC frame with payload for clock test mode enable received

Once the arbitrator has granted access to a request, the Framer will commence building the frame. Any new requests for frame or data rate change will not be granted access until the framer has finished transmitting the current frame. If a data rate change request for the Tx interface is received while the Transmit controller is in the middle of sending a frame then the rate change request to the Clocking Module will be delayed. This allows for the frame to be completed before the change in speed mode. This prevents any speed mode change during the transmission of a frame. Once the speed mode request is sent to the Clocking Module by the Tx Interface Controller, it will then not allow any new requests to be processed for a specific time period defined by the bit field RCDCCR[DRCNT].

71.7.4.3 Line Driver digital connections

71.7.4.3.1 Line Driver states

The LD has the following states:

- **Shutdown**
The LD enters the Shutdown state when the LD powerdown signal and the output buffer enable is high. In this state, the LD regulator is not supplying power and the LD outputs are connected to ground. Once LD powerdown signal is negated, a settling

time is required before the LD may be used for communication. The settling time is defined by the SLCR[LWKCNT] and SLCR[HWKCNT] bitfields.

- Sleep

The LD enters in sleep state when the signal is asserted. In this state, the LD is enabled, but held in a power-saving state. Sleep mode may be used during inter-frame gaps that are long compared to the frame durations but not long enough to allow the interface(s) or high-speed clock generators to be powered down completely. In the sleep state the LD outputs are connected to V_{cm} (common mode voltage). To exit from Sleep mode the LD sleep signal is negated. The LD is required to transmit a logic 0 level on the interface for a predefined minimum time. The minimum time is the summation of settling time of LD after negation of LD sleep signal and the wakeup time of the LR on the other side. This delay is programmed in the SLCR[HSCNT] and SLCR[LSCNT] bitfields.

Figure 1723. Example of Sleep mode

As shown in [Figure 1723](#) before every normal mode burst on the txdatap line there is one guard bit period (minimum inter-frame gap) where a logic 0 will be transmitted.

- Normal

In the Normal state the LD is primed for transmission. The LD shall drive the interface as dictated by the input data bit that is supplied by a shift register under the control of a finite state machine. The LD moves back to the shutdown state when the LFAST master sends an ICLC Rx data off command.

Table 1603. Line Driver States

LD State	LFAST Slave Triggers
Shutdown	– LFAST interface enable (lfast_sysclk_en) negation/assertion – Programing LVDS[SWOFFLD] and LVDS[SWONLD] – ICLC command from LFAST master – Programing MCR[TXEN] and MCR[DRFEN]
Sleep	– Programing LVDS[SWSLPLD] and LVDS[SWWKLD]
Normal	Absence of above mentioned conditions

71.7.5 Frames supported

[Table 1604](#) provides the frames supported and their permissible payload sizes

Table 1604. Frames supported by LFAST interfaces

Frame Type	LCT Code	Supported by 1. LFAST Master Tx 2. LFAST Slave Rx	Supported by 1. LFAST Slave Tx 2. LFAST Master Rx	Payload Size (bits)
Data Frame	Rx – 0100b, 1000b – 1011b Tx – All	YES	YES	TX: 96 RX: 128
Unsolicited Frame	0001b	YES	YES	8, 32, 64, 96, 128, 256 and 288
ICLC Frame	0000b	YES	NO ⁽¹⁾	8
CTS Frame	n/a	NO	NO	n/a
Reserved	All others	—	—	—

1. Except the ICLC PING response frame.

71.7.6 Frame flow

Following sections describe Data Frame Flow, ICLC Flow and Rx Unsolicited Data Flow.

71.7.6.1 Data flow

LFAST supports the transfer of data between master and slave LFAST devices.

71.7.6.1.1 Data transmit

System Side Module is the initiator of all the Tx data frame to LFAST peer device. Data frame transmit is triggered whenever the Tx Data FIFO has at least one valid frame. The MCR[DATAEN], MCR[DRFEN] and MCR[TXEN] bits, should be set to enable the transfer of Tx data.

If MCR[DATAEN] = 0, then the valid frames in the in Tx data FIFO will be ignored for transmission. The Payload Size and channel type of each frame is specified by the System Side Module interface during transfer of the frame to the LFAST interface. The frame header is stored in the Tx packet FIFO and the payload in the Tx data FIFO. Whenever the Tx FIFO has at least one frame then a data transmit request is made to the Tx arbiter of the LFAST. Tx block arbitrates the data transmit request and schedules it depending on the priority of all the pending transmit requests. When data request is scheduled by Tx block, the required data is fetched from Tx data FIFO. The number of frames present in the Tx FIFO for transmission is indicated by the bitfield DFSR[TXFCNT].

71.7.6.1.1.1 Programing model for Tx data transmit

1. Program MCR[DATAEN] = 1, MCR[TXEN] = 1 and MCR[DRFEN] = 1 to enable the Tx path of LFAST device.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR] bits.
3. Frame present in TX FIFO (Data and Packet FIFO) are sent.
4. TISR[TXDTE] = 1 after each frame transfer.

71.7.6.1.2 Data receive

LFAST master and slave supports reception of data frame. The received frame is determined to be of data frame type by decoding channel type field of the header present in the received frame. The MCR[DATAEN], MCR[TXEN] and MCR[DRFEN] bits should be set to enable the data frame reception. When MCR[DATAEN] = 0 the received data frames will be ignored and will not be placed in the Rx data FIFO.

The Rx data frames received by Rx block are stored in the Rx FIFO. Whenever the frame is received in the Rx FIFO the System Side Module is indicated by assertion of LFAST Rx FIFO ready signal. The frame size and the Channel type is passed to the LFAST. The frame boundaries are indicated by start of frame and end of frame signals. The number of unread frames in the Rx Data FIFO are indicated by DFSR[RXFCNT]. When Rx DATA FIFO is full and cannot accommodate current frame completely, then the remaining data of the Rx frame is discarded.

71.7.6.2 Unsolicited flow

71.7.6.2.1 Unsolicited frame transmit flow

The S/W is the initiator for unsolicited frames to the LFAST peer device. The unsolicited frame header and payload is programed into the Unsolicited Data and Control registers. Once the Payload is programed UNSTCR[USNDRQ] is set, generating a request for unsolicited frame transfer to the Tx arbiter.

71.7.6.2.1.1 Programing model for unsolicited frame transmit

1. Program MCR[TXEN] = 1 and MCR[DRFEN] = 1 in the Mode Configuration Register (MCR) to enable the Tx path.
2. Select the desired clock rate at which data should be transmitted, using ICLC transfers and appropriate programing of SCR[TDR].
3. Read the UNSTCR[USNDRQ].
 - If UNSTCR[USNDRQ] = 1 then wait for either of the following:
 - UNSTCR[USNDRQ] = 0
 - TISR[TXUNSF] = 1.
 - If UNSTCR[USNDRQ] = 0 then:
 - Program the unsolicited payload in UNSTD0–UNSTD8, and can be written up to a payload of frame of a maximum of 288 bits.
 - Program the unsolicited frame header in UNSTCR[UNSHDR].
 - Program UNSTCR[USNDRQ] = 1.
4. UNSTCR[USNDRQ] is cleared by the Tx Block after the frame transfer.
5. TISR[TXUNSF] = 1 when the frame is transmitted.

71.7.6.2.2 Unsolicited frame receive flow

Whenever an Unsolicited frame is received from the peer device, the following steps are performed:

If UNSRSR[URXDV] = 0 then:

1. The payload size field of the header is first saved into the UNSRSR[URPCNT].
2. The payload is stored in the UNSTDRO–UNSTD8.
3. UNSRSR[URXDV] = 1 and the RISR[RXUNSF] = 1 indicating the successful reception of the frame.

If UNSRSR[URXDV] = 1 then:

1. The current unsolicited frame is ignored.
2. RISR[RXUOF] = 1.

Typical steps by the processor after RISR[RXUNSF] = 1 is as follows:

1. The processor reads UNSRSR to get the payload size of the frame.
2. It then reads the complete frame by reading UNSRDR8–UNSRDR0 for the payload size as received in the frame.

71.7.6.3 ICLC flow

The ICLC (Interface Control Logical Channel) is defined as a separate logical channel type, which is mainly meant for implementing the data rate change in the LFAST interface and initiating the test modes.

71.7.6.3.1 ICLC data receive flow

When the bits 4 to 1 of a receive frame are 0000b it indicates that the payload is an ICLC. ICLC payloads are always 8 bits.

71.7.6.3.1.1 Ping request ICLC

The LFAST slaves ICLC decoder will decode the ping request and set RIISR[ICPRF] = 1. The S/W can also write to PICR[PNGREQ] to indicate to the Tx block that a ping response frame needs to be transmitted. The PICR[PNGAUTO] indicates whether Tx block can respond automatically to the request by the LFAST master ICLC Ping Request frame. The Tx block will arbitrate the ping response frame request and send a ping frame with ping data defined by bitfield PICR[PNGPLYD]. Once the ping response frame has been sent the Tx block will set TISR[TXPNGF] and clear PICR[PNGREQ], if set.

71.7.6.3.1.2 LFAST Slaves RxData Interface Slow/Fast ICLC

The LFAST Slaves Rx Interface has two speed modes supported: slow (Low speed) and fast (High speed). The ICLC command will write RIISR[ICRSF] = 1 (Low speed) or RIISR[ICRFF] = 1 (High speed).

71.7.6.3.1.3 LFAST Slaves TxData Interface Slow/Fast ICLC

The LFAST slaves Tx Interface Controller has two speed modes: slow (Low speed), and fast (High speed). The ICLC command will write RIISR[ICTSF] = 1 (Low speed) or RIISR[ICTFF] = 1 (High speed).

71.7.6.3.1.4 Enable/Disable LFAST Slaves TxData Interface ICLC

The ICLC commands, Enable RxData Interface and Disable RxData Interface are decoded and the appropriate enable/disable signal sent to the Tx block Controller. These ICLC command writes RIISR[ICTEF] = 1 and RIISR[ICTDF] = 1. The ICLC Tx enable command will write MCR[TXEN] = 1.

No frames can be sent on the LFAST Slave Tx interface until the either LFAST master has enabled it via an ICLC frame or S/W programs MCR[TXEN] = 1.

71.7.6.3.1.5 Clock Test mode ICLC

This ICLC command is decoded, and then is used to write TMCR[CLKTST] = 1. This indicates to the Tx interface to output an alternating pattern of 1 and 0 at the currently configured clock rate. The Rx interface generates RIISR[ICCTF] = 1 on reception of this ICLC command.

The exit from this mode happens on reception of Test mode off ICLC command.

71.7.6.3.1.6 Loopback payload on ICLC

This ICLC command is decoded and TMCR[LPON] = 1 to indicate to the Tx Block that the received payload is to be sent back. The exit from this mode happens on reception of Test mode off ICLC command. The Rx interface causes RIISR[ICLPF] = 1 on reception of this ICLC command.

71.7.6.3.1.7 Test mode off ICLC

This ICLC command is decoded and TMCR[LPON] and TMCR[CLKTST] are cleared to indicate to the Tx block to exit from loopback mode or clock test mode.

Another option is for the payload loopback option to remain enabled until negated on the toggling of LFAST interface enable (lfast_sysclk_en).

71.7.7 Test and Debug Support

The test and debug interface helps to debug the LFAST module. These signals can be brought out for ease of validation.

71.7.7.1 Loopback Test mode

The loopback function allows to verify the correct operation of the physical interface and the basic checks for the LFAST module without a peer device.

There are certain prerequisites before entering the Loopback mode:

- LD and LR should be turned on.
- Tx and Rx mode should be enabled.
- Interrupts needed for S/W should be enabled.
- Both Tx and Rx interface should be in same speed mode.
- For Automatic Test mode TMCR[LPFRMTH] should be programmed.

The LFAST module supports four loopback modes, defined by TMCR[LPMOD].

Table 1605. Loopback modes

LPMOD[2:0]	Mode Selected
000	Rx Loopback (default)
001	Rx LVDS Loopback
010	Tx Loopback without Automatic frame generation
011	Tx Loopback with Automatic frame generation
100	Tx LVDS Loopback (external) with Automatic frame generation

The TMCR[LPON] bit controls the state of the loopback function, and the default setting is 0 (off). This can be written by S/W, or in the case of the LFAST slave, the TMCR[LPON] bit can be modified by the Rx interface controller on decoding of a valid ICLC loopback on or Test mode off commands. The LPMOD should not be changed when the LPON bit is set.

In all loopback modes, except Tx loopback without automatic frame generation, the decoding of frame and error flags is stopped. Only decoding of following is done:

- ICLC Turn Test mode Off frame.
- CTS bit of all frames.
- Automatic Loopback frame decoding (only in Automatic frame generation mode).

71.7.7.1.1 Rx Loopback mode

For Rx loopback mode the output of the LR is passed to the LD with manipulation via the Rx and Tx Interface controllers. Bit b0 of the header is guaranteed to be asserted when the incoming data from the other device is looped back. In Rx Loopback mode the Rx Interface controller operates in normal mode, decoding the frames (header, payloads). This allows the LFAST Master to control the Loopback mode on and off by sending ICLC commands.

Figure 1724. Rx LoopBack mode

Entry to Rx Loopback mode:

1. S/W programs TMCR[LPMOD] = 000b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: - Reception of ICLC Frame with Payload FFh (Loopback mode on), from LFAST Master

Exit from Rx Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0
- For LFAST Slave: - Transmission of ICLC Frame with payload 38h (Test mode off), from LFAST Master
- For LFAST Slave: - Deassertion of the LFAST interface enable (lfast_sysclk_en).

The peer LFAST device is required to maintain at least 2-bit IFG between two Loopback frames in this mode.

71.7.7.1.2 Rx LVDS LoopBack mode

This loopback mode is provided to verify and characterize the LVDS pads. In this loopback mode the data received by LFAST on Rx LVDS input is loopback to Tx LVDS output, bypassing LFAST. For LVDS loopback the output of the LR is passed to the LD via “Rx LVDS LoopBack Mux”. Bit 0 of the header cannot be guaranteed to be asserted when the incoming data from the other device is looped back. In this loopback, the Rx Interface Controller operates in normal mode, decoding the frames (header, payloads) but the Tx Interface Controller is ignored.

Figure 1725. Rx LVDS LoopBack mode

Entry to Rx LVDS Loopback mode:

1. S/W programs TMCR[LPMOD] = 001b.
2. Loopback can be turned ON by either of the following methods:
 - S/W writes TMCR[LPON] = 1.
 - For Slave Only: - Reception of ICLC Frame with Payload = FFh (Loopback mode ON), from LFAST Master.

Exit from Rx LVDS Loopback mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave:
 - Transmission of ICLC frame with payload 38h (Test mode off), from LFAST Master.
 - Deassertion of the LFAST interface enable (lfast_sysclk_en).

71.7.7.1.3 Tx loopback mode without automatic frame generation

This loopback mode is provided to verify the LFAST functionality, if LVDS pads are not functional. In this loopback mode the data transmitted by LFAST on Tx LVDS output is loopbacked internally on Rx LVDS input, bypassing LVDS pads.

Figure 1726. Tx LoopBack mode without automatic frame generation

Entry to Tx Loopback without Automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 010b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from LFAST Master

Exit from Tx Loopback without Automatic frame generation mode can be done by any of the following methods:

- S/W programs $\text{TMCR}[\text{LPON}] = 0$.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off), from Tx interface (using unsolicited frame).
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

All frames and error flags are decoded in this mode.

71.7.7.1.4 Automatic frame generation

The LFAST module supports two Loopback modes where predefined frames are generated automatically by the Tx Interface and Rx Interface indicates its successful reception by dedicated signals and status registers. These modes are defined for BIST like check for the LFAST, with minimal S/W intervention.

The Control register used for these modes are:

- $\text{ALCR}[\text{LPCNTEN}]$ defines whether fixed number of auto loopback frames to be transmitted.
- $\text{ALCR}[\text{LPFMCNT}]$ defines the number of loopback frames to be transmitted if $\text{ALCR}[\text{LPCNTEN}] = 1$.

The Status signals and register used for these modes are:

- $\text{GSR}[\text{LPCSDV}]$: Valid Synchronization received.
- $\text{GSR}[\text{LPCHDV}]$: Frame with Header of 13h received.
- $\text{GSR}[\text{LPCPDV}]$: Frame with Payload of CBh received.
- $\text{GSR}[\text{LPTXDN}]$: Number of Auto Loopback frame transmitted with valid Synchronization, Header (13h) and Payload (CBh) is equal to $\text{ALCR}[\text{LPFMCNT}]$.

Figure 1727. Automatic Loopback Test status signal timings

The two Loopback with automatic frame generation modes are:

- Tx Loopback with Automatic frame generation.
- Tx LVDS (external) with Automatic frame generation.

71.7.7.1.4.1 Tx LoopBack mode with automatic frame generation

When $TMCR[LPMOD] = 011b$ (Tx Loopback mode with Automatic frame generation) the frames are generated by the Tx Interface. This mode helps to validate the Tx and Rx Path with minimal intervention from the S/W. The frames generated have fixed header of 13h and payload of CBh. The successful reception of this frame is indicated by the status signals and registers.

Figure 1728. Tx LoopBack mode with automatic frame generation

Entry to Tx Loopback with automatic frame generation mode:

1. S/W programs $TMCR[LPMOD] = 011b$.
2. Loopback can be turned on by either of the following methods:
 - S/W programs $TMCR[LPON] = 1$.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on), from the LFAST Master.

Exit from Tx Loopback with Automatic frame generation mode can be done by any of the following methods:

- S/W programs $TMCR[LPON] = 0$.
- For LFAST Slave: Deassertion of the LFAST interface enable ($lfast_sysclk_en$).

71.7.7.1.4.2 Tx LVDS loopback (external) mode with automatic frame generation

In this mode the LD/Tx Controller is used to test the LR/Rx Controller. The idea is to use a test frame (predefined) from the Tx Controller out through the LD, loopback completed on the DUT-board (LD connected to LR via a transmission line), back into the LR, synchronized and correlated in the Rx Controller and compared to what was sent in the Downlink controller.

Figure 1729. Tx LVDS Loopback (external) mode with automatic frame generation

Entry to Tx LVDS loopback with automatic frame generation mode:

1. S/W programs TMCR[LPMOD] = 100b.
2. Loopback can be turned on by either of the following methods:
 - S/W programs TMCR[LPON] = 1.
 - For Slave Only: Reception of ICLC frame with payload FFh (Loopback mode on) from LFAST Master

Exit from Tx LVDS Loopback with automatic frame generation mode can be done by any of the following methods:

- S/W programs TMCR[LPON] = 0.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

71.7.7.2 Clock test mode

The bit TMCR[CLKTST] enables or disables the Clock Test mode of the LFAST module. In this mode the LFAST sends fixed pattern out on the LD at the current configured RxData clock rate. It is a RWM bitfield and the default setting is 0 (off). This bit can be set under one of the following conditions:

- S/W programs TMCR[CLKTST].
- For Slave Only: Reception of ICLC frame with payload 34h (Clock Test mode on) from LFAST Master.

The Tx Controller will send out a pattern of alternating 1 and 0 (pattern 101010...). This provides a divide by 2 test clock of the current Tx clock.

The Clock Test mode can be cancelled by any of the following methods:

- S/W programs TMCR[CLKTST] = 0.
- For LFAST Slave: Reception of ICLC frame with payload 38h (Test mode off) from LFAST Master.
- For LFAST Slave: Deassertion of the LFAST interface enable (lfast_sysclk_en).

In clock test mode the Tx Controller does not output any synchronization pattern or header, just a pattern of alternating 1's and 0's.

This mode does not affect the functionality of the Rx Interface.

71.8 Packet memory

The LFAST stores packet frames for transmission, and reads packet frames after reception. The transmitter has its own dedicated buffer and the receiver has its own dedicated buffer, and they are not shared between each other.

Table 1606. Frames Supported by LFAST interfaces

Frame Type	Tx Buffer (in bits)	Rx Buffer (in bits)	Memory Type
Data Frame	6 × 32 max 2 packets	8 × 32 max 2 packets	FIFO
Unsolicited Frame	9 × 32 max 1 packet	9 × 32 max 1 packet	Registers UNSTD[8-0], UNSRDR[8-0]
ICLC Frame	N/A	1 × 8 max 1 packet ⁽¹⁾	Registers PICR[PNGPYLD]
CTS Frame	N/A	N/A	N/A

1. Ping response packet

71.9 Resets

The various blocks in LFAST are reset as described in [Table 1607](#).

Table 1607. Recommended receive exception handling mechanism

Reset	Blocks Reset
Asynchronous Hardware reset	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFRST bit of Mode Configuration Register (MCR)	Polarity: Active High – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Register Space
DRFEN bit of Mode Configuration Register (MCR)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ]
LFAST interface enable (lfast_sysclk_en)	Polarity: Active Low – Clock control module (CCM) – LFAST Domain Logic (Rx and Tx block) – System Side Module Interface FIFOs – LFAST Status Registers except the following: TISR, RISR, RIISR, GSR[LPTXDN] and GSR[LPFPDV] These bits remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: Negedge only – SCR[RDR] and SCR[TDR] – TMCR[CLKTST] and TMCR[LPON] – ICR[ICLCSEQ] and ICR[SNDICLC] – PICR[PNGREQ] – UNSTCR[USNDRQ] These bits does not remain reset while the LFAST interface enable (lfast_sysclk_en) is Low.
	Polarity: positive edge only – TISR, – RISR, – RIISR, – GSR[LPTXDN] and GSR[LPFPDV] These bits does not remain reset while the LFAST interface enable (lfast_sysclk_en) is High.

71.10 Clocks

The LFAST mainly works on two clocks:

- System Bus Clock, used to program the registers.
- System Side Module clock, which is synchronous to the System Bus clock.

71.10.1 Clocking strategy

[Figure 1730](#) shows the clock domain in which each module functions. The Clock Module will generate four phases of slow speed clock using both the edges of `lfast_sysclk`, muxes high speed and low speed clocks and provides a muxed clock to the Sampler Module.

Figure 1730. LFAST module clock domains

71.10.2 Slow speed clock

71.10.2.1 External muxing

The Clock Control Module will receive `lfast_sysclk` from the clocking subsystem as shown in [Figure 1731](#), [Figure 1732](#) and [Figure 1733](#).

Figure 1731. External clock muxing of lfast_sysclk

All the reference clocks will be muxed first to provide lfast_sysclk to the module and then either div/2 or direct muxed clock will be used to generate 4 slow speed phases in the Clock Control Module of LFAST as shown in [Figure 1731](#).

The lfast_sysclk could be either 20/26 MHz or 10/13 MHz. When lfast_sysclk is 20/26 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency lfast_sysclk/4 when MCR[LSSEL] = 1. If lfast_sysclk is 20/26 MHz it needs to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in [Figure 1732](#) (selected clock path shown in green).

Figure 1732. External clock muxing of lfast_sysclk of 20/26 MHz

In this case, `lfast_sysclk` is 10/13 MHz frequency, the clock control module will generate 4 phases of slow speed clock of frequency $\text{lfast_sysclk}/2$ when `MCR[LSSEL] = 0`. If `lfast_sysclk` is 10/13 MHz then it does not need to be first divided by 2 before using it for 4 phase generation in LFAST Clock Module, which generates 4 phases of half of the input frequency as shown in [Figure 1733](#) (selected clock path selected shown in magenta).

Figure 1733. External clock muxing of lfast_sysclk of 10 MHz

71.10.2.2 Slow speed 4-phase generator

Clock control module will generate 4 phases of slow speed clock of frequency of 10/13 MHz. For instance, if lfast_sysclk is 10 MHz then 4 phases of 5 MHz will be generated.

[Figure 1734](#) Shows 4 phases getting generated using lfast_sysclk.

Figure 1734. Slow speed 4 phases generation

71.10.3 Rx controller clocks

71.10.3.1 Clocking module requirements for high speed phases

The high speed Phases are obtained from the PLL via the Clocking Module as shown in [Figure 1735](#).

Figure 1735. Clock Enables and Clock Paths

The LFAST block will know which of the phases will be required for the different modes of operations. Therefore, the LFAST block will provide enables and speed mode switches to the Clocking Module. The Clocking Module will use these signals to control the enables to the clock phases to reduce the power consumption.

The 8 phases of clocks signal are fed to the Clocking Module and muxed with the low speed phases. Depending on enables and data rate speed modes, the selected clocks are passed to the Sampler block and interface block.

COCR[PHSSEL] is connected to the Clocking Module, which selects whether 8 or 4 phases are selected for High Speed mode. It is only valid for high speed.

The routing of the 8 high speed phases to the interface is critical. Each clock phase will need to have the same routing track length from the PLL to the interface of Clocking Module. Each of the 8 high speed phases are separated by 45 degrees. This separation needs to be maintained from the phase generator to the interface.

71.10.3.2 Clock module requirements for low speed phases

71.10.3.2.1 Low speed

The low speed clock phases are generated in Clocking Module. These four phases are required to sample the data correctly at Low Speed mode. The LFAST block will provide the enable for the phases. The clock source for the low speed phases is SYSCLK. The Clocking Module block will need to generate the 4 phases of low speed clock 90 degrees apart.

Using the Low Speed mode on the interface allows the polyphase generation logic to be turned off and the requirement of high-speed-freq $\times$ 8 MHz clock from the PLL is not needed.

Table 1608. Rx clocks summary

Rx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

71.10.4 Tx controller clocks

71.10.4.1 Clocking module requirements for speed phases

The low speed phase 0 clock is sourced from the lfast_sysclk and the high speed phase 0 clock is sourced from the PLL. See [Table 1609](#).

Table 1609. Tx clocks summary

Tx Speed mode	Source
Low Speed	lfast_sysclk
High Speed	PLL

Figure 1736. Transmit Clocks Muxing

71.10.4.3 Tx Request Clock Control

The Tx phase 0 clock is enabled when all the resets are negated.

72 Development Trigger Semaphore (DTS)

72.1 Introduction

The Development Trigger Semaphore (DTS) module enables software to signal an external tool by driving a persistent (affected only by reset or an external tool) signal on an external device pin. There are a variety of ways this module can be used, including as a component of an external real-time data acquisition system.

Note: When used as a component of a triggered data acquisition system, Nexus read/write access is different than the data acquisition protocol defined in the IEEE-ISTO 5001-2003 or IEEE-ISTO 5001-2011 Nexus standards, which use the Nexus Auxiliary port.

72.2 Overview

The Development Trigger Semaphore (DTS) module consists of registers and a small amount of combinational logic to generate an output signal—DTS Trigger Output (DTS_OUT). The registers are as follows:

- DTS_SEMAPHORE register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN bit is set in the DTS_ENABLE register. This enables an external tool to detect up to 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.
- DTS_SEMAPHORE_B register—Any bit in this 32-bit register, when set to a value of logic '1', causes the DTS module output signal to be asserted if the corresponding DTS_EN_B bit is set in the DTS_ENABLE register. This enables an external tool to detect an additional 32 signals from the application software. In an application, each bit is generally associated with a specific data set. Only the processor core and DMA module can set bits in this register. The bits can only be cleared by a tool access via Nexus Read/Write Access.
- DTS_STARTUP register—This register provides a mechanism for the external tool to notify software running on the CPU that the tool is connected and can provide information about either the type of tool or options that can be used by the software.
- DTS_ENABLE register—This register provides an enable/disable capability for the DTS feature.

The architecture is shown in [Figure 1737](#).

Figure 1737. DTS block diagram

The DTS Trigger Output ($\overline{DTSO}$) signal is connected to one of the $\overline{EVTO}$ inputs of the Debug and Calibration Interface (DCI). The other $\overline{EVTO}$ inputs are connected to the other Nexus modules in the device. $\overline{DTSO}$ is asserted when any bit in a semaphore register is set and the DTS function of that register is enabled.

Note: When the DTS module is enabled ($DTS_ENABLE[DTS_EN] = 0b1$ or $DTS_ENABLE[DTS_EN_B] = 0b1$), all other Nexus $\overline{EVTO}$ functions associated should be disabled by the tool and $\overline{EVTO}$ becomes the $\overline{DTSO}$. Unlike the $\overline{EVTO}$ function that only asserts for one clock, the $\overline{DTSO}$ function remains asserted until the tool reads the semaphore register that is the source of the assertion, clearing the register's contents.

Figure 1738 shows an example of the chain of events that begins with setting of a bit in the DTS_SEMAPHORE register and the clearing of the register caused by a Nexus read.

Figure 1738. DTSO event sequence example

72.3 DTS device connections

Figure 1739 shows the DTS device connections. The DTS module connects to the Peripheral Bridge (PBRIDGE) for access to the registers. The PBRIDGE is connected to the device modules through a slave port of the Crossbar bus interface (XBAR).

Figure 1739. DTS device connections

The registers have limited access as described in [Section 72.3.1, DTS register access](#). Access is based on the XBAR Master ID of the accessing module. Writing to the semaphore registers is limited to the cores and the eDMA module and is restricted to only setting bits. Only an access via a Nexus Read/Write Access from an external tool can clear bits in the semaphore registers (semaphore register bits are cleared automatically when read via Nexus/Write Access). Similarly, the DTS_ENABLE and DTS_STARTUP registers can only be written via a Nexus Read/Write Access.

Note: Nexus Read/Write Accesses use the core load/store bus to perform accesses, but Nexus accesses have a different Master ID than normal core load/stores.

72.3.1 DTS register access

A summary of accesses to all DTS registers by bus masters is provided in [Table 1610](#). Only proper 32-bit accesses are valid. The effects of write accesses that are not 32 bits are not defined.

Table 1610. DTS register access effects

Register	32-bit read				32-bit write			
	RWA ⁽¹⁾	Core	eDMA	FlexRay ⁽²⁾	RWA ⁽¹⁾	Core	eDMA	FlexRay ²
DTS_ENABLE	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_STARTUP	Data	Data	Data	Data	Data	No effect	No effect	No effect
DTS_SEMAPHORE	Data and Clear ⁽³⁾	Data	Data	Data	No effect	Bit OR	Bit OR	No effect
DTS_SEMAPHORE_B	Data and Clear ⁽³⁾	Data	Data	Data	No effect	Bit OR	Bit OR	No effect

1. Nexus Read/Write access via an external tool

2. FlexRay or other master

3. A read of the semaphore registers by Nexus Read/Write Access module is destructive and clears all bits in the register

Access to DTS module registers is controlled based on the XBAR Master ID of the accessing module.

Note: *The XBAR Master ID should not be confused with the Master Port number of the XBAR. See [Chapter 13, Crossbar Switch \(XBAR\)](#), for details.*

Tools must access the DTS registers through the Nexus Read/Write Access mechanism of a core. External tool accesses through either core appear as if the access is via the core and therefore do not have the same level of access as a Nexus Read/Write Access.

72.4 Memory map and register definition

[Table 1611](#) shows the memory map of the DTS module registers.

Table 1611. DTS memory map

Offset	Register	Access	Reset Value	Section/Page
0x0	ENABLE—DTS Output Enable Register	Restricted R/W ⁽¹⁾	0x0000_0000	72.4.1.1/3112
0x4	STARTUP—DTS Startup Register	Restricted R/W ⁽¹⁾	0x0000_0000	72.4.1.2/3112
0x8	SEMAPHORE—DTS Semaphore Register	Restricted R/W ⁽¹⁾	0xFFFF_FFFF	72.4.1.3/3113
0xC	SEMAPHORE_B—DTS Semaphore Extension	Restricted R/W ⁽¹⁾	0xFFFF_FFFF	72.4.1.4/3114

1. Only certain types of accesses are allowed. See the register figure note of each register for a description of the accesses that are allowed.

72.4.1 Register descriptions

72.4.1.1 DTS output enable register (ENABLE)

The DTS_ENABLE register controls the DTS Trigger Output ($\overline{DTO}$) and whether $\overline{DTO}$ is active on the $\overline{EVTO}$ output pin of the device. [Figure 1740](#) shows the format of the DTS_ENABLE register.

Note: Access to the DTS_SEMAPHORE, DTS_SEMAPHORE_B, and DTS_STARTUP registers are unaffected by the state of this register.

Figure 1740. DTS_ENABLE register

1. The DTS_ENABLE register can be read by the core, but can only be written by a Nexus Read Write Access (RWA).

The DTS_ENABLE register is described in [Table 1612](#).

Table 1612. DTS_ENABLE register field descriptions

Field	Description
DTS_EN	DTS Enable. Controls whether the $\overline{DTO}$ signal is routed to the $\overline{EVTO}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{RESET}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE register asserts the DTS trigger output signal (DTO).
DTS_EN_B	DTS Enable B. Controls whether the $\overline{DTO}$ signal is routed to the $\overline{EVTO}$ pin. The DTS Enable bit is cleared by a device reset (either the assertion of the external $\overline{RESET}$ or by an internally generated reset). A Nexus reset does not change the state of this register. 0 DTS output disabled. Any bit set in the DTS_SEMAPHORE_B register does not assert the DTS trigger output signal. 1 DTS output enabled. Any bit set in the DTS_SEMAPHORE_B register asserts the DTS trigger output signal (DTO).

72.4.1.2 DTS startup register (STARTUP)

[Figure 1741](#) shows the format of the DTS_STARTUP register, used for tool detection and startup information exchange between external data acquisition tool and the embedded controller.

Figure 1741. DTS_STARTUP register

1. The DTS_STARTUP register can be read by the core, the eDMA module and Nexus but can only be updated by a Nexus Read Write Access (RWA).

The DTS_STARTUP register is described in [Table 1613](#).

Table 1613. DTS_STARTUP register field descriptions

Field	Description
AD	Application Dependent register bits. The bits have no defined meaning to the microcontroller. They are used to by an external tool to pass information (for example, application options and status) to application software running on target microcontroller at startup time. Use a Nexus RWA 32-bit write access to update the contents of this register. A device reset (either from the $\overline{\text{RESET}}$ pin or an internally generated reset) clears all bits in the register. A Nexus reset does not change the contents of the register.

72.4.1.3 DTS semaphore register (SEMAPHORE)

[Figure 1742](#) shows the format of the DTS_SEMAPHORE register. The DTS_SEMAPHORE register is used by software to assert the DTO signal on the device EVTO pin. A one in any bit of this register causes the DTO signal on the EVTO pin to be driven low. The intended use of this register is for the DTO signal to notify tools that data is available. Individual bits are used to identify the specific data.

Figure 1742. DTS_SEMAPHORE register

The DTS_SEMAPHORE register is described in [Table 1614](#).

Table 1614. DTS_SEMAPHORE register field descriptions

Field	Description
ST	Semaphore Trigger. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. – All register bits are set to '1' by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

72.4.1.4 DTS semaphore extension (SEMAPHORE_B)

[Figure 1743](#) shows the format of the DTS_SEMAPHORE_B register. The DTS_SEMAPHORE_B register is used by software to assert the DTO signal on the device EVTO pin. A one in any bit of this register causes the DTO signal on the EVTO pin to be driven low. The intended use of this register is for the DTO signal to notify tools that data is available. Individual bits are used to identify the specific data.

Figure 1743. DTS_SEMAPHORE_B register

The DTS_SEMAPHORE_B register is described in [Table 1615](#).

Table 1615. DTS_SEMAPHORE_B register field descriptions

Field	Description
ST_B	Semaphore Trigger Extension. When a core or eDMA writes a logical '1' to a bit, the bit is set. A write of '0' by the core or DMA does not change the state of the bit. – All register bits are set to '1' by a device reset. – A Nexus reset does not change the state of this register. – The register can be accessed, with restrictions, by any core, DMA or any Nexus RWA. – For the core or DMA, only 32-bit write or read accesses are valid. – A core or DMA valid read access returns the current value of the register and leaves the register unchanged. 0 No flag 1 Flag is set

72.5 Example application

The calibration process of a new engine requires real-time access to calibration tables and the ability to update the tables in real-time. The DTS module enables this capability by enabling software to assert a signal to an external device pin to notify an external tool that data is available. The tool can then retrieve the data.

In this type of application the DTS_SEMAPHORE register and DTS Trigger Output (DTO) signal provide a mechanism to notify the calibration tool that the calibration variable or variables (or sets of measurements), up to 32, have been updated with new values and are available for the tool to access.

Note: It is the user's responsibility to ensure that the tool has time to retrieve the data prior to that particular trigger being set a second time. It is also permissible to have multiple triggers active at the same time or for a second trigger to be set before a previous trigger has been serviced, as long as it is not the same trigger (unless it is acceptable to the tool to not receive every data set).

Figure 1744 shows an example DTS startup sequence for an external real-time data acquisition system. The startup and synchronization sequence can be as simple or as complicated as the need requires. However, a typical startup sequence is as follows:

1. The DTS_STARTUP register is cleared by a power on reset or any CPU reset.
2. The tool writes a non-zero value to the DTS_STARTUP register.
3. The CPU (user application software) then reads the value of the DTS_STARTUP register. Based on this value, different initialization options can be selected. The bits can be used for any application specific definitions.
4. Since the DTS_SEMAPHORE register is cleared when the tool reads the current value. The tool should perform all necessary initialization before reading this register. The application software can then check that the DTS_SEMAPHORE register was cleared by the tool, to determine that it is safe to start using it for its intended raster trigger semaphore function.
5. An optional hand shake from the CPU can be used to inform the tool that the user software has detected that the tool is attached and the CPU has performed the proper initialization for the tool by writing a predefined value to the DTS_SEMAPHORE register (the example shown in the figure above uses 0xAAAA_AAAA—all A's was used since it is unrealistic that 16 channels could be enabled very quickly after start up after a reset).

Figure 1744. DTS startup sequence example

73 Nexus Aurora Router (NAR)

73.1 Introduction

On the device, there are multiple blocks that require development interface support. The blocks that are Nexus-compliant (based on the IEEE-ISTO 5001 standard) are expected to interface with the development tool through a dedicated high-bandwidth debug port. The Nexus Aurora Router (NAR) controls the usage of the output port in a manner that allows all the individual development interface blocks to share the port, and appear to the development tool to be a single block.

Top-level architecture is shown in [Figure 1745](#). Multiple clients send messages by sharing the high-bandwidth port through the NAR. For a list of the specific clients that are connected to the NAR, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Figure 1745. NAR top level block diagram

The trace memory bus port provides added flexibility to the channel trace data to memory on the Nexus Aurora crossbar. Setup and configuration of the NAR is performed by accessing the configuration registers via a JTAG (1149.1) port.

Each Nexus client has a dedicated receive queue to allow seamless switching between sources at Nexus message boundaries. Incoming Nexus data is parsed into the receive queues so that end-of-message can be determined. Messages are then transferred into the main queue. An arbitration block determines the order in which clients are serviced, using an optional client request level bus to prioritize the data (lacking request level data, a simple round-robin algorithm is used). The NAR has two output ports: the high bandwidth debug port (Aurora out) and the trace memory bus. If both output ports are enabled at the same time, the main queue is logically partitioned inside NAR. The Production Device (PD) does not support partitioning of the main queue; therefore, only one of the ports can be active at a time. Data going through the Aurora out port or the Trace port goes through an additional translation block to put the data in the correct format. The actual Aurora formatting is done in the NAL. Additional blocks for message generation and timestamp generation are described in more detail in the following sections.

The NAR supports the following client interfaces:

- Legacy interface to support existing client interface protocol through a conversion gasket logic with clock domain transfer
- New client interface with clock domain transfer

73.2 Overview

The NAR serves as an arbiter for the high-bandwidth debug port (HBDP). The NAR pulls Nexus messages from multiple clients, queues the data, and forwards it (based on the user-controlled configuration) to the high-speed Aurora Out port and/or the Trace port. The trace memory bus controller allows the NAR to transmit data via the normal system interface. NAR control and configuration registers are accessed via JTAG (1149.1) port.

73.3 Features

The NAR supports the following features:

- Connects 7 client(s) with dedicated receive queue(s). Clients can transmit data as long as there is space in its associated receive queue, but only the active port receive queue empties into the main queue.
- Legacy client interface for backward compatibility
- Aurora output data format for dedicated high-bandwidth serial transmission
- Aurora output format support at client interface
- Trace Memory port (64-bit address and data) can be used to write Nexus messages directly to external overlay memory. Block transfer mode provides highest-bandwidth option.
- Configurable Start Address and Range Selection for Trace Memory port write operation provides flexibility to choose Overlay memory Section and range to store Trace data.
- Time-stamping provides a central synchronization resource for message ordering. Gray coded timer output for clients working in different clock domains.
- Re-allocatable receive queues allow queue-space of an inactive client to be reassigned to an active client
- Stall detection and handling allows NAR to continue when a client stops sending data in the middle of a message
- Event generation on External Trace Memory (overlay) programmable full
- Suppress mode can be used to shut down message delivery and relieve back-pressure to clients without turning off Nexus messaging in the clients.

73.4 Register definition

The NAR configuration registers provide configuration and control for all NAR operations. They are accessible through the JTAG (1149.1) port. Addressing (within the local NAR address space) for the NAR registers is shown in the following table. If the NAR clock is turned off, the NAR registers cannot be accessed.

Table 1616. NAR registers

Register name	Read/ Write	JTAG index (NAR relative)	Location
NAR_CR—NAR Control Register	R/W	0	on page 3119
NAR_ST—NAR Status Register	R	1	on page 3121
NAR_SFR—Source Filter Register	R/W	2	on page 3123
NAR_TFR—Type Filter Register	R/W	3	on page 3124
NAR_TBALO—Trace memory port base address, low	R/W	4	on page 3125
NAR_TBAHI—Trace memory port base address, high	R/W	5	on page 3125
NAR_TCR—Trace Memory bus control register	R/W	6	on page 3127
NAR_STCR—Suppress Trigger Control Registers 1–4	R/W	7 (Trigger 1) 8 (Trigger 2) 9 (Trigger 3) A (Trigger 4)	on page 3128
NAR_CSSR—Client Suppress Status Register	R	B	on page 3129
NAR_CDR—Client Disable Register	R/W	C	on page 3130
NAR_AHFPAR—Trace memory fill level and partition configuration	R/W	E	on page 3131

73.4.1 Register descriptions

73.4.1.1 NAR control register (NAR_CR)

The NAR control register provides all the main control and enable bits for the NAR and its output ports. The following figure shows the format of the NAR_CR.

Figure 1746. NAR control register (NAR_CR)

Register index: 0

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_CR is described in the following table.

Table 1617. NAR_CR field descriptions

Field	Description
31 NEN	NAR Enable. 0 NAR is disabled unless HBDP is independently enabled. See Section 73.5.2.2, Disabled for more information. 1 NAR is enabled.
30 NCD	NAR Communication Disable. 0 NAR monitors clients for activity 1 NAR communication with clients is disabled
29 TEN	Timestamp Enable. 0 Timestamp packet is not included in messages 1 Timestamp packet is included in messages from all client including NAR generated messages
28 TRS	Timestamp Reset. 0 to 1 transition: reset timestamp counter in NAR
27–26 TSG	Timestamp Granularity (Mode). <i>Note: Some clients may only support timestamps on every message.</i> 00 Add timestamp to every message 01 Add timestamp to every 4th message 10 Add timestamp to every 16th message 11 Add timestamp to every 32nd message
25 SED	Stall Error Disable. 0 NAR injects dummy complete message when active client stalls 1 NAR does not inject dummy complete message
24 SRD	Stall Recovery Disable. 0 Stalled receive queue resumes operation when its client comes back on line 1 Stall error recovery is disabled
23 TBW	Tracebuffer Wrap. 0 NAR does not capture new data when main queue is full 1 NAR begins overwriting main queue from the beginning upon queue overflow
22–21 AQP	Alternate Queue Partition. 00 Queue partitioning is disabled 01 Reserved 10 Reserved 11 Reserved
20	Reserved and must be written with 0
19–16	Reserved and must be written with 0s
15–13 WPE	Watchpoint Enable 000 NAR watchpoint messaging is disabled xx1 NAR generates a watchpoint message upon a sync event x1x NAR generates a watchpoint message upon a trace memory bus or tracebuffer block full/wrap event 1xx NAR generates a watchpoint message upon a suppress-mode event
12	Reserved
11	Reserved. This bit must be written with 0.
10–9	Reserved and must be written with 0s.

Table 1617. NAR_CR field descriptions (continued)

Field	Description
8	Reserved
7–6 ALT	Alternate Port. Defines which port is the target for non-filtered messages; main port in single-port applications. 00 No alternate port. Running in trace-buffer mode. 01 Aurora out is the ALT 10 Trace memory bus is the ALT 11 Reserved
5	Reserved
4 AFA	Automatic Flush Accumulators. 0 Output queue accumulators do not flush stranded beats 1 Accumulators automatically flush stranded beats
3	Reserved. This bit must be written with 0.
2	Reserved and must be written with 0.
1 PUS	Power-Up Suppressed. 0 NAR powers up active 1 NAR powers up in global suppressed mode
0 NSR	NAR Soft Reset. 1 Resets all configuration registers and sets queue address pointers to the top of their respective queues. Also resets itself after a single-cycle delay. (This does not affect other blocks)

73.4.1.2 NAR status register (NAR_ST)

The NAR_ST register provides information on NAR activity and queue status, as well as HBDP status and errors. It is a read-only register. The following figure shows the format of the NAR_ST.

Figure 1747. NAR status register (NAR_ST)

Register index: 1

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	NEN	NUM			NCE				0	0	0	0	0	0	0	0
W

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HPR	HPE	MPE	MOV	0	TOV	QWA									
W		w1c	w1c	w1c		w1c										
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

The NAR_ST register is described in the following table.

Table 1618. NAR_ST field descriptions

Field	Description
31 NEN	NAR Enabled. 0 NAR is disabled and inactive 1 NAR is enabled with clocks on
30–28 NUM	NAR Mode. 000 NAR is in disabled mode 001 NAR is in global suppressed mode 010 NAR is in communication-disabled mode 011 NAR is in tracebuffer mode 100 NAR is in active transmit mode 101 Reserved 110 Reserved 111 NAR is in run-control mode
27–24 NCE	NAR Config Error. See Table 1632 for coding
23–16	Reserved
15 HPR	HBDP Ready. 0 HBDP (Aurora Out port) is not ready 1 HBDP is ready and accepts data for transmission
14 HPE	HBDP Error. 0 No HBDP error 1 Error condition exists on HBDP
13 MPE	Trace memory bus Error. 0 No Trace memory bus error 1 Error condition detected on trace transaction
12 MOV	Trace memory bus block overflow. 0 No Trace memory bus overflow 1 Targeted external memory block is full. Trace memory bus writes are halted (or wrapped).
11	Reserved
10 TOV	Tracebuffer Overflow. 0 No tracebuffer overflow 1 The tracebuffer has overflowed/wrapped at least once
9–0 QWA	Queue Write Address. Current value of the output queue write pointer (last valid write + 1)

73.4.2 Message filtering registers

The two output ports (HBDP and trace memory bus) are independently controllable. In the BD NAR, two ports can be active simultaneously. When multiple ports are active, user-programmable filters are determine which port receives a message, based on the message source or type. Filters apply to the designated Message Select Port (MSP), and are used to select messages for that port. All other messages go to the other (alternate) port. If multiple ports are used, an MSP must be designated; otherwise a configuration error results. See [Section 73.5.6, Output arbitration](#), for details on how the NAR arbitrates between multiple output ports. These registers should only be set in the BD NAR because partitioning is not supported in the PD NAR.

73.4.2.1 Source filter register (NAR_SFR)

The MSP can be configured to accept or exclude messages from up to four sources. The sources which are to be filtered are programmed in the source filter register (NAR_SFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Figure 1748. Source filter register (NAR_SFR)

Register index: 2

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	SFI	FE0	SF0				0	0	0	FE1	SF1				0	0
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	FE2	SF2				0	0	0	FE3	SF3				0	ACC
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_SFR is described in the following table. The source trace IDs, that are compared to the source filter fields (SF_n), are device specific. For a list of the clients that are connected to the NAR and their corresponding Nexus source trace IDs, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1619. NAR_SFR field descriptions

Field	Description
31 SFI	Source Filter Invert. 0 Match if message source equals any of the enabled filters 1 Match if message source equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. SF0 ignored 1 Filter 0 enabled and contained in SF0
29–26 SF0	Source Filter 0. The message source trace ID is compared with this field. See Section 73.5.6, Output arbitration for an example.
25–23	Reserved.
22 FE1	Enable Filter 1. 0 Filter 1 disabled. SF1 ignored 1 Filter 1 enabled and contained in SF1
21–18 SF1	Source Filter 1. The message source trace ID is compared with this field. See Section 73.5.6, Output arbitration for an example.
17–15	Reserved
14 FE2	Enable Filter 2. 0 Filter 2 disabled. SF2 ignored 1 Filter 2 enabled and contained in SF2

Table 1619. NAR_SFR field descriptions (continued)

Field	Description
13–10 SF2	Source Filter 2. The message source trace ID is compared with this field. See Section 73.5.6, Output arbitration for an example.
9–7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. SF3 ignored 1 Filter 3 enabled and contained in SF3
5–2 SF3	Source Filter 3. The message source trace ID is compared with this field. See Section 73.5.6, Output arbitration for an example.
1	Reserved
0 ACC	OR source and type filters. 0 Match if source AND type filters match 1 Match if source OR type filters match

73.4.2.2 Message type filter register (NAR_TFR)

The MSP can be configured to accept or exclude messages of up to four types, as encoded in the message TCODE field. The TCODEs which are to be filtered are programmed in the message type filter register (NAR_TFR) as shown in the following figure. This register should only be set in the BD NAR because partitioning is not supported in the PD NAR.

Figure 1749. Message type filter register (NAR_TFR)

Register index: 3

The NAR_TFR is described in the following table.

Table 1620. NAR_TFR field descriptions

Field	Description
31 TFI	Type Filter Invert. 0 Match if message TCODE equals any of the enabled filters 1 Match if message TCODE equals none of the enabled filters
30 FE0	Enable Filter 0. 0 Filter 0 disabled. TF0 ignored 1 Filter 0 enabled and contained in TF0
29–24 TF0	Type Filter 0. The message TCODE is compared with this field. See Section 73.5.6, Output arbitration for an example.
23	Reserved
22 FE1	Enable Filter 1. 0 Filter 1 disabled. TF1 ignored 1 Filter 1 enabled and contained in TF1
21–16 TF1	Type Filter 1. The message TCODE is compared with this field. See Section 73.5.6, Output arbitration for an example.
15	Reserved
16 FE2	Enable Filter 2. 0 Filter 2 disabled. TF2 ignored 1 Filter 2 enabled and contained in TF2
13–8 TF2	Type Filter 2. The message TCODE is compared with this field. See Section 73.5.6, Output arbitration for an example.
7	Reserved
6 FE3	Enable Filter 3. 0 Filter 3 disabled. TF3 ignored 1 Filter 3 enabled and contained in TF3
5–0 SF3	Type Filter 3. The message TCODE is compared with this field. See Section 73.5.6, Output arbitration for an example.

73.4.3 Trace memory bus configuration registers

The trace memory bus can be used to transfer debug messages out to a dedicated block of external memory space. The trace memory bus configuration registers are used to specify the location and size of the external debug space.

73.4.3.1 Trace memory bus base address registers (NAR_TBALO and NAR_TBAHI)

The trace memory bus base address registers determine where Nexus data sent out through the trace memory bus goes. The NAR sends out blocks of data on the trace memory bus, writing to an address block defined by the specified base address. Data can be transmitted either on an as-available, word-wide basis, or in larger blocks. In block transfer mode, the size of the data block is determined by the BTM field of the Control Register; the default is 64 bytes. Even if block transfer mode is not used, the 5, 6, 7, or 8 (depending on the BTS field in NAR_TCR register) LSBs of the base address are not accessible. This forces the debug memory space to be aligned to a block boundary.

When read, the address registers return the current address, allowing the user to monitor the progress of a trace memory transfer. The following figures show the format of the trace memory base address registers (NAR_TBALO and NAR_TBAHI). For a description of the allowed address for these registers, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Figure 1750. Trace memory base address register NAR_TBAHI

Register index: 5

Figure 1751. Trace memory base address register NAR_TBALO

Register index: 4

The NAR_TBALO and NAR_TBAHI registers are described in the following tables.

Table 1621. NAR_TBAHI field descriptions

Field	Description
31–0 TBAHI	Trace Debug Memory Base Address on AHB-EW port, upper part. For 32-bit address applications this field is all zeros.

Table 1622. NAR_TBALO field descriptions

Field	Description
31–10 TBALO	Trace Debug Memory Base Address on AHB-EW port, lower part
9 ADRLO[9]	Base Address LSB for BTS = 11 (384-byte block)
8 ADRLO[8]	Base Address LSB for BTS = 10 (256-byte block)
7 ADRLO[7]	Base Address LSB for BTS = 01 (128-byte block)

Table 1622. NAR_TBALO field descriptions (continued)

Field	Description
6 ADRLO[6]	Base Address LSB for BTS = 00 (64-byte block)
5–0	Reserved

73.4.3.2 Trace memory bus control register (NAR_TCR)

The trace memory bus control register is used to control the attributes of the trace memory bus port, such as block transfer size and message priority. Since the trace memory bus transfers are expected to go to a static block of external memory, a maximum transfer size must be specified to prevent the NAR from overwriting memory it is not authorized to access. This is done via the MXFR max transfer size register field. The memory allocation is specified in units of the trace memory bus block transfer size (64, 128, 256, or 384 bytes), so the actual size of the reserved memory block depends on the BTS setting. The following figure shows the format of the NAR_TCR.

Figure 1752. Trace memory bus control register (NAR_TCR)

Register index: 6

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	BTM	BTS	BTH	0	0	0	TBW	MXFR								
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MXFR															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_TCR is described in the following table.

Table 1623. NAR_TCR field description

Field	Description
31 BTM	Block Transfer Mode. 0 Data for the Trace Memory bus port is transmitted one word at a time, upon first availability 1 Data to the Trace Memory bus port is bundled into blocks before transmitting
30–29 BTS	Block Transfer Size. 00 Block transfer size = 64 bytes 01 Block transfer size = 128 bytes 10 Block transfer size = 256 bytes 11 Block transfer size = 384 bytes

Table 1623. NAR_TCR field description (continued)

Field	Description
28–27 BTH	Block Transfer Threshold. 00 Full threshold. Number of entries in partition must equal block transfer size before block transfer starts 01 Begin transfer when block is 25% full 10 Begin transfer when block is 50% full 11 Begin transfer when block is 75% full
26–24	Reserved. These bits must be written with 0.
32 TBW	Trace Memory Bus Block Wrap. 0 NAR stops writing to the Trace Memory bus debug memory space once Max Size has been reached 1 NAR overwrites Trace Memory bus debug memory from the beginning upon Trace Memory bus block overflow.
22–0 MXFR	Trace Memory Bus Max Transfer Size. Total size of the dedicated debug memory space, in Trace Memory bus data transfer blocks.

73.4.4 Suppress mode triggers register (NAR_STCR)

Four suppress mode triggers are provided for precise control of the NAR suppress mode feature described in [Section 73.5.4, Suppress mode](#). The suppress mode triggers are only available on the PD NAR and do not apply to the BD NAR. The registers are present in the BD NAR, but input suppress triggers are not connected. Each trigger can be programmed to suppress or wake clients individually or the entire NAR. All receive queues can be suppressed on the occurrence of a selected trigger, or the full NAR can be brought out of suppress mode upon the occurrence of the appropriate trigger. A trigger can also be programmed to toggle one or more clients between the suppressed and active states. Each Suppress Trigger Control Register, shown in the following figure, is associated with one of the triggers, and are used to determine the action taken, if any, upon the assertion of that trigger. The suppress triggers are connected to the Sequence Processing Unit (SPU) action unit.

Figure 1753. Suppress trigger control registers (NAR_STCR1–4)

Register index: 7–A

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	GST	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	LST															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_STCR are described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress trigger, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1624. NAR_STCR field descriptions

Field	Description
31 GST	Global Suppress Trigger. 0 The associated trigger cannot cause NAR to enter global suppress mode 1 The associated trigger is enabled for global suppress mode
29–16	Reserved
15–0 LST	Local Suppress Trigger. 0000000000000000The associated trigger is disabled for local suppress mode for all clients xxxxxxxxxxxxx1Trigger is enabled for Client 1 local suppress xxxxxxxxxxxxx1xTrigger is enabled for Client 2 local suppress xxxxxxxxxxxxx1xxTrigger is enabled for Client 3 local suppress xxxxxxxxxxxxx1xxxTrigger is enabled for Client 4 local suppress xxxxxxxxxxxxx1xxxxTrigger is enabled for Client 5 local suppress xxxxxxxxxxxxx1xxxxxTrigger is enabled for Client 6 local suppress xxxxxxxxxxxxx1xxxxxxTrigger is enabled for Client 7 local suppress xxxxxxxxxxxxx1xxxxxxxTrigger is enabled for Client 8 local suppress xxxxxxxxxxxxx1xxxxxxxTrigger is enabled for Client 9 local suppress xxxxxx1xxxxxxxxxTrigger is enabled for Client 10 local suppress xxxxx1xxxxxxxxxxTrigger is enabled for Client 11 local suppress xxxx1xxxxxxxxxxxTrigger is enabled for Client 12 local suppress xxx1xxxxxxxxxxxxTrigger is enabled for Client 13 local suppress xx1xxxxxxxxxxxxxTrigger is enabled for Client 14 local suppress x1xxxxxxxxxxxxxxTrigger is enabled for Client 15 local suppress 1xxxxxxxxxxxxxxxTrigger is enabled for Client 16 local suppress All other optionsReserved

73.4.4.1 Client suppress status register (NAR_CSSR)

Clients can be individually suppressed, leaving the rest of the NAR unaffected. When enabled for local suppress, assertion of one of the suppress triggers causes one or more client receive queues to stop queueing messages. A subsequent pulse of the same trigger causes the client(s) to awaken. Local suppress mode is enabled by setting the appropriate bit in one of the NAR_STCRs. An additional status register, Client Suppress Status (NAR_CSSR), shown in the following figure, can then be read to determine which clients are suppressed, and which are active.

Figure 1754. Client suppress status register (NAR_CSSR)

Register index: B

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
R	LSS																0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_CSSR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the local suppress status, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1625. NAR_CCSR field descriptions

Field	Description
31–16 LSS	Local Suppress Status. 0000000000000000No client is in local suppress mode xxxxxxxxxxxxxxx1Client 1 is suppressed xxxxxxxxxxxxxxx1xClient 2 is suppressed xxxxxxxxxxxxxxx1xxClient 3 is suppressed xxxxxxxxxxxxxxx1xxxClient 4 is suppressed xxxxxxxxxxxxxxx1xxxxClient 5 is suppressed xxxxxxxxxxxxxxx1xxxxxClient 6 is suppressed xxxxxxxxxxxxxxx1xxxxxxClient 7 is suppressed xxxxxxxx1xxxxxxClient 8 is suppressed xxxxxxx1xxxxxxClient 9 is suppressed xxxxxx1xxxxxxClient 10 is suppressed xxxxx1xxxxxxClient 11 is suppressed xxxx1xxxxxxClient 12 is suppressed xxx1xxxxxxClient 13 is suppressed xx1xxxxxxClient 14 is suppressed x1xxxxxxClient 15 is suppressed 1xxxxxxClient 16 is suppressed All other optionsReserved
15–0	Reserved

73.4.5 Receive queue client disable register (NAR_CDR)

Disabling a client reallocates its receive queue to the next active client, allowing that memory space to be put to use. The Client Disable Register, shown in the following figure, allows the user to individually disable or enable clients as needed. The status bits also inform the user when the client has new data available.

Figure 1755. Client disable register (NAR_CDR)

The NAR_CDR is described in the following table. The set of clients connected to the NAR is device specific. For a list of the clients that are connected to the NAR and their corresponding NAR client index for the client activity status and receive queue disable, see the Calibration and Debug configuration chapter which describes how the modules are configured.

Table 1626. NAR_CDR field descriptions

Field	Description
31–16 CAS	Client Activity Status. xxxxxxxxxxxxxxxx1 Client 1 is active with new data xxxxxxxxxxxxxxxx1x Client 2 is active with new data xxxxxxxxxxxxxxxx1xx Client 3 is active with new data xxxxxxxxxxxxxxxx1xxx Client 4 is active with new data xxxxxxxxxxxxxxxx1xxxx Client 5 is active with new data xxxxxxxxxxxxxxxx1xxxxx Client 6 is active with new data xxxxxxxxxxxxxxxx1xxxxxx Client 7 is active with new data xxxxxxxxxxxxxxxx1xxxxxxx Client 8 is active with new data xxxxxxxxxxxxxxxx1xxxxxxx Client 9 is active with new data xxxxxxxxxxxxxxxx1xxxxxxx Client 10 is active with new data xxxxxxxxxxxxxxxx1xxxxxxx Client 11 is active with new data xxxxx1xxxxxxxxxxxx Client 12 is active with new data xxx1xxxxxxxxxxxxxx Client 13 is active with new data xx1xxxxxxxxxxxxxxx Client 14 is active with new data x1xxxxxxxxxxxxxxx Client 15 is active with new data 1xxxxxxxxxxxxxxx Client 16 is active with new data All other optionsReserved

73.4.6 Trace Memory fill level and partition configuration register (NAR_AHFPAR)

This register provides the configuration to set the fill level marker for debug trace memory, connected at the trace memory bus, to generate the partial full event indication and the partition related configuration for main queue (internal central queue). The following figure shows the format of the NAR_AHFPAR.

Figure 1756. Trace memory fill level and partition configuration register (NAR_AHFPAR)

Register index: E

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The NAR_AHFPAR is described in the following table.

Table 1627. NAR_AHFPAR field description

Field	Description
31-11	Reserved and must be written with 0s
10 AHB01kEN	Enable 1K Marker Event
9-4	Reserved and must be written with 0s
3-0 AHB_01K_Marker	Value at this field is used to compare a 4-bit slice of internal Trace Memory address bus which works at boundary of 1K. A match with this value generates an event to SPU to indicate the fill status of External Overlay Trace memory. See Section 73.5.12 <i>Note: This is used in PD as it has memory ranges from 1K to 15K</i>

73.5 Functional description

High-level descriptions of the operation of the NAR and its main functional blocks are given in the following sections.

73.5.1 Reset/Startup

Assertion of global reset causes the NAR operation to immediately cease. All queues and configuration registers are reset. Upon exiting reset, the Nexus Port Controller (NPC) block inside the NAR is disabled. Holding TMS high for five consecutive rising edges of TCK puts TAP controller into the Test-Logic-Reset state regardless of the current state. This applies reset to only TAP controller and JTAG related logic. Applying soft reset through the NAR_CR resets the entire NAR including the TAP controller and configuration registers.

The typical startup procedure for running a trace through the NPC is as follows:

1. Reset the block
2. Upon exiting reset, the Aurora Phy configuration is determined by sampling the configuration pin values from the Nexus Aurora Phy (NAP). If the NAP is enabled, then the NAR is enabled. The Aurora communication is started only when the NAP is ready

to accept data. (If any debug lanes are enabled, the Aurora Link begins training at this time.)

3. Debugger/external user sets the NAR enable (NEN) bit in the NAR_CR and configures the NAR. The configuration includes setting up message selection/filtering when two output ports are enabled, enabling timestamp and so on.
4. User programs additional device level debug facilities, such as event-processing, performance-monitoring, and so on.
5. User sets up trace filtering.
6. Enable Nexus transmission in clients.

To enable NAR operation, either the Aurora Link must be enabled at reset, or the user must set the NEN bit in the NAR control register.

Note: *The HBDP may already be active by the time the NAR comes up. The NAR only tries to initialize the HBDP if it is currently inactive.*

The NAR can be enabled to begin immediate operation, or to start in suppress mode, see [Section 73.5.4, Suppress mode](#). Once the NAR and desired ports are enabled, the user should wait until the NAR-ready and HBDP port-ready status bits are set in the NAR status register before beginning Nexus messaging in the clients.

73.5.2 Operation modes

The NAR operating mode is determined by the state of the main control signals: reset and Phy enable. In its enabled state, operation is controlled by its configuration registers. A truth table for all the NAR states is given in this table.

Table 1628. NAR operational modes truth table

Reset	NAR enable	NAR comm disable	Global suppress	HBDP enable	ALT partition	MSP partition	Mode
0	x	x	x	x	x	x	RESET
1	0	x	x	0	x	x	Disabled
1	1	1	x	0	x	x	Trace-Disable
1	x	1	x	1	x	x	Trace-Disable
1	0	x	x	1	x	x	Trace-Disable
1	1	0	1	x	x	x	Suppressed
1	1	0	0	x	Trace Memory bus	x	NAR Transmit
1	1	0	0	1	AUR	x	NAR Transmit
1	1	0	0	1	Trace Memory bus	AUR	NAR Transmit
1	1	0	0	1	AUR	Trace Memory bus	NAR Transmit

There can be overlap between modes as modes are not mutually exclusive.

73.5.2.1 Reset

During reset all internal resources and queues are reset and all output ports are disabled. All inputs are ignored. Upon exiting reset mode, the NAR is in a fully disabled state.

73.5.2.2 Disabled

In the disabled state, all message traffic is ignored, and all output ports are disabled. The NAR is disabled if and only if the NAR enable bit of the NAR control register is not set and the Aurora Link is inactive.

73.5.2.3 Suppressed

The suppressed state differs from the disabled state in that the NAR is on. The NAR pulls out any messages that come up at the clients, keeping the Message Start-End Out (MSEO) bits (so that it can keep track of message boundaries) and discarding the rest.

In the suppressed state, the NAR is waiting for a trigger to begin normal operation. Once that trigger is received, the NAR begins queueing messages that started after the trigger arrived. Incomplete messages that were in transit to the NAR when the trigger arrived are discarded. The NAR can be put into suppressed mode by enabling one of the global suppress states.

73.5.2.4 Trace disable

In trace disable mode, the NAR is powered up but all client-trace is disabled, and no messages are pulled. This mode is also useful for port initialization (to prevent any activity from occurring before the outputs are ready) or for debug/trace-buffer mode, to ensure that, during data retrieval, the NARs queues are stable.

The NAR goes into trace disable (communication-disable) mode when the NAR-enable and NAR communication-disable bits are set or when the HBDP channel is active while the NAR-enable bit is not set.

73.5.2.5 NAR transmit

This is the standard operational mode of the NAR when it is transferring Nexus messages from multiple clients to one or two enabled output port(s). The NAR performs four main operations as described in this table on the incoming messages before transmitting to one of the output ports.

Table 1629. NAR transmit operations

Operation	Description
Data reception	NAR accepts data from each client based on the status of the client receive queue status. The maximum data rate is 8×32 -bit data words (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word) per cycle per client. MSEO bits of incoming data are monitored to identify end-of-message boundaries.
Input Arbitration	Active receive queue unloads into main queue(s), 8×32 bits per cycle (where 8 is the number of Nexus message beats in a full entry and 32 is the number of bits in the Nexus word). If end-of-message detected, new active receive queue is determined based on client request level or round-robin algorithm.
Output Arbitration	If multiple output ports are enabled, route messages from top of queue to appropriate output port based on message type or source. If split queue is used, outputs can run simultaneously, with each sub-queue communicating directly with a port.
Translation	Data going out the Aurora or trace memory bus ports must be translated into the correct format prior to transmission.

Enabling the NAR and one or more output ports without setting the communication-disable bit puts the NAR into transmit mode.

73.5.3 Data reception and arbitration

The NAR supports 7 clients. Each client has a dedicated input port on the NAR and communicates with its associated input port via a dedicated data bus. A data transmission must consist of an integer number of 32-bit Nexus words (32-bit word is called a beat). The number of beats varies from client to client. The number of beats (B_n) for each client are described in the Calibration and Debug configuration chapter which describes how the modules are configured.

There are two types of clients supported at NAR client interface. The client types have their own protocols to send Nexus messages. The only common parameter is the Nexus word size (beat). One Nexus word consists of 30 Message Data Out (MDO) bits plus two Message Start/End Out (MSEO) control bits. Internally, the NAR converts all client interfaces to a common interface. To achieve this, the NAR instantiates interface level gaskets that handle the protocol conversion and clock domain transfer.

When new data is available in the core, it is transferred over to the asynchronous gasket in the internal NAR clock domain. The gasket then asserts enough data valids to fill internal receive queue, using a receive queue available signal to track available space in the associated queue, under the assumption that the receive queue available signal is initialized with the size of the queue. If the internal arbiter consumes any of its queued entries, it responds with a data accept signal, which increments the receive queue available signal and allows the gasket to send the next piece of data. Under certain circumstances, like receive queue reallocation, it is possible for the internal arbiter to send out surplus data accept signals such that the receive queue available signal can become larger than the size of the queue. If the receive queues are sized correctly, when NAR is actively servicing a particular client, then asserted data accept signals allow the client to continually stream data until the NAR switches to a new client. The data tracking at the gasket assures that it never sends more data than the receive queue can accept and inactive queues are always full and ready for when they are switched to.

The client gaskets must always be in sync with the internal logic of NAR in terms of the number of available entries in each receive queue. For this reason, the internal NPC and its client gaskets need to be reset by the same signal. Any soft-reset of the NAR (via the SRESET configuration bit) is communicated to all gaskets and used to reset every thing inside it.

Each input port has a dedicated receive queue with a minimum of two entries, where an entry is wide enough to store an entire $B_n \times 32$ data word (where 32 is the number of bits in the Nexus word or the beat). The receive queue can be made larger to allow the NAR to continue transmitting during switches from one client to another in a pipelined environment. Every cycle, if there is space in a particular receive queue, it latches in one full AUX word from its client. Because the client may be running at a much higher frequency than the NAR, several cycles worth of Nexus messages are contained in a single transaction, as shown in the following figure for a 3-beat per word transaction.

Figure 1757. AUX bus parsing

Each AUX word consists of B_n cycles of Nexus data, along with an optional request-level sideband signal consisting of a priority field (bit 0) and a weight field (bits 1 and 2). Request level priority indicates to the NAR the clients queue status, allowing it to give preferential treatment to clients that are closer to queue overflow. Clients with a set priority bit are always chosen ahead of clients without the bit. For this reason, priority should be used sparingly, only when a client is in danger of overflowing. Request-level weighting also gives a client preferential treatment, but without entirely shutting out the other clients. Normally, the NAR attempts to switch to a new client every time it sees an end-of-message boundary.

As the AUX word is pulled into the receive queue, the MSEO bits are monitored to determine the current Nexus state of the data flow; since Nexus is a variable-length protocol, messages can end in any cycle. If the start message or end message state is detected on any data beat, the beat is marked as containing an end-of-message boundary.

Any received beat which is in the idle state, indicating null data content, is discarded (see the IEEE-ISTO 5001-2003 standard for details of the Nexus protocol). At the same time, if two outputs are enabled, then the source and TCODE fields are extracted from each new message and compared with the user-programmed filters. Messages that generate a match are tagged with an MSP bit, which allows the NAR to route it to the correct port.

Every cycle, the NAR transfers 8 beats of data from the receive queues into the main output queue. Only one port (the active port) is allowed to empty into the main queue at a time: the active port unloads its receive queue into the main queue until the end of the current Nexus message is detected. At that point, a new active port is selected based on the latest request level received at each port. In the case where multiple ports have the same request level (or when request level is not used), then the active port is rotated amongst those ports. If the end of message occurs in the middle of an AUX word, then all the beats up to the end of message are transferred from the old active port, while the rest of the beats come from the new active port. For example, if the message ended at beat two of a three-beat AUX word, then the first two beats into the main queue would come from the original active port, while the last beat would come from the new active port.

73.5.4 Suppress mode

The suppress mode feature enables the user to quickly turn Nexus messaging through the NAR on or off, based on the four dedicated suppress-mode triggers. Suppress mode is only supported in the PD NAR, it is not supported in the BD NAR. A suppress can either be global, meaning messaging is turned off for all clients, or local, which only applies to selected clients. In suppress mode, the NAR pulls messages from the suppressed client(s), but does not queue or deliver them. After extracting the MSEO bits to keep track of

message boundaries, the rest of the message is discarded. This allows the NAR to better keep up with fast-running Nexus clients without having to turn off messaging in the client.

Typically, a client would be suppressed during less interesting periods, and would be awakened when some preset condition is detected. This is communicated to the NAR via the one of the suppress triggers, which can be sourced by a client or an external Event Processing block. When an enter suppress trigger is received, the NAR output queue finishes servicing the current active ports until the end of the message. If the end of the message occurs in a middle beat of a Nexus word, then the remainder of the word is padded with null messages. Once the last message has been loaded into the output queue, the receive queues are all emptied. New messages are pulled from clients as they appear, go through their respective receive queues and then are discarded. In this way, the NAR can naturally monitor the MSEO bits and keep track of each client's Nexus state. In suppress mode, the output ports remain active until the output queue is emptied, meaning there is a delay between the assertion of the suppress trigger and the end of messaging.

When the NAR is in suppress mode and receives a wake-up trigger, it continues discarding any partial messages still in the receive queues. Any message that begins after the trigger is queued normally, insuring that only complete messages are sent to the output queue.

Global suppress mode applies to all clients. Any of the suppress triggers can be programmed to cause the NAR to toggle between suppressed and awake by setting the GST bit of the associated Suppress Trigger Control Register (NAR_STCR). Additionally, the NAR starts up in global suppress mode if the PUS bit of the Control Register is set when the NAR is enabled. All clients are then suppressed until a wake-up trigger is received. If the PUS bit is set without enabling any of the triggers for global suppress, a configuration error results and the NAR powers up in active mode.

Clients can go also into local suppress mode without putting the entire NAR to sleep. Each NAR_STCR has a 16-bit LST field. Setting one or more of these bits causes the trigger assigned to that NAR_STCR to toggle the associated clients between suppressed and awake. All other clients are unaffected. Thus, suppress trigger one can be assigned to one set of clients, while suppress trigger two can be assigned to another set of clients, and different parts of the device can be ignored at different times, all based on different, programmable events. Global suppress always has higher priority than local suppress. That is, if the NAR is in global-suppressed mode, any local suppress wake-up triggers are ignored. Also, if some clients are in local suppress when a global suppress trigger hits, then all go into suppress mode; however, upon the subsequent global wake-up, the clients that were previously in local suppress remain so.

73.5.5 Stall detection

Since the NAR can only switch between clients on an end-of-message boundary, every message that goes into the NAR must complete. If a client happens to die or stall in the middle of transmitting a message, this uncompleted message could cause the NAR to stall, at a time when other clients might still be able to deliver useful information. To prevent this from occurring, the NAR monitors each client for a stall condition, which is defined as occurring when data is not valid in the middle of a Nexus message for a set number of cycles.

When a stall condition is detected, the NAR can do one thing. If the client stalls, then the NAR must complete the current stalled message to continue operating. This scenario is termed a stall error. On a stall error, the NAR injects a dummy message beat into the message stream after the last valid beat of data received from the stalled client. The dummy message is a single beat injected at the output of the receive queue into the main queue.

The MSEO bits of the data payload are set to 2b11 regardless of the previous Nexus state. This forces the dummy message into the End Message state. When the NAR injects a dummy message, it also generates an error message to notify the user what has happened.

Injecting a dummy message is an intrusive act, which alters the data stream from the client. If a stalled client is thought likely to recover cleanly, it might be advisable to suppress stall errors to prevent the data stream from being corrupted. This can be done by setting the SED bit of the configuration register, which carries the risk of a truly dead client causing the NAR to hang. Otherwise, the default operation is for the NAR to inject the dummy message and then monitor the client for signs of recovery. If the client does come back online, the NAR attempts to wait until it sees an end-of-message boundary before capturing new data. At best, if the client recovers smoothly, only the interrupted message is lost; if the client does not recover smoothly, it might not be possible for the client and NAR to get back in sync in terms of their Nexus states, which would lead to nothing but garbled data coming out. For this reason, it is also possible to prevent the NAR from trying to recover from a stall error, by setting the SRD bit of the NAR_CR. If the SRD bit is set, a stalled client is not allowed to recover until the SRD bit is unset or the NAR is reset.

73.5.6 Output arbitration

The NAR allows two output ports to be active at the same time. This feature is only available on the BD NAR. Typically, this feature is only useful if one of the ports is used to service messages of a specific type and/or messages from a particular client, while the other port supports all the rest of the message traffic. For example, the NAR could be set up to send in-circuit trace (ICT) traffic out the HBDP and to reserve the trace memory bus port for all other Nexus messages.

If two output ports are enabled, one of them must be designated as the Message Select Port (MSP). The MSP is the destination for those messages that satisfy a set of user-defined requirements as to the source and type of message. All other traffic is sent to the other enabled port. Ports are enabled by setting the port enable bits in the BD NAR_CR. The MSP is designated by setting bits [10–9] and ALT is designated by setting bits [7–6]. Once the MSP has been specified, other bits in the NAR_CR, along with the Source Filter Register (NAR_SFR) and Type Filter Register (NAR_TFR), are used to determine which messages go to the MSP and which do not. These facilities can be used to build a logical expression that can filter messages based on up to four types and/or four sources.

The NAR_SFR can be programmed with up to four source codes, while the NAR_TFR can hold up to four message-type codes. Each filter also includes an enable bit to turn it on or off. A source match occurs if a messages source code matches one of the source filters or (if the SFI bit is set) if it does not match any of the source filters. Similarly, a type match occurs if a messages type code matches one of the type filters or (if the TFI bit is set) if it does not match any of the type filters. Finally, the ACC bit of the NAR_SFR determines when both source and type filters are used, whether the two are ANDed together (ACC = 0) or ORed together (ACC = 1). For example, to send ICT messages out the HBDP and all other traffic to the trace memory bus port:

- Set ALT = 10 in the NAR_CR—sets trace memory bus port as the alternate port
- Set MSP = 01 in the NAR_CR—sets HBDP as the message select port
- Set FE0 = 1 & TF0 = 100010 (0x22) in the NAR_TFR—enables type filter 0 to match ICT messages

To send everything but data trace from source 13 to the trace memory bus port, while all other traffic goes to the HBDP:

- Set ALT = 01 in the NAR_CR—sets HBDP as the alternate port
- Set MSP = 10 in the NAR_CR—sets trace memory bus port as the message select port
- Set TFI = 1—inverts type-filter logic
- Set FE0 = 1 & TF0 = 000101 (0x05) in the NAR_TFR to select data trace of size 8 bits
- Set FE1 = 1 & TF1 = 000110 (0x06) in the NAR_TFR to select data trace of size 16 bits
- Set FE2 = 1 & TF2 = 001101 (0x0d) in the NAR_TFR to select data trace of size 32 bits
- Set FE3 = 1 & TF3 = 001110 (0x0e) in the NAR_TFR to select data trace size of 64 bits
- Set FE0 = 1 & SF0 = 001101 (0x0d) in the NAR_SFR to select source trace ID = 13
- Set ACC = 0 in NAR_SFR so the final filter is $\sim(\text{data_trace}) \text{ AND } (\text{source} = 13)\text{HBDP}$

Data is written into the output queue at a maximum rate of one entry per cycle. If the current messages source and type pass the filters, then the message is marked for the MSP. When the entry is later pulled from the queue, it is then sent to the MSP. Unmarked entries are sent to the alternate port. Message destination must be recalculated on every end-of-message boundary, using the fixed-width SRC and TYPE fields at the beginning of each Nexus message.

73.5.7 Message translation and formatting

The NAR performs the formatting on Nexus messages before sending them to an output port. The exact translation performed depends on the destination port.

73.5.7.1 Aurora format

Nexus messages are pre-translated before sending to the HBDP using the Aurora protocol. The NAR output is a stream of 16×4 -bit words (where 4 is the width of the NAR Aurora out port) that are further encoded by an external Aurora block before being sent for transmission on the Aurora (HBDP) port.

Entries from the output queue are chopped into chunks of 4×16 -bit words. The amount of data that can be transmitted per Aurora cycle depends on the number of lanes available in the HBDP (transmitted HBDP word = $16 \times \text{number of lanes}$).

73.5.7.2 Trace memory bus format

The trace memory bus works on AHB-EW protocol. Data destined for the trace memory bus port is split back out into 32-bit beats (Nexus word). Depending on the relative sizes of the beat and the width of the trace memory bus port, one or more Nexus words are packed into a trace memory bus data word, with any remaining bits padded to 0.

For example, if the size of the beat = 32 and the width of the trace memory bus = 64, then each trace memory bus data packet contains two beats of Nexus data. Since the data is stored in a regular format (MSEO bits in same place at every location), this makes data interpretation straightforward, regardless of where the trace memory bus port is sending the data. The trace memory bus translation block performs the necessary accumulation and resizing in the likely case where the trace memory bus width does not equal the queue entry size.

73.5.8 Aurora interface

The external Nexus Aurora Link (NAL) contains all of the link-layer, PCS, and control logic for the HBDP channel. The Aurora data is transmitted from the NAR to the NAL for sending to the HBDP. Typically, the NAL powers up coming out of reset, but it can also be enabled by the NAR by turning on the NAR with the HBDP enabled. The reverse is true as well. If the NAL is active while the NAR is disabled, then the NAR powers up to communication-disabled mode.

Data flow between the NAR and the NAL uses a simple, synchronous interface. If the NAL is active, it indicates this by a ready signal from the NAL. If Aurora is configured as output it is indicated by a signal from the NAR.

The Aurora interface can either be operated in framing or streaming mode. Streaming mode provides the highest performance and lowest communication overhead through the link. Whereas framing mode provides greater robustness and improved error-handling at the receive side of the link. When framing mode is enabled, the NAR encapsulates the Aurora data in frames consisting of 256 Aurora chunks; that is, after every 256 Aurora transmissions, the NAR asserts end of frame and start of frame to mark the end of the last frame and the beginning of the next frame. In either mode, the NAR always asserts a start-of-frame when beginning transmission, and an end-of-frame when its output queue empties, to notify the channel partner of the end of valid data.

73.5.9 Trace memory bus output port usage

The NAR can communicate directly to external memory by sending Nexus data out onto the trace memory bus port, using the AHB-EW (Early Write) protocol. This provides a convenient, secondary area for data in applications or in situations where the HBDP is not available. The trace memory bus access are generated internally by trace memory bus controller.

Because in many systems it is desirable to have the trace memory bus interface run at a divided clock rate relative to the main platform clock, the trace memory bus port operates off of a separate AHB clock. This clock is assumed to be free-running (i.e. unaffected by NAR-enable and the status of the Aurora Link), synchronous to the platform clock used by the rest of the NAR, and either running at the same rate as the platform clock or an integer divide of that rate.

The trace memory bus interface protocol is a slightly modified version of AMBA AHB specification. The write data comes in the address phase instead of data phase and it is termed as Early Write (EW). When NAR uses the trace memory bus port as a destination for Nexus data, it performs a series of writes to a predefined block of memory space.

This memory space is specified through the trace memory bus base address and trace memory bus max transfer configuration registers. The size of the block is set by the max transaction count (MXFR field in NAR_TCR) times the size of a transaction (trace memory bus-width, 64-byte, 128-byte, 256-byte, or 384-byte, depending on block transfer mode and block transfer size). For example, if:

- Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
- NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
- NAR_TCR[BTS] = 00 (Block-transfer size = 64-byte)
- NAR_TCR[MXFR] = 0x100 (max transaction count)

then the total block size would be $0x100 \times 0x40 = 0x4000$ bytes. The dedicated debug address range would then be $0x0D00_0000 - 0x0D00_3FFF$.

The NAR can either write to the debug space one (trace memory bus-width) word at a time, or for improved performance, it can use a block transfer. If the BTM bit of the trace memory bus Control Register (NAR_TCR) is set, then the NAR uses block transactions to send data through the trace memory bus port, where the size of the block is determined by the setting of the BTS field of the NAR_TCR.

In block transfer mode, the NAR waits until the main queue partition dedicated to the trace memory bus port reaches a specified threshold point, determined by the BTH field of the NAR_TCR, before initiating a block transfer. The default threshold is the size of the block transfer. That is, a block transfer does not start until there is enough data in the associated partition to fill the block. But it might be desirable, for bandwidth reasons or because the associated partition is smaller than the block transfer size, to begin the transfer sooner. Hence, based on BTH, a transfer can begin when the partition is at 25%, 50%, or 75% of the block transfer size. This capability should be used with caution. If the Nexus client does not generate enough new data during the transfer to fill the block, then a block transfer error results.

The NAR generates Nexus trace write transactions for the trace memory bus port using the address from the base address register for the first transaction and then incrementing through the memory space. Once the programmed max number of transactions have been sent, the NAR sets the trace memory bus overflow status bit and, if desired, asserts the NAR event-out. At this point, the NAR can either shut down the trace memory bus port for trace, or, if the TBW bit of the NAR_TCR is set, reset the address to the beginning of the debug space and continue sending trace data. This allows the debugger to view the most recent data, in cases where the buffer overflows.

When TBW bit of NAR_TCR is not set then NAR shuts down the trace memory bus port. To restart the trace memory write again from trace memory base address, the user should write either the NPC trace memory bus base address (TBALO/TBAHI) or the transaction count (MXFR). The user does not have to actually change the value, but can write the same target base address again. The NAR sees any write to one of these registers as a reconfiguration of the trace memory bus port, and resets its internal address pointer to the base address along with clearing the target-space-full flag.

73.5.10 Internal message generation

Generally, the NAR simply conveys Nexus messages from client to port, and does not generate messages of its own. There are, however, certain situations when the NAR needs to communicate directly with the debugger. Internally generated messages are added to the queue the same as external messages. If the queue is partitioned, then internal messages are always channeled to whichever partition is dedicated to the HBDP.

The NAR generates the following message types:

- **Device_ID**—The first message transmitted when the NAR comes up. It consists of a 6-bit TCODE (TCODE = 1) and the 32-bit device ID. The first beat of the message is always an IDLE (MSEO = 2b11, MDO = all 0s) to allow the debugger Nexus state machine to correctly initialize (by moving to end message or idle state). Device_ID is also generated if the queue is repartitioned (by changing either the ALT or MSP setting in the NAR_CR) while it is not empty. This serves the dual purpose of insuring that the

user always gets at least one device_ID message and providing a message boundary in the case where there might have been corruption due to the lost data.

- Watchpoint—The NAR generates its own watchpoint match message under the following circumstances as shown in [Table 1633](#).
- NAR_Error (TCODE = 8)—If an error condition is detected inside the NAR, it generates its own error message. An NAR_Error message consists of the 6-bit TCODE, the 6-bit NAR source ID, and a 32-bit data field which corresponds to the NAR status register. An NAR error can be triggered by:
 - HBDP error
 - Illegal configuration
 - Stall Error
 - Trace memory bus read/write access error

This table describes the NAR message formats.

Table 1630. NAR message formats

Message name	Min packet size (bits)	Max packet size (bits)	Packet type	Packet name	Packet description
Device ID	6	6	fixed	TCODE	TCODE value = 1
	32	32	fixed	DID	DID register value
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Error Message ⁽¹⁾	6	6	fixed	TCODE	TCODE value = 8
	6	6	fixed	SRC ⁽²⁾	NAR source ID
	4	4	fixed	ETYPE	See Table 1631
	12	12	fixed	ECODE	See Table 1632
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp
Watchpoint Hit Message ⁽³⁾	6	6	fixed	TCODE	Value = 15
	6	6	fixed	SRC ⁽²⁾	NAR source ID
	6	6	fixed	WPHIT	See Table 1633
	0	24	variable	TSTAMP	Optional, globally synchronized timestamp

1. The Error message conforms to the IEEE-ISTO 5001-2011 standard.
2. Tools should treat the NAR SRC field as a 4-bit SRC field and a 2-bit unused field. The extra 2-bit field (the two most significant bits of the 6-bit TCODE) is always 0b00. This operation is not compliant to the IEEE-ISTO 5001 Nexus standard.
3. The Watchpoint Hit message does not conform to the IEEE-ISTO 5001-2011 standard, it conforms to the IEEE-ISTO 5001-2003 standard. The WPHIT should be a variable length packet, but is implemented as a fixed length packet. In most cases, tools will not see a difference, however, a difference will be seen if a timestamp field is appended to the message.

73.5.10.1 Error conditions

NAR errors can occur upon events such as illegal memory accesses, block-transfer overloads, communication errors, or when the NAR is configured incorrectly. If the configuration registers are programmed incorrectly, it is possible to put the NAR into an illegal state. The NARs response varies depending on the error. For a minor error, the NAR

reverts to a default mode and continues operation, while major errors result in complete shutdown.

In either case, a Nexus error message is sent to the Aurora out port, if its enabled, otherwise to the trace memory bus port. The Nexus error message contains both ETYPE and ECODE fields:

- ETYPE is used to denote the basic type of error that has occurred
- ECODE carries specific additional information about the error

All NAR error types are defined in this table.

Table 1631. NAR error types

ETYPE	Description	Classification	NAR action	Comment
0000 (h'0)	Receive queue overrun	Minor	Dropped message	If a client sends a data word that the NAR cannot accept (due to a full receive queue), the new data word is dropped.
0001 (h'1)	Internal message contention	Minor	Dropped message	Internal errors/watchpoints occurred faster than NAR could generate messages for them, causing lower-priority message(s) to be dropped. The type of message dropped is conveyed in the ECODE field, see Table 1632 .
0011 (h'3)	Trace memory bus port read/write access error	Minor	Access fails	Unable to send an Aurora-to-trace memory bus request. Typical causes would be writes larger than the data buffer or sending in a new request before the previous one completes. ⁽¹⁾
0101 (h'5)	Invalid NRR	Minor	Access fails	Tried to access an un-implemented NRR.
1001 (h'9)	Config error	Major	See Table 1632	The specific configuration error is conveyed in bits 0–3 of the ECODE field (Table 1632), as well as the NCE field of Status Register.
1100 (h'C)	HBDP error	Minor	N/A	A hard error is automatically reset the Aurora Link and causes it to re-initialize. Although the Link is down, the error message is queued and released as soon as the Link comes back up.
1110 (h'E)	Block transfer error	Minor	Dummy fill	If the Trace memory bus port becomes data-starved during a block transfer, it fills the rest of the block with IDLE messages.
1111 (h'F)	Stall error	Minor	—	—

1. In the case where a request was successfully translated to a Trace memory bus transaction which itself returned an error, that is conveyed in the STATUS field of the Nexus Target Response message subsequently returned to the debugger.

Typically, the ECODE field is used to communicate which type of message was dropped in queue overflow or message contention situation, but for the NAR it is also used to denote the type of configuration error that occurred. If a configuration error is detected, the NAR generates a Config Error Nexus message and transmits it, with the actual type of error encoded in the four MSBs of ECODE, as well as the NCE field of the Status Register. The ECODE field encodings are listed in this table.

Table 1632. Configuration error codes

ECODE	ETYPE	Description	NAR action	Comment
0000xxxxxx1	0001	Watchpoint message dropped	N/A	Occurs with internal message overflow error.
0000xxxxxx1x	0001	Data trace message dropped	N/A	Occurs with internal message overflow error; MMA response message was dropped.
00001xxxxxx	0001	Response message dropped	N/A	Occurs with internal message overflow error; target response (memory access or NRR) message was dropped.
0000xxx1xxxx	0001	Status message dropped	N/A	Occurs with internal message overflow error.
000100000000	1001	Config error: multiply defined port	Communication disable mode	Both MSP and ALT were assigned to the same port. NPC waits until the configuration is fixed before proceeding.
001000000000	1001	Config error: no ALT defined	Tracebuffer	An MSP was defined without defining the ALT. The NPC reverts to tracebuffer mode.
001100000000	1001	Config error: cannot enable port	Communication disable mode	User has attempted to enable a port that does not exist in this implementation of the NPC.
010000000000	1001	Config error: cannot support message filtering	Message filtering and/or queue partitioning disabled	User has attempted to enable message filtering or queue partitioning with only one output enabled. Filtering/partitioning is turned off.
100100000000	1001	Config error: no wakeup trigger	Power up in active mode	Occurs if none of the defined clients in the system can cause a wakeup (PUS is set in NAR_CR, but no NAR_STCRs have WUT set).

73.5.10.2 Watchpoint messages

The NAR generates its own watchpoint match message under the circumstances shown in the following table. The value of the Watchpoint Hit field of the Watchpoint Message is also shown in this table.

Table 1633. Watchpoint Hit values

WPHIT	Description	Comment
b010000	Entering Suppress Mode	If (local or global) suppress mode is enabled and the appropriate trigger is received, the NAR generates a watchpoint message. The type of event (in this case, a suppress event) is encoded in the WPHIT field of the watchpoint message (see the Nexus standard, sec. 5.3.21).
b100000	Client Sync	If sync messaging is enabled, the NAR generates a sync watchpoint message whenever a client sync event occurs.

Table 1633. Watchpoint Hit values (continued)

WPHIT	Description	Comment
b000100	Trace Memory bus Block Overflow (TBO)	If the trace memory bus block is filled, causing it to either disable trace memory bus data trace or wrap back to the beginning of the dedicated debug memory block and if trace memory bus overflow messaging is enabled, then an TBO message is generated.
b001000	Tracebuffer Wrap	If the NAR is being used in tracebuffer mode with the wrap-around feature, then a watchpoint message is generated every time the tracebuffer wraps back to address 0. This would be useful in informing the user that the buffer had wrapped and that older data had been overwritten.

73.5.11 Timestamp function

The NAR and all of its clients are required to transmit timestamps, to allow precise ordering of events. All clients synchronous or asynchronous uses NAR timer value broadcasted over a bus, this ensures that all timestamps are in sync as shown in [Figure 1758](#). The NAR uses enable signal to centrally control the enabling of time stamping, which informs the clients to start adding the timestamp field to their message traffic.

Figure 1758. Timestamp architecture

Timestamping is enabled by setting the TEN bit of the NAR_CR. This causes the NAR to assert the time stamp enable signal to clients. Typically, the user would also set the TRS bit at this time to reset the NAR Time stamp counter. Internally the NAR has a 30-bit counter external to the NPC block. This 30-bit counter is broadcast to all clients after encoding its value in Gray code. This minimizes the error in synchronization by the clients. The NPC

uses an additional internal 24-bit counter to send the timestamp inside its messages. The client converts the gray coded timestamp to binary to append to the Nexus messages.

The Time stamp mode, a 2-bit field, is broadcasted to all client which tells the granularity of sending time stamps into message. This is controlled by the TSG bits of the NAR_CR.

Asynchronous clients, those on a separate clock domain from the NAR, synchronize the enable, mode and timestamp value in their domain. The error introduced by this is assumed to be within tolerable range by application.

A timestamp counter reset can be forced by causing a 0 to 1 transition in the TRS bits of the NAR_CR. The NAR deasserts the enable signal to clients while the reset occurs, and then the counter is restarted (assuming the TEN bit is set). Data throughput can be increased (at the loss of timestamp granularity) by controlling the TSG bits of the NAR_CR. Rather than adding a timestamp to every message, clients can be told to only stamp every 4th, 16th, or 32nd message, easing the bandwidth requirements on the output ports.

The timestamp block maintains the timestamp counter for NAR. It is the central time source for all synchronous/asynchronous clients.

73.5.12 Overlay and internal trace memory full status generation

In certain events, such as main memory (internal trace memory) full or external overlay trace memory full, it is required to control the clients to stop sending data, to avoid any loss of messages from the clients.

The NAR provides three outputs (triggers) to indicate three different situations as described below:

- Internal trace memory (the main queue) is full
- External debug memory on trace memory bus is full
- External debug memory on trace memory bus is full up to a programmable watermark set by the configuration register

The last two triggers are used by SPU to generate stall and suppress triggers. Typically the stall request should be generated whenever space in the external memory connected to trace memory bus has been exhausted. The NAR starts writing from the first location (wrap) as specified in trace memory bus address register in this condition if overwrite trace memory bus debug memory (TBW bit) is set in the NAR_TCR.

The user should configure the partial full watermark register such that it can give around 90% full indication of external debug memory on the trace memory bus. The emulator tool memory full indication is typically generated from the DCI block which actually communicates with the tool.

For example, the following steps can be used to generate event at around 90% fill level for trace memory connected in AHB-EW and to set the watermark in the configuration register.

- From the configuration, the programmer knows the following:
 - AHB start (base) address—Base address = 0x0D00_0000 (i.e. TBAHI = 0x0, TBALO = 0x0D00_0000)
 - Block transfer size—NAR_TCR[BTM] = 1 (Block-transfer mode enabled)
 - Max transfer count—NAR_TCR[MXFR] = 0xC0 (maximum transaction count)
- Thus, the total block size is $(0xC0 \times 0x40) = 0x3000$ bytes. The dedicated debug address range is then 0x0D00_0000 – 0x0D00_2FFF.
- To generate an event at nearly 90% fill level of the trace memory at 1 KB boundary, the value to be programmed in the register NAR_AHFPAR[3:0] is calculated as:
 - Number of 1K blocks in 0x3000 bytes = $(3000 \text{ right shift by } 10 \text{ bits}) = C = 12$
 - So the value to be programmed should be 11 as 90% of 12 is almost 11.
- $\text{NAR_AHFPAR}[3:0] = (\text{NAR_TBALO}[13:10] + 0xB) = (0x7 + 0xB) \text{ } 0x2$ (upper bits truncated due to width) and enable this with $\text{NAR_AHFPAR}[10] = 1$.

This assumes that NAR starts writing from base address and stops at maximum address and no reading is done in overlay memory trace data area during this operation. Whenever the address bus bits [13:10] match with this value, the partial event is generated (toggled).

73.5.13 Configuration/debug interface JTAG (1149.1)

The configuration and status registers of the NAR are accessed through the standard IEEE 1149.1 JTAG interface. The JTAG frequency (TCK) must be 1/2 of the NAR operating clock. The access mechanism through JTAG is described in this section.

The NAR block uses the IEEE 1149.1-2001 TAP for accessing registers. TAP signals include TCK, TDI, TMS, and TDO. The NAR implements a TAP controller state machine that transitions based on the state of the IEEE 1149.1-2001 16-state state machine. It also implements Nexus controller state machine as defined by the IEEE-ISTO 5001-2001 standard.

The instructions implemented by the NAR TAP controller are listed in [Table 1634](#). Each unimplemented instruction acts like the BYPASS instruction. The size of the NAR instruction register is 4 bits.

Figure 1759. Nexus controller state machine

Table 1634. Implemented instructions

Instruction Name	Private/ Public	Opcode	Description
NEXUS_ENABLE	Public	0x0	Activate Nexus controller state machine to read and write NAR registers.
BYPASS	Private	0x0F	NAR BYPASS instruction. Also the value loaded into the NAR IR upon exit of reset.

Data is shifted between TDI and TDO starting with the least significant bit as illustrated in the following figure. This applies for the instruction register and all Nexus tool-mapped registers.

Figure 1760. Shifting data into register

73.5.13.1 Enabling the NAR TAP controller

Assertion of the power-on reset signal resets the NAR TAP controller. When not in power-on reset the NAR TAP controller is enabled by driving JCOMP with the NAR enable value and exiting the Test-Logic-Reset state. Loading the NEXUS-ENABLE instruction then grants access to Nexus debug.

73.5.13.2 Loading NEXUS-ENABLE instruction

Access to the NAR registers is enabled when the TAP controller instruction register is loaded with the NEXUS-ENABLE instruction. This instruction is shifted in via the SELECT-

IR-SCAN path and loaded in the UPDATE-IR state. At this point, the Nexus controller state machine, shown in [Figure 1759](#), transitions to the REG_SELECT state. The Nexus controller has three states: idle, register select, and data access. The following table illustrates the IEEE 1149.1 sequence to load the NEXUS-ENABLE instruction.

Table 1635. Loading NEXUS-ENABLE instruction

Clock	TMS	IEEE 1149.1 state	Nexus state	Description
0	0	RUN-TEST/IDLE	IDLE	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	IDLE	Transitional state
2	1	SELECT-IR-SCAN	IDLE	Transitional state
3	0	CAPTURE-IR	IDLE	Internal shifter loaded with current instruction
4	0	SHIFT-IR	IDLE	TDO becomes active, and the IEEE 1149.1-2001 shifter is ready. Shift in all but the last bit of the NEXUS-ENABLE instruction.
5 TCKS				
12	1	EXIT1-IR	IDLE	Last bit of instruction shifted in
13	1	UPDATE-IR	IDLE	NEXUS-ENABLE loaded into instruction register
14	0	RUN-TEST/IDLE	REG_SELECT	Ready to be read/write Nexus registers

73.5.13.3 Selecting a JTAG register to create a bus (memory or peripheral) access

When the NEXUS-ENABLE instruction is decoded by the TAP controller, the input port allows the development tool access to all NAR registers. Each register has a 7-bit address index.

All register access is performed via the SELECT-DR-SCAN path. The Nexus controller defaults to the REG_SELECT state when enabled. Accessing a register requires two passes through the SELECT-DR-SCAN path: one pass to select the register and the second pass to read/write the register.

The first pass through the SELECT-DR-SCAN path is used to enter an 8-bit Nexus command consisting of a read/write control bit in the LSB followed by a 7-bit register address index, as illustrated in [Figure 1761](#). The read/write control bit is set to 1 for writes and 0 for reads. The index for registers are shown in [Table 1616](#).

MSB	LSB
7-bit register index	R/W

Figure 1761. Nexus command format for register selection

The second pass through the SELECT-DR-SCAN path is used to read or write the register data by shifting in the data (LSB first) during the SHIFT-DR state. When reading a register, the register value is loaded into the IEEE 1149.1-2001 shifter during the CAPTURE-DR state. When writing a register, the value is loaded from the IEEE 1149.1-2001 shifter to the register during the UPDATE-DR state. When reading a register, there is no requirement to shift out the entire register contents. Shifting may be terminated once the required number of bits have been acquired.

This table illustrates a sequence which writes a 32-bit value to a register.

Table 1636. Writing a 32-bit value to a register

Clock	TMS	IEEE 1149.1 State	Nexus State	Description
0	0	RUN-TEST/IDLE	REG_SELECT	IEEE 1149.1-2001 TAP controller in idle state
1	1	SELECT-DR-SCAN	REG_SELECT	First pass through SELECT-DR-SCAN path
2	0	CAPTURE-DR	REG_SELECT	Internal shifter loaded with current value of controller command input.
3	0	SHIFT-DR	REG_SELECT	TDO becomes active, and write bit and 4 bits of register index shifted in.
7 TCKs				
11	1	EXIT1-DR	REG_SELECT	Last bit of register index shifted into TDI
12	1	UPDATE-DR	REG_SELECT	Controller decodes and selects register
13	1	SELECT-DR-SCAN	DATA_ACCESS	Second pass through SELECT-DR-SCAN path
14	0	CAPTURE-DR	DATA_ACCESS	Internal shifter loaded with current value of register
15	0	SHIFT-DR	DATA_ACCESS	TDO becomes active, and outputs current value of register while new value is shifted in through TDI
31 TCKs				
47	1	EXIT1-DR	DATA_ACCESS	Last bit of current value shifted out TDO. Last bit of new value shifted in TDI.
48	1	UPDATE-DR	DATA_ACCESS	Value written to register
49	0	RUN-TEST/IDLE	REG_SELECT	Controller returned to idle state. It could also return to SELECT-DR-SCAN to write another register.

73.5.14 Trace memory bus controller

The purpose of the trace memory bus is to transfer trace data from main queue to external overlay memory. This port works on a modified AHB protocol that supports early write. It has AHB interface signals as defined in AMBA specification (Rev 2.0). In addition, there are side-band signals for added functionality.

Key features of the module include:

- AHB-EW Interface
 - Early Write (for higher BW in special module)
 - Configurable 32/64-bit address bus width
 - 64-bit data bus width
 - Transfer Types
 - IDLE, NONSEQ, SEQ
 - Single Transfers
 - Burst Transfers
 - Configurable support for INCR
 - Configurable support for INCR4, INCR8, INCR16, WRAP4
 - Response Type
 - OKAY, ERROR
 - Transfer Size
 - Byte, Half Word, Word, Double-Word
 - Protection Control
 - Cacheable/ Non Cacheable Access Control
 - User/Privilege Access
- Endianess Support
 - Configurable Little Endian/Big Endian support on AMBA-AHB interface
- Pipeline Support
 - Total of two transactions (One plus one ongoing)

73.5.14.1 Operation

The trace memory bus controller allows all read/write operations to be cut through. The controller has a pipeline depth of two. While the data phase of one transaction is ongoing, it can accept one more read/write request from the internal bus master and initiate the address phase on the AHB interface during the last data cycle of the ongoing transaction.

73.5.14.2 Write operation

When the trace memory bus initiator asserts a request for a write operation, it can find the acknowledge signal parked asserted if the controller is ready to accept the transaction. If the pipeline is full or in case of an ongoing read transaction, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB interface once it accepts the transaction by asserting the acknowledge on the trace memory bus interface. The write data from the trace memory bus initiator is accepted by the gasket by asserting the acknowledge only on completion of address phase at AHB interface, which is signified by receiving the ready signal asserted. Simultaneously, the data is sent to the data bus. Once the requisite number of bytes have been accepted from the trace memory bus initiator, the gasket generates end of data and transfer according to the Trace memory bus protocol.

The AHB protocol supports data transactions of byte, half-word, word and double-word (when both trace memory bus and AHB data bus width is 64 bits). A write transaction from the trace memory bus initiator take place as single/multiple transactions on the AHB side.

73.5.14.3 Read operation

When the trace memory bus initiator asserts a request signal to request for a read operation, it can find the acknowledge signal parked asserted if the gasket is ready to accept the transaction. If the pipeline is full, the controller inserts wait states by keeping the acknowledge low. The trace memory bus controller initiates the address phase on AHB-EW interface once it accepts the transaction by asserting the acknowledge on trace memory bus interface. The controller reads the data from the bus when the ready signal is sensed asserted. The data is transferred on the trace memory bus data bus with the data acknowledge asserted. The gasket asserts end of data and transfer at the end of transaction as per trace memory bus protocol.

The AHB protocol supports data transactions of byte, word, half-word and double-word (when both trace memory bus and AHB data bus width is 64-bits). A read transaction from trace memory bus initiator takes place as single/multiple transaction on the AHB interface before the read data is merged and sent on the trace memory bus read data bus.

In case of variable data bus width on trace memory bus and AHB interface (32-bit data bus on one interface and 64-bit data bus on the other interface), a maximum of 64 bits is read on each beat.

73.5.15 Legacy client interface controller

This block converts the legacy client protocol into internal client protocol that is accepted by the internal NPC block. The Nexus beat size must be same for both interfaces. The Nexus beat is composed of MDO bits along with two MSEO bits. The trace data width from the legacy client is fixed at one beat. The architecture of this block is shown in [Figure 1762](#).

The legacy client sends each message after arbitrating the bus. It requests the gasket with a 2-bit request signal whenever it has data to send. A 00 means no request, 01 a low-priority request, 10 a medium-priority request, and 11 a high-priority request. The legacy client can send one maximum message sized data on receiving a grant from the block. There is no backpressure mechanism during transfer of a message from the client to this block. The block asserts a grant if it has at least one max message size space in its FIFO. Seeing the grant the client asserts busy signal and holds it until it wants to send data, it may hold it up to max message size data is transferred.

The following architecture describes the legacy client to internal client protocol conversion block. There is a small FIFO of parameterizable depth used to store the data from client. The block asserts a grant only when at least one max message sized space is available in FIFO. The write happens in the client's clock domain. The write pointer is passed to other domain which is NPC clock domain.

The logic on other side compares read and write pointer to check the data availability in the block's FIFO and space availability in NPC's receive queue. If space and data both are available it tries to send message to the NPC.

Figure 1762. Legacy client Interface controller

The size of the receive queue of the corresponding client at NPC must be known to the block. The block drives a not empty signal whenever it has data in FIFO and looks for a ready signal. It can send as many Nexus beats as receive queue can store. It operates on decrements a counter after sending data to the NPC so that it can track how much data it can send. The counter is incremented by the value of acknowledge from NPC which tells how many spaces are freed in receive queue.

73.6 Initialization information

The NAR is initialized by asserting the block reset signal for a minimum of one cycle of the slowest clock. Reset clears all latches to 0, with the only exception being the output queue, whose initialization state depends on the reset behavior of the compiled memory used. Upon exiting reset, the NAR is in the disabled state, as described in [Section 73.5.2.1, Reset](#).

Pointers and state machines are initialized by the starting of NAR functional clocks (which occurs either upon the setting of the NAR enable bit or upon the assertion of the Phy enable signal) or by an NAR soft reset.

73.7 Application information

The base application for the NAR is collecting and collating Nexus trace data. Programming examples for how to set up the NAR for trace are given in [Section 73.5.6, Output arbitration](#).

74 e200z420n3 Nexus 3 Module

The e200z420n3 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

74.1 Introduction

74.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

74.1.2 Terms and Definitions

[Table 1637](#) contains a set of terms and definitions associated with the Nexus 3 module.

Table 1637. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 1637. Terms and Definitions (continued)

Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

74.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated.

An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.

- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
 - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
 - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
 - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
 - One (1) Read/Write Error pin (**nex_err_b**) pin
 - One (1) Watchpoint Event output pin (**nex_evto_b**)
 - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
 - One (1) Event In pin (**nex_evti_b**)
 - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)

Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

74.1.4 Functional Block Diagram

Figure 1763. Nexus 3 functional block diagram

74.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (NEXUS3-ACCESS) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the

Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test-Logic-Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

74.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

74.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in [Table 1638](#).

Table 1638. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
Data Trace — Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 1643)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 1643)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)

Table 1638. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from DEVENT _{DQTAG} register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace — Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Program Trace — Indirect Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Data Trace — Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 1643)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)

Table 1638. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 1643)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to Table 1641) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See Section 74.12.4, Resource Full Messages.)
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (see Section 74.12.1, Branch Trace Messaging types)
Program Trace — Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Section 74.12.1, Branch Trace Messaging types.)

Table 1638. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 1642)
	2	2	CDF	fixed	# fields of information in CDATE. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATE2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (See Section 74.12.5, Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2 — PID info (See Section 74.12.5, Program Correlation Messages.)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in [Section 74.12.1, Branch Trace Messaging types](#). If the Branch History method is selected, the shaded TCODEs above will not be messaged out.

[Table 1639](#) shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 1639. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxx1xx	Program Trace Message(s) Lost
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

[Table 1640](#) shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 1640. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

[Table 1641](#) shows the encodings used for resource codes for certain messages.

Table 1641. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

[Table 1642](#) shows the event code encodings used for certain messages.

Table 1642. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via mtspr PID0/NPIDR
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to $MSR_{PMM} = 0$ and $DC4_{PTMARK} = 1$
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

[Table 1643](#) shows the data trace size encodings used for certain messages.

Table 1643. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte

Table 1643. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14) (continued)

DTM Size Encoding	Transfer Size
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

74.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#) and [Section 74.6, Nexus 3 Register Access via Software](#) for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

[Table 1644](#) details the register map for the Nexus 3 module.

Table 1644. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/Write	Read Address	Write Address	DCR # ⁽¹⁾

1. Software access via the **mfdcr** and **mtocr** instructions use these values for the DCR number. Software writes to these registers via **mtocr** when **nex_sfvcntl_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

74.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Figure 1764. Client Select Control (CSC) register

Table 1645. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx Nexus client (SoC level)

74.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Figure 1765. Port Configuration Register (PCR)

OPC	0	MCK_EN	MCK_DIV	0																											
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# PCR_INDEX; Read/Write; Reset: 0x0

Table 1646. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# nex_mdo[n:0] pins defined by SOC) 1 Full Port Mode configuration (max# nex_mdo[n:0] pins defined by SOC)
30	—	Reserved for future functionality
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 nex_mcko is disabled 1 nex_mcko is enabled
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 nex_mcko is 1x processor clock freq. 001 nex_mcko is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 nex_mcko is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 nex_mcko is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

74.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in [Figure 1766](#) and its fields are described in [Table 1647](#).

Figure 1766. Development Control 1 (DC1) register

OPC	MCK_DIV	0	PTM	0	OTS	0	POTD	TSEN	EOC	EIC	0	TM																			
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# 0x2; DCR: 368; Read/Write; Reset: 0x0

Table 1647. DC1 field descriptions

Bits	Name	Description
31	OPC	Output Port Mode Control 0 — Reduced Port Mode configuration (min# nex_mdo[n:0] pins defined) 1 — Full Port Mode configuration (max# nex_mdo[n:0] pins defined)
30:29	MCK_DIV	MCKO Clock Divide Ratio (see note below) 00 — nex_mcko is 1x processor clock freq. 01 — nex_mcko is 1/2x processor clock freq. 10 — nex_mcko is 1/4x processor clock freq. 11 — nex_mcko is 1/8x processor clock freq.
28	—	Reserved for future functionality
27	PTM	Program Trace Method 0 — Program Trace uses traditional Branch Messages 1 — Program Trace uses Branch History Messages
26:25	—	Reserved for future functionality
24	OTS	Ownership Trace PID Select 0 — PID0 data is transmitted within Ownership Trace Messages 1 — Nexus PID Register (NPIDR) data is transmitted within Ownership Trace Messages
26:15	—	Reserved for future functionality
14	POTD	Periodic Ownership Trace Disable 0 — Periodic Ownership Trace message events are enabled 1 — Periodic Ownership Trace message events are disabled
13:12	TSEN	Timestamp Enable — (not implemented, write to 00) 00 — Timestamp is disabled
11:10	EOC	EVTO Control 00 — nex_evto_b upon occurrence of Watchpoints (configured in DC2 and DC3) 01 — nex_evto_b upon entry into Debug Mode 1x — Reserved

Table 1647. DC1 field descriptions (continued)

Bits	Name	Description
9:8	EIC	EVTI Control 00 — nex_evti_b is used for synchronization (Program Trace Sync msg is generated) 01 — nex_evti_b is used for Debug request 10 — nex_evti_b is disabled 1x — Reserved
7:6	—	Reserved for future functionality
5:0	TM	Trace Mode ⁽¹⁾ 000000 — All Trace Disabled xxxxx1 — Ownership Trace enabled xxxx1x — Data Trace enabled xxx1xx — Program Trace enabled xx1xxx — Watchpoint Trace enabled x1xxxx — Reserved 1xxxxx — Data Acquisition Trace enabled

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to [Section 74.4.7, Watchpoint Trigger \(WT, PTSTC, PTETC, DTSTC, DTETC\) registers](#) for more information on watchpoint triggering. Refer to [Section 74.16, External Hardware Trigger Controls](#) for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) **MUST ONLY** be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

74.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

Development Control Register 2 is shown in [Figure 1767](#) and its fields are described in [Table 1648](#).

Figure 1767. Development Control 2 (DC2) register

1. Refer to [Table 1642](#) for implemented EVCODEs.

74.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Figure 1770. Development Status (DS) register

DBG	LPS	LPC	0																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

74.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For

example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z420n3) Core Debug Support chapter.

74.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

Figure 1779. Data Trace Control (DTC) register

RWT1	RWT2	RWT3	RWT4	0								STDC1	STDC2	STDC3	STDC4	0				RC1	RC2	RC3	RC4	DI	0

[Table 1659](#) illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1659. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: *DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings indicating “within range,” and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating “outside of range.”*

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when $DTC_{DI} = 1$, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

74.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per [Table 1661](#).

Figure 1788. Read/Write Access Control/Status (RWCS) register

AC	RW	SZ		MAP		PR		ATTR		0		CNT																ERR	DV		
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# 0x7; Read/Write⁽¹⁾; Reset: 0x0

1. ERR and DV are read-only

Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

74.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Figure 1789. Read/Write Access Data (RWD) register

Read/Write Data																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Nexus Reg# 0xA; Read/Write; Reset: 0x0																															

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. [Table 1662](#) shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 1662. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword						
first RWD pass (low order data)	0 0 0	0 1 1	X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

“X” indicates byte lanes with valid data

“—” indicates byte lanes that will contain unused data.

[Table 1663](#) shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 1663. RWD byte lane mapping

Doubleword @000	0 0 0				
first RWD pass		AHB[31:24]	AHB[23:16]	AHB[15:8]	AHB[7:0]
second RWD pass		AHB[63:56]	AHB[55:48]	AHB[47:40]	AHB[39:32]

Table Notes:

“—” indicates byte lanes that will contain unused data.

74.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Figure 1790. Read/Write Access Address (RWA) register

Read/Write Address																													
--------------------	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--	--

31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 15 14 13 12 11 10 9 8 7 6 5 4 3 2 1 0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

74.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction (“NEXUS3-ACCESS”) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in [Table 1644](#).

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See [Section 74.23, IEEE 1149.1 \(JTAG\) RD/WR sequences](#).)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see [Table 1644](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 1791. JTAG DR format

Table 1664. JTAG DR field descriptions

Nexus Register Index	Selected from values in Table 1644
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
- a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the “Capture-DR” state.
 - b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the “Update-DR” state.

74.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdc** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. [Table 1644](#) shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

74.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

74.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

74.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

74.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) = 0x0003FC01, New Address (A2) = 0x0003F365

Message Generation: A1 = 0000 0000 0000 0011 1111 1100 0000 0001 A2 = 0000 0000 0000 0011 1111 0011 0110 0101 A1 $\oplus$ A2 = 0000 0000 0000 0000 0000 1111 0110 0100 Address Message (M1) = 1111 0110 0100 Address Re-creation: A1 $\oplus$ M1 = A2 A1 = 0000 0000 0000 0011 1111 1100 0000 0001 M1 = 0000 0000 0000 0000 0000 1111 0110 0100 A2 = 0000 0000 0000 0011 1111 0011 0110 0101
--

Figure 1792. Relative address generation and recreation

74.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

74.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

74.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

74.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to [Section 74.4.9, Nexus Overrun Control \(OVCR\) register](#), for complete programming options.

74.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in [Section 74.8.1, Message Queue Overrun](#). Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

74.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

[Table 1665](#) lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in [Table 1665](#).

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction 1 (newer instruction) (WPM → DQM → OTM → BTM → DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 1665. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A ⁽¹⁾
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A ⁽¹⁾
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message

	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

74.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

74.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

74.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

74.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

74.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

74.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Fixed length = 18 bits

Figure 1793. Debug Status message format

74.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see [Table 1639](#) and [Table 1640](#)):

(6 bits)	(4 bits)	(4 bits)	(6 bits)
Error Code	Error Type	Src. Proc.	TCODE (001000)

Fixed length = 20 bits

Figure 1794. Error message format

74.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

74.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

74.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z420n3) processors contain a *PowerISA 2.06* defined "Process ID" register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.

Figure 1795. Nexus 3 Process ID Register (NPIDR)

Nexus 3 Process ID																															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR — 517; Read/Write; Reset: 0

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the DC1_{OTS} control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and DC1_{OTS} indicates PID0 should be used, or when the NPIDR register is written to by the processor and DC1_{OTS} indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting DC1_{POTD}.

Ownership trace information is messaged out in the following format:

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15–46 bits

Figure 1796. Ownership Trace Message format

74.12 program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z420n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z420n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

74.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. (**evsel**)Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

74.12.1.1 Indirect Branch Message instructions

[Table 1666](#) shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 1666. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	bcctr, bcctrl, bclr, bclrl, se_bctr, se_bctrl, se_blr, se_blrl
System Call / Trap exceptions taken	se_sc, tw
Return from interrupts / exceptions	se_rfi, se_rfc, se_rfdi
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

74.12.1.2 Direct Branch Message Instructions

[Table 1667](#) shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 1667. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	b, ba, bl, bla, bc, bca, bcl, bcla, se_b, se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync

74.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.

Branch History Messaging solves this problem by providing a predicated instruction history field in each Indirect Branch Message. Each bit in the history represents a predicated instruction or direct branch, or a not-taken indirect branch. A value of one (1) indicates the conditional instruction was executed or the direct branch was taken. A value of zero (0) indicates the conditional instruction was not executed or the branch was not taken. (**evsel**)

Branch History Messages solve predicated instruction tracking and save bandwidth since only indirect branches cause messages to be queued.

74.12.1.4 BTM using Traditional Program Trace Messages

Based on the PTM bit in the DC1 Register, Program Tracing can utilize either Branch History Messages (PTM = 1) or traditional Direct/Indirect Branch Messages (PTM = 0).

Branch History will save bandwidth and keep consistency between methods of Program Trace, yet may lose temporal order between BTM messages and other types of messages. Since direct branches are not messaged, but are instead included in the history field of the Indirect Branch History Message, other types of messages may enter the FIFO between Branch History Messages. The development tool cannot determine the ordering of “events” that occurred with respect to direct branches simply by the order in which messages are sent out.

Traditional BTM messages maintain their temporal ordering because each event that can cause a message to be queued will enter the FIFO in the order it occurred and will be messaged out maintaining that order.

74.12.2 BTM Message For mats

The Nexus 3 block supports three types of traditional BTM Messages — Direct, Indirect, and Synchronization Messages. It supports two types of branch history BTM Messages — Indirect Branch History, and Indirect Branch History with Synchronization Messages.

74.12.2.1 Indirect branch messages (history)

Indirect branches include all taken branches whose destination is determined at run time, interrupts, and exceptions. If DC1_{PTM} is set to ‘1’, indirect branch information is messaged out in the following format:

(1-32 bits)	(1-32 bits)	(1-8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Relative Address	Sequence Count	(0)	Source Proc.	TCODE (011100)

Max length = 83 bits; Min length = 14 bits

Figure 1797. Indirect branch message (history) format

74.12.2.2 Indirect branch messages (traditional)

If DC1_{PTM} is cleared to ‘0’, indirect branch information is messaged out in the following format:

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Relative Address	Sequence Count	(0)	Source Proc.	TCODE (000100)

Max length = 51 bits; Min length = 13 bits

Figure 1798. Indirect branch message format

74.12.2.3 Direct branch messages (traditional)

Direct branches (conditional or unconditional) are all taken branches whose destination is fixed in the instruction opcode. Direct branch information is messaged out in the following format:

(1–8 bits)	(4 bits)	(6 bits)
Sequence Count	Src. Proc.	TCODE (000011)

Max length = 18 bits; Min length = 11 bits

Figure 1799. Direct branch message format

Note: When $DC1_{PTM}$ is set, Direct Branch Messages will not be transmitted. Instead, each direct branch, not-taken indirect branch, or predicated instruction will be recorded in the history buffer.

74.12.3 Program Trace Message Fields

The following subsections describe specific fields used for Program Trace messages.

74.12.3.1 Sequential Instruction Count Field (ICNT)

Most of the program trace messages include an instruction count field. For traditional Branch messages, ICNT represents the number of sequential instructions including non-taken branches since the last Direct/Indirect Branch messages. Branch instructions that trigger message generation are included in the ICNT.

For Branch History messages, ICNT represents the number of instructions executed since the last taken/non-taken direct branch, predicate instruction, last taken/not-taken indirect branch, or exception. Branch instructions that trigger message generation are included in the ICNT. Instructions that generate history bits are not included in the ICNT.

The sequential instruction counter overflows after its value reaches 255 and is reset to 0. In addition, the next BTM Message (corresponding to the 256th or later instruction) will be converted to a w/sync type message.

The instruction counter is reset every time the instruction count is transmitted in a message or whenever there is a branch/predicate history event, as well as on exiting from debug mode.

74.12.3.2 Branch/Predicate Instruction History (HIST)

If $DC1_{PTM}$ is set, BTM messaging will use the Branch History format. The branch history (HIST) field in these messages provides a history of branch execution used for reconstructing the program flow. The branch/predicate history buffer stores information about branch and predicate instruction execution. The buffer is implemented as a left-

shifting register. The buffer is preloaded with a one (1), which acts as a stop bit (the most significant 1 in the history field is a termination bit for the field). The pre-loaded bit itself is not part of the history, but is transmitted with the packet.

A value of one (1) is shifted into the history buffer for each taken direct branch (program counter relative branch) or predicate instruction whose condition evaluates to true. A value of zero (0) is shifted into the history buffer for each not-taken branch (including indirect branch instructions) or predicate instruction whose condition evaluates to false. For the **evsel** instruction, two bits are shifted in, corresponding to the low element (shifted in first) and the high element (shifted in second) conditions.

This history buffer information is transmitted as part of an Indirect Branch with History message, as part of a Program Correlation message, or as part of a Resource Full message if the history buffer becomes full. The history buffer is reset every time the history information is transmitted in a message, as well as on exiting from debug mode.

Table 1668. Branch/Predicate history events

Branch/Predicate History Event	History Bit(s)	Relevant Instructions
Not taken register indirect branches	0	bcctr, bcctrl, bclr, bclrl
Not taken direct branches	0	b, ba, bc, bca, bla, bcla, bl, bcl
Taken direct branches	1	b, ba, bc, bca, bla, bcla, bl, bcl⁽¹⁾
evsel instruction	00,01,10, or 11	evsel

1. If the EVCODE for direct branch function calls is not masked in DC4, taken bl and bcl instructions will generate Program Correlation Messages and will not be logged in the history buffer.

74.12.3.3 Execution Mode Indication

In order for a development tool to properly interpret instruction count and history information, it must be aware of the execution mode context of that information. VLE instructions will be interpreted differently from non-VLE instructions.

Program trace messages provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

74.12.4 Resource Full Messages

The Resource Full Message is used in conjunction with Branch Trace and Branch History Messages. The Resource Full Message is generated when either the internal branch/predicate history buffer is full, or if the BTM Instruction sequence counter (I-CNT) overflows. If synchronization is needed at the time this message is generated, the synchronization is delayed until the next Branch Trace Message that is not a Resource Full Message.

For history buffer overflow, the Resource Full Message transmits a Resource Code (RCODE) of 0b0001 and the current contents of the history buffer, including the stop bit, are transmitted in the Resource Data (RDATA) field. This history information can be concatenated by the development tool with the branch/predicate history information from subsequent messages to obtain the complete branch/predicate history between indirect changes of flow.

For instruction counter overflow, the Resource Full Message transmits an RCODE of 0b0000 and a value of 0xFF is transmitted in the RDATA field, indicating that 255 sequential instructions have been executed since the last change of flow; or, if program trace is in history mode, since the last instruction that recorded history information.

(1–32 bits)	(4 bits)	(4 bits)	(6 bits)
RDATA	RCODE	Src. Proc.	TCODE (011011)

Max length = 46 bits; Min length = 15 bits

Figure 1800. Resource Full Message format

[Table 1669](#) shows the RCODE encodings and RDATA information used for Resource Full Messages.

Table 1669. RCODE encoding

RCODE	Description	RDATA field
0000	Program Trace Instruction counter reached 255 and was reset.	0xFF
0001	Program Trace, Branch / Predicate Instruction History full.	Branch History. This type of packet is terminated by a stop bit set to 1 after the last history bit.

74.12.5 Program Correlation Messages

Program Correlation Messages (PCMs) are used to correlate events to the program flow that may or may not be associated with the instruction stream. The following events will result in a PCM when program trace is enabled:

- When the CPU enters debug mode, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to debug mode entry.
- When the CPU first enters a low power mode in which instructions are no longer executed, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to low power mode entry.
- Whenever program trace is disabled by any means, a PCM is generated. The instruction count and history information provided by the PCM can be used to determine the last sequence of instructions executed prior to disabling program trace.
- When a “Branch and Link” instruction executes (direct branch function call — **bl/bcl/bla/bcla**-type instructions)
- When program trace becomes masked due to $MSR_{PMM}=0$ and $DC4_{PTMARK}=1$.
- When a write to the process ID register selected by $DC1_{OTS}$ (PID0 or NPIDR) is made via a **mtspr** PID0 or **mtspr** NPIDR.

Refer to [Table 1642](#) for the event codes that are supported in this implementation. Event code masking is available via the EVCDM field of the DC4 register to allow for control over generation of Program Correlation messages for each event type.

Program Correlation is messaged out in the following formats:

Max length = 56 bits; Min length = 18 bits

* CDF= 01,

EVCODE = Any but 0101, 1100

Figure 1801. Program Correlation message formats

74.12.5.1 Program Correlation message generation for PID updates

When a (potentially) new value is established in the selected process ID register via a **mtspr** PID0/NPIDR, a Program Correlation message is generated containing the information regarding the new process ID value. This PCM also contains the current history and instruction count. The message is provided so that address translation information can be processed by the development tool in the proper program flow. The **mtspr** PID0/NPIDR is included in the instruction count information. Note that Ownership Trace Messages (other than the periodic OTM) are redundant with the information provided, and may be disabled to avoid unnecessary message bandwidth or collisions.

74.12.6 Program Trace Overflow Error messages

an Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard incoming messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied.

74.12.7 Program Trace Synchronization messages

By default, program trace messages will perform XOR compression on the branch target address to produce the address field for the message. This compression is consistent with the specification in IEEE-ISTO 5001.

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see

[Table 1670](#)):

- Initial Program Trace message after exit from system reset or whenever program trace is enabled.
- Upon exiting from a CPU Low Power state.
- Upon exiting from Debug Mode.
- Upon occurrence of queue overrun (can be caused by any trace message), provided Program Trace is enabled.
- Upon assertion of the Event In (**nex_evti_b**) pin if the EIC bits within the DC1 Register have enabled this feature.
- When program trace becomes unmasked due to $MSR_{PMM} \rightarrow '1'$ with $DC4_{PTMARK} = '1'$.

Note that the ICNT information for these messages is driven to zero, thus will not always be meaningful for some of these cases.

The format for Program Trace Synchronization messages is as follows:

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Seq. Count (0)	(0)	Source Proc.	TCODE (001001)

Max length = 51 bits; Min length = 13 bits

Figure 1802. Program Trace Synchronization message format

Exception conditions that result in Program Trace Synchronization are summarized in [Table 1670](#).

Table 1670. Program Trace exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (j_trst_b), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. Upon exiting system reset (p_reset_b), if Program Trace is already enabled, a Program Trace Sync Message is sent.
Program Trace Enabled	The first Program Trace Message (after Program Trace has been enabled or re-enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode, a Program Trace Sync Message is sent.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next BTM message in the queue will be a Program Trace Sync Message.
Event In	If the Nexus module is enabled, a nex_evti_b assertion initiates a Program Trace Sync Message if Program Trace is enabled and the EIC bits of the DC1 Register have enabled this feature.

Note that for cases where program trace sync messages are generated due to program trace being enabled, the address contained in the sync message may either be the address of the instruction that caused program trace to be enabled, or may be the address of the first

instruction of an exception handler that is executed in response to unsuccessful completion of that instruction.

74.12.8 Program Trace Direct/Indirect Branch with Sync messages

Under some conditions an uncompressed address is sent to provide development tools with a baseline reference address. A Program Trace Synchronization or a Direct/Indirect Branch with Sync message is messaged via the auxiliary port (provided Program Trace is enabled) for the following conditions (see [Table 1670](#)):

- Upon direct/indirect branch after a Program Sync Message was lost due to a collision while attempting to enter the message queue.
- Upon direct/indirect branch after the sequential instruction counter has expired indicating 255 instructions have occurred since the last change of flow.
- When the periodic program trace counter has expired indicating 255 *without-sync* Program Trace messages have occurred since the last *with-sync* message occurred.

Note that the ICNT and History information for the first message will not always be meaningful, since the temporary masking of program trace may result in ambiguous values. Subsequent w/sync messages will not have this issue.

The format for Program Trace Direct/Indirect Branch with Sync messages is as follows:

(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (001011 or 001100)

Max length = 51 bits; Min length = 13 bits

Figure 1803. Direct/Indirect Branch with Sync message format

The format for Program Trace Indirect Branch History with Sync. Messages is as follows:

(1–32 bits)	(1–32 bits)	(1–8 bits)	(1 bit)	(4 bits)	(6 bits)
Branch History	Full Target Address	Sequence Count	(0)	Source Proc.	TCODE (011101)

Max length = 83 bits; Min length = 14 bits

Figure 1804. Indirect Branch History w/ Sync message format

Exception conditions that result in Program Trace Synchronization using a w/Sync message type are summarized in [Table 1671](#).

Table 1671. Program Trace Exception Summary for w/Sync BTM messages

Exception Condition	Exception Handling
Periodic Program Trace Sync.	A forced synchronization occurs periodically after 255 non-sync Program Trace Messages have been queued. A Direct/Indirect Branch w/ Sync. Message is queued. The periodic program trace message counter then resets.
Sequential Instruction Count Overflow	After the sequential instruction counter reaches its maximum count (up to 255 sequential instructions may be executed), a forced synchronization occurs. The sequential counter then resets. A Program Trace Direct/Indirect Branch w/ Sync. Message is queued upon execution of the next branch. A Resource Full Message is Queued on the overflow event. If a branch instruction is the 255th instruction to occur, and causes a Program Trace message to be queued, then no Resource Full Message is queued, and the w/Sync message will be queued for the <i>next</i> Program Trace Direct/Indirect Branch Message.
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCMPIDMSG → OTM → BTM → DTM) → Instruction 1 (WPM → DQM → OTM → BTM → DTM), where instruction 0 is the oldest instruction. A BTM Message from Instruction 1 that attempts to enter the queue at the same time as three higher priority messages from either instruction will be lost. An Error Message will be sent indicating the BTM was lost. The following direct/indirect branch will queue a Direct/Indirect Branch w/ Sync. Message. The count value within this message will reflect the number of sequential instructions executed after the last successful BTM Message was generated. This count will include the branch that did not generate a message due to the collision.

74.12.9 Enabling Program Trace

Program Trace Messaging can be enabled in one of three ways:

- Setting the TM field of the DC1 Register to enable Program Trace
- Using the PTS field of the WT Register to enable Program Trace on Watchpoint hits (watchpoints are configured within the CPU)
- Using the external hardware trace enable input signal (nex_ptm_starttr)
- Filtering of Program Trace messages may be performed using the MSR_{PTMM} bit and the setting of DC4_{PTMARK}

74.12.10 Program Trace Timing Diagrams (2 MDO / 1 MSEO configuration)

Figure 1805. Program Trace — Indirect Branch message (Traditional)

Figure 1806. Program Trace — Indirect Branch message (history)

Figure 1807. Program Trace — Direct Branch (traditional) & Error messages

Figure 1808. Program Trace — Indirect Branch w/ Sync message

74.13 Data Trace

This section deals with the Data Trace mechanism supported by the Nexus 3 module. Data Trace is implemented via Data Write Messaging (DWM) and Data Read Messaging (DRM), as per the **IEEE-ISTO 5001** standard.

74.13.1 Data Trace Messaging (DTM)

Data Trace Messaging is accomplished by snooping the internal address and data buses, and storing the information for qualifying accesses (based on enabled features and matching target addresses). The Nexus 3 module traces all data access that meet the selected range and attributes.

Note: Data Trace is only performed on the internal data buses. This allows for data visibility for Core (e200z420n3) processors that incorporate a data cache. Only CPU initiated accesses will be traced. No DMA accesses to the AHB system bus will be traced.

Data Trace Messaging can be enabled in one of three ways.

- Setting the TM field of the DC1 Register to enable Data Trace.
- Using the DTS field of the WT Register to enable Data Trace on Watchpoint hits (watchpoints are configured within the Nexus1 module).
- Using the external hardware trace enable signal (**nex_dtm_starttr**)

74.13.2 DTM Message formats

The Nexus 3 block supports five types of DTM Messages — Data Write, Data Read, Data Write Synchronization, Data Read Synchronization, and Error Messages.

74.13.2.1 Data Write messages

The Data Write message contains the data write value and the address of the write access, relative to the previous Data Trace message. Data Write message information is messaged out in the following format:

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000101)

Max length = 111 bits; Min length = 17 bits

Figure 1809. Data Write message format

74.13.2.2 Data Read messages

The Data Read message contains the data read value and the address of the read access, relative to the previous Data Trace message. Data Read message information is messaged out in the following format:

Figure 1810. Data Read message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value(s)*	Relative Address	Data Size	(0)	Src. Proc	TCODE (000110)

Max length = 111 bits; Min length = 17 bits

Note: . * Core (e200z420n3)-based CPUs are capable of generating two (2) reads or writes per clock cycle in cases where multiple registers are accessed with a single instruction (lmw/stmw). These will have a double word pair size encoding (**p_tsiz** = 0b000). In these cases, the Nexus 3 module will send one (1) Data Trace Message with the two 32-bit data values as one combined 64-bit value for each message.

For Core (e200z420n3)-based CPUs, the doubleword encoding (**p_tsiz** = 0b000) may also indicate a doubleword access and will be sent out as a single Data Trace Message with a single 64-bit data value.

The debug/development tool will need to distinguish the two cases based on the family of processor.

74.13.2.3 Data Trace Synchronization messages

A Data Trace Write/Read with Sync. message is messaged via the auxiliary port (provided Data Trace is enabled) for the following conditions (see [Table 1672](#)):

- Initial Data Trace Message after exit from system reset or whenever Data Trace is enabled.
- Upon returning from a CPU Low Power state.
- Upon returning from Debug Mode.
- After occurrence of queue overrun (can be caused by any trace message), provided Data Trace is enabled.
- After the periodic data trace counter has expired indicating 255 *without-sync* Data Trace messages have occurred since the last *with-sync* message occurred.
- Upon assertion of the Event In (**nex_evti_b**) pin, the first Data Trace Message will be a synchronization message if the EIC bits of the DC1 Register have enabled this feature.
- Upon Data Trace Write/Read after the previous DTM message was lost due to an attempted access to a secure memory location (for SOC's w/ security).
- Upon Data Trace Write/Read after the previous DTM message was lost due to a collision entering the FIFO between the DTM message and any two of the following: Watchpoint message, Ownership Trace message, or Program Trace message.

Data Trace Synchronization Messages provide the full address (without leading zeros) and insure that development tools fully synchronize with Data Trace regularly. Synchronization messages provide a reference address for subsequent DTMs, in which only the unique portion of the Data Trace address is transmitted. The format for Data Trace Write/Read with Sync. Messages is as follows:

Figure 1811. Data Write/Read with Sync message format

(1–64 bits)	(1–32 bits)	(4 bits)	(1 bit)	(4 bits)	(6 bits)
Data Value	Full Address	Data Size	(0)	Source Proc.	TCODE (001101 or 001110)

Max length = 111 bits; Min length = 17 bits

Exception conditions that result in Data Trace Synchronization are summarized in [Table 1672](#).

Table 1672. Data Trace Exception summary

Exception Condition	Exception Handling
System Reset Negation	At the negation of JTAG reset (j_trst_b), queue pointers, counters, state machines, and registers within the Nexus 3 module are reset. If Data Trace is enabled, the first Data Trace Message is a Data Write/Read w/ Sync. Message.
Data Trace Enabled	The first Data Trace Message (after Data Trace has been enabled) is a synchronization message.
Exit from Low Power/Debug	Upon exit from a Low Power mode or Debug mode the next Data Trace Message will be converted to a Data Write/Read with Sync. Message.
Queue Overrun	An Error Message occurs when a new message cannot be queued due to the message queue being full. The FIFO will discard messages until it has completely emptied the queue. Once emptied, an Error Message will be queued. The error encoding will indicate which type(s) of messages attempted to be queued while the FIFO was being emptied. The next DTM message in the queue will be a Data Write/Read w/ Sync. Message.
Periodic Data Trace Sync.	A forced synchronization occurs periodically after 255 Data Trace Messages have been queued. A Data Write/Read w/ Sync. Message is queued. The periodic data trace message counter then resets.
Event In	If the Nexus module is enabled, a nex_evti_b assertion initiates a Data Trace Write/Read w/ Sync. Message upon the next data write/read (if Data Trace is enabled and the EIC bits of the DC1 Register have enabled this feature).
Collision Priority	All Messages have the following priority: Instruction 0 (WPM → DQM → PCMPIDMSG → OTM → BTM → DTM) → Instruction1 (WPM → DQM → OTM → BTM → DTM), where instruction0 is the oldest instruction. A DTM Message that attempts to enter the queue at the same time as three other higher priority messages will be lost. A subsequent read/write will queue a Data Trace Read/Write w/ Sync. Message.

74.13.3 DTM operation

74.13.3.1 Data Trace windowing

Data Write/Read Messages are enabled via the RWT field in the Data Trace Control Register (DTC) for each DTM channel. Data Trace windowing is achieved via the address range defined by the DTEA and DTSA Registers and by the RC field in the DTC register. All CPU initiated read/write accesses that fall inside or outside these address ranges, as programmed, are candidates to be traced.

74.13.3.2 Data Access / Instruction Access Data Tracing

The Nexus3 module is capable of tracing either instruction access data or data access data and can be configured for either type of data trace by setting the DI1 field within the Data Trace Control Register. This setting applies to all DTM channels.

74.13.3.3 Data Trace filtering

Data Trace filtering is available base on the settings of MSR_{PMM} and DC4_{DTMARK}.

74.13.3.4 Bus cycle special cases

Table 1673. Bus cycle special cases

Special case	Action
Bus cycle aborted	Cycle ignored
Bus cycle with data error ($\overline{\text{TEA}}$) ⁽¹⁾	Data Trace Message discarded
Bus cycle completed without error ⁽¹⁾	Cycle captured & transmitted
AHB bus cycle initiated by Nexus 3	Cycle ignored
Bus cycle is an instruction fetch	Cycle selectively ignored based on DTC _{DI} setting
Bus cycle accesses misaligned data (across 64-bit boundary) — both 1st & 2nd transactions within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction out of data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction within data trace range — 2nd transaction (regardless of within range or not) receives a bus error	Data Trace Message discarded
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within data trace range	1st & 2nd cycle captured & a single or a pair of DTM(s) is (are) transmitted (see Note)
Bus cycle accesses misaligned data (across 64-bit boundary) — 1st transaction out of data trace range — 2nd transaction within range, receives a bus error	Data Trace Message discarded

1. Buffering of stores in the CPU store buffer may generate a DTM prior to the actual memory access, regardless of an error termination condition from memory.

Note: For misaligned accesses (crossing 64-bit boundary), the access is broken into two accesses by the CPU. If either access is within the data trace range, a single DTM will be sent with a size encoding indicating the size of the original access (i.e. word), and the address indicating the original misaligned accesses, unless the misaligned access wraps into the doubleword at address 0. In this case, since the two portions of the misaligned access are not contiguous, two DTMs will be sent, one for each portion. The size encodings and the addresses of the DTMs will indicate the accessed bytes of data. The data trace port handles these cases in the same manner. (See the Data Trace Port section in the Core (e200z420n3) Core Debug Support chapter.)

Note: A store to the cache's store buffer within the data trace range may initiate a DTM message prior to completion of the actual memory access.

74.13.4 Data Trace Timing Diagrams (8 MDO / 2 MSEO configuration)

Figure 1812. Data Trace — Data Write message

Figure 1813. Data Trace — Data Read w/ Sync message

74.14 Data Acquisition messaging

this section details the Data Acquisition mechanisms supported by the Nexus 3 module. Data Acquisition Trace is implemented using Data Acquisition Trace Messages in accordance with IEEE-ISTO 5001 definitions. The control mechanism to export the data is different from the recommendations of the standard, however.

Data Acquisition Trace provides a convenient and flexible mechanism for the debugger to observe the architectural state of the machine through software instrumentation.

74.14.1 Data Acquisition ID Tag field

The DQTAG Tag field (DQTAG) is an 8-bit value specifying control or attribute information for the data included in the Data Acquisition message. DQTAG is sampled from $DEVENT_{DQTAG}$ when a write to DDAM is performed via **mtspr** operations. The usage of the DQTAG is left to the discretion of the development tool to be used in whatever manner is deemed appropriate for the application.

74.14.2 Data Acquisition Data field

The Data Acquisition Data field (DQDATA) is the data captured from the DDAM write operation via **mtspr** operations. Leading zeros are omitted from the message.

74.14.3 Data Acquisition Trace event

For DQM, a dedicated SPR has been allocated (DDAM). It is expected that the general use case is to instrument the software and use **mtspr** operations to generate Data Acquisition messages.

There is no explicit error response for failed accesses as a result of contention between an internal and external debugger. Software may be blocked or given ownership of DDAM and the DQTAG field of the DEVENT register via control in EDBRAC0 while in External Debug Mode. Hardware always has access to these registers. Refer to the “External Debug Resource Allocation Control Register (EDBRAC0)” section in the Core (e200z420n3) Core Debug Support chapter for more detail on EDBRAC0.

Reads from the Data Acquisition channel do not generate a Data Acquisition event and will return zeroes for the read data.

(1–32 bits)	(8 bits)	(4 bits)	(6 bits)
DQDATA	DQTAG	Src. Proc.	TCODE (011011)

Max length = 50 bits; Min length = 19 bits

Figure 1814. Data Acquisition message format

74.15 Watchpoint Trace messaging

Enabling Watchpoint messaging is done by setting the Watchpoint Trace Enable bit in the DC1 Register. Setting the individual Watchpoint sources is supported through the Nexus1 module and the Performance Monitor unit. The Nexus1 module is capable of setting multiple types of watchpoints. Please refer to the Core (e200z420n3) Core Debug Support chapter for details on watchpoint initialization.

When watchpoints occur due to one or more asserted watchpoint event signals and Watchpoint Trace Messaging is enabled, a Watchpoint Trace message will be sent to the message queue to be messaged out. This message includes the watchpoint number indicating which watchpoint(s) caused the message. If more than one enabled watchpoint occurs in a single cycle, only one Watchpoint Trace message is generated and multiple bits of the watchpoint hit field will be set. The settings of the WMSK_{WEM} field control which watchpoints are enabled to generate watchpoint trace messages.

The occurrence of any of the defined watchpoints can also be programmed to assert the Event Out (**nex_evto_b**) pin for one (1) period of the output clock (**nex_mcko**) based on settings in the DC2 and DC3 registers. See [Table 1677](#) for details on **nex_evto_b**.

Watchpoint information is messaged out in the following format:

Figure 1815. Watchpoint message format

(1–30 bits)	(4 bits)	(6 bits)
Watchpoint Source	Src. Proc.	TCODE (001111)

Variable length = 11–40 bits

The Watchpoint Source message field will contain a ‘1’ for each asserted watchpoint. Leading zeros are truncated.

Table 1674. Watchpoint source encoding

Watchpoint source (1–30 bits)	Watchpoint description
00000000000000000000000000000000	No Watchpoints enabled for Watchpoint Trace Messaging
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1	Watchpoint #0 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1x	Watchpoint #1 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xx	Watchpoint #2 enabled for WTM
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx1xxx	Watchpoint #3 enabled for WTM

74.15.1 Watchpoint Timing Diagram (2 MDO / 1 MSEO configuration)

Figure 1816. Watchpoint Message & Watchpoint Error message

74.16 External Hardware Trigger Controls

The Nexus 3 module provides a set of hardware trigger inputs to allow for external hardware to also independently control enabling/disabling of Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace messaging. These signals can be used to produce a “window” for trace messaging for each type.

When a start trigger condition is detected for one of the trace types, and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace features become enabled, and the corresponding enable bit(s) of the DC1 register is set. When a stop trigger condition is detected and the corresponding trace type has not already been enabled by a software write to the DC1 register, the designated trace feature becomes disabled, and the corresponding enable bit of the DC1 register is cleared. If a simultaneous trigger condition is received for both start and stop triggering, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For example, if tracing is enabled, and a start and stop trigger condition occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature control action that is derived from external hardware triggering, and if the corresponding trace feature has been enabled by a direct write to DC1, then the corresponding hardware trigger signals will have no effect.

[Table 1675](#) details the external hardware trigger signals.

Table 1675. External Hardware Trigger Signals

Name	Description
nex_dtm_starttr	Data Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_dtm_stoptr	Data Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_otm_starttr	Ownership Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_otm_stoptr	Ownership Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

Table 1675. External Hardware Trigger Signals (continued)

Name	Description
nex_ptm_starttr	Program Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_ptm_stoptr	Program Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.
nex_wtm_starttr	Watchpoint Trace Messaging start trigger input. A transition from 0→1 on this input signals a start trace condition.
nex_wtm_stoptr	Watchpoint Trace Messaging stop trigger input. A transition from 0→1 on this input signals a stop trace condition.

These signals are active-high inputs and are transition sensitive. A 0→1 transition on the signal indicates the corresponding condition is requested. These signals are not synchronized, and must meet setup and hold requirements relative to **nex_clk**.

74.17 Nexus 3 Read/Write access to memory-mapped resources

The Read/Write access feature allows access to memory-mapped resources via the JTAG/OnCE port. The Read/Write mechanism supports single as well as block reads and writes to AHB resources.

The Nexus 3 module is capable of accessing resources on the system bus (AHB). Memory-mapped registers and other non-cached memory can be accessed via the standard memory map settings.

All accesses are setup and initiated by the Read/Write Access Control/Status Register (RWCS), as well as the Read/Write Access Address (RWA) and Read/Write Access Data Registers (RWD). Nexus 3 read/write accesses are run as privileged data non-cacheable accesses by default, and drive the **p_d_hprot[5:0]** bus access attributes to 6'b000011 accordingly. The RWCS_{ATTR} field is provided to allow a portion of these default values to be modified when performing read or write accesses using the Nexus 3 Read/Write access mechanism.

Using the Read/Write Access Registers (RWCS/RWA/RWD), memory mapped AHB resources can be accessed through Nexus 3. The following subsections describe the steps required to access memory-mapped resources.

Note: *Read/Write Access can only access memory mapped resources when system reset is de-asserted and clocks are running.*

Misaligned accesses are NOT supported in the Nexus 3 module.

Uncorrectable ECC errors on Nexus 3 read access will result in the RWD register being updated with the raw data received.

74.17.1 Single write access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
 - a) Write Address → 32h'xxxxxxxx (write address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure the bits as follows:
 - a) Access Control (AC) → 1b'1 (to indicate start access)
 - b) Map Select (MAP) → 3b'000 (primary memory map)
 - c) Access Priority (PR) → 2b'11 (highest priority)
 - d) Read/Write (RW) → 1b'1 (write access)
 - e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
 - f) Access Count (CNT) → 14h'0000 or 14h'0001(single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. Initialize the Read/Write Access Data Register (RWD) through the access method outlined in [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
 - a) Write Data → 32h'xxxxxxxx (write data)
4. The Nexus block will then arbitrate for the AHB system bus and transfer the data value from the data buffer RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed, Nexus clears the AC and DV bits in the RWCS Register. If the access has completed without error, (ERR=1'b0), Nexus asserts the **nex_rdy_b** pin (see [Table 1677](#) for details) and clears the ERR bit in the RWCS Register. Otherwise, if the access completes with an error, the **nex_err_b** pin will be asserted and the ERR bit will be set to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once DV has been cleared, this indicates that the device is ready for the next access, or that an error has occurred.

Note: Only the **nex_ahb_start**, **nex_rdy_b**, and **nex_err_b** pins as well as the AC, DV, and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

74.17.2 Block write access

1. For a block write access, follow Steps 1, 2, and 3 outlined in [Section 74.17.1, Single write access](#) to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and transfer the first data value from the RWD Register to the memory mapped address in the Read/Write Access Address Register (RWA). The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, and the **nex_rdy_b** pin is asserted. If the access has completed without error, Nexus clears the ERR and DV bits in the RWCS Register, otherwise the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the **nex_err_b** pin is asserted, the block transfer is aborted, and the AC bit in the RWCS register is cleared. Once DV has

been cleared, this indicates that the device is ready for the next access in the block transfer, or an error has occurred.

3. If AC has not been cleared due to an error, repeat Step 3 in [Section 74.17.1, Single write access](#) until the internal CNT value is zero (0). When this occurs, the AC bit within the RWCS will be cleared to indicate the end of the block write access.

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block write access. The original values can be read by the external development tool at any time.

74.17.3 Single read access

1. Initialize the Read/Write Access Address Register (RWA) through the access method outlined in [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure as follows:
 - a) Read Address → 32h'xxxxxxx (read address)
2. Initialize the Read/Write Access Control/Status Register (RWCS) through the access method outlined in [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#). Configure the bits as follows:
 - a) Access Control (AC) → 1b'1 (to indicate start access)
 - b) Map Select (MAP) → 3b'000 (primary memory map)
 - c) Access Priority (PR) → 2b'11 (highest priority)
 - d) Read/Write (RW) → 1b'0 (read access)
 - e) Word Size (SZ) → 3b'0xx (32-bit, 16-bit, 8-bit)
 - f) Access Count (CNT) → 14h'0000 or 14h'0001 (single access)

Note: Access Count (CNT) of 14'h0000 or 14'h0001 will perform a single access.

3. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. The **nex_ahb_start** output will be asserted during the first clock of the address phase of the transfer. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and asserts the **nex_rdy_b** pin (see [Table 1677](#) for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#).

Note: Only the **nex_ahb_start**, **nex_rdy_b**, and **nex_err_b** pins as well as the AC, DV and ERR bits within the RWCS provide Read/Write Access status to the external development tool.

74.17.4 Block read access

1. For a block read access, follow Steps 1 and 2 outlined in [Section 74.17.3, Single read access](#) to initialize the registers, but using a value greater than one (14'h0001) for the CNT field in the RWCS Register.
2. The Nexus block will then arbitrate for the AHB system bus and the read data will be transferred from the AHB to the RWD Register. When the access has completed without error, Nexus clears the ERR bit and sets the DV bit in the RWCS Register and

asserts the **nex_rdy_b** pin (see [Table 1677](#) for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. The AC bit will be cleared in either case.

3. When the transfer has completed without error, the address from the RWA Register is incremented to the next word size (specified in the SZ field), the number from the CNT field is decremented, Nexus clears the ERR bit and sets the DV bit in the RWCS Register, and asserts the **nex_rdy_b** pin (see [Table 1677](#) for detail on **nex_rdy_b**). Otherwise, if the access has completed with an error, the **nex_err_b** pin will be asserted, the ERR bit will be set and the DV bit will be cleared to indicate an error has occurred, the AC bit is cleared and the block transfer is aborted, and the **nex_rdy_b** pin will not be asserted. Once ERR or DV has been set, this indicates that the device is ready for the next access, or that an error has occurred. Once DV has been set, this indicates that the device is ready for the next access in the block transfer, or if ERR is set (AC will be cleared), the block transfer has been aborted.
4. The data can then be read from the Read/Write Access Data Register (RWD) through the access method outlined in [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#).
5. If AC has not been cleared due to an error, repeat Steps 3 and 4 in [Section 74.17.3, Single read access](#) until the CNT value is zero (0). When this occurs, the AC bit within the RWCS is cleared to indicate the end of the block read access.

Note: The data values must be shifted out 32 bits at a time LSB first (i.e. doubleword read = two word reads from the RWD).

Note: The actual RWA value as well as the CNT field within the RWCS are not changed when executing a block read access. The original values can be read by the external development tool at any time.

74.17.5 Error handling

The Nexus 3 module handles various error conditions as follows:

74.17.5.1 AHB Read/Write error

All address and data errors that occur on read/write accesses to the AHB system bus will return a transfer error encoding on the **p_hresp[1:0]** signals. If this occurs:

1. The access is terminated without retrying (AC bit is cleared).
2. The ERR bit in the RWCS Register is set.
3. The Error Message is sent (TCODE = 8) indicating Read/Write error.

74.17.5.2 Access termination

The following cases are defined for sequences of the Read/Write protocol that differ from those described in the above sections.

1. If the AC bit in the RWCS Register is set to start Read/Write accesses and invalid values are loaded into the RWD and/or RWA, then an AHB access error may occur. This is handled as described above.
2. If a block access is in progress (all cycles not completed), and the RWCS Register is written, then the original block access is terminated at the boundary of the nearest completed access.
 - a) If the RWCS is written with the AC bit set, the next Read/Write access will begin and the RWD can be written to/ read from.
 - b) If the RWCS is written with the AC bit cleared, the Read/Write access is terminated at the nearest completed access. This method can be used to break (early terminate) block accesses.

74.17.6 Read/Write access error message

The Read/Write Access Error Message is sent out when an AHB system bus access error (read or write) has occurred.

Error information is messaged out in the following format:

(5 bits)	(4 bits)	(6 bits)
Error Code (00011)	Src. Proc.	TCODE (001000)

Fixed length = 15 bits

Figure 1817. Error message format

74.18 Nexus 3 pin interface

This section details information regarding the Nexus 3 pins and pin protocol.

The Nexus 3 pin interface provides the function of transmitting messages from the messages queues to the external tools. It is also responsible for handshaking with the message queues.

74.18.1 Pins implemented

The Nexus 3 module implements an auxiliary port consisting of one (1) **nex_evti_b** and one (1) **nex_mseo_b** or two (2) **nex_mseo_b[1:0]**. It also implements a configurable number of **nex_mdo[n:0]** pins, (1) **nex_rdy_b** pin, (1) **nex_err_b** pin, (1) **nex_evto_b** pin, (4) **nex_wevto[3:0]** pins, and one (1) clock output pin (**nex_mcko**), as well as additional configuration pins described in [Table 1677](#). The output pins are synchronized to the Nexus 3 output clock (**nex_mcko**).

All Nexus 3 input functionality may be controlled through the JTAG/OnCE port in compliance with IEEE 1149.1 (see [Section 74.5, Nexus 3 Register Access via JTAG/OnCE](#) for details). The JTAG pins are incorporated as I/O to the processor, and are further described in the “JTAG/OnCE Pins” section of the Core (e200z420n3) Core Debug Support chapter.

Table 1676. JTAG pins for Nexus 3

JTAG pins	Input/ Output	Description of JTAG pins (included in Nexus 1)
j_tdo	O	The Test Data Output (j_tdo) pin is the serial output for test instructions and data. j_tdo is three-stateable and is actively driven in the “Shift-IR” and “Shift-DR” controller states. j_tdo changes on the falling edge of j_tclk .
j_tdi	I	The Test Data Input (j_tdi) pin receives serial test instruction and data. TDI is sampled on the rising edge of j_tclk .
j_tms	I	The Test Mode Select (j_tms) input pin is used to sequence the OnCE controller state machine. j_tms is sampled on the rising edge of j_tclk .
j_tclk	I	The Test Clock (j_tclk) input pin is used to synchronize the test logic, and control register access through the JTAG/OnCE port.
j_trst_b	I	The Test Reset (j_trst_b) input pin is used to asynchronously initialize the JTAG/OnCE controller.

The auxiliary pins are used to send and receive messages and are described in [Table 1677](#).

Table 1677. Nexus 3 auxiliary pins

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_mcko	O	Message Clock Out (nex_mcko) is a free running output clock to development tools for timing of nex_mdo[n:0] & nex_mseo_b[1:0] pin functions. nex_mcko is programmable through the DC1 Register.
nex_mdo[n:0]	O	Message Data Out (nex_mdo[n:0]) are output pins used for OTM, BTM, and DTM. External latching of nex_mdo[n:0] shall occur on the rising edge of the Nexus3 clock (nex_mcko).
nex_mseo_b[1:0]	O	Message Start/End Out (nex_mseo_b[1:0]) are output pins that indicate when a message on the nex_mdo[n:0] pins has started, when a variable length packet has ended, and when the message has ended. External latching of nex_mseo_b[1:0] shall occur on the rising edge of the Nexus3 clock (nex_mcko). One or two pin MSEO functionality is determined at integration time per SOC implementation
nex_rdy_b	O	Ready (nex_rdy_b) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access. If Nexus is enabled, this signal is asserted upon successful (without error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, nex_rdy_b remains deasserted
nex_err_b	O	Error (nex_err_b) is an output pin used to indicate to the external tool that the Nexus block is ready for the next Read/Write Access and an error has occurred on the previous access. If Nexus is enabled, this signal is asserted upon unsuccessful (with error) completion of an AHB system bus transfer (Nexus read or write) & is held asserted until the JTAG/OnCE state machine reaches the “Capture_DR” state. Upon exit from system reset or if Nexus is disabled, nex_err_b remains deasserted

Table 1677. Nexus 3 auxiliary pins (continued)

Auxiliary pins	Input/ Output	Description of auxiliary pins
nex_evto_b	O	Event Out (nex_evto_b) is an output that, when asserted, indicates one of two events has occurred based on the EOC bits in the DC1 Register. nex_evto_b is held asserted for one (1) cycle of nex_mcko : 1) One (or more) watchpoints has occurred (from Nexus1) & EOC = 2'b00 2) Debug mode was entered (jd_debug_b asserted from Nexus1) & EOC = 2'b01
nex_evti_b	I	Event In (nex_evti_b) is an input that, when asserted, will initiate one of two events based on the EIC bits in the DC1 Register (if the Nexus module is enabled at reset): 1) Program Trace & Data Trace synchronization messages (provided Program Trace & Data Trace are enabled & EIC = 2'b00). 2) Debug request to Nexus1 module (provided EIC = 2'b01 and this feature is implemented).
nex_wevto[3:0]	O	Watchpoint Event Out 3:0 (nex_wevto[3:0]) are outputs that, when asserted, indicates one or more watchpoint events has occurred based on the settings in the DC2 and DC3 registers. nex_wevto[3:0] is held asserted for one (1) cycle of nex_mcko .
nex_ext_src_id[0:3]	I	nex_ext_src_id[0:3] is used to provide the SRC field value used in each message. These pins are tied to a predetermined value at SoC integration time
nex_sfwcntl_en]	I	nex_sfwcntl_en is used to allow software to control the module resources via the DCR register mappings. SoC logic should drive this signal appropriately in a semi-static manner based on the presence of an external hardware debugger and appropriate security precautions.

The Nexus auxiliary port arbitration pins are used when the Nexus 3 module is implemented in a multi-Nexus SoC that shares a single auxiliary output port. The arbitration is controlled by an SoC level Nexus Aurora Router (NAR). Refer to [Section 74.20, Auxiliary port arbitration](#), for detail on Nexus port arbitration.

Table 1678. Nexus port arbitration signals

Nexus port arbitration pins	Input/ Output	Description of arbitration pins
nex_aux_req[1:0]	O	Nexus Auxiliary Request (nex_aux_req[1:0]) output signals indicate to an SoC level Nexus arbiter a request for access to the shared Nexus auxiliary port in a multi-Nexus implementation. The priority encodings are determined by how many messages are currently in the message queues (See Table 1680 .)
nex_aux_busy	O	Nexus Auxiliary Busy (nex_aux_busy) is an output signal to an SoC level Nexus arbiter indicating that the Nexus 3 module is currently transmitting its message after being granted the Nexus auxiliary port.
nar_aux_grant	I	Nexus Auxiliary Grant (nar_aux_grant) is an input from the SoC level NAR that the auxiliary port has been granted to the Nexus 3 module to transmit its message.
ext_multi_nex_sel	I	Multi-Nexus Select (ext_multi_nex_sel) is a static signal indicating that the Nexus 3 module is implemented within a multi-Nexus environment. If set, port control and arbitration is controlled by the SoC level arbitration module (NAR).

74.18.2 Pin protocol

The protocol for the processor transmitting messages via the auxiliary pins is accomplished with the MSEO pin function outlined in [Table 1679](#). Both single and dual pin cases are shown.

nex_mseo_b[1:0] is used to signal the end of variable-length packets, and not fixed length packets. **nex_mseo_b[1:0]** is sampled on the rising edge of the Nexus 3 clock (**nex_mcko**).

Single pin MSEO is not supported on the SPC57EM80xx.

Table 1679. MSEO pin(s) protocol

nex_mseo_b function	Single nex_mseo_b data (serial)	Dual nex_mseo_b[1:0] data
Start of message	1-1-0	11-00
End of message	0-1-1-(more 1's)	00 (or 01)-11-(more 1's)
End of variable length packet	0-1-0	00-01
Message transmission	0's	00's
Idle (no message)	1's	11's

[Figure 1818](#) illustrates the state diagram for single pin MSEO transfers.

Figure 1818. Single pin MSEO transfers

Note that the “End Message” state does not contain valid data on the `nex_mdo[n:0]` pins. Also, It is not possible to have two consecutive “End Packet” messages. This implies the minimum packet size for a variable length packet is 2x the number of `nex_mdo[n:0]` pins. This ensures that a false end of message state is not entered by emitting two consecutive ‘1’s on the `nex_mseo_b` pin before the actual end of message.

[Figure 1819](#) illustrates the state diagram for dual pin MSEO transfers.

Figure 1819. Dual pin MSEO transfers

The dual pin MSEO option is more robust than the single pin option. Termination of the current message may immediately be followed by the start of the next message on the consecutive clocks. An extra clock to end the message is not necessary as with the one MSEO pin option. The dual pin option also allows for consecutive “End Packet” states. This can be an advantage when small, variable sized packets are transferred.

Note: The “End Message” state may also indicate the end of a variable-length packet as well as the end of the message when using the dual pin option.

74.19 Rules for output messages

Class 3 compliant embedded processors must provide messages via the auxiliary port in a consistent manner as described below:

- A variable-sized packet within a message must end on a port boundary.
- A variable-sized packet may start within a port boundary only when following a fixed length packet. (If two variable-sized packets end and start on the same clock, it is

impossible to know which bit is from the last packet and which bit is from the next packet.)

- Whenever a variable-length packet is sized such that it does not end on a port boundary, it is necessary to extend and zero fill the remaining bits after the highest-order bit so that it can end on a port boundary.

For example, if the **nex_mdo[n:0]** port is 2 bits wide, and the unique portion of an indirect address TCODE is 5 bits, then the remaining 1 bit of **nex_mdo[n:0]** must be packed with a 0.

74.20 Auxiliary port arbitration

In a multi-Nexus environment, the Nexus 3 module must arbitrate for the shared Nexus port at the SoC level. The request scheme is implemented as a 2-bit request with various levels of priority. The priority levels are defined in [Table 1680](#) below. The Nexus 3 module will receive a 1-bit grant signal (**nar_aux_grant**) from the SoC level arbiter. When a grant is received, the Nexus 3 module will begin transmitting its message following the protocol outlined in [Section 74.18.2, Pin protocol](#). The Nexus 3 module will maintain control of the port, by asserting the **nex_aux_busy** signal, until the MSEO state machine reaches the “End Message” state.

Table 1680. MDO request encodings

Request level	MDO request encoding (nex_aux_req[1:0])	Condition of queue
No Request	00	No message to send
Low Priority	01	Message queue less than 1/2 full
—	10	Reserved
High Priority	11	Message queue 1/2 full or more

74.21 Examples

The following are examples of Program Trace and Data Trace Messages.

[Table 1681](#) illustrates an example Indirect Branch Message with 2 MDO / 1MSEO configuration. [Table 1682](#) illustrates the same example with an 8 MDO / 2 MSEO configuration.

Note that T0 and S0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Ix = Number of instructions (variable)
- Ax = Unique portion of the address (variable)

Note that during clock 13, the **nex_mdo[n:0]** pins are ignored in the single MSEO case.

Table 1681. Indirect branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I0	MAP	0	Normal Transfer
7	I2	I1	0	Normal Transfer
8	I4	I3	1	End Packet
9	A1	A0	0	Normal Transfer
10	A3	A2	0	Normal Transfer
11	A5	A4	0	Normal Transfer
12	A7	A6	1	End Packet
13	0	0	1	End Message
14	T1	T0	0	Start Message

Table 1682. Indirect branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	I4	I3	I2	I1	I0	M A P	S3	S2	0	1	End Packet
3	A7	A6	A5	A4	A3	A2	A1	A0	1	1	End Packet/End Message
4	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

[Table 1683](#) and [Table 1684](#) illustrate examples of Direct Branch Messages: one with 2 MDO / 1 MSEO, and one with 8 MDO / 2 MSEO.

Note that T0 and I0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- Ix = Number of Instructions (variable)

Table 1683. Direct branch message example (2 MDO / 1 MSEO)

Clock	nex_mdo[1:0]		nex_mseo_b	State
0	X	X	1	Idle (or end of last message)
1	T1	T0	0	Start Message
2	T3	T2	0	Normal Transfer
3	T5	T4	0	Normal Transfer
4	S1	S0	0	Normal Transfer
5	S3	S2	0	Normal Transfer
6	I1	I0	1	End Packet
7	0	0	1	End Message

Table 1684. Direct branch message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	0	0	0	0	I1	I0	S3	S2	1	1	End Packet/End Message
3	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message

[Table 1685](#) illustrates an example Data Write Message with 8 MDO / 1 MSEO configuration, and [Table 1686](#) illustrates the same DWM with 8 MDO / 2 MSEO configuration

Note that T0, A0, D0 are the least significant bits where:

- Tx = TCODE number (fixed)
- Sx = Source processor (fixed)
- MAP = (always set to 0)
- Zx = Data size (fixed)
- Ax = Unique portion of the address (variable)
- Dx = Write data (variable 8-, 16- or 32-bit)

Table 1685. Data write message example (8 MDO / 1 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b	State
0	X	X	X	X	X	X	X	X	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	0	Normal Transfer
4	0	0	0	0	0	0	0	0	1	End Packet
5	0	0	0	0	0	0	0	0	1	End Message

Table 1686. Data write message example (8 MDO / 2 MSEO)

Clock	nex_mdo[7:0]								nex_mseo_b[1:0]		State
0	X	X	X	X	X	X	X	X	1	1	Idle (or end of last message)
1	S1	S0	T5	T4	T3	T2	T1	T0	0	0	Start Message
2	A0	Z3	Z2	Z1	Z0	0	S3	S2	0	1	End Packet
3	D7	D6	D5	D4	D3	D2	D1	D0	1	1	End Packet/ End Message

74.22 Electrical characteristics

For all electrical characteristics related to core processor and Nexus 3 operation, please refer to the SPC57EM80xx Data Sheet.

74.23 IEEE 1149.1 (JTAG) RD/WR sequences

This section contains example JTAG/OnCE sequences used to access resources.

74.23.1 JTAG sequence for accessing internal Nexus registers

Table 1687. Accessing internal Nexus 3 registers via JTAG/OnCE

Step #	TMS Pin	Description
1	1	IDLE → SELECT-DR_SCAN
2	0	SELECT-DR_SCAN → CAPTURE-DR (Nexus Command Register value loaded in shifter)
3	0	CAPTURE-DR → SHIFT-DR
4	0	(7) TCK clocks issued to shift in direction (rd/wr) bit and first 6 bits of Nexus reg. addr.
5	1	SHIFT-DR → EXIT1-DR (7th bit of Nexus reg. shifted in)
6	1	EXIT1-DR → UPDATE-DR (Nexus shifter is transferred to Nexus Command Register)
7	1	UPDATE-DR → SELECT-DR_SCAN
8	0	SELECT-DR_SCAN → CAPTURE-DR (Register value is transferred to Nexus shifter)
9	0	CAPTURE-DR → SHIFT-DR
10	0	(31) TCK clocks issued to transfer register value to TDO pin while shifting in TDI value
11	1	SHIFT-DR → EXIT1-DR (MSB of value is shifted in/out of shifter)
12	1	EXIT1-DR → UPDATE -DR (if access is write, shifter is transferred to register)
13	0	UPDATE-DR → RUN-TEST/IDLE (transfer complete — Nexus controller to Reg. Select state)

74.23.2 JTAG sequence for read access of memory-mapped resources

Table 1688. Accessing memory-mapped resources (reads)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Address Register (RWA)
2	37	Write RWA (initialize starting read address — data input on TDI)
3	13	Nexus Command = write to Read/Write Control/Status Register (RWCS)
4	37	Write RWCS (initialize read access mode and CNT value — data input on TDI)
5	—	Wait for falling edge of nex_rdy_b or nex_err_b pin
6	13	Nexus Command = read Read/Write Access Data Register (RWD)
7	37	Read RWD (data output on TDO)
8	—	If CNT > 0, go back to Step #5

74.23.3 JTAG sequence for write access of memory-mapped resources

Table 1689. Accessing memory-mapped resources (writes)

Step #	TCLK clocks	Description
1	13	Nexus Command = write to Read/Write Access Control/Status Register (RWCS)
2	37	Write RWCS (initialize write access mode and CNT value — data input on TDI)
3	13	Nexus Command = write to Read/Write Address Register (RWA)
4	37	Write RWA (initialize starting write address — data input on TDI)
5	13	Nexus Command = read Read/Write Access Data Register (RWD)
6	37	Write RWD (data output on TDO)
7	—	Wait for falling edge of nex_rdy_b or nex_err_b pin
8	—	If CNT > 0, go back to Step #5

75 e200z425n3 Nexus 3 Module

The e200z425n3 Nexus 3 module provides real-time development capabilities for corresponding core processors in compliance with the IEEE-ISTO 5001 standard. This module provides development support capabilities without requiring the use of address and data pins for internal visibility.

A portion of the pin interface (the JTAG port) is also shared with the OnCE / Nexus 1 unit. The IEEE-ISTO 5001 standard defines an extensible auxiliary port that is used in conjunction with the JTAG port in these processors.

75.1 Introduction

75.1.1 General Description

This chapter defines the auxiliary pin functions, transfer protocols and standard development features of a Class 3 device in compliance with the IEEE-ISTO 5001 standard. The development features supported are Program Trace, Data Trace, Watchpoint Messaging, Ownership Trace, Data Acquisition Messaging, and Read/Write Access via the JTAG interface. The Nexus 3 module also supports two Class 4 features: Watchpoint Triggering, and Processor Overrun Control.

75.1.2 Terms and Definitions

[Table 1690](#) contains a set of terms and definitions associated with the Nexus 3 module.

Table 1690. Terms and Definitions

Term	Description
IEEE-ISTO 5001	Consortium & standard for real-time embedded system design. World wide Web documentation at http://www.ieee-isto.org/Nexus5001
Auxiliary Port	Refers to Nexus auxiliary port. Used as auxiliary port to the IEEE 1149.1 JTAG interface.
Branch Trace Messaging (BTM)	Visibility of addresses for taken branches and exceptions, and the number of sequential instructions executed between each taken branch.
Data Read Message (DRM)	External visibility of data reads to memory-mapped resources.
Data Write Message (DWM)	External visibility of data writes to memory-mapped resources.
Data Trace Messaging (DTM)	External visibility of how data flows through the embedded system. This may include DRM and/or DWM.
Data Acquisition Messaging (DQM)	Data Acquisition Messaging (DQM) allows code to be instrumented to export customized information to the Nexus Auxiliary Output Port.
JTAG Compliant	Device complying to IEEE 1149.1 JTAG standard
JTAG IR & DR Sequence	JTAG Instruction Register (IR) scan to load an opcode value for selecting a development register. The JTAG IR corresponds to the OnCE command register (OCMD). The selected development register is then accessed via a JTAG Data Register (DR) scan.

Table 1690. Terms and Definitions (continued)

Term	Description
Nexus1	The (OnCE) debug module. This module integrated with each processor provides all static (core halted) debug functionality. This module is compliant with Class1 of the IEEE-ISTO 5001 standard.
Ownership Trace Message (OTM)	Visibility of process/function that is currently executing.
Public Messages	Messages on the auxiliary pins for accomplishing common visibility and controllability requirements
SoC	“System-on-a-Chip”. SoC signifies all of the modules on a single die. This generally includes one or more processors with associated peripherals, interfaces & memory modules.
Standard	The phrase “according to the standard” is used to indicate according to the IEEE-ISTO 5001 standard.
Transfer Code (TCODE)	Message header that identifies the number and/or size of packets to be transferred, and how to interpret each of the packets.
Watchpoint	A Data or Instruction Breakpoint or other debug event that does not cause the processor to halt. Instead, a pin is used to signal that the condition occurred. A Watchpoint Message may also be generated.

75.1.3 Feature List

The Nexus 3 module is compliant with Class 3 of the IEEE-ISTO 5001 standard, with additional Class 4 features available. The following features are implemented:

- Program Trace via Branch Trace Messaging (BTM). Branch trace messaging displays program flow discontinuities (direct and indirect branches, exceptions, etc.), allowing the development tool to interpolate what transpires between the discontinuities. Thus static code may be traced.
- Data Trace via Data Write Messaging (DWM) and Data Read Messaging (DRM). This provides the capability for the development tool to trace reads and/or writes to selected internal memory resources.
- Ownership Trace via Ownership Trace Messaging (OTM). OTM facilitates ownership trace by providing visibility of which process ID or operating system task is activated.

An Ownership Trace Message is transmitted when a new process/task is activated, allowing the development tool to trace ownership flow.

- Run-time access to embedded processor memory map via the JTAG port. This allows for enhanced download/upload capabilities.
- Watchpoint Messaging via the auxiliary pins
- Watchpoint Trigger enable of Program and/or Data Trace Messaging
- External hardware trigger inputs to independently enable/disable Program Trace, Data Trace, Ownership Trace, and Watchpoint Trace Messaging
- Auxiliary interface for higher data input/output
 - Configurable (min/max) Message Data Out pins (**nex_mdo[n:0]**)
 - One (1) or two (2) Message Start/End Out pins (**nex_mseo_b[1:0]**)
 - One (1) Read/Write Ready pin (**nex_rdy_b**) pin
 - One (1) Read/Write Error pin (**nex_err_b**) pin
 - One (1) Watchpoint Event output pin (**nex_evto_b**)
 - Four (4) additional Watchpoint Event output pins (**nex_wevto[3:0]**) for SoC use
 - One (1) Event In pin (**nex_evti_b**)
 - One (1) MCKO (Message Clock Out) pin
- Registers for Program Trace, Data Trace, Ownership Trace and Watchpoint Trigger.
- All features controllable and configurable via the JTAG port
- Conditional software control of the module via SoC signaling input (**nex_sfwcntl_en**)

Note: For multi-Nexus implementations, the configuration of the Message Data Out pins is controlled by the Port Control Register (@ the SoC level). For single Nexus implementations (not normally implemented on an SoC), this configuration is controlled by Development Control Register 1 (DC1) within the Nexus 3 module.

In either implementation, Full Port Mode (FPM — maximum number of MDO pins) or Reduced Port Mode (RPM — minimum number of MDO pins) are supported. This setting should not be changed while the system is running.

Note: The configuration of the Message Start/End Out pins (1 or 2) is determined at the SOC integration level. This option will be hard-wired based on SOC bandwidth requirements.

75.1.4 Functional Block Diagram

Figure 1820. Nexus 3 functional block diagram

75.2 Enabling Nexus 3 Operation

The Nexus module is enabled by loading a single instruction (*NEXUS3-ACCESS*) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus3 module, the OCMD value is 0b0001111100. The Nexus 3 module may alternately be enabled if the nex_evti_b input signal is asserted at the time that j_trst_b is initially negated, or is asserted during the

Test-Logic-Reset TAP state. Once enabled, the module will be ready to accept control input via the JTAG/OnCE pins.

Enabling the Nexus 3 module automatically enables the generation of Debug Status Messages.

The Nexus 3 module is disabled when the JTAG state machine initially reaches the Test-Logic-Reset state from any other state. This state can be reached by the assertion of the **j_trst_b** pin or by cycling through the state machine using the **j_tms** pin. The Nexus module will also be disabled if a Power-on-Reset (POR) event occurs. If the Nexus 3 module is disabled, no trace output will be provided, and the module will disable (drive inactive) auxiliary port output pins (**nex_mdo[n:0]**, **nex_mseo[1:0]**, **nex_mcko**). Nexus registers will not be available for reads or writes.

In order to support software control of the Nexus 3 module when no external development tool is present, the Nexus 3 module is not forced to be disabled when the JTAG state remains in the Test-Logic-Reset state. Software is allowed to control the Nexus 3 module when the input signal **nex_sfwcntl_en** is asserted by the SoC. This signal is intended to provide a mechanism for allowing software to use the Nexus 3 module to fill on-chip trace buffers or other visibility mechanisms. It is up to the SoC to determine whether a top-level Nexus 3 controller has been enabled by a hardware debugger, or whether appropriate security mechanisms have granted the capability for software to use these resources, and to drive the appropriate value to the **nex_sfwcntl_en** input. Software can enable the module by a write to any of the module's DCRs when **nex_sfwcntl_en** is asserted.

Reset of the Nexus 3 module is accomplished by a transition on **j_trst_b**, on initial entry into the Test-Logic-Reset state from another state, or if a Power-on-Reset (POR) event occurs. The module is not reset by the CPU's **p_reset_b** signal, even when software has control of the module.

75.2.1 Interaction with Low Power Modes

The Nexus 3 module will continue to operate in the Waiting and Halted states, as long as **nex_clk** remains active. In the Stopped state, **nex_clk** is gated off internally to the Nexus 3 logic, therefore watchpoint or hardware triggering recognition, message generation, and Nexus 3 read-write access to memory is suspended. The Nexus 3 logic will wait to enter the Stopped state until the message FIFOs are empty and any in-progress Nexus R/W transfer has completed. If a block transfer has been requested, the remainder of the block transfer is not completed, and the RWCS AC bit is cleared, and the ERR bit is set. Once the Stopped state has been entered, no further messages are queued and no triggering conditions are monitored. Also, Nexus R/W accesses are no longer available. Upon exiting the Stopped state, normal functions will resume assuming **nex_clk** is active.

75.3 TCODEs supported

The Nexus 3 pins allow for flexible transfer operations via Public Messages. A TCODE defines the transfer format, the number and/or size of the packets to be transferred, and the purpose of each packet. The IEEE-ISTO 5001-2003 standard defines a set of public messages and allocates additional TCODEs for vendor-specific features outside the scope of the public messages. The Nexus 3 block supports the TCODEs shown in [Table 1691](#).

Table 1691. Supported TCODEs

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Debug Status	6	6	TCODE	fixed	TCODE number = 0
	4	4	SRC	fixed	source processor identifier
	8	8	STATUS	fixed	Development Status Register (DS[31:24])
Ownership Trace Message	6	6	TCODE	fixed	TCODE number = 2
	4	4	SRC	fixed	source processor identifier
	1	32	PROCESS	variable	Task/Process ID tag
Program Trace — Direct Branch Message	6	6	TCODE	fixed	TCODE number = 3
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
Program Trace — Indirect Branch Message	6	6	TCODE	fixed	TCODE number = 4
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
Data Trace — Data Write Message	6	6	TCODE	fixed	TCODE number = 5
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 1696)
	1	32	U-ADDR	variable	unique portion of the data write address
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace — Data Read Message	6	6	TCODE	fixed	TCODE number = 6
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 1696)
	1	32	U-ADDR	variable	unique portion of the data read address
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)

Table 1691. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Acquisition Message	6	6	TCODE	fixed	TCODE number = 7
	4	4	SRC	fixed	source processor identifier
	8	8	DQTAG	fixed	identification tag taken from DEVENT _{DQTAG} register field
	1	32	DQDATA	variable	exported data taken from DDAM register
Error Message	6	6	TCODE	fixed	TCODE number = 8
	4	4	SRC	fixed	source processor identifier
	4	4	ETYPE	fixed	error type
	8	8	ECODE	fixed	error code
Program Trace — Synchronization Message	6	6	TCODE	fixed	TCODE number = 9
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow. Cleared for most sync conditions.
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
Program Trace — Direct Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 11
	4	4	SRC	fixed	source processor identifier
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)
Program Trace — Indirect Branch Message w/ Sync	6	6	TCODE	fixed	TCODE number = 12
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	ICNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zeros truncated)

Table 1691. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Data Trace — Data Write Message w/ Sync	6	6	TCODE	fixed	TCODE number = 13
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 1696)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data write value(s) (see Data Trace section for details)
Data Trace — Data Read Message w/ Sync	6	6	TCODE	fixed	TCODE number = 14
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	4	4	DSZ	fixed	data size (Refer to Table 1696)
	1	32	F-ADDR	variable	full access address (leading zeros truncated)
	1	64	DATA	variable	data read value(s) (see Data Trace section for details)
Watchpoint Message	6	6	TCODE	fixed	TCODE number = 15
	4	4	SRC	fixed	source processor identifier
	1	32	WPHIT	variable	Field indicating watchpoint source(s) (leading zeros truncated)
Resource Full Message	6	6	TCODE	fixed	TCODE number = 27
	4	4	SRC	fixed	source processor identifier
	4	4	RCODE	fixed	resource code (Refer to Table 1694) — indicates which resource is the cause of this message
	1	32	RDATA	variable	branch / predicate instruction history (See Section 75.12.4, Resource Full Messages.)
Program Trace — Indirect Branch History Message	6	6	TCODE	fixed	TCODE number = 28 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	U-ADDR	variable	unique part of target address for taken branches/exceptions
	1	32	HIST	variable	branch / predicate instruction history (see Section 75.12.1, Branch Trace Messaging types)

Table 1691. Supported TCODEs (continued)

Message Name	Min Field Size (bits)	Max Field Size (bits)	Field Name	Field Type	Field Description
Program Trace — Indirect Branch History Message w/ Sync	6	6	TCODE	fixed	TCODE number = 29 (see Note below)
	4	4	SRC	fixed	source processor identifier
	1	1	MAP	fixed	(always set to 0)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	F-ADDR	variable	full target address (leading zero (0) truncated)
	1	32	HIST	variable	branch / predicate instruction history (See Section 75.12.1, Branch Trace Messaging types.)
Program Trace — Program Correlation Message	6	6	TCODE	fixed	TCODE number = 33
	4	4	SRC	fixed	source processor identifier
	4	4	EVCODE	fixed	event correlated w/ program flow (Refer to Table 1695)
	2	2	CDF	fixed	# fields of information in CDATA. 00 — reserved, 01 — one field (CDATA1) (reserved), 10 — two fields (CDATA1 + CDATA2), 11 — three fields (reserved)
	1	8	I-CNT	variable	# sequential instructions completed since last predicate instruction, transmitted instruction count, or taken change of flow
	1	32	CDATA1	variable	correlation data field 1 — [branch / predicate instruction history] (See Section 75.12.5, Program Correlation Messages.)
	0	32	CDATA2	variable	correlation data field 2— PID info (See Section 75.12.5, Program Correlation Messages.)

Note: Program Trace can be implemented using either Branch History/Predicate Instruction Messages, or traditional Direct/Indirect Branch Messages. The user can select between the two types of Program Trace. The advantages for each are discussed in [Section 75.12.1, Branch Trace Messaging types](#). If the Branch History method is selected, the shaded TCODEs above will not be messaged out.

[Table 1692](#) shows the error code encodings used when reporting an error via the Nexus 3 Error Message.

Table 1692. Error Code (ECODE) Encoding (TCODE = 8)

Error Code	Description
xxxxxx1	Watchpoint Trace Message(s) Lost
xxxxxx1x	Data Trace Message(s) Lost
xxxxxx1xx	Program Trace Message(s) Lost

Table 1692. Error Code (ECODE) Encoding (TCODE = 8) (continued)

Error Code	Description
xxxx1xxx	Ownership Trace Message(s) Lost
xxx1xxxx	Status Message(s) Lost (Debug Status messages, etc.)
xx1xxxxx	Data Acquisition Message(s) Lost
x1xxxxxx	Reserved
1xxxxxxx	Reserved

[Table 1693](#) shows the error type encodings used when reporting an error via the Nexus 3 Error Message.

Table 1693. Error Type (ETYPE) Encoding (TCODE = 8)

Error Type	Description
0000	Message Queue Overrun caused one or more messages to be lost
0001	Contention with higher priority messages caused one or more messages to be lost
0010	Reserved
0011	Reserved
0100	Reserved
0101	Invalid access opcode (Nexus Register unimplemented)
0110 – 1111	Reserved

[Table 1694](#) shows the encodings used for resource codes for certain messages.

Table 1694. Resource Code (RCODE) values (TCODE = 27)

Resource Code	Description
0000	Program Trace Instruction counter reached 255 and was reset.
0001	Program Trace, Branch / Predicate Instruction History full. This type of packet is terminated by a stop bit set to 1 after the last history bit.

[Table 1695](#) shows the event code encodings used for certain messages.

Table 1695. Event Code (EVCODE) Encoding (TCODE = 33)

Event Code	Description
0000	Entry into Debug Mode
0001	Entry into Low Power Mode (CPU only)
0010–0011	Reserved for future functionality
0100	Disabling Program Trace
0101	Process ID value is established in PID0/NPIDR via mtspr PID0/NPIDR

Table 1695. Event Code (EVCODE) Encoding (TCODE = 33) (continued)

Event Code	Description
0110–1000	Reserved for future functionality
1001	Begin masking of program trace messages due to $MSR_{PMM} = 0$ and $DC4_{PTMARK} = 1$
1010	Branch and link occurrence (direct branch function call)
1011–1111	Reserved for future functionality

[Table 1696](#) shows the data trace size encodings used for certain messages.

Table 1696. Data Trace Size (DSZ) Encodings (TCODE = 5,6,13,14)

DTM Size Encoding	Transfer Size
0000	0 — no data
0001	Byte
0010	Halfword (2 bytes)
0011	Three bytes
0100	Word (4 bytes)
0101	Five bytes
0110	Six bytes
0111	Seven bytes
1000	Doubleword (8 bytes)
1001–1111	Reserved

75.4 Nexus 3 Programmer's Model

This section describes the Nexus 3 programmers model. Nexus 3 registers are accessed using the JTAG/OnCE port in compliance with IEEE 1149.1, or by software via DCRs. See [Section 75.5, Nexus 3 Register Access via JTAG/OnCE](#) and [Section 75.6, Nexus 3 Register Access via Software](#) for details on Nexus 3 register access.

Note: Nexus 3 registers and output signals are numbered using bit 0 as the least significant bit. This bit ordering is consistent with the ordering defined by the IEEE-ISTO 5001 standard.

[Table 1697](#) details the register map for the Nexus 3 module.

Table 1697. Nexus 3 Register Map

Nexus Register	Nexus Access Opcode	Read/Write	Read Address	Write Address	DCR # ⁽¹⁾
Client Select Control (CSC) ⁽²⁾	0x1	R	0x02	—

1. Software access via the **mfdcr** and **mtocr** instructions use these values for the DCR number. Software writes to these registers via **mtocr** when **nex_sfvcnt1_en** is negated are ignored.
2. The CSC and PCR registers are shown in this table as part of the Nexus programmer's model. They are only present at the top level SoC Nexus controller in a multi-Nexus implementation, not in the Nexus 3 module. The SoC's CSC Register is readable through Nexus, but the PCR is shown for reference only here.
3. The "PCR_INDEX" is a parameter determined by the SoC.

75.4.1 Client Select Control (CSC) register

The CSC Register determines which Nexus client is under development. This register is present at the top-level SOC Nexus 3 controller to select one of multiple on-chip Nexus 3 units.

Figure 1821. Client Select Control (CSC) register

Table 1698. CSC field descriptions

Bits	Description
CSC[7:4]	Reserved for future Nexus Clients (read as 0)
CSC[3:0]	Client Select Control 0xx Nexus client (SoC level)

75.4.2 Port Configuration Register (PCR) — reference only

The Port Configuration Register (PCR) controls the basic port functions for all Nexus modules in a multi-Nexus environment. This includes clock control and auxiliary port width. All bits in this register are writable only once after system reset.

Figure 1822. Port Configuration Register (PCR)

Table 1699. PCR field descriptions

Bit	Name	Description
31	OPC	Output Port Mode Control (SoC Level) 0 Reduced Port Mode configuration (min# nex_mdo[n:0] pins defined by SOC) 1 Full Port Mode configuration (max# nex_mdo[n:0] pins defined by SOC)
30	—	Reserved for future functionality
29	MCK_EN	MCKO Clock Enable (SoC Level) 0 nex_mcko is disabled 1 nex_mcko is enabled

Table 1699. PCR field descriptions (continued)

Bit	Name	Description
28:26	MCK_DIV	MCKO Clock Divide Ratio (see note below) (SoC Level) 000 nex_mcko is 1x processor clock freq. 001 nex_mcko is 1/2x processor clock freq. 010 Reserved (default to 1/2x processor clock freq.) 011 nex_mcko is 1/4x processor clock freq. 100 Reserved (default to 1/2x processor clock freq.) 101 Reserved (default to 1/2x processor clock freq.) 110 Reserved (default to 1/2x processor clock freq.) 111 nex_mcko is 1/8x processor clock freq.
25:0	—	Reserved for future functionality

Note: The CSC and PCR Registers exist in a separate module at the SoC level in a multi-Nexus environment. If the core Nexus 3 module is the only Nexus module, these registers are not implemented and the Nexus 3 defined Development Control Register 1 (DC1) is used to control the SoC-level Nexus port functionality.

75.4.3 Nexus Development Control Register 1 (DC1)

Nexus Development Control Register 1 is used to control the basic development features of the Nexus 3 module. Development Control Register 1 is shown in [Figure 1823](#) and its fields are described in [Table 1700](#).

Figure 1823. Development Control 1 (DC1) register

OPC	MCK_DIV	0	PTM	0	OTS	0	POTD	TSEN	EOC	EIC	0	TM																			
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# 0x2; DCR: 368; Read/Write; Reset: 0x0

Table 1700. DC1 field descriptions

Bits	Name	Description
31	OPC	Output Port Mode Control 0 — Reduced Port Mode configuration (min# nex_mdo[n:0] pins defined) 1 — Full Port Mode configuration (max# nex_mdo[n:0] pins defined)
30:29	MCK_DIV	MCKO Clock Divide Ratio (see note below) 00 — nex_mcko is 1x processor clock freq. 01 — nex_mcko is 1/2x processor clock freq. 10 — nex_mcko is 1/4x processor clock freq. 11 — nex_mcko is 1/8x processor clock freq.
28	—	Reserved for future functionality
27	PTM	Program Trace Method 0 — Program Trace uses traditional Branch Messages 1 — Program Trace uses Branch History Messages

Table 1700. DC1 field descriptions (continued)

Bits	Name	Description
26:25	—	Reserved for future functionality

26:15	—	Reserved for future functionality
14	POTD	Periodic Ownership Trace Disable 0 — Periodic Ownership Trace message events are enabled 1 — Periodic Ownership Trace message events are disabled
13:12	TSEN	Timestamp Enable — (not implemented, write to 00) 00 — Timestamp is disabled
11:10	EOC	EVTO Control 00 — nex_evto_b upon occurrence of Watchpoints (configured in DC2 and DC3) 01 — nex_evto_b upon entry into Debug Mode 1x — Reserved
9:8	EIC	EVTI Control 00 — nex_evti_b is used for synchronization (Program Trace Sync msg is generated) 01 — nex_evti_b is used for Debug request 10 — nex_evti_b is disabled 1x — Reserved
7:6	—	Reserved for future functionality
5:0	TM	Trace Mode ⁽¹⁾ 000000 — All Trace Disabled xxxxx1 — Ownership Trace enabled xxxx1x — Data Trace enabled xxx1xx — Program Trace enabled xx1xxx — Watchpoint Trace enabled x1xxxx — Reserved 1xxxxx — Data Acquisition Trace enabled

1. This field may be updated by hardware in response to watchpoint triggering or external hardware trigger inputs if not already enable for tracing by a previous direct write to DC1. Direct writes to this field to enable one or more trace types take precedence over hardware updates. Refer to [Section 75.4.7, Watchpoint Trigger \(WT, PTSTC, PTETC, DTSTC, DTETC\) registers](#) for more information on watchpoint triggering. Refer to [Section 75.16, External Hardware Trigger Controls](#) for more information on external hardware triggering.

Note: The Output Port Mode Control bit (OPC) and MCKO Clock Divide Ratio bits (MCK_DIV) **MUST ONLY** be modified during system reset or debug mode to insure correct output port and output clock functionality. It is also recommended that all other bits of the DC1 also only be modified in one of these two modes.

75.4.4 Nexus Development Control Registers 2 & 3 (DC2, DC3)

Nexus Development Control Registers 2 and 3 are used to control output signaling on the Nexus 3 module. A table of watchpoints can be found in the Core (e200z425n3) Core Debug Support chapter.

Development Control Register 2 is shown in [Figure 1824](#) and its fields are described in [Table 1701](#).

1. EOC bits in DC1 must be programmed to trigger EVTO on Watchpoint occurrence for EWC bits to have any effect.

75.4.5 Nexus Development Control Register 4 (DC4)

Nexus Development Control Register 4 is used to control mark selection for Program and Data Trace Messaging, as well as masking of events that initiate Program Correlation Messages on the Nexus 3 module.

Development Control Register 4 is shown in [Figure 1826](#) and its fields are described in [Table 1703](#).

Figure 1826. Development Control 4 (DC4) register

75.4.6 Development Status Register (DS)

The Development Status Register is used to report system debug status. When Debug Mode is entered or exited, or an SoC- or core-defined Low Power Mode is entered (see note below), a Debug Status Message is transmitted with DS[31:24]. The external tool can read this register at any time.

Figure 1827. Development Status (DS) register

DBG	LPS	LPC	0																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

25:0	—	Reserved for future functionality (read as 0)

75.4.7 Watchpoint Trigger (WT, PTSTC, PTETC, DTSTC, DTETC) registers

The Watchpoint Trigger Registers allows the watchpoints defined within the Nexus1 logic to trigger actions. These watchpoints can control Program and/or Data Trace enable and disable. The control bits can be used to produce a related “window” for triggering Trace Messages. Watchpoint trigger register WT is used to control triggering by a single selected watchpoint. The Program Trace Start Trigger Control (PTSTC), Program Trace End Trigger Control (PTETC), Data Trace Start Trigger Control (DTSTC), and Data Trace End Trigger Control (DTETC) are used for extended trigger controls for the respective function. If multiple watchpoints are desired for triggering, or a watchpoint beyond watchpoint #13 is required, then one or more of the extended watchpoint trigger registers may be used. A field encoding of 4'b1111 in one of the WT register fields enables the corresponding extended trigger register. For all other WT field encodings, the corresponding extended trigger register is disabled and the contents are ignored. Note that direct writes to enable program trace and/or data trace in DC1 will override these controls, and trace will remain enabled until another direct write to DC1 to disable program and/or data trace occurs.

When a start trigger is detected, the designated trace features become enabled, and the corresponding enable bits of the DC1 register are set. Whenever a stop trigger is detected, the designated trace features become disabled, and the corresponding enable bits of the DC1 register are cleared. If the same trigger condition is used for both start and stop triggering, then the designated trace features will toggle between being enabled and disabled at each occurrence of the trigger condition. Similarly, if start and stop triggers for a trace feature occur simultaneously, then the designated trace feature will toggle between enabled and disabled depending on the enable state at the time of the trigger events. For

example, if tracing is enabled, and a start and stop trigger occur simultaneously, then tracing will be disabled. Direct writes of the DC1 register take precedence over any trace feature enable state that is derived from watchpoint triggering. A table of watchpoints can be found in the Core (e200z425n3) Core Debug Support chapter.

75.4.10 Data Trace Control (DTC) register

The Data Trace Control Register controls whether DTM Messages are restricted to reads, writes, or both for a user programmable address range. In addition, control is provided to restrict data trace message generation to only those load or store accesses that are not stack-related, in order to minimize required data trace message bandwidth.

There are four Data Trace channels controlled by the DTC for the Nexus 3 module. Channels can be programmed to trace data accesses or instruction accesses, but not independently.

Figure 1836. Data Trace Control (DTC) register

Table 1711. DTC field descriptions (continued)

Bits	Name	Description
12	STDC4	Stack Trace Disable Control 4 0 Tracing of stack accesses are not disabled for range 4 1 Tracing of stack accesses are disabled for range 4; data accesses using GPR R1 in effective address computations are not traced and do not generate data range watchpoint outputs
11:8	—	Reserved for future functionality (read as 0)
7	RC1	Range Control 1 0 Condition trace on address within range 1 Condition trace on address outside of range
6	RC2	Range Control 2 0 Condition trace on address within range 1 Condition trace on address outside of range
5	RC3	Range Control 3 0 Condition trace on address within range 1 Condition trace on address outside of range
4	RC4	Range Control 4 0 Condition trace on address within range 1 Condition trace on address outside of range
3	DI	Data Access / Instruction Access Trace 0 Condition trace on data accesses 1 Condition trace on instruction accesses <i>Note: The support for monitoring instruction accesses is not guaranteed to be present in all versions of the Nexus 3 module.</i> <i>Note: The setting of the DI bit also affects the information provided on the data trace port outputs (See the “Data Trace Port Signals” section in the Core (e200z425n3) Core Debug Support chapter.)</i>
2:0	—	Reserved for future functionality (read as 0)

75.4.11 Data Trace Start Address Registers (DTSA1–4)

The Data Trace Start Address Registers define the start addresses for each trace channel.

Figure 1837. Data Trace Start Address 1 (DTSA1) register

[Table 1712](#) illustrates the range that will be selected for Data Trace for various cases of DTSA being less than, greater than, or equal to DTEA.

Table 1712. Data trace — address range options

Programmed values	Range Control Bit Value	Range Selected
DTSA < DTEA	0	DTSA → ← DTEA
DTSA < DTEA	1	← DTSA DTEA →
DTSA > DTEA	N/A	Invalid Range — no trace
DTSA = DTEA	N/A	Invalid Range — no trace

Note: DTSA must be less than DTEA in order to guarantee correct Data Write/Read Traces. Data Trace ranges are inclusive of the DTSA and DTEA addresses for Range Control settings indicating “within range,” and are exclusive of the DTSA and DTEA addresses for Range Control settings indicating “outside of range.”

Accesses that meet the range and access type qualifiers will cause assertion of a watchpoint output for Ranges 1, 2, and 3. There are three dedicated watchpoint outputs, one for each DTSA/DTEA sets 1, 2, and 3. Range 4 does not provide a watchpoint output. Note that when $DTC_{DI} = 1$, all instruction fetches and prefetches (including discarded prefetches) are monitored, and thus these range watchpoints differ from the IACx watchpoint outputs, which are not asserted for instructions that are not executed (i.e. when the instruction prefetch is discarded).

75.4.13 Read/Write Access Control/Status (RWCS) register

The Read Write Access Control/Status Register provides control for Read/Write Access. Read/Write access provides DMA-like access to memory-mapped resources on the AHB System bus either while the processor is halted, or during runtime. Control is provided over access type, size, count, and certain bus attributes. Note that the internal CPU interfaces to the caches and local memory are not accessible or utilized by this mechanism. Since the external interface is used, base address port settings are used to access local memory, and not the settings of local memory control register base address values. The RWCS Register also provides Read/Write Access Status information per [Table 1714](#).

Figure 1845. Read/Write Access Control/Status (RWCS) register

AC	RW	SZ		MAP		PR		ATTR		0		CNT																ERR	DV		
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# 0x7; Read/Write⁽¹⁾; Reset: 0x0

1. ERR and DV are read-only

Table 1713. RWCS field descriptions

Bits	Name	Description
RWCS[31]	AC	Access Control 0 End access/ Access has completed 1 Start access

RWCS[0]	DV ⁽²⁾	Read/Write Access Data Valid (see Table 1714)

1. The priority functionality is not currently implemented.
2. ERR and DV are read-only.

Table 1714. Read/Write Access Status Bit Encoding

Read Action	Write Action	ERR	DV
Read Access has not completed	Write Access completed without error	0	0
Read Access error has occurred	Write Access error has occurred	1	0
Read Access completed without error	Write Access has not completed	0	1
Not Allowed	Not allowed	1	1

75.4.14 Read/Write Access Data (RWD) register

The Read/Write Access Data (RWD) register provides the data to/from system bus memory-mapped locations when initiating a read or a write access.

Figure 1846. Read/Write Access Data (RWD) register

Read/Write Data																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Nexus Reg# 0xA; Read/Write; Reset: 0x0																															

Read/Write accesses to the AHB require that the debug firmware properly retrieve/place the data in the RWD. [Table 1715](#) shows the proper placement of data into the RWD. Note that doubleword transfers require two passes through RWD.

Table 1715. RWD data placement for transfers

Transfer Size and byte offset	RWA(2:0)	RWCS[SZ]	RWD			
			31:24	23:16	15:8	7:0
Byte	x x x	0 0 0	—	—	—	X
Half	x x 0	0 0 1	—	—	X	X
Word	x 0 0	0 1 0	X	X	X	X
Doubleword						
first RWD pass (low order data)	0 0 0	0 1 1	X	X	X	X
second RWD pass (high order data)			X	X	X	X

Table Notes:

“X” indicates byte lanes with valid data

“—” indicates byte lanes that will contain unused data.

[Table 1716](#) shows the mapping of RWD bytes to byte lanes of the AHB read and write data buses.

Table 1716. RWD byte lane mapping

Transfer Size and byte offset	RWA(2:0)	RWD			
		31:24	23:16	15:8	7:0

second RWD pass					

Table Notes:
 “—” indicates byte lanes that will contain unused data.

75.4.15 Read/Write Access Address (RWA)

The Read/Write Access Address Register provides the system bus address to be accessed when initiating a read or a write access.

Figure 1847. Read/Write Access Address (RWA) register

Read/Write Address																															
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Nexus Reg# 0x9; Read/Write; Reset: 0x0

75.5 Nexus 3 Register Access via JTAG/OnCE

Access to Nexus 3 register resources is enabled by loading a single instruction (“NEXUS3-ACCESS”) into the JTAG Instruction Register (IR) (OnCE OCMD register). For the Nexus 3 block, the OCMD value is 0b0001111100.

Once the NEXUS3-ACCESS instruction has been loaded, the JTAG/OnCE port allows tool/target communications with all Nexus 3 registers according to the register map in [Table 1697](#).

Reading/writing of a Nexus 3 register then requires two (2) passes through the Data-Scan (DR) path of the JTAG state machine. (See [Section 75.23, IEEE 1149.1 \(JTAG\) RD/WR sequences](#).)

1. The first pass through the DR selects the Nexus 3 register to be accessed by providing an index (see [Table 1697](#)), and the direction (read/write). This is achieved by loading an 8-bit value into the JTAG Data Register (DR). This register has the following format:

Figure 1848. JTAG DR format

Table 1717. JTAG DR field descriptions

Nexus Register Index	Selected from values in Table 1697
Read/Write (R/W)	0 Read 1 Write

2. The second pass through the DR then shifts the data in or out of the JTAG port, LSB first.
- a) During a read access, data is latched from the selected Nexus register when the JTAG state machine passes through the “Capture-DR” state.

b) During a write access, data is latched into the selected Nexus register when the JTAG state machine passes through the “Update-DR” state.

75.6 Nexus 3 Register Access via Software

Access to most Nexus 3 register resources by software is supported by mapping the Nexus 3 registers to privileged DCRs (device control registers) that are accessible via the **mfdcr** and **mtdcr** instructions. It is intended that these access only occur when no possible conflicts with hardware-based accesses are possible. A conflict between hardware and software accesses will produce undefined results. [Table 1697](#) shows the mappings of Nexus 3 registers to DCR numbers. Software writes to Nexus 3 register resources are blocked when the **nex_sfwcntl_en** input signal is negated, without signaling an exception. Note that the Nexus 3 Read/Write Access functionality is not available to software, since software can use load and store instructions to access memory.

75.7 Nexus Message Fields

Nexus messages are comprised of fields. Each field contains a distinct piece of information within a message, and each message contains multiple fields. Messages are transferred in packets over the Auxiliary Output protocol. A packet is a collection of fields. A packet may contain any number of fixed length fields, but may contain at most one variable length field. The variable length field must be the last field in a packet. The following sub-sections describe a subset of the message field types.

75.7.1 TCODE Field

The TCODE field is a 6-bit fixed length field that identifies the type of message and its format. The field encodings are assigned by IEEE-ISTO 5001.

75.7.2 Source ID Field (SRC)

Each Nexus module in a device is identified by a unique Client Source Identification Number. The number assigned to each Nexus module is determined by the SoC integrator, and is provided on the **nex3_ext_src_id[0:3]** input signals. Multi-threaded processors may assign additional source ID information to indicate which thread a message is associated with. The Nexus 3 module implements a 4-bit fixed length Source ID field consisting of a Client Source ID.

75.7.3 Relative Address Field (U-ADDR)

The non-sync forms of the Program and Data Trace messages include addresses that are relative to the address that was transmitted in the previous Program or Data Trace message, respectively. The relative address format is compliant with IEEE-ISTO 5001 and is designed to reduce the number of bits transmitted for address fields.

The relative address is generated by XORing the new address with the previous, and then using only the results up to the most significant '1'. To recreate the original address, the relative address is XORed with the previously decoded address.

The relative address of a Program Trace message is calculated with respect to the previous Program Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Program Trace messages.

The relative address of a Data Trace message is calculated with respect to the previous Data Trace message, regardless of any address information that may have been sent in any other trace messages in the interim between the two Data Trace messages.

Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

Previous Address (A1) = 0x0003FC01, New Address (A2) = 0x0003F365

Message Generation: A1 = 0000 0000 0000 0011 1111 1100 0000 0001 A2 = 0000 0000 0000 0011 1111 0011 0110 0101 $A1 \oplus A2 = 0000\ 0000\ 0000\ 0000\ 0000\ 1111\ 0110\ 0100$ Address Message (M1) = 1111 0110 0100 Address Re-creation: $A1 \oplus M1 = A2$ A1 = 0000 0000 0000 0011 1111 1100 0000 0001 M1 = 0000 0000 0000 0000 0000 1111 0110 0100 A2 = 0000 0000 0000 0011 1111 0011 0110 0101

Figure 1849. Relative address generation and recreation

75.7.4 Full Address Field (F-ADDR)

Program Trace synchronization messages provide the full address associated with the trace event (leading zeroes may be truncated) with the intent of providing a reference point for development tools to operate from when reconstructing relative addresses. Synchronization messages are generated at significant mode switches and are also generated periodically to ensure that development tools are guaranteed to have a reference address given a sufficiently large sample of trace messages. Program trace messages also provide the execution mode status in the least significant bit of the **reconstructed** address field. A value of '0' indicates that preceding instruction count and history information should be interpreted in a non-VLE context. A value of '1' indicates that the preceding instruction count and history information should be interpreted in a VLE context.

75.8 Nexus Message Queues

The Nexus 3 module implements internal message queues capable of storing up to three messages per cycle into a small initial queue, which then fills a larger queue at up to two messages per cycle. Messages that enter the queues are transmitted in the order in which they are received.

If more than three messages attempt to enter the queue in the same cycle, the highest priority messages are stored and the remaining message(s) will be dropped due to a collision. Collision events are expected to be rare.

The Overrun Control register (OVCR) controls the Nexus behavior as the message queue fills. The Nexus block may be programmed to:

- Allow the queue to overflow, drain the contents, queue an overrun error message and resume tracing.
- Stall the processor when the queue utilization reaches the selected threshold.
- Suppress selected message types when the queue utilization reaches the selected threshold.

75.8.1 Message Queue Overrun

In this mode, the message queue will stop accepting messages when an overrun condition is detected. The contents of the queues will be allowed to drain until empty. Incoming messages are discarded until the queue is emptied. Once empty, an overrun error message is enqueued that contains information about the types of messages that were discarded due to the overrun condition.

75.8.2 CPU Stall

In this mode, processor instruction issue is stalled when the queue utilization reaches the selected threshold. The processor is stalled long enough to drop one threshold level below the level that triggered the stall. For example, if stalling the processor is triggered at 1/4 full, the stall will stay in effect until the queue utilization drops to empty. There may be significant skid from the time that the stall request is made until the processor is able to stop completing instructions. This skid should be taken into consideration when programming the threshold. Refer to [Section 75.4.9, Nexus Overrun Control \(OVCR\) register](#), for complete programming options.

75.8.3 Message Suppression

In this mode, the message queue will disable selected message types when the queue utilization reaches the selected threshold. This allows lower bandwidth tracing to continue and possibly avoid an overrun condition. If an overrun condition occurs despite this message suppression, the queue will respond according to the behavior described in [Section 75.8.1, Message Queue Overrun](#). Suppressed message types are reported in the error message if they occur after overrun in addition to other discarded message types. Once triggered, message suppression will remain in effect until queue utilization drops to the threshold below the level selected to trigger suppression.

75.8.4 Nexus Message Priority

Nexus messages may be lost due to contention with other message types under the following circumstances:

- More than three messages are generated in the same cycle

[Table 1718](#) lists the various message types and their relative priority from highest to lowest.

Up to three message requests can be queued into the message buffer in a given cycle. If more than three message requests exist in a given cycle, the three highest priority message classes are queued into the message buffer. The remaining messages that did not successfully queue into the message buffer in that cycle will generate subsequent responses, as detailed in [Table 1718](#).

The CPU is capable of completing two instructions per cycle. If multiple trace messages need to be queued at the same time, they will be queued with the following priority: Instruction 0 (oldest instruction) (WPM → DQM → PCM_{PIDMSG} → OTM → BTM → DTM) → Instruction 1 (newer instruction) (WPM → DQM → OTM → BTM → DTM). As many as three messages may be simultaneously queued. Note that for the cycle following a dropped PTM, non-periodic OTM, or DQM message, only two other messages may be queued in addition to the dropped Error Message.

Watchpoint Messages from instructions that complete at the same time or events that occur during the same cycle will be combined.

Table 1718. Message Type Priority and Message Dropped Responses

Message Type	Message	Priority	Message Dropped Response
Error	Error	0 (highest)	N/A ⁽¹⁾
WP (Watchpoint Trace)	WPM (Watchpoint Message)	1	N/A ⁽¹⁾
DQ (Data Acquisition)	DQM (Data Acquisition Message)	2	DQM Error Message
Program Trace (PID MSG)	PCM — PID/NPIDR update (Program Correlation Message)	2	OTM Error Message
OT (Ownership)	OTM — PID/NPIDR update (Ownership Trace Message)	2	OTM Error Message ⁽²⁾
Program Trace	BTM (Branch Trace Message)	2	BTM Error Message, Sync upgrade next BTM
	Sync (Program Sync Message)	3	Sync upgrade next BTM
	RFM (Resource Full for Instruction counter or history buffer)	4	BTM Error Message Sync upgrade next BTM
	DS (Debug Status Message)	5	Sync upgrade next BTM
	PCM (Program Correlation Message)	6	BTM Error Message Sync upgrade next BTM
DT (Data Trace)	DTM (Data Trace Message)	7	Sync upgrade next DTM
OT (Ownership)	OTM — Periodic update (Ownership Trace Message)	8 (lowest)	none

1. Error and Watchpoint messages are not dropped due to collisions, due to their priority.
2. Message will always be dropped if program trace is enabled, and program correlation messages for PID messages are not masked (Event Code = 0101). No error message is sent for this case since the PID value is contained in the higher priority message.

75.8.5 Data Acquisition Message Priority Loss Response

If a Data Acquisition Message (DQM) loses arbitration due to contention with higher priority messages, an error message will be generated to indicate that a DQM has been lost due to contention.

75.8.6 Ownership Trace Message Priority Loss Response

If an Ownership Trace message (OTM) due to software updates to the Process ID state loses arbitration due to contention with higher priority messages other than a program correlation message with EVCODE = 0101 (PID update), an error message will be generated to indicate that a OTM has been lost due to contention. If the pending OTM is a periodic update, the event is dropped without generating an error message.

75.8.7 Program Trace Message Priority Loss Response

If a Program Trace message (PTM) loses arbitration due to contention with higher priority messages, and the discarded PTM is a Program Correlation message, a Resource Full message for instruction count or history buffer, or a Branch Trace message, then an Error message is generated to indicate that branch trace information has been lost, and the next Branch Trace message will be upgraded to a sync-type message.

If the discarded PTM is a Program Correlation message with PID information (EVCODE=0101), the Error message will indicate a dropped OTM and a dropped Program Trace (Error code = xxxx11xx).

75.8.8 Program Trace Sync Message Priority Loss Response

If a Program Trace Sync message (SYNC) loses arbitration due to contention with higher priority messages, the Sync event is discarded, and the next Branch Trace message will be upgraded to a sync-type message.

75.8.9 Data Trace Message Priority Loss Response

If a Data Trace message (DTM) loses arbitration due to contention with higher priority messages, the DTM event is discarded, and the next DTM will be upgraded to a sync-type message.

75.9 Debug Status messages

Debug Status Messages report low power mode and debug status. Debug Status messages are enabled when Nexus 3 is enabled. Entering/exiting Debug Mode as well as entering, exiting, or changing Low Power Mode(s) will trigger a Debug Status message, indicating the value of the most significant byte in the Development Status register. Debug status information is sent out in the following format:

Fixed length = 18 bits

Figure 1850. Debug Status message format

75.10 Error messages

Error messages are enabled whenever the debug logic is enabled. There are two conditions that will produce an error message, each receiving a separate error type designation:

- A message is discarded due to contention with other (higher priority) message types. These errors will have an Error Type value of 1.
- The message queue overruns. After the queue is drained, an error message is enqueued with an error code that indicates what types of messages were discarded during the interim. These errors will have an Error Type value of 0.

Note: The OVCR Register can be used in order to alleviate potential overrun situations.

Error information is messaged out in the following format (also see [Table 1692](#) and [Table 1693](#)):

(6 bits)	(4 bits)	(4 bits)	(6 bits)
Error Code	Error Type	Src. Proc.	TCODE (001000)

Fixed length = 20 bits

Figure 1851. Error message format

75.11 Ownership trace

This section details the ownership trace features of the Nexus 3 module.

75.11.1 Overview

Ownership trace provides a macroscopic view, such as task flow reconstruction, when debugging software written in a high level (or object-oriented) language. It offers the highest level of abstraction for tracking operating system software execution. This is especially useful when the developer is not interested in debugging at lower levels.

75.11.2 Ownership Trace Messaging (OTM)

Ownership trace information is messaged via the auxiliary port using an Ownership Trace Message (OTM). Core (e200z425n3) processors contain a *PowerISA 2.06* defined “Process ID” register within the CPU. It is updated by the operating system software to provide task/process ID information. The contents of this register are replicated on the pins of the processor and connected to Nexus. The Process ID (PID) register value can be accessed using the **mfspr/mtspr** instructions.

Note: The CPU includes a Process ID register (PID0), thus the Nexus UBA functionality is not implemented.

In addition, to decouple trace information from the PID0 register and to provide a full independent 32-bit process ID for debug use, the Nexus PID Register (NPIDR) may be used instead of PID0 to provide OTM process ID information. It is updated by the operating system software to provide task/process ID information. The Nexus Process ID (NPIDR) register value can be accessed using the **mfspr/mtspr** instructions. This register is accessible in user or supervisor mode.

Figure 1852. Nexus 3 Process ID Register (NPIDR)

Nexus 3 Process ID																															
0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31

SPR — 517; Read/Write; Reset: 0

Note: OS updates to NPIDR should be performed in addition to normal PID0 updates when a process switch occurs, in order to properly generate OTM messages with new process ID information when NPIDR is selected for OTM use.

The process ID source (PID0 or NPIDR) is selected by the setting of the DC1_{OTS} control bit.

There are two conditions that will cause an Ownership Trace Message when Ownership Trace is enabled:

- When the PID0 register is written to by the processor and DC1_{OTS} indicates PID0 should be used, or when the NPIDR register is written to by the processor and DC1_{OTS} indicates NPIDR should be used, the data is latched within Nexus, and is messaged out via the auxiliary port, allowing development tools to trace ownership flow. However, if Program Trace is enabled, and program correlation messages for PID updates are not masked (Event Code = 0101), then an OTM will not be generated for an update to the selected process ID register, since the program correlation message will provide this process ID update information.
- Periodically, at least once every 256 messages, the most recent state of the selected process ID register is messaged out. The resulting Ownership Trace message will indicate in the PID Index sub-field that PID0/NPIDR status is being reported and the most recent value of the PID0/NPIDR register will be conveyed in the Process ID value sub-field. These periodic Ownership Trace message events can be disabled by setting DC1_{POTD}.

Ownership trace information is messaged out in the following format:

(1-32 bits)	(4 bits)	(4 bits)	(6 bits)
Process ID	PID Index (0000)	Src. Proc.	TCODE (000010)

Variable length = 15–46 bits

75.12 program Trace

This section details the program trace mechanism supported by Nexus3 for the e200z425n3 processor. Program trace is implemented via Branch Trace Messaging (BTM) as per the **IEEE-ISTO 5001** standard definition. Branch Trace Messaging for Core (e200z425n3) processors is accomplished by snooping the internal address bus (between the CPU and Cache), attribute signals, and CPU Status (**p_mode[0:3]**, **p_pstat_pipe{0,1}[0:5]**).

75.12.1 Branch Trace Messaging types

Traditional Branch Trace Messaging facilitates program trace by providing the following types of information:

- Messaging for taken direct branches includes how many sequential instructions were executed since the last taken branch or exception, including the taken direct branch. Branch instructions are included in the count of sequential instructions.
- Messaging for taken indirect branches and exceptions includes how many sequential instructions were executed since the last taken branch or exception and the unique portion of the branch target address or exception vector address. Branch instructions are included in the count of sequential instructions. For taken indirect branches that trigger generation of a message, the branch is also included in the count.

Branch History Messaging facilitates program trace by providing the following information.

- Messaging for taken indirect branches and exceptions includes a) how many sequential instructions (I-CNT) were executed since the last predicate instruction, taken/not taken direct branch, taken/not-taken indirect branch, or exception, b) the unique portion of the branch target address or exception vector address, and c) a branch/predicate instruction history field. Each bit in the history field represents a direct branch or predicated instruction where a value of one (1) indicates taken, and a value of zero (0) indicates not taken. Certain instructions (**zvselh**) (**evsel**) generate a pair of predicate bits that are both reported as consecutive bits in the history field. Not-taken indirect branches will generate a history bit with a value of zero (0). Instructions that generate history bits are not included in instruction counts. For taken indirect branches that trigger generation of this message type, the branch is included in the count, but not in the history field.

75.12.1.1 Indirect Branch Message instructions

[Table 1719](#) shows the types of instructions and events that cause Indirect Branch Messages or Branch History Messages to be encoded.

Table 1719. Indirect Branch Message sources

Source of Indirect Branch Message	Instructions / Detail
Taken branch relative to a register value	bcctr , bcctrl , bclr , bclrl , se_bctr , se_bctrl , se_blr , se_brlr
System Call / Trap exceptions taken	se_sc , tw
Return from interrupts / exceptions	se_rfi , se_rfc , se_rfdi
Exit from reset with Program Trace Enabled	Indirect branch with Sync, target address is initial instruction, count = 1

75.12.1.2 Direct Branch Message Instructions

[Table 1720](#) shows the types of instructions that will cause Direct Branch Messages or will toggle a bit in the instruction history buffer to be messaged out in a Resource Full Message or Branch History Message.

Table 1720. Direct Branch Message sources

Source of Direct Branch Message	Instructions
Taken direct branch instructions Instruction Synchronize	b, ba, bl, bla, bc, bca, bcl, bcla, se_b, se_bc, se_bl, e_b, e_bc, e_bl, e_bcl, se_isync

75.12.1.3 BTM using Branch History Messages

Traditional BTM Messaging can accurately track the number of sequential instructions between branches, but cannot accurately indicate which instructions were conditionally executed, and which were not.
